ABSTRACT

This Final Environmental Impact Statement describes twelve alternatives for managing the 1,092,302 acres of land administered by the Siskiyou National Forest. Each alternative responds differently to the major issues and concerns identified Alternative NC, No Change, continues management under the 1962 Timber Management Plan without adjustment for requirements of the National Forest Management Act of 1976 (NFMA). Alternative A, Current Direction (No-Action), continues the management of the Forest according to current plans and policies but is updated to meet NFMA requirements. Current management direction, with a timber harvest schedule that departs from the nondeclining flow policy, is depicted in Alternative A-Departure Alternative B responds to the 1980 Forest and Rangeland Renewable Resources Planning Act (RPA) Program Alternative C provides the highest sustainable annual timber harvest yield. Market-oriented outputs with a balance between timber, minerals, developed recreation, and commercial fisheries are emphasized in Alternative D. Identical to D, but maintaining a high level of timber output by decreasing rotation lengths, is Alternative D1. Alternative E emphasizes aesthetic values by promoting the production of goods and services that do not necessarily have established market prices (e.g., soil, water, fish, recreation, scenery) Protection and enhancement of nontimber resources are emphasized in Alternative G Alternative K accommodates the desires of a wide range of user groups and interests, while continuing to supply goods and services vital to economic development. Alternative S (the Preferred Alternative) was developed in response to comments on the Draft Environmental Impact Statement; it incorporates many suggestions from the public, continues the supply of goods and services, and emphasizes the maintenance of a healthy ecosystem for the future Alternative M emphasizes preservation, rather than human use of the Forest's resources

SUMMARY

INTRODUCTION

This Final Environmental Impact Statement (FEIS) discusses the alternative strategies for future management of the Siskiyou National Forest. The preferred alternative is developed into the accompanying Land and Resource Management Plan (the Forest Plan). The Record of Decision describes the decision to implement the Forest Plan and the rationale for that decision While the Forest Plan will guide the management of the Forest for the next 10 to 15 years, the analysis covers a planning horizon of 150 years to evaluate and display the long-term effects of current actions.

The Draft Environmental Impact Statement (DEIS) and Proposed Land and Resource Management Plan were released for public review and comment in August, 1987 This FEIS and Forest Plan were developed in response to those comments and incorporates many suggestions made by the public and other agencies Changes that were made between the DEIS and FEIS are described throughout the document and highlighted in sections near the beginning of each chapter

This is a general summary of the entire FEIS It emphasizes the issues and concerns raised by the public, other agencies, and Forest Service personnel regarding management of the Siskiyou National Forest The Summary describes the public response to the DEIS, changes made between the DEIS and FEIS, affected environment, purpose of and need for the proposed action, how the major issues and concerns identified have been formulated into Planning Problems, how 12 widely differing alternatives respond to these Planning Problems, and the environmental consequences of implementing each of the alternatives.

PUBLIC RESPONSE TO THE DEIS

On August 28, 1987 the DEIS and Proposed Forest Plan were released to the public. A total of 750 copies were distributed to government agencies, local libraries, and interested members of the public In addition a "Reviewer's Digest" was sent to hundreds of individuals, and 62,000 copies of a 20-page newspaper insert titled "An Invitation to Comment" were printed and circulated through local newspapers.

The Forest received nearly 17,000 responses to the DEIS during the 150-day review period. The most popular form of response was the form letter (91 percent), followed by the letter or post card (7 percent) Resolutions, petitions, and Forest mailers made up the balance Responses came from 49 states, the District of Columbia, and five foreign countries The bulk of replies came from Oregon (10,469), followed by Illinois (1,601), Texas (1,592), Wisconsin (877), and California (649) Most of the responses were a direct result of campaigns initiated by proponents of a proposed National Park and by Southern Oregon Timber Industries Association.

Each response contained one or more comments. These were analyzed and categorized by type. The Interdisciplinary Team read the comments, considered them in preparing the FEIS, and responded to the comments. The largest group of respondents (23 percent) commented on the broad area of socioeconomics. There are many people concerned about jobs and timber harvest levels, and as a result, community stability. This subject area also includes social considerations, such as the effects on people, families, and communities not directly economic in nature. Respondents are interested in maintaining lifestyles and occupations consistent with family tradition

The second largest group of respondents (18 percent) commented on timber management, an issue which continues to be highly polarized and emotionally charged. Many respondents ask that old-growth forests be protected and unroaded areas preserved. Some feel that the level of harvest is over-optimistic, reforestation is inadequate, and yield table projections show unrealistic growth. Many objected to clearcutting, suggesting that monocultures are being created Others point out the dependence of local

communities on the supply of timber to maintain jobs and social and economic stability They maintain that the Forest is capable of significantly higher timber outputs than were projected in the DEIS

Sixteen percent of respondents commented on the roadless issue, which is also very polarized. Timber and mining interests perceive a critical need to maintain a land base The environmental community feels that the unroaded tracts of low elevation, coastal old-growth Douglas-fir are the last large vestiges of a rapidly vanishing ecosystem.

A large group of respondents (10 percent) commented on the issues of fisheries and water quality. They are concerned about timber harvest dispersion constraints, riparian prescriptions, cumulative effects of sediment, and water temperature Some think that the Forest is not doing enough to protect the fishery and water quality values; others think there is too much being done, resulting in less timber production.

The issues of tourism and recreation were commented on by eight percent of the respondents Many want to develop and enhance the recreational use of the Siskiyou National Forest, a number of people want the Forest to actively contribute to the counties' efforts to encourage tourism Several thousand comments urge the development of a National Park alternative, emphasizing the natural beauty and recreational opportunities on the Forest.

There is broad support among respondents for designation of the inventoried Chetco and North Fork Smith Rivers as Wild and Scenic. Comments went beyond the present scope of the DEIS to include suggestions that other rivers, such as the Elk, Pistol, Winchuck, South Fork Coquille, and Sixes, be added to the National Wild and Scenic River System as well.

CHANGES BETWEEN DRAFT AND FINAL

The tremendous public response to the DEIS provided the Forest with a wealth of suggestions for improvements about how to provide more benefits to the public These ranged from broad conceptual approaches to specific technical changes.

Alternative K was the Preferred Alternative in the DEIS Using Alternative K as a base, the Interdisciplinary Team evaluated suggestions while carefully considering the effects. Alternative S, though not in the DEIS, is a response to public input; it evolved through a series of meetings with the Forest Management Team, and with the Regional Forester Suggestions and comments from the public and other agencies are incorporated in Alternative S, such as adjustments of the timber harvest dispersion constraints which could achieve the desired effect of dispersing activities over time and space with less timber opportunity cost. High value fisheries are given more streamside shade protection by managing six more Planning Basins under the Riparian Prescription C

It was pointed out that fertilization is being used on many Forests to increase timber yields, since on-Forest trials verified its feasibility, fertilization is included in Alternative S Higher levels of capital investments for recreation and more allocations to Partial Retention and Retention visual management in selected high use areas are intended to complement the tourism emphasis of local governments and private industry. Allocation of nearly all of the potential Botanical areas and the increased attention to biological diversity through Standards and Guidelines respond to numerous comments on sensitive plant protection and diversity.

The name of Management Area 6 in the DEIS was "Custodial (Roadless)." A number of people observed that the name did little for clarifying management direction for the areas. Recognizing the tremendous support for maintaining more of the Forest in undeveloped condition to provide primitive and semi-primitive recreation opportunities, the name was changed to "Backcountry Recreation " To accommodate historic use of motorbikes and four-wheel drive roads in some areas, Backcountry Recreation areas in Alternative S include both motorized and non-motorized use.

Many people pointed out that the level of mineral restrictions proposed in the DEIS went beyond the intent of mining legislation This issue was re-evaluated; the level of access restrictions was reduced, and no additional mineral withdrawal is proposed in any alternatives.

Lightning ignited a number of fires on August 30, 1987. Several major fires, including the Silver Fire which received wide publicity, burned over 110,000 acres of the Siskiyou National Forest. About half of that total acreage burned in the Kalmiopsis Wilderness The fire intensity varied greatly, leaving a mosaic of burned and unburned vegetation. The majority of area was not severely burned About 17 percent of the total area that burned at medium and high intensity was tentatively suitable for timber production The Silver Fire Recovery Project FEIS (1988) documented the analysis of resource impacts of the fire and alternatives for salvage of dead trees and resource restoration activities As a result of the Silver Fire Recovery Project decision to salvage fire-killed timber and continuing timber harvest activity since 1984, the amount of inventoried roadless area has been reduced from 314,000 to 284,000 acres. The decision for the Silver Fire Recovery Project, itself, accounts for approximately 19,000 acres of the reduction

Three other actions occurring after issuance of the DEIS affected the outcome of this Forest Plan. The Final Supplement to the EIS for an Amendment to the Pacific Northwest Regional Guide (released July 1988) affected only minor changes in the network for northern spotted owl habitat on the Siskiyou National Forest since the DEIS. A few Spotted Owl Habitat Areas were added, but these changes had minimal timber opportunity cost. Proposed vegetative management in the Siskiyou National Forest FEIS and Forest Plan is also consistent with the FEIS for Managing Competing and Unwanted Vegetation (released December 1988). The Omnibus Oregon Wild and Scenic River Act of 1988 was passed just before printing this FEIS One of the key issues deals with Wild and Scenic Rivers, the effects of this recent legislation are discussed below

PURPOSE AND NEED

The purpose of the Forest Plan is to direct all natural resource management activities on the Forest. Preparation of the Land and Resource Management Plan is required by the Forest and Rangeland Renewable Resources Planning Act of 1974 (RPA), as amended by the National Forest Management Act of 1976 (NFMA), plus the associated Planning Regulations (36 CFR 219).

The preparation of an Environmental Impact Statement disclosing a preferred alternative and a broad range of additional alternatives is required by the National Environmental Policy Act of 1969 (NEPA) and its implementing regulations (40 CFR 1500), and the implementing regulations of NFMA (36 CFR 219). The FEIS is required because the Forest Plan is a major Federal action with a significant effect on the quality of the human environment. For purpose of disclosure under NEPA, this FEIS and the accompanying Forest Plan are treated as combined documents.

The Forest is currently managed through direction provided within the Chetco-Grayback, Rogue-Illinois, Rogue, and Mt. Butler-Dry Creek Unit Plans, the Powers and Illinois Valley District Multiple Use Plans, the Timber Management Plan, and other sources, including the Forest Service Manual, Regional Guide for the Pacific Northwest Region, and numerous environmental documents, laws, regulations, and Executive orders These provide a blend of land uses. Fish and wildlife, developed and dispersed recreation, and the Wilderness resources are emphasized along with timber and minerals management Other values associated with visual quality, old growth, water, and sensitive plants and animals also receive considerable attention

The present plans do not provide the direction to appropriately meet the intent of NFMA These dated plans do not adequately respond to or have the ability to resolve many of the newer issues and concerns. Therefore, the FEIS and Forest Plan have been prepared, with direct involvement of other agencies and the public, to provide totally integrated and detailed management direction with land allocations which are complementary to the intent of multiple-use

THE PLANNING PROCESS

The National Forest Management Act's implementing regulations require that several planning steps be used to develop the FEIS and Forest Plan These planning steps are·

1. Identification of issues, concerns, and opportunities
2. Development of planning criteria
3. Inventory of data and collection of information
4. Analysis of the management situation
5. Formulation of alternatives.
6. Determination of estimated effects of the alternatives.
7. Evaluation of alternatives.
8 Selection of the proposed action
9. Plan implementation.
10. Plan monitoring and evaluation.

AFFECTED ENVIRONMENT

The Siskiyou National Forest is a publicly owned area of great diversity, natural beauty, and productivity. The Forest, situated in southwestern Oregon and northwestern California, consists of 1,092,302 acres. All but 33,000 acres are in Oregon. Another 70,000 acres within the Forest boundary are private and other-Agency administered land. The Forest is about 70 miles long and 30 to 55 miles wide

Located mostly within the Klamath Mountain and Coast Range Geologic Provinces, the terrain is extremely steep and rugged, having been deeply carved by numerous rivers and streams. Elevations on the Forest range from about 100 feet to more than 7,000 feet Several rivers, including the Rogue and Illinois, flow through the Forest, offering white water experience for recreationists and habitat for anadromous (migratory) and native fish

Areas near the crest of the Coast Range receive up to 150 inches of precipitation each year, some coming in the form of snow. Moisture declines markedly to the east, with only 40 inches of precipitation falling on the lower eastern fringes of the Forest.

The geologic variety and a wide difference in precipitation across the Forest yields an unusual diversity in vegetation and an associated richness of wildlife species. The area has been termed a "botanist's paradise " Vegetation changes are dramatic and vary primarily with aspect, elevation, soil, and climate. Grass, shrubs, and scattered pines occur on the serpentine soils, while very productive stands of Douglas-fir and western hemlock are supported on other youthful soils. Many tree species with limited ranges, such as redwood, Port-Orford-cedar, and sugar pine, occur on the Forest Tanoak, Pacific madrone, and other hardwoods are found intermixed throughout the Forest. Where large wildfires burned in the past, stands of hardwoods have replaced Douglas-fir and other species In the higher elevations are stands of mountain hemlock, true firs, and isolated pockets of Alaska yellow-cedar

The diversity of the Forest has led to a great variety of wildlife species An estimated 270 species of fish and wildlife reside within the Forest. These vary from stately elk to the tiny Pacific shrew; from soaring bald eagles to hummingbirds and butterflies with limited ranges; and from plentiful salmon and steelhead to native trout.

Recreation and tourism play a significant part in the economy, life-style, and use of southwestern Oregon. Local counties have chosen tourism as their "Oregon Economic Comeback Strategy," and look for support and participation by their neighboring National Forests in this strategy. This wealth of water, wildlife, and scenery, plus dependably sunny summer weather attracts thousands of recreationists People come to

camp, hike, hunt, fish, view the scenery, raft, take pictures, swim, drive 4-wheel vehicles, ride motorbikes, pan for gold, cut firewood, gather mushrooms, and pick berries

Receiving the greatest amount of recreation use on the Forest are activities which center around the Rogue and Illinois Wild and Scenic Rivers Both private and commercially-guided parties use the rivers Coupled with hiking use along the river trails, thousands of visitors annually enjoy these vestiges of a primitive America In late 1988, the Chetco, Elk, and North Fork Smith were also designated as Wild and Scenic Rivers under the Omnibus Oregon Wild and Scenic Rivers Act.

The Forest manages five Wildernesses totaling 232,495 acres. Managed for their primitive characteristics, these areas contain a variety of ecological types and recreational opportunities. In addition, the Forest has several large inventoried roadless areas.

The Siskiyou National Forest is an important contributor to the production of sawtimber and other wood products. Trees cut by local companies are processed into lumber, plywood, paper, furniture, and firewood. Wood residue is also used for the production of power and heat. The wood products industry has long been an important employer in many communities within and adjacent to the Forest.

The Forest is subject to periodic natural disasters like wildfire, floods, and windstorms. The 1987 fires are a good example of naturally occurring catastrophes. These events require costly mobilization of people and equipment to minimize damage to Forest resources and to rehabilitate impacted areas. Coupled with these problems, a large amount of steep and unstable terrain contributes to the inherent risks and hazards of management.

The great diversity of Forest resources and multiple uses produces an extremely complex management situation. The variety of uses leads to competition for the limited resources. Land allocations, which emphasize various uses, also generate tradeoffs between conflicting interests. The range of possible solutions to these management dilemmas is reflected in the responses to the Planning Problems which characterize each alternative.

ISSUES, CONCERNS, AND OPPORTUNITIES

An extensive and continuing process has been used to identify the issues, concerns, and opportunities. Public meetings, the local news media, newsletters, many personal contacts by Forest Service officials, and the overwhelming response to the DEIS and Proposed LRMP have been used to gather and confirm the issues. In 1979, an interdisciplinary team of specialists prepared the initial set of issues and concerns based on public comments and summarized these into "Planning Problems." This set has been revised as needed in order to keep current with public interests and changes in policies and procedures.

Several issues or aspects of issues have received fresh emphasis since the publication of the DEIS and Proposed Forest Plan. Increased attention has surfaced related to Wild and Scenic Rivers, tourism and recreation, biological diversity, reforestation, and various technical questions regarding timber harvest amounts. The 1987 fires generated much concern and interest which surfaced through the extensive public involvement in the Silver Fire Recovery Project. Most of the key issues and concerns expressed in that project were the same as those that have surfaced over the years in the Forest planning effort.

The Final Supplement to the EIS for an Amendment to the Pacific Northwest Regional Guide has resulted in minor changes in the Standards and Guidelines and the habitat network for northern spotted owls which have been incorporated in this FEIS The revised direction is not substantially changed for the Siskiyou National Forest; changes in the alternatives for this analysis are negligible.

PLANNING PROBLEMS

Many of the issues and concerns are highly interrelated Having more of one thing often requires having more or less of something else, whether desired or not. Nine Planning Problems to be addressed through the evaluation of alternatives were developed from the major issues and concerns Key indicators are measures of how well each alternative responds to Planning Problems The nine Planning Problems and associated key indicators are:

1. How Much Timber Should the Forest Produce?

There is a wide divergence of opinion concerning the production of timber from this Forest. The timber industry is an important part of the local and regional economic base, and the Forest has historically supplied significant amounts of timber. There is concern that current sell program levels of 31.0 million cubic feet (MMCF), or 167.5 million board feet (MMBF) per year), cannot or will not be maintained As a result, local communities will suffer economic hardship. More than any other, the timber issue is intertwined with the other resource issues. Production of timber often conflicts with managing for fish habitat, wildlife habitat, old growth, unroaded recreation, visual quality, and other values

The ability to respond to the timber issue is complicated by the inventory structure existing on the Forest. Standing volume, age class distribution, and the Forest's productive potential combine to create a situation characterized as "deficit inventory." The Forest has the potential to grow timber at a rate higher than can be sustained by the current inventory. To sustain timber flows, the existing inventory must be metered out until the regenerated stands reach harvestable size and age. Intensive management practices can do little to relieve this situation in the short term. Some people believe that the Forest should utilize a variety of technical applications to increase yield including yield table adjustments, short rotations, fertilizer applications to plantations, and other program and model changes.

The key indicators of resolution for this Planning Problem by alternative are the acres suitable for timber production (Management Areas 10-14), the Allowable Sale Quantity (ASQ) for the first decade, the ASQ for the fifth decade (this shows the low point for the departure alternatives), and the Long-Term Sustained Yield (LTSY).

2. How Much Old-Growth Forest Should be Preserved?

Harvest of old-growth trees has become a controversial topic. A large part of the available timber inventory is in mature and old-growth forest stands There is also desire to preserve old growth for wildlife habitat, for aesthetics, to contribute to biological diversity, and for its own intrinsic value. Based on the 1979 inventory with some parts updated through 1984, there are currently 443,000 acres of mature and old-growth trees. Of this, 137,000 acres are reserved in designated areas such as Wilderness and other areas unsuitable for the production of timber.

The key indicators used to measure how the alternatives respond to this problem are the acres of mature and old-growth habitat reserved (protected) through land allocations (primarily Management Areas 1-9), and the old-growth habitat that would remain by the fifth decade The latter is a determinate of the rate at which timber harvest would occur.

3. How Can the Forest's Fish Habitat, Water Quality, and Soil Productivity be Maintained or Improved?

Fish habitat is highly dependent on water quality Water quality is a reflection of the health of the forest and streamside (riparian) areas, and the quality of management and tending of these ecosystems Water temperature and sedimentation are critical to maintenance and protection of the Forest's fisheries habitat. Capability (biologic carrying capacity) of streams and rivers is enhanced primarily through capital

expenditures for improvement projects such as rearing pools and fish ladders. Soil erosion and vegetative cover along streams are extremely important aspects in providing for fisheries and other riparian values Soil productivity is primarily maintained through the application of Standards and Guidelines (set forth in the Forest Plan, Chapter IV) Management of the soil and water resources are highly interrelated with fisheries management on this Forest These resources are considered the same in resolution of this Planning Problem.

Indicators that vary by alternative include Planning Basins assigned to various Riparian Prescriptions, the level of capital investments, acres allocated to Management Areas 1-9 (no programmed harvest), timber harvest dispersion constraints, the anadromous sport fishing user days, pounds of commercial fish catch, and tons of sediment over current conditions. The timber harvest dispersion constraints are applied to the land tentatively suitable for the production of timber in each of the 19 Planning Basins; the constraint varies by alternative.

4. How, and to What Extent, Should Lands in and Adjacent to River Corridors be Managed to Protect, Preserve, and Enhance Wild and Scenic River Attributes?

Parts of the Rogue and Illinois Rivers that flow through the Forest are designated as National Wild and Scenic Rivers. Two other rivers, the Chetco and North Fork Smith, were inventoried as potential candidates to the Wild and Scenic River System The Elk River was recently determined eligible for potential inclusion. In October, the Chetco, Elk and North Fork Smith Rivers were designated in the Omnibus Oregon Wild and Scenic River Act of 1988. As a result of this bill, the issue has changed slightly since the DEIS; whether or not to recommend designation is no longer a question The issues to be dealt with here are: (1) What *management direction for the Recreation, Scenic, and Wild sections of the five designated river corridors* needs to be established or reaffirmed; and (2) what should management direction be for lands adjacent to the Wild and Scenic River corridors?

Management plans for the newly designated river corridors, as directed by the Act, will have to be prepared within a few years from the date of the legislation. River Management Plans exist for the Rogue and Illinois. Plans which will provide specific measures to implement management objectives for new rivers will not be a product of the Forest Planning process or accompanying decision for the Forest Plan.

The part of this Planning Problem that remains to be resolved deals with management in the viewshed of these rivers outside of the Congressionally designated corridors. The range of allocations to visual management objectives and other Management Areas adjacent to the river corridors will be evaluated.

The key indicator for this Planning Problem pertains to management direction within the viewshed. The area adjacent to (as seen from) the Wild and Scenic Rivers corridors that meets or exceeds the inventoried Visual Quality Objective (VQO) is used to track the response to this question.

5. How Should Sensitive Plant Resources be Managed?

The Forest contains habitat for numerous rare plants. Protecting this habitat often involves limiting disturbance from activities such as timber harvest, road building, and mining. The Standards and Guidelines provide some protection for this habitat under all the alternatives. Land allocations that restrict activities (Management Areas 1-9) would provide additional protection. Key indicators are the acres *allocated to Botanical and Research Natural Areas.*

6. How, and to What Extent, Should Forest Scenic Values be Protected through Visual Resource Management?

The visual resource management issue revolves around the degree of protection scenic values are given, and the costs and impacts of this resource on other activities Timber harvest and road construction often

change the condition of the scenery. Two key indicators are used to evaluate the alternatives. The number of viewsheds allocated to meet the full inventory of Visual Quality Objectives is one. Corollary to this is the total acres assigned to meet or exceed Retention and Partial Retention objectives.

7. How Should Wildlife Habitats on the Forest be Managed?

The Forest is inhabited by more than 250 wildlife species. The controversy in the wildlife question is not found in the desirability of maintaining diverse and healthy populations, but in the management actions needed to accomplish this objective. Vegetation-altering activities such as timber harvest change the character of the habitat and its ability to provide for various species. Activities are often beneficial to some species and detrimental to others. There is a divergence of opinion as to the appropriate balance of habitats that should be maintained, and the acceptable level of effect on timber production resulting from wildlife management prescriptions.

There are several key indicators used to evaluate the alternatives. Potential habitat capability to support spotted owl pairs over time, along with the potential habitat (snags) capable of supporting a given percentage of woodpecker populations over time, are used to track habitat quality and trends. The other indicators are wildlife user days, capital investments, and the area of Special Wildlife Sites allocated.

8. How Will Management Direction Affect Recreation Opportunities in the Wilderness and Unroaded Areas?

The most polarized issue addressed in this analysis involves the management direction for the inventoried roadless areas. The Forest has 232,000 acres of Wilderness and, as reported in the DEIS, 314,000 acres of unroaded areas outside of Wilderness. Since 1984, continued management under current direction and implementation of the Silver Fire Recovery Project has resulted in some road construction in former roadless areas. There are currently 284,000 acres of unroaded areas This Planning Problem deals with management of the existing Wilderness and with the land allocations and management of the remaining unroaded areas.

Numerous responses to the DEIS addressed this issue. Many people want the unroaded areas to remain in their natural state and provide Primitive and Semi-primitive recreation opportunities, reserve the remaining larger tracts of old-growth forest, protect certain wildlife habitats, and other benefits. Timber and commodity interests see the land base rapidly eroding for the production of timber as additional area is allocated to uses that preclude development. People on both sides of this issue feel that they are continually losing ground.

There are two key indicators for this Planning Problem. The first defines the acres that would remain undeveloped The inventoried unroaded area allocated to Management Areas 1 through 9 where little or no roading exists and management objectives are highly oriented to nondevelopment best provides this indices. The second indicator is the area of recreation opportunities remaining in Primitive and Semi-primitive status

9. How Should Mineral Resources of the Forest be Developed in Coordination With Management of Other Resources?

There has been increased interest in developing the mineral resources of the Forest during recent years As this interest has grown, with the prospect of added ground-disturbing activities, concern for environmental protection has similarly grown Particular concern is expressed over the potential conflict between mineral development and the protection of unroaded areas, sensitive plants, and visual quality. Some of the unusual geologic sites that are habitat for rare plants are also high in minerals potential.

The indicator used for evaluation is the number of acres available for mineral exploration and development with limited (i.e , low and moderate) restrictions.

MANAGEMENT REQUIREMENTS

The Management Requirements (MR's) are designed to assure compliance with the applicable laws and regulations, specifically 36 CFR 219.27. There are many requirements that are implemented to protect specific resources which do not significantly affect the Forest-wide analysis Those that impose substantive standards and significantly interact with other resources are those for mature and old-growth dependent wildlife species, dispersal of created openings, and maintenance of water quality and riparian areas along perennial streams. The MR's have been designed to provide the protection needed with the least adverse impact on other resources. The development and effects of the MR's are described in Appendix B, Appendix J, and summarized in Chapter II.

The MR level for water quality and riparian management is essentially the same as the current Siskiyou Riparian Policy which has evolved over a number of years as results of field implementation, monitoring, and application of research findings The harvest dispersion constraint MR limits final timber harvest in any Planning Basin to 20 percent of the suitable land base per decade. The objective is to minimize watershed impacts through distributing the effects of activity over both space and time. A side benefit is that the basin constraint further assures that the Forest has the flexibility to meet the opening size restrictions required by NFMA and Regional Guide for the Pacific Northwest. This MR has minimal effect on timber outputs.

The habitat areas for mature and old-growth dependent wildlife species (indicator species are pine marten, pileated woodpecker, and spotted owl) are identified in a network across the Forest to provide dispersion of suitable habitat throughout the planning area. This is the only new MR of significance to other resources installed in this analysis. It has the potential to reduce timber outputs by approximately six to seven percent.

All the alternatives, except the No Change Alternative, meet the MR's and would assure the maintenance of water quality, vegetative diversity, and habitat to sustain viable populations of fish and wildlife. The Forest Service has attempted to base the MR's on the available scientific research, supplemented by experience and professional judgement As knowledge of these resources expands and additional research findings come to light, the Forest Service is prepared to modify management direction including the MR's to stay current with the state-of-the-art in forest resource management.

MANAGEMENT AREAS

A critical part of each alternative design is the recommended land allocation. All lands of the Siskiyou National Forest are assigned to one of 14 Management Areas in each alternative. A Management Area is a category of land with capability to respond to certain issues or to meet specific management objectives (not necessarily contiguous acres) While the objectives for all Management Areas include some multiple uses, they often emphasize one or a few resources and therefore result in dominant use management for some areas In the Management Area descriptions that follow, the acres tentatively suitable for timber production are identified It should be noted that these acres may or may not be selected for timber management in a particular alternative, and that this determination and the suitability inventory itself are subject to review at ten year intervals.

Although many areas have multiple resource values, lands can logically be assigned to only one Management Area (each acre can only be managed under one prescription). In order to systematically assign the land base to Management Areas, a hierarchy was developed based on the level of ground disturbance or vegetation manipulation provided for in each Management Area. The Management Areas are numbered in order of increasing activity from the least ground disturbance and vegetation manipulation to the most. Management Area 1, Wilderness, is the most restrictive. Management Area 14, General Forest, is at the other end of the spectrum with the most road construction and timber management activity, and

the least restrictions on mining Where alternative design results in **overlaps**, the acres **are assigned to the Management Area higher up in the hierarchy** *(the lower number). This precludes double counting* and assures that each acre will have only one set of management direction

Management Area 1 - Wilderness

Wilderness is an essentially undisturbed area where natural processes continue with a minimum of human interference Wildernesses are pristine, scenic landscapes that provide an opportunity for solitude The areas are managed to comply with the requirements of the Wilderness Act of 1964. The size of this Management Area remains fixed by alternative.

Management Area 2 - Wild River

Management Area 2 consists of the "Wild" segments of Wild and Scenic Rivers designated by Congress under the National Wild and Scenic Rivers Act. The Wild designation was reserved for those rivers that are free flowing, free of impoundments and generally inaccessible except by trail These areas are managed to maintain the natural, free-flowing, and primitive character of the rivers and their immediate environment. An inventoried 5,029 acres are in the "Wild" river segments

Management Area 3 - Research Natural Area

Management Area 3 contains distinctive natural ecosystems designated (or proposed) as part of the Research Natural Area Program for scientific and educational purposes Research Natural Areas (RNA's) are sites which typify an undisturbed aquatic or terrestrial ecosystem where natural features are preserved for scientific purposes and natural processes are allowed to dominate. Three existing RNA's remain constant at 1,957 acres in all alternatives. Four additional areas, totaling 2,799 acres (1,505 acres tentatively suitable for the production of timber), are being considered for recommendation to the RNA program in this FEIS.

Management Area 4 - Botanical

Management Area 4 includes the best representations found on the Forest of unusual plants indigenous to southwestern Oregon. There are three existing Botanical Areas totaling 4,475 acres. An additional 24 areas containing a total of 36,917 acres (17,851 tentatively suitable) are being considered for designation in this FEIS. Acres allocated to this Management Area would be managed with emphasis on the protection and enhancement of the rare plant resources; other uses consistent with these goals would be allowed These areas would not have programmed timber harvest; other ground disturbing or vegetation manipulating activities may be significantly restricted.

Management Area 5 - Unique Interest

Management Area 5 protects significant cultural or exceptional geologic sites on the Forest Development or vegetative manipulation for commodity production would not be allowed Thirteen such areas containing 1,705 acres (766 tentatively suitable) are considered for designation

Management Area 6 - Backcountry Recreation

This Management Area contains areas that will be retained in their natural state and will provide motorized and non-motorized recreational and other resource opportunities associated with large unroaded areas Various levels of trail development are prescribed to increase recreation carrying capacity, yet maintain the Primitive and Semi-primitive character of the undeveloped landscape Eighteen unroaded areas are being considered, totaling 314,162 acres (171,844 acres tentatively suitable timber land) Approximately 284,000 acres are inventoried as roadless, any area allocated to Backcountry Recreation that may be partially developed would require restoration to return the area to a natural-appearing landscape over time

Management Area 7 - Supplemental Resource

Areas considered highly productive (or critical) habitat for fish or wildlife, provide a valuable recreational setting, or necessary for the maintenance of high quality watershed conditions, are included in this Management Area designation Many of the Supplemental Resource Management Areas cover the sensitive inner gorge corridors of the larger streams and rivers found throughout the Forest. Management objectives include maintenance of near-natural conditions while permitting limited levels of activity, such as through-road construction or habitat improvement projects. No timber harvest is programmed from these areas, but activity is permitted to salvage or protect stands from disease and insect infestations Thirty-two areas, totaling 76,281 acres (45,312 acres tentatively suitable for the production of timber), are evaluated for Supplemental Resource designation.

Management Area 8 - Designated Wildlife Habitat

Management direction for this designation protects habitat for spotted owls, pileated woodpeckers, and pine martens. These three animals are indicator species for all wildlife inhabitants of mature or old-growth forests. This Management Area includes habitat needed to meet Management Requirement (MR) objectives in all alternatives, except in the No Change Alternative Management direction for this designation includes requirements to maintain those old-growth characteristics necessary for the sustenance of dependent wildlife species. No timber harvest activity is programmed A total of 153,400 acres are necessary to meet MR's that provide viable population levels in perpetuity. Much of this is overlapped by more restrictive Management Areas (e.g., Wilderness) Only 29,363 acres are tentatively suitable for timber production. An additional 57,758 acres (41,074 tentatively suitable) is considered in some alternatives to supplement the MR's.

Management Area 9 - Special Wildlife Site

Management Area 9 consists of special wildlife sites which are important components for overall wildlife habitat diversity. Examples include meadows, ponds, tanoak stands, wet areas, rock bluffs, and other sites frequented by wildlife. Management direction for this area precludes programmed timber harvest activity, but allows site-disturbing activities that are not contrary to the overall objective of preserving the special wildlife habitat A total of 25,004 acres (including 6,994 acres of tentatively suitable land) are considered for designation.

Management Area 10 - Scenic/Recreation River

Management Area 10 currently includes segments of rivers classified as "Scenic" and "Recreational" by the National Wild and Scenic Rivers Act. These rivers and their immediate environment are managed for multiple uses, with the emphasis on recreation and scenic quality. Timber management is planned at a low level where it can be accomplished consistent with meeting these other objectives. Of the 10,317 acres in Scenic/Recreation Rivers, 7,614 acres are tentatively suitable for the production of timber.

Management Area 11 - Riparian

Management Area 11 contains the riparian area along perennial streams within the lands tentatively suitable for timber production The actual width of the riparian area is determined on the ground and varies with site-specific conditions. There are an estimated 175,500 acres of riparian areas Forest-wide with approximately 99,000 acres tentatively suitable for timber production Prescriptions for this Management Area include multiple uses, with primary emphases on watershed, fisheries, and wildlife values. Timber production is limited and permissible where impacts are not unacceptable relative to the primary values.

Management Area 12 - Retention Visual

This Management Area consists primarily of land that is immediately adjacent to, and visible from, major travel routes, rivers and other high use recreation areas Maintenance of scenic quality is emphasized, and

timber would be produced at a low level There are 81,480 acres inventoried with a "Retention" Visual Quality Objective, of which 46,657 are tentatively suitable for timber production Part or all of these acres are assigned to Retention based on the objectives of the alternative being considered.

Management Area 13 - Partial Retention Visual

Management Area 13 consists of land that is visible in the middle to background of major and secondary travel routes, rivers and other high use recreation areas. The total area inventoried as Partial Retention on the Forest is 287,700 acres, of which 194,190 are tentatively suitable for timber production. These areas are managed for multiple uses including recreation, timber production, and wildlife habitat. There is a priority on the maintenance of scenic quality which results in a minor reduction in timber production to allow for accomplishing these visual objectives.

Management Area 14 - General Forest

This Management Area includes forested land which is managed for multiple uses including timber production and the maintenance of many wildlife habitats A number of other uses and land classifications are also included in the General Forest Management Area. These include developed campgrounds, roads, utility corridors, cultural sites, administrative sites, and land unsuitable for the production of timber

ALTERNATIVES

Twelve alternatives were formulated providing a broad range of options to serve as a basis for identifying the alternative that best maximizes net public benefit (NPB) while responding to public issues. Each alternative emphasizes the resolution of one or more Planning Problems through a combination of land allocations, Standards and Guidelines, and capital expenditures. The distribution of National Forest land to one of 14 Management Areas establishes permissible management practices and activity schedules that provide unique combinations of resource outputs, land uses, and environmental effects. Management Area allocations are summarized for each alternative in Table S-1. Outputs and effects that indicate the degree of resolution for each Planning Problem by alternative are displayed in Table S-2

Two alternatives (K-Departure and L), which were presented in the DEIS, have been dropped from full development through the FEIS Other existing alternatives fill a range of resource objectives which these two alternatives emphasized, and there was very little input on them.

Identification of the "Preferred Alternative" was made after careful comparison of all the alternatives on the basis of their resource outputs, environmental effects, implementation costs, and the "tradeoffs" between them The Preferred Alternative is that alternative which best maximizes the Net Public Benefits in an environmentally sound manner Alternative K was the preferred in the DEIS. With Alternative K as a base, Alternative S was developed, considering the comments received on the DEIS, and is the Preferred Alternative in this FEIS.

Alternative NC - No Change

The "No Change" alternative was developed in response to an appeal brought by the Northwest Forest Resource Council in 1986 The substance of the appeal was that a "true no-action alternative representing current management plans" was not included in Forest Plan EIS's The purpose of Alternative No Change (NC) is to continue the levels of goods and services as set out in plans formulated and approved prior to the passage of the NFMA, specifically the 1962 Timber Management Plan This alternative does not comply with all provisions of NFMA and the regulations promulgated by the Secretary of Agriculture to implement NFMA, and could not be implemented or used in future management of the Forest under the Forest Plan without Congressional and/or Secretary of Agriculture action to change the law or regulations.

Alternative A - Current Direction

This is the "No Action" alternative required by the NEPA. It would continue the present course of action established in plans and policies formulated and approved prior to passage of the NFMA that are consistent with present laws and regulations. Relatively high levels of timber production, combined with maintenance of inventoried Visual Quality Objectives and moderate levels of fish and wildlife, are emphasized

Alternative A - Departure

Using the same land allocations and management direction as Alternative A, timber production would be further emphasized through a harvest scheduling plan that departs from the policy of nondeclining yield to maintain the current timber program for the next two decades. Average annual timber harvest levels in subsequent decades would decline.

Alternative B - RPA

This alternative is designed to meet the RPA production targets displayed in the Regional Guide (1984) Very high levels of timber production would be emphasized during the first two decades through departures from nondeclining yield Large expenditures in capital improvements for fisheries would be necessary to realize program objectives, while big-game wildlife objectives would be achieved using the forage that results from timber harvest activity

Alternative C

Timber management opportunities would be emphasized in this alternative, producing current levels of timber volume on a nondeclining yield basis Under implementation of NFMA regulations, Alternative C would have the highest amount of land selected as suitable for timber production, and the highest LTSY Hunting and roaded recreation opportunities would be enhanced as a result of the timber program. Land allocations for other resource objectives would be among the lowest of the alternatives considered.

Alternative D

Goods and services having established market prices would be emphasized in this alternative. Intensive timber production would utilize 98 percent of the land suitable for timber production. A moderate increase in anadromous fish would be achieved by applying prescriptions that provide additional stream protection

Alternative D1

This alternative is identical to Alternative D, except timber harvest rotation lengths would be shortened. The culmination of mean annual increment (CMAI) requirement would be relaxed to allow harvest of trees that are as much as 20 years younger than the normal rotation age of 100 years. Average annual timber harvest volumes would increase approximately 10 percent relative to Alternative D

Alternative E

Aesthetic values of the Forest would be emphasized in this alternative by promoting goods and services which do not necessarily have established market values Land allocations displayed in Table S-1 reflect the subordinate role of timber production in this alternative. Land allocations that would benefit old growth, anadromous fish, Wild and Scenic Rivers, sensitive plants, visual quality, and roadless recreation would be among the highest of any alternative considered. Former inventoried roadless areas (RARE II), for example, would remain undeveloped

Alternative G

This alternative is designed to promote the health and productivity of the Forest's water-related resources, particularly rivers and streams associated with the Illinois drainage Alternative G would preserve many existing unroaded areas and favors management governed by high Visual Quality Objectives to maintain the area's reputation for natural beauty and to accommodate recreation-oriented industries Low to moderate levels of timber production would be provided by a land allocation that would emphasize wildlife diversity and travel corridors, preservation of old growth, enhancement of water quality for fisheries, and protection of sensitive plants This was the Preferred Alternative in the DEIS

Alternative K

This alternative is designed to minimize the tradeoffs between competing goods and services by capitalizing on the multi-product nature of various land allocation possibilities The preservation of aesthetic values, for example, would be limited to areas of high recreational value, but would be achieved by utilizing land allocations that provide some development opportunities. High levels of anadromous fish would be provided along with moderate levels of timber, old growth, wildlife habitat, and protection of sensitive plants

Alternative M

This alternative would preserve the Forest as it is today by limiting all development activities to those portions of the Forest currently under active management. Timber management would utilize rotation lengths of 250 years, and harvest activity would occur only on lands accessible from existing roads Land allocations for this alternative would yield the fewest development opportunities, and the greatest level of protection for old growth, Wild and Scenic Rivers, visual quality and unroaded areas, of any alternative considered.

Alternative S

This alternative is designed in response to public input through incorporating numerous suggestions from agencies, groups, and individuals. Alternative S would continue to supply goods and services vital to National and local economies while providing a healthy ecosystem for the future. Achievement of that objective would require the Forest to capitalize on the multi-product nature of land allocations that minimize tradeoffs between goods and services High levels of anadromous fish and sensitive plant habitat would be provided, as well as moderately high levels of timber, mature and old-growth wildlife habitat, and unroaded recreation opportunities.

Table S-1. Acreage in Management Areas by Alternative

Management Area No.-Name	ALTERNATIVE

1/ Alternative N includes 98,000 acres of General Forest which was not selected suitable for timber harvest.

Full titles of planning problems:

1 How Much Timber Should the Forest Produce?
2 How Much Old growth Forest Should be Preserved?
3 How Can the Forest's Fish Habitat, Water Quality, and Soil Productivity be Maintained or Improved?
4 How, and to What Extent, Should Lands in and Adjacent to River Corridors be Managed to Protect, Preserve, and Enhance Wild and Scenic River Attributes?
5 How Should Sensitive Plants Resources be Managed?
6 How, and to What Extent, Should Forest Scenic Values be Protected *Through Visual Resource Management*?
7 How Should Wildlife Habitats on the Forest be Managed?
8 How Will Management Direction Affect Recreation Opportunities in the Wildernesses and Unroaded Areas?
9 How Should Mineral Resources of the Forest be Developed in Coordination with Management of Other Resources?

ENVIRONMENTAL CONSEQUENCES AND MITIGATION

Projected consequences of the alternatives are arranged by the problems of timber supply, old-growth preservation, fish habitat, water quality, and soil productivity Other problems include Wild and Scenic Rivers, sensitive plant habitat, scenic values, wildlife habitat, primitive recreation opportunities, and development of mineral resources. The quantitative measures are displayed for each alternative in Table S-2. Mitigation is accomplished primarily through land allocations, capital investments, and Standards and Guidelines. These provide means to avoid or minimize impacts, rehabilitate and restore resources, or preserve and maintain opportunities.

TIMBER SUPPLY

Alternatives K, S, A, D, NC, A-Departure, C, D1, and B would have first decade timber outputs progressively greater than the historical average harvest from 1974-1985. Alternatives B and D1 would have first decade timber outputs significantly higher than the current situation. Associated with the outputs would be increased Present Net Value (PNV), jobs, income, payment to counties, and revenue to the U.S. Treasury. Increased sediment production and significantly decreased land allocations preserving mature and old growth would also be a result of increased timber outputs.

Alternatives G, E, and M would have progressively fewer timber outputs than the historical average harvest. Alternatives E and M would have very significant decreases in timber outputs. Associated with the decreased outputs would be decreased. PNV, jobs, payments to counties, and revenue to the U S Treasury Additional allocations to the more restrictive Management Areas would result in reductions in sediment and a higher amount of mature and old-growth forests

OLD-GROWTH PRESERVATION

Alternatives G, E, and M would have progressively more areas where programmed timber harvest is excluded from mature and old-growth stands Alternatives E and M would have very significant amounts of mature and old-growth reserves More opportunities for Primitive recreation, pristine scenic vistas, and increased old-growth wildlife habitat would be consequences associated with these alternatives Reduced amounts of harvest with subsequent declines in payments to counties, reduced revenue to the U S Treasury, and reduced game wildlife benefits would also be consequences of preserving the old-growth stands.

Alternatives S, K, A, A-Departure, D, D1, B, C, and NC would have progressively less old growth reserved. The designated Wildernesses, and designated Wild and Scenic Rivers would provide most of the reserved mature and old-growth stands for these alternatives, with some area contributed through allocations to Backcountry Recreation in Alternatives S and K. The difference between the amount of mature and old growth in existence today and that which would be retained in a particular alternative is an impact which cannot be avoided if the objectives of an alternative are going to be satisfied

FISH HABITAT, WATER QUALITY, AND SOIL PRODUCTIVITY

Fish production is primarily a function of the fisheries capital investment program and riparian management prescriptions. Taken together, these factors would contribute to the highest levels of anadromous fish in Alternatives B, S, and K Moderate levels would be provided in Alternatives G, M, E, D, and D1 Alternatives A, A-Departure, C, and NC would have the lowest outputs Riparian conditions, at a minimum, would be maintained through the application of the Standards and Guidelines

The amount and concentration of soil erosion is primarily a function of the road construction, area harvested, and the basin-specific timber harvest dispersion constraints Soil erosion, loss of productivity, or reduction by construction of roads and other facilities represents a permanent, long-term loss. There

is nearly a linear relationship between acres harvested and the amount of sediment produced Alternatives G, E, and M would produce the least amount of sediment due to limited road construction and timber harvest Alternatives B, D, and C would produce greater amounts of sediment because of the greater level of activity Alternative C would produce the largest amount of sediment and highest peaks of sediment due to high harvest levels, a large hardwood conversion program, and the least restrictive basin harvest constraints Alternatives NC, A, A-Departure, K, S, and D1 would be within the mid-range of sediment outputs

WILD AND SCENIC RIVERS

River Management Plans for the Rogue and Illinois Wild and Scenic Rivers will not be affected through the range of alternatives. The Omnibus Oregon Wild and Scenic Rivers Act (1988) was passed just before release of this FEIS. As a result, this Planning Problem is reduced to the question of land allocation decisions and activities adjacent to Wild and Scenic Rivers' corridors Alternatives were designed in the DEIS to offer an array of management options for Wild and Scenic Rivers, and the rivers are allocated in the FEIS as originally designed. Any alternative selected would be brought into conformance with the recent legislation prior to harvest

Alternatives which assign at least the full inventory of Visual Quality Objectives in areas adjacent to Wild and Scenic Rivers and allocate greater amounts of land to Management Areas 1-9 provide the highest level of benefits to the Wild and Scenic River resource Alternatives M, E, and G would be the most complementary. Progressively less benefits would be provided by NC, A and A-Departure, S, and K, although the natural/near natural character of the river corridors will be maintained

Alternatives B, D, and D1 would reduce visual quality due to timber harvests adjacent to the Rogue and Illinois River corridors. Alternative C would have the most significant impact on visual quality adjacent to the Wild and Scenic Rivers by allocating the maximum amount of land to General Forest where the Visual Quality Objective of Modification would be applied.

As the visual quality along Wild and Scenic Rivers would be managed at increasingly higher levels, less amount of timber would be produced Subsequent consequences would include reduced payments to counties, reduced revenue to the U.S Treasury, and reduced economic values of the alternative. Where the visual quality is maintained at a higher level, the recreational experience on and adjacent to the rivers would be of higher quality with more natural-appearing views

SENSITIVE PLANT HABITAT

Designation of Research Natural Areas (RNA's) and Botanical Areas protects sensitive plant habitat from site-disturbing activities. The three existing RNA's and three existing Botanical Areas provide for scientific study and educational use in a protected environment Four new areas are considered for RNA designation, while 24 areas are potential Botanical Area candidates. No timber harvest would be programmed from the existing or candidate areas Mineral accessibility would also be slightly limited due to restrictions placed on mining operations within these two land allocations.

As the acreage of Botanical Management Areas increases, the probability of adverse effects on sensitive plant populations decreases. Alternatives S, E, G, and M would have progressively more acreage included in Botanical Areas Alternatives A, A-Departure, and NC would have no new candidate areas allocated, while the rest of the alternatives have about the same mid-range levels of new areas

In addition to the Botanical Areas, four RNA's would be proposed under different alternatives. Alternatives A and A-Departure would have one additional RNA proposed, while Alternatives B, C, D, and D1 propose two Alternatives E, G, K, S, and M would include all four additional RNA's which also include representatives of many plant communities on the Forest.

FOREST SCENIC VALUES

The preservation of natural-appearing scenery generally would increase as lands are allocated to the first nine Management Areas. Timber production would decrease as lands are allocated to Partial Retention, Retention, and Preservation status.

Alternative M would provide the most natural forest setting with an extended harvest rotation of 250 years and a lower harvest level. Alternative E would be similar to M in land allocation, however, harvest rotations are shorter in Partial Retention Visual and General Forest Management Areas so that visual impacts are greater on that part of the Forest. Both alternatives would have large amounts of natural-appearing views due to large amounts of land allocated to the Backcountry Recreation.

Alternatives G and S would have less area of natural-appearing views due to progressively less land allocated to the Backcountry Recreation Management Areas Alternatives A, A-Departure, D, C, D1, and B would have natural-appearing views mainly in designated Wildernesses, and along Wild and Scenic Rivers. However, Alternatives NC, A, and A-Departure would provide the most land in Retention and Partial Retention Visual Management Areas which provide high quality scenery throughout all the major travel routes on the Forest. Alternative K would reduce visual management with high quality scenery oriented only to the high recreation use areas

WILDLIFE HABITAT

The amount of old-growth habitat declines with increased harvest levels Alternatives M, E, G, and S would provide the most habitat suitable for old-growth species; Alternatives K, A, A-Departure, D, C, D1, and B would provide progressively less old-growth habitat. Alternative NC would provide the least because of the absence Management Requirements (MR's) for old-growth wildlife habitat All other alternatives would sustain viable populations of dependent species through the maintenance of MR's

Deer and elk forage, and opportunities for wildlife-viewing would increase with increased harvest levels Alternatives C, B, D1, and D would provide the most forage within the first decade. Alternatives A-Departure, NC, A, and K provide progressively less. Alternatives S, G, E, and M would provide the least deer and elk forage, and opportunities for wildlife recreational use.

UNROADED RECREATIONAL OPPORTUNITIES

Recreational opportunities for Primitive and Semi-primitive Non-motorized experiences would increase as the land allocated to Backcountry Recreation becomes larger. Alternatives S, G, M, and E would have progressively greater amounts of land allocated to the Backcountry Recreation Management Area Alternatives K, NC, A, A-Departure, D, C, D1, and B would have Primitive recreation opportunities mainly limited to existing Wildernesses, and Wild and Scenic Rivers.

As the opportunities for Primitive Non-motorized recreation increase, more old-growth habitat would be preserved, more sensitive plant habitat would be reserved, and risk to the water and soil resources would be minimized. The opportunities for dispersed motorized recreation, timber production, payment to counties, revenue to the U.S. Treasury, and employment opportunities would decrease as the opportunities for Primitive recreation increase.

Surplus capacity presently exists for Primitive recreational use However, the development of several unroaded areas would displace existing Primitive recreational use to other less desirable areas Potential development would occur in Alternatives NC, A, A-Departure, B, C, D, and D1, and to some extent in Alternative K.

MINERAL ACCESSIBILITY

Mineral accessibility is primarily a function of the area of land allocated to management categories where mineral restrictions apply. Alternative C would have fewest restrictions, followed closely by B, D, A, A-Departure, and NC. Slightly greater restrictions would be in Alternatives K and S. Alternatives M, E, and G would have the greatest restrictions primarily due to greater acreage allocated to Management Areas which either do not provide for road development or severely limit access

The alternatives that restrict mining activities the most could increase costs of mining operations and difficulty of access. The alternatives that would have fewer restrictions for mining could provide opportunities for easier access and more economically efficient mining operations

NET PUBLIC BENEFIT

Net Public Benefit (NPB) is the overall long-term value to the Nation of all outputs and positive effects, (called "benefits"), less all associated Forest inputs and negative effects, (called "costs"), resulting from management. Many "priced" benefits and all financial costs of management can be measured in dollars However, other "nonpriced" public concerns, benefits, and negative effects cannot be fully valued in economic terms. One purpose of this document is to identify these benefits and costs so that a judgement can be made about which alternative provides the mix of goods and services that most closely maximizes NPB while responding to expressed public concerns.

The future value to society of this Forest will depend upon the mix of economic and other values that are produced and the costs of managing the Forest to produce these values. Judgements about the various mixes associated with each alternative may differ. Understanding competitive and complementary relationships among alternatives provides a useful starting point

Emphasizing responses to issues that focus on nonpriced outputs reduces net economic values principally because of reductions in the land base for timber production. Land allocations to the Backcountry Recreation, Supplemental Resource, Research Natural Area, Botanical, Unique Interest, and Designated Wildlife Habitat Management Areas would reduce the area for programmed timber harvest While not reducing the land base, allocations to Riparian, Retention Visual, and Partial Retention Visual Management Areas limit the amount of timber that can be produced over time

All alternatives except Alternative M would provide for economic growth in payments to counties and receipts to the U S Treasury over the 150-year planning horizon Alternatives B, C, D, and D1 would increase levels above historical conditions for the first decade provided all outputs are consumed. Alternatives NC, A, A-Departure, S, and K would provide payments approximately equal to historical conditions Alternatives G, E, and M would result in progressively and significantly lower levels of timber harvest and associated benefits in the first decade.

The mixes of outputs, land allocations, and management emphasis of the various alternatives will be judged differently depending on community and individual social values Although changes in management activities and physical conditions would be phased in gradually, alternatives that provide the biggest change in development or preservation of the timber resource are likely to lead to the greatest conflicts within communities

PRESENT NET VALUE

The primary measure of economic efficiency used by the Forest Service is PNV. It is the sum of the benefits minus the sum of the costs for the 150-year planning horizon, discounted to the present at the rate of four percent per year Table S-3 displays PNV and total discounted benefits and costs for the alternatives and the Max PNV Benchmark. The alternatives are listed in order of decreasing PNV. Generally, both discounted costs and discounted benefits decrease as PNV decreases All three variables are directly related to the level of timber harvest. As the amount of timber harvested increases, PNV, discounted benefits, and discounted costs all increase (and, conversely, decrease as timber harvest declines). PNV and level of timber harvest would range from a maximum in Alternative B to a minimum in Alternative M.

Table S-3. Present Net Value, Discounted Costs, and Discounted Benefits, with Incremental Changes between Alternatives (MM $ discounted at 4 percent for 15 periods). Alternatives are ranked in order of decreasing PNV.

Alternative	PNV	Change	Costs	Change	Benefits	Change
Max PNV Benchmark	1,278		785		2,062

Chapter I
PURPOSE OF AND NEED FOR ACTION
INTRODUCTION

The Siskiyou National Forest has proposed and analyzed several alternatives for managing the Siskiyou's land and resources. This chapter presents the purpose of, and the need for, proposing these alternatives.

There is widespread public interest in the resources of the National Forests and diverse viewpoints on how they should be managed. The purpose of this analysis and disclosure is to examine the Forest resources and, in full awareness of these viewpoints, recommend a course of action to best guide the management of these resources in the future; and display the environmental impacts associated with this action This Final Environmental Impact Statement (FEIS) describes a range of alternatives for future management of the Siskiyou National Forest and discloses the environmental consequences, including significant impacts, of implementation The management alternatives considered include a Preferred Alternative, i e , the Proposed Action.

The alternatives suggest various means of: (1) addressing local, regional, and National public issues and management concerns, (2) providing for the use and protection of Forest resources; and (3) fulfilling National legislative requirements Each alternative generates a different mix of goods and services which the Siskiyou National Forest is capable of producing For this Plan, multiple use and sustained yield become the guiding principles

Each alternative was evaluated to determine its potential to provide a sustained yield of goods and services in a way that would meet multiple-use objectives and best maximizes long-term net public benefits (NPB) while responding to the Planning Problems. NPB represents the cumulative net value of all Forest outputs and activities, whether assigned a dollar value or not This is an overall goal and its determination is dependent on the degree of resolution for each of the Planning Problems identified later in this chapter For a full explanation of the analytic concepts used in addressing this problem (net public benefits, present net value, and net subjective value), see Appendix B. The Preferred Alternative is that alternative which, in the considered opinion of the Forest Service, would best meet these objectives

The Preferred Alternative, as modified by the Record of Decision, is the basis for the accompanying *Land and Resource Management Plan* (LRMP, or the Forest Plan), which is a separate document The purpose of the Forest Plan is to guide future natural resource management activities on the Siskiyou.

The preparation of an Environmental Impact Statement (EIS) that discloses the proposed action and its alternatives is required by the National Environmental Policy Act of 1969 (NEPA), the Council on Environmental Quality's (CEQ) Regulations for implementing NEPA (40 CFR 1500 et seq), and the implementing regulations of the National Forest Management Act of 1976 (NFMA) (36 CFR 219). Preparation of the Forest Plan is required by the Forest and Rangeland Renewable Resources Planning Act of 1974 (RPA), as amended by NFMA, plus the associated National Forest System Land and Resource Planning Regulations (36 CFR 219). For purposes of disclosure under NEPA, this FEIS and the accompanying Forest Plan are treated as combined documents In addition, the FEIS (1988) for the Silver Fire Recovery Project is incorporated by reference.

The EIS is required because the implementation of the Forest Plan is a major Federal action significantly affecting the quality of the human environment Its purpose is to provide decisionmakers with an environmental disclosure sufficiently detailed to aid in the selection of management direction for the Forest. Equally important, its purpose is to make information on the alternative environmental impacts available to the public, and to encourage public participation in the development and refinement of that information

The Record of Decision (ROD) accompanies this FEIS and Forest Plan The ROD identifies the selected alternative that will be implemented, and provides the accompanying rationale for the decision

Due to the length and complexity of this FEIS, Appendices, and accompanying Forest Plan, reader aids are provided to help in searching for the presence and location of given subjects. The TABLE OF CONTENTS is at the beginning of the FEIS to provide information on how the documents are organized and their general content The ACRONYMS AND GLOSSARY defining terms, units, and abbreviations is located after the last chapter; an INDEX to key subjects is also provided there. A list of references cited in the FEIS is also provided (LITERATURE CITED). For additional assistance, please contact the Forest Supervisor's planning staff (telephone number and address are on the Abstract preceding this Chapter)

CHANGES BETWEEN DRAFT AND FINAL

The Draft Environmental Impact Statement (DEIS) and Proposed Land and Resource Management Plan were released to the public on August 28, 1987. Chapter I in the DEIS differs from the FEIS Chapter I in several ways Changes that have occurred since the DEIS was published are incorporated in this (FEIS) chapter including the 1987 fires, inventory update, public involvement during the Silver Fire Recovery Project, the Silver Fire Recovery FEIS, and the three newly designated rivers under the Omnibus Oregon Wild and Scenic Rivers Act of 1988. This chapter also provides discussion of the public involvement in Forest planning following the release of the DEIS and public attention to some aspects of the planning issues including reforestation, biological diversity, Wild and Scenic rivers, tourism and recreation, and various technical questions related to timber harvest amounts Discussion under **PLANNING PROBLEMS** gives more information on the issues which were ratified and those receiving fresh emphasis.

The Final Supplement to the EIS for an Amendment to the Pacific Northwest Regional Guide (USDA 1988b) that addresses spotted owl guidelines has been completed since the publication of the Siskiyou DEIS The changes in direction have been incorporated in this FEIS resulting in minor changes in the Standards and Guidelines and the habitat network The revised direction is not substantially changed for the Siskiyou, and changes in the alternatives for this analysis are negligible The EIS for Managing Competing and Unwanted Vegetation (USDA 1988c) was also released since the DEIS, the plan assumes that all methods of managing competing vegetation are available and is consistent with the analysis in this FEIS and Forest Plan for the Siskiyou National Forest

NATIONAL, REGIONAL, AND FOREST PLANNING

As required by RPA, NFMA, and the related implementing regulations cited above, the Forest Service uses a three-level, integrated planning process At the National level, the RPA Program establishes long-range resource objectives that are based on the present and anticipated supply of, and demand for, various resources. Portions of each of the National resource objectives included in the RPA Program are distributed to each of the nine Forest Service Regions

At the Regional level, a Regional Guide is developed This guide distributes the Region's portion of RPA National objectives to each National Forest within the Region The Regional Guide also establishes Regional management standards and guidelines The Pacific Northwest Regional Guide (USDA 1984b) provides this direction for the Siskiyou National Forest Standards and guidelines for management of spotted owl habitat are established in the Final Supplement to the EIS for an Amendment to the Pacific Northwest Regional Guide (USDA 1988b) The EIS for Managing Competing and Unwanted Vegetation (USDA 1988c) provides direction for vegetation management for the Pacific Northwest Region

At the Forest level, a proposed Forest Plan is prepared. Ranges of different resource objectives form the basis for alternatives considered in the EIS for the Plan, one of these alternatives incorporates the tentative RPA Program resource objectives displayed in the Regional Guide The Forest Plan includes direction provided by RPA, NFMA (including the implementing regulations) and the Regional Guide

The planning process is a continuously repeating process Information from the Forest level flows up to the National level, is incorporated into the RPA Program, and then flows back to the Forest level The RPA Program and Regional Guide are updated every five years The Forest Plan analysis considers a 150-year planning horizon to ensure that management plans can be implemented over the long term, and to disclose and evaluate long-term environmental consequences

The alternatives presented in this document contain management direction for the Plan period. The Forest Plan period covers the next 10 to 15 years. NFMA regulations define the Plan period as one decade, while the law permits a 15-year maximum Within the Plan period, conditions on the Forest will be reanalyzed every 5 years, and under certain circumstances, the Plan may be revised

Management actions, outputs, and environmental effects for several decades beyond the Plan period are also discussed for the alternatives The purpose of these discussions is twofold (1) To present to decisionmakers and the public a long-term analysis of the management necessary for each alternative to achieve and maintain, in perpetuity, a high level of regular periodic outputs of various resources without impairment to the productivity of the land. This analysis also provides an estimate of the level of long-term outputs for each alternative. (2) Program development for RPA requires information for four decades beyond the Plan period In order for the analysis of alternatives for an RPA program to link with actual conditions and local issues at the Forest level, a complete estimate of outputs, costs, and effects for the RPA time horizon is imperative.

The projection of effects and attributes of the alternatives beyond the Plan period, although required by law, does not legally bind the Forest to action beyond the Plan period The Forest Service is required to revise the Plan within 15 years of its adoption; this revision may establish different long-term goals with different projected effects and outputs

The Planning Steps leading to the development of the DEIS and Proposed Land and Resource Management Plan are·

1 Identification of issues, concerns, and opportunities
2 Development of planning criteria.
3. Inventory data and information collection.
4 Analysis of the management situation.
5. Formulation of alternatives.
6. Estimated effects of alternatives
7. Evaluation of alternatives

(Refer to Appendices A and B for a detailed description of the process used in Planning Steps 1 through 6) *Planning Records*, the documents and files which chronicle the first seven planning actions, are available for review at the Forest Supervisor's Office in Grants Pass, Oregon. The planning records are referenced in the text and appendices of this FEIS and Forest Plan

Government agencies and the public were consulted for comments on the DEIS and the accompanying proposed Forest Plan. Comments received have been used to evaluate the results of the first seven planning steps and modify, where necessary, the Preferred Alternative and Forest Plan. Appendix K describes the public involvement process between the DEIS and FEIS, it also displays the comments received and the Forest's response to those comments.

This FEIS will be used by the Regional Forester as the information base for a Record of Decision. The ROD will be made available to the public Issuance of the ROD will complete Planning Step 8 and initiate the last two Planning Steps

8. Selection of the Preferred Alternative and documentation of its proposed implementation in the Forest Plan.
9 Plan implementation
10. Monitoring and evaluation

Figure I-1 displays the major steps of the Forest Planning Process

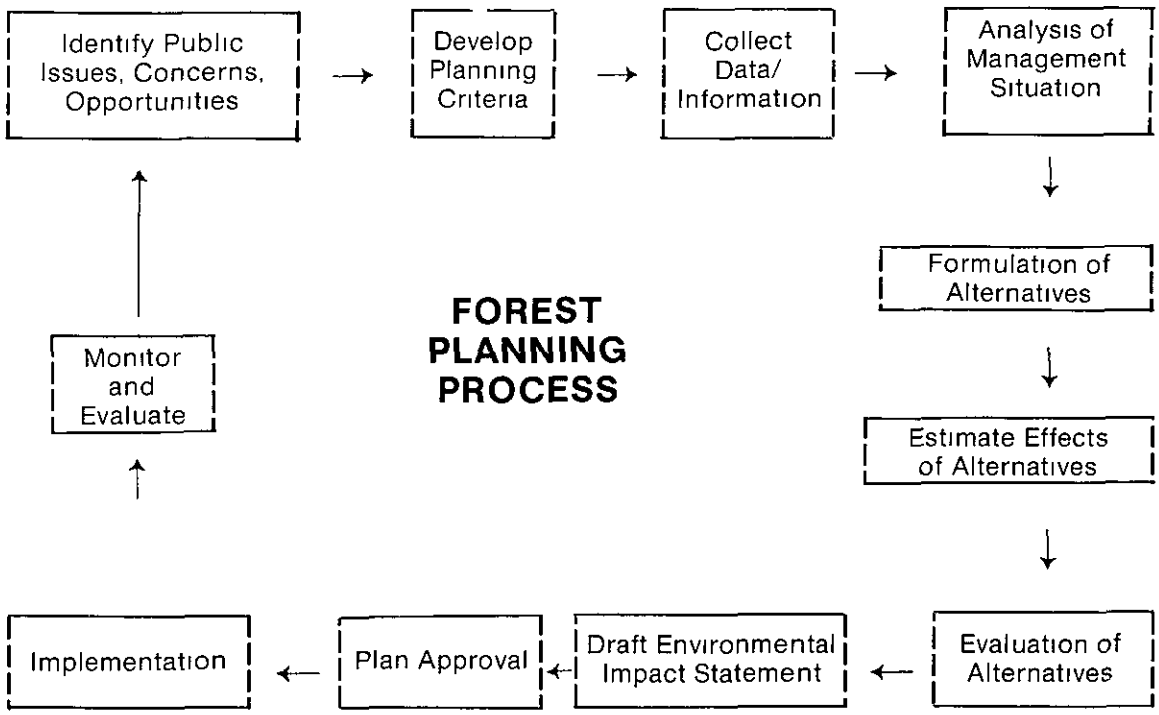

Figure I-1. Forest Planning Process

Upon implementation, the FEIS and Forest Plan will be used for "tiering" in accordance with the CEQ regulations. Tiering means that the environmental analyses conducted for site-specific projects and implemented under the direction of the Forest Plan will refer to the FEIS, Forest Plan, and associated documents Information will be used from them to help narrow discussions and concentrate on issues pertinent to the project This will help minimize repetition of information contained in documents having broader authority or coverage Project scoping, public and other agency involvement, and the ensuing environmental analyses will then be able to focus on issues unique to those projects and site conditions.

The Forest Plan supersedes or incorporates all previous land and resource management plans prepared for the Siskiyou National Forest Upon implementation, Forest management activities will comply with the Forest Plan. Appropriated budgets may alter the schedule of activities. In addition, all permits, contracts, and other instruments for the use and occupancy of National Forest System Lands and resource uses must be in conformance with the Forest Plan. Such documents shall be revised where needed as soon as practicable, subject to valid existing rights. This updating will generally be done within three years

The NFMA regulations guiding the development of Forest Plans state, "...if in a particular case, special area authorities require the preparation of a separate special area plan, the direction in any such plan may be incorporated into the Forest Plan without modification " For this reason, the Rogue National Wild and Scenic River Management Plan (Federal Register, July 7, 1972) and Illinois Wild and Scenic River Management Plan (1985) will be incorporated unchanged in all Forest Plan alternatives

Major wildfires impacted parts of the Forest during the review period of the DEIS and draft Forest Plan Rehabilitation and timber salvage opportunities were evaluated in a separate environmental analysis Full public involvement and scoping were used in addressing the major issues surrounding the management of the fire area and recovery of burned timber. The Silver Fire Recovery Project FEIS is incorporated by reference in this FEIS.

The Forest planning process will be used to provide the mandated direction for the Wildernesses which have separate area management plans. The Rogue River National Forest is the lead Forest to complete the Red Buttes Wilderness Plan. The Klamath National Forest will carry the lead on the Siskiyou Wilderness Plan

OVERVIEW OF FOREST

The Siskiyou National Forest is located in the Klamath Mountains and Coast Range of southwestern Oregon (Josephine, Curry, and Coos Counties), with a small segment of the Forest extending into northwestern California (Del Norte County) The Siskiyou contains 1,162,030 acres within its boundaries, 69,728 acres of which are privately owned or managed by other government agencies The FEIS and Forest Plan apply only to National Forest System lands

The Forest Supervisor's Office is in Grants Pass, Oregon Ranger District offices are in Grants Pass (Galice Ranger District), Cave Junction (Illinois Valley Ranger District), Brookings (Chetco Ranger District), Gold Beach (Gold Beach Ranger District), and Powers (Powers Ranger District). These locations are shown on the Vicinity Map (Figure I-2), district boundaries are shown on the Ranger District Map (Figure I-3).

The topography of the Forest is very mountainous, with elevations ranging from 100 feet to over 7,000 feet. It is characterized by a variety of landforms ranging from knife ridges and deep canyons to flat ridgetops and rounded sideslopes The Forest is drained by many fast-flowing rivers characterized by steep-sided inner gorges

Principal Forest resources include very productive timber lands, high quality anadromous fisheries, five Wild and Scenic Rivers, a wide variety of plant and animal life, five Wilderness areas, a road system, diverse mineral deposits, and a wide range of recreational opportunities.

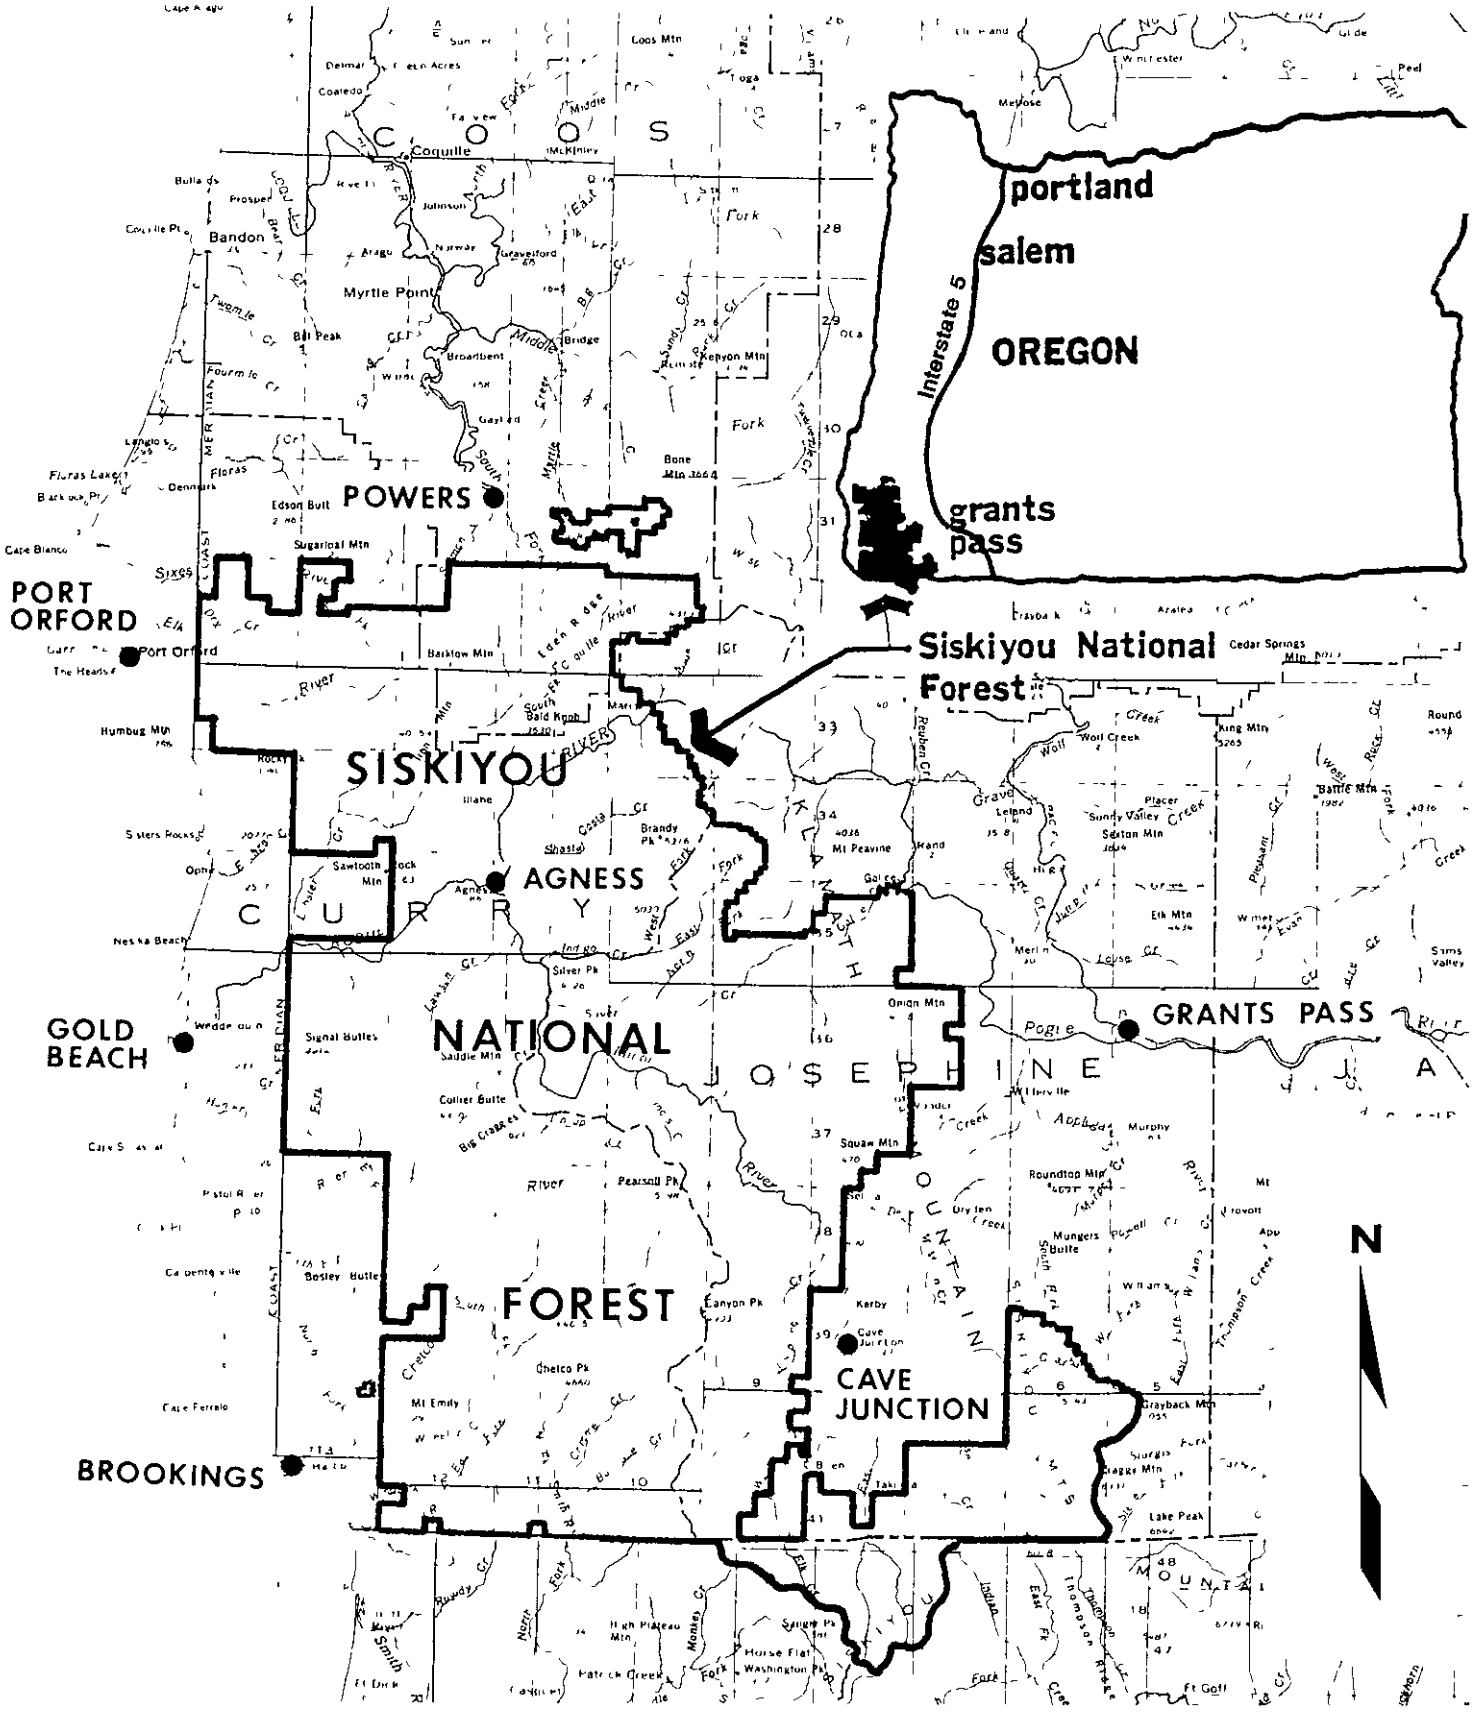

Figure I-2 Siskiyou National Forest Vicinity Map

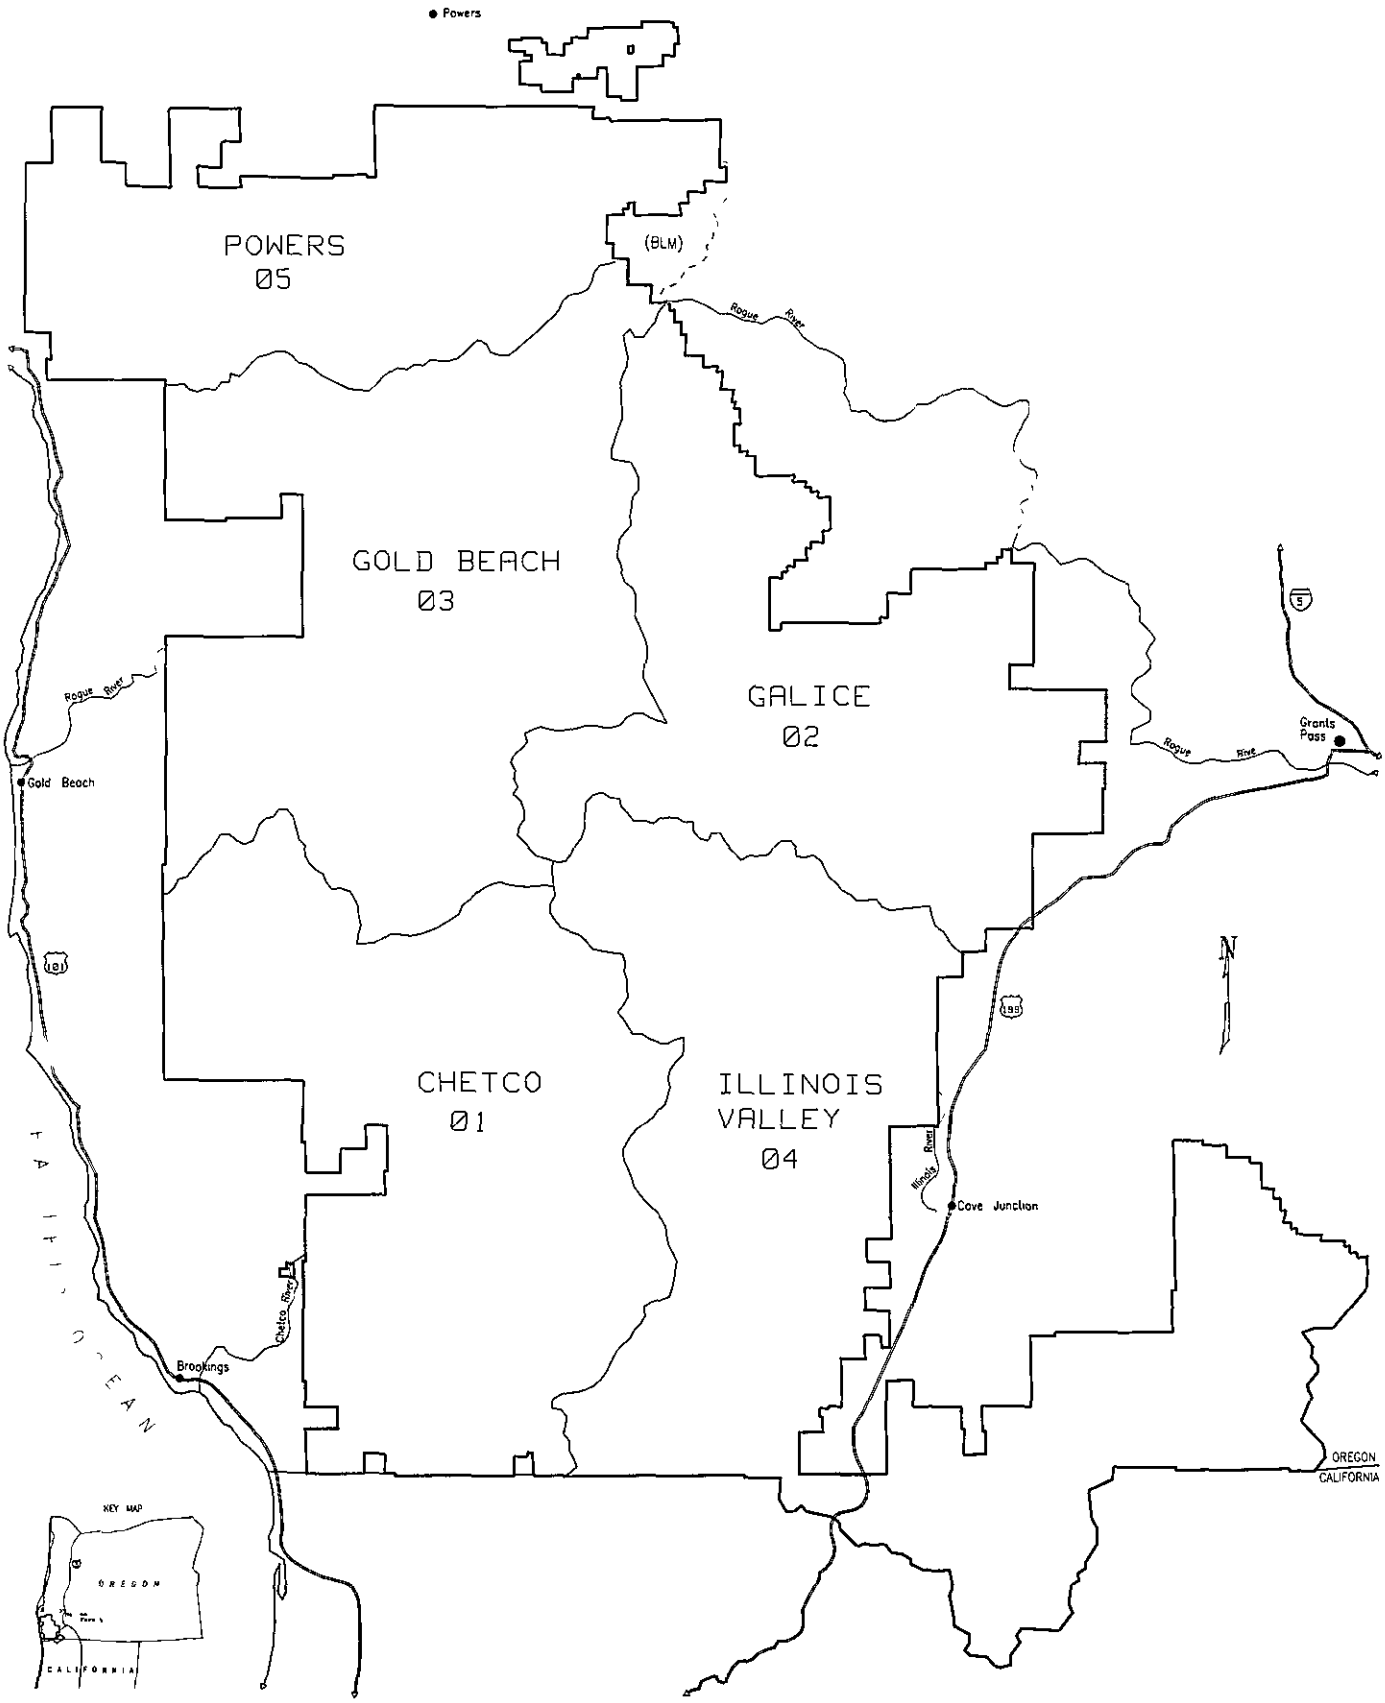

Figure I-3 Ranger District Map

The four counties that are most interrelated with the Siskiyou National Forest are Jackson, Josephine, Coos, and Curry The total population of the local four-county area is approximately 271,000 County populations range from a high of 132,500 in Jackson County, to a low of 17,000 in Curry County (Figure I-4)

The dominant employer in the area is the lumber and wood products sector. Timber outputs from the Siskiyou National Forest account for an estimated 2,500 jobs in the total employment picture. The timber industry accounted for 15 percent of total employment in the four-county area in 1983 This proportion has been declining for the past several years. Concurrently, electronics, light manufacturing, and service industries are accounting for a greater share of total employment.

Recreation and tourism also contribute to local jobs and economic stability Total developed and dispersed recreation use is approximately 700,000 visitor days annually. An additional 67,000 sport fishing user days are attributable to Forest resources, and 76,000 wildlife user days occur on the Forest In total, these Forest resources support 847,000 user days and account for an estimated 1,000 jobs. A detailed description of the affected environment is in Chapter III.

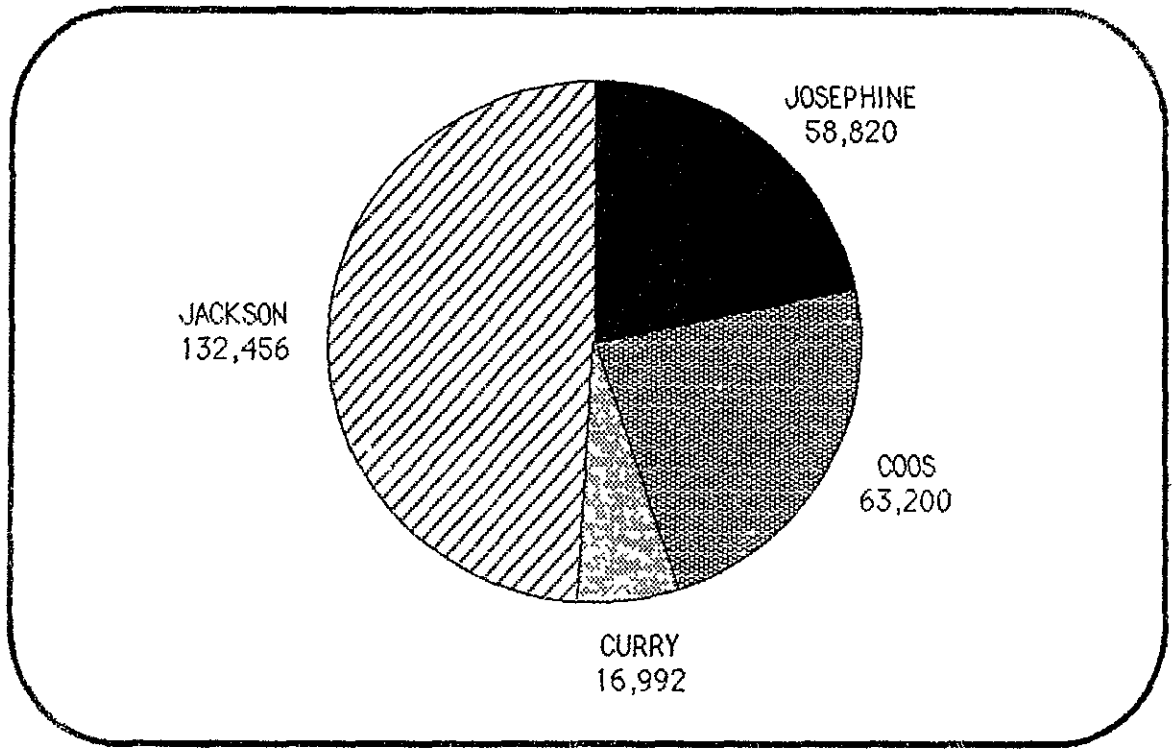

Figure I-4 Population by County - 1980 Census

ISSUES, CONCERNS, AND OPPORTUNITIES

DEVELOPMENT AND CONFIRMATION

The Siskiyou National Forest consists of complex natural systems that can be managed for different mixes of resource outputs, land uses, and environmental conditions. The public has differing views on how the Forest should be managed, each viewpoint emphasizes a different combination of outputs, uses, and conditions Because all the resources, uses, and conditions of a Forest are ecologically and economically interrelated, a management emphasis for certain resource outputs will result in changes in other Forest resources. These tradeoffs occur as a direct result of the implementation of management schemes which emphasize selected resource outputs, land uses, and environmental conditions at the expense of other potential outputs, uses, and conditions. There are practical and natural limits to what a Forest can provide

The Issues, Concerns, and Opportunities (ICO's) are identified to provide the context for analyzing the Forest's potential to provide the various mixes of outputs, uses, and conditions that are encompassed by differing public views. A public *Issue* is a subject or question of widespread public interest relating to management of the National Forest resources

A management *Concern* is an issue, problem, or condition which constrains the range of management practices identified by the Forest Service in the planning process.

A third component influencing alternatives comes from the various resource use and development *Opportunities* suggested by both the public and Forest Service. These opportunities give rise to many of the issues and concerns identified here. The opportunities to preserve or develop and use the resources of the National Forest are the focus of many of the Agency's programs, and are the principal focus of the management alternatives developed here. Because there are both public issues and management concerns about these opportunities, most of them are incorporated within the discussion of issues and concerns. The opportunities that have been identified are listed and discussed in Appendix A.

Identification of the ICO's has been a critical step in the planning process This information has been collected and refined throughout the entire planning effort. This process began in 1979 when a potential list of ICO's was developed from previous public comments on Forest management problems and several Forest Service employee and public meetings. In early 1980, the ICO's were published as a Forest Plan Report and sent to a wide variety of interested citizens and groups, and local, state, and Federal agencies in Oregon and California.

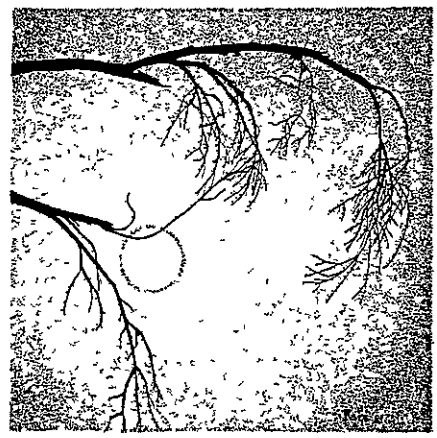
The ICO's have changed somewhat with time As new events occurred and local, regional, and National goals and policies changed, the ICO's were modified accordingly. This confirmation was essential in order to keep the lengthy planning process updated and the analysis tracking with current conditions and views. Additional information on how the ICO's were collected, evaluated, and selected for inclusion in the planning analysis is presented in Appendix A.

The ICO's for Forest planning were ratified again through extensive public comment received after publication of the DEIS and proposed Forest plan. The Forest received a total of 16,983 responses (with 17,277 signatures) during the 150-day review period The normal 90-day public review period was extended twice. The first extension was related to the impacts of the fires on the Forest's ability to meet with all the public. The second extension came in response to local officials' requests.

Several issues or aspects of ICO's received fresh emphasis. Numerous meetings with interested agency officials, groups, and individuals have continued to clarify ICO's Appendix K describes the public involvement process between the DEIS and FEIS, it also displays public comments received and the Forest response to the comments In addition, Appendix K lists the names of those who commented, and

photocopies of letters received from elected officials, local, state, and Federal agencies, and Native American groups

1987 FIRES

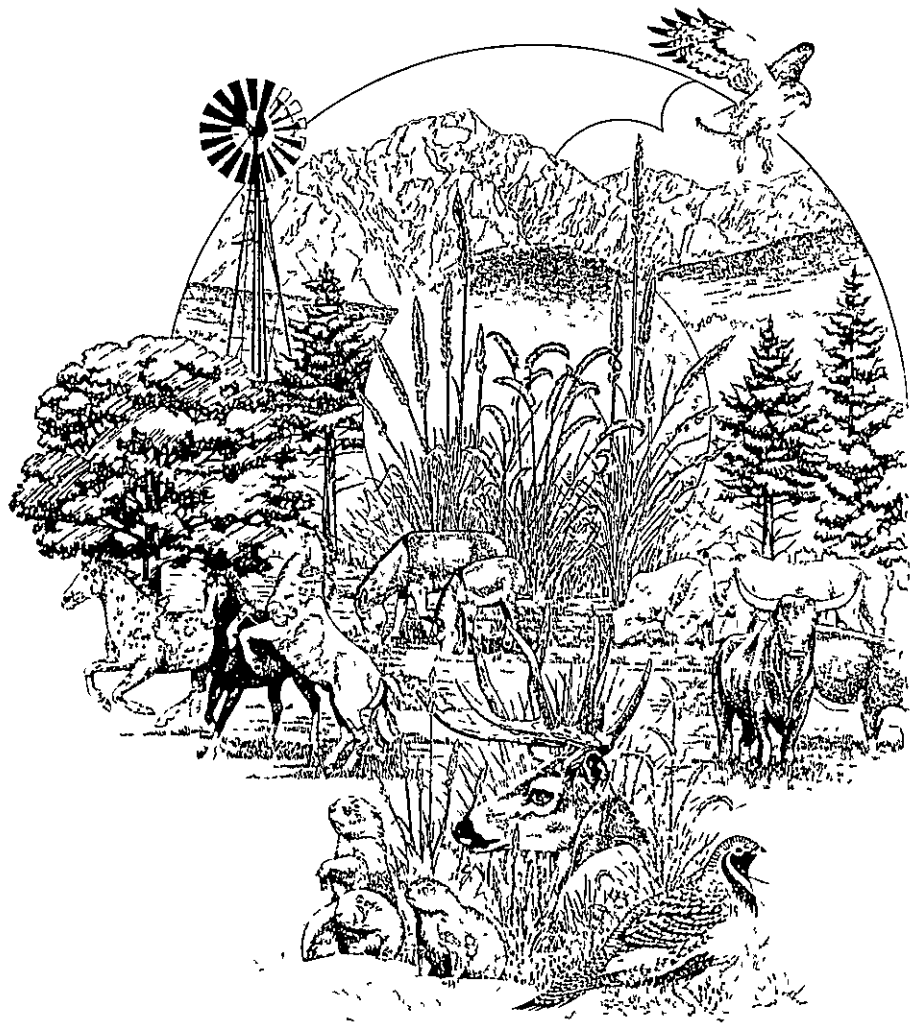


Lightning ignited several fires on August 30, 1987, two days after release of the DEIS and proposed Forest Plan for public review. The Silver, Galice, and Longwood Fire Complexes involved a total area on the Siskiyou National Forest of approximately 110,000 acres. Planning for salvage of fire-killed timber and resource restoration occurred on these fire areas Public involvement in this planning process was extensive, especially on the Longwood and Silver Fires, numerous meetings and workshops were held with interested people

The public involvement process during the Silver Fire Recovery Project was one of the most comprehensive in Forest Service history Nearly 28,000 responses to the Silver Fire Recovery Project DEIS were received. With the exception of the issue of "rapid timber recovery," public interest was focused on similar ICO's (or aspects of issues) as those described in the Planning Problems below The Silver Fire Recovery Project FEIS and ROD was released in July, 1988. An amendment to the 1989 Appropriations Act modified the implementation of the project plan in the Bald Mountain area

The effects of the fires on various resources are described in Chapter III, Affected Environment, 1987 Fires The effects, viewed from a Forest-wide perspective, are not significant. Approximately three percent of the land base suitable for the production of timber was impacted. The maximum effect on the Forest's potential to produce timber is about 2 MMBF in ASQ The intensive survey work needed for the project provided an update of some inventory information, including tentatively suitable land and timber inventory. Inventory update information is also given in Chapter III.

Wildlife species or habitat for either plant or animal, including the spotted owl habitat network proposed in the DEIS, do not appear to be seriously affected Fisheries and watershed effects include increased stream temperature and sedimentation, with a corresponding reduction in smolt from Silver and Indigo drainages of one half of one percent of total Forest production



While fire itself does not appreciably change recreation opportunities, timber harvest and associated road construction of the Silver Fire Recovery Project will reduce the unroaded acres Forest-wide by approximately seven percent. A roadless inventory update for changes resulting from both the Silver Fire and other Forest activities between 1984 and present is provided in Appendix C - Roadless Areas

PLANNING PROBLEMS

The central tasks in Forest planning are the development of alternative ways of managing the National Forest and the determination of the implications of these management alternatives for the Forest environment and its potential for supplying human needs. The differing emphases on goods, services, uses, and environmental conditions that various concerned communities, groups, and individuals desire, as well as the physical, biological, and legal limits of Forest management, are reflected in the ICO's that thread through the entire planning process. The ICO's have been analyzed and grouped or restated in the following Planning Problems and posed as questions that can be used to guide the development of alternatives The alternatives are then evaluated to determine how well they respond to these Planning Problems in an attempt to resolve the conflicts and identify the best course for land and resource management.

Appendix A documents the development of the following Planning Problems from the ICO's The resources that these questions address are more fully described in Chapter III

KEY INDICATORS

The measure of the Forest's ability to respond to each Planning Problem is referred to as a Key Indicator Indicators include the outputs, uses, or conditions that can be measured or described to gauge the response of the various alternatives, these are displayed in Table I-1

Table I-1 Key Indicators of Planning Problem Resolution

PLANNING PROBLEMS/ Key Indicators	Unit of Measure
1 TIMBER PRODUCTION	
Selected Suitable Area	M Acres
First Decade Volume	MMCF
Fifth Decade Volume	MMCF
Long-Term Sustained Yield (LTSY)	MMCF
2 OLD-GROWTH FOREST	
Reserved Area 1/	M Acres
Available at End of Fifth Decade	M Acres
3 SOIL, WATER, AND FISHERIES	
Management Areas 1 through 9	M Acres
Riparian Prescriptions C and M 2/	M Acres
Capital Investments 3/	M $
Harvest Dispersion Constraint 4/	Number of Basin
Anadromous Sport Fish User Days	M WFUD's
Commercial Fish	M Pounds
Average Annual Sediment 5/	M Tons
4 WILD AND SCENIC RIVERS	
Adjacent Area Meeting VQO's 6/	M Acres
5 SENSITIVE PLANTS	
Research Natural Area	M Acres
Botanical Area	M Acres
6 VISUAL RESOURCES	
Viewsheds Meeting VQO's 7/	Number
Meets or Exceeds Partial Retention 8/	M Acres
7 WILDLIFE HABITAT	
Spotted Owl Capability 9/	Pairs
Woodpecker Habitat Capability 10/	Percent
Wildlife User Days	M WFUD's
Capital Investments	M $
Special Wildlife Sites	M Acres
8 WILDERNESS AND UNROADED	
Unroaded Condition - Management Area 1 through 9 11/	M Acres
ROS--Primitive and Semi-primitive	M Acres
9 MINERALS	
Area Accessible with Limited Restriction 12/	M Acres

1/ Mature and old-growth forest reserved (protected) in Management Areas 1 through 9 (MA 1-9) plus unsuitable acres in Management Areas 10 through 14 (MA 10-14), from 5 3 acre cells.
2/ Riparian Prescriptions M (Minimum Level) and C; both exceed the Management Requirement (MR) level for water quality as reflected in Prescription B
3/ The combination of capital investments from fisheries habitat and soil and water resource improvement projects, includes appropriated and K-V funds, both enhancement and mitigation work represented
4/ Timber harvest dispersion ("basin") constraints are applied to planning basins, they are individually tailored based on Planning Basin values, characteristics, and activity level, they constrain activity more than the MR of 20 percent
5/ Total average annual sediment output, includes background natural plus existing road loss rates, along with accelerated rates accounted for in the alternatives, calculation does not include other prior disturbances (harvest units or old burns)
6/ Area adjacent to (as seen from) existing or potential Wild and Scenic Rivers that meet or exceed their inventoried VQO's
7/ Viewsheds which meet or exceed the inventoried VQO's
8/ Area meeting or exceeding Partial Retention (Partial Retention plus Retention plus Preservation)
9/ Potential habitat capability to support spotted owl pairs over time (long term)
10/ Potential habitat capable of supporting a given percentage of woodpecker populations over time (long term)
11/ Inventoried unroaded area allocated to Management Areas 1 through 9 (MA 1-9) where little or no roading exists and management objectives are highly oriented to nondevelopment
12/ Area accessible to mineral exploration, development, and extraction with limited (low to moderate) restrictions imposed by other resource protection needs or standards

1. How Much Timber Should the Forest Produce?

Many individuals and groups feel that the Forest should help sustain regional and local economies by maintaining or increasing annual timber harvests. Along with this they feel that the land base available for commercial timber production should be conserved and not allocated to competing uses, and that intensive timber management practices should be applied on these lands to maximize timber yields On the other hand, there is concern about the effects of timber management on other resources, such as plant, animal, fisheries, and water quality. Concerns are also expressed by those who commented on the DEIS about our ability to provide for biological diversity and maintain species richness and distribution over time and space Some focus on reforestation success, growth and yield potential, and sustaining harvest levels in the future. Many feel that the amount of timber harvest should be reduced to benefit wildlife and recreation resources, and to preserve natural ecosystems.

The expectations from timber interests Nationally, regionally, and locally are that the Forest should continue to supply a significant amount of timber. Historically, the Forest has sold approximately 35 million cubic feet (MMCF) of timber annually The current sell program is 31 2 MMCF According to the Pacific Northwest Region's distribution of timber targets for the 1980 RPA program, the Forest's share of the timber supply should be about 37 MMCF per year (or 200 MMBF per year). Recent analysis of resource potentials indicates the Forest can only supply up to 33 MMCF per year (or 185 MMBF per year) in the first decade and maintain a nondeclining flow harvest schedule Thus, the timber supply potential on the Forest is lower than expectations, and lower than what past projections have indicated.

The ability to respond to the timber issue is complicated by the inventory structure existing on the Forest Standing volume, age class distribution, and the Forest's productive potential combine to create a situation characterized as "deficit inventory". The Forest has the potential to grow timber at a rate higher than can be sustained by the current inventory until the managed plantations reach harvestable ages Many of the natural stands on the Forest are slow growing mature trees with significant amounts of the growing space occupied by unmerchantable vegetation This condition results in relatively low volumes per acre compared to the potential of the sites. As these stands are regenerated, the timber growth increases dramatically. However, to sustain timber flows, the existing inventory must be metered out until these regenerated stands reach harvestable size and age. There are few stands in intermediate age classes, consequently, the critical period of scheduling the existing inventory is approximately 70 to 80 years Intensive management practices can do little to relieve this situation in the short term

Some of those who commented on the DEIS believe that the Forest should utilize a variety of technical applications to increase yield. These include adjustments to the yield tables, changes in the board foot/cubic foot conversion ratio, utilizing shorter rotations, applying fertilizer to plantations, selecting other programs or models to predict yields, and so forth.

This problem also encompasses the question of whether the Forest should harvest timber on a nondeclining flow schedule, or harvest at a higher level in the near future and plan for a decline in harvest volume in future decades. Departing from nondeclining flow could help sustain local economies by supplying a higher level of National Forest timber during a period when harvests from private lands are expected to be at low levels. Opponents to departure claim that this only shifts the burden of an inevitable decline to the future and increases the risk of adverse environmental impacts by harvesting at the higher level.

More than any other issue, the timber issue affects and is affected by the resolution of other resource issues. Sometimes this relationship is complementary, and sometimes competitive For example, timber harvesting may enhance deer and elk habitat (through forage production in harvest units), but reduce the amount of wildlife habitat available for species dependent on mature conifer forest.

The most significant effect of other resource uses on timber is the allocation of land to uses that exclude or greatly restrict timber management. Managing for fish habitat, mature forest wildlife habitat, soil protec-

tion, water quality, wilderness, unroaded recreation, Botanical areas, and Research Natural Areas all reduce the number of acres available for timber management Another significant effect on timber production occurs when management emphasis results in reduced yield from certain acres This occurs when rotations are lengthened (visual management emphasis), or when harvest is constrained to a fraction of the volume in the stand (streamside management emphasis).

This Planning Problem involves allocation of Forest land to timber production and the selection of management intensities, including harvest schedules and treatments such as commercial thinning and site preparation Potential timber production of lands allocated to other purposes must also be considered. Factors that vary by alternative include the number of acres selected for timber harvest (selected suitable), long-term sustained yield (LTSY), allowable sale quantity (ASQ), and the number of acres on extended rotation lengths or reduced yields.

Resolution of this problem also involves the consideration of opportunities to convert shrub and hardwood stands to timber-producing conifer stands There are approximately 48,000 acres of tentatively suitable timber land presently growing predominantly hardwood trees Even though the hardwood volume is considerable, particularly on the better sites, most of this volume is unmerchantable or of low value in today's market and only minimal amounts are accessible for fuelwood Conversion to conifers could increase commercial timber production by bringing acres under management. However, large amounts of residue are created, and there is concern that potentially useful material may be wasted In addition, hardwood stands contribute to the biological diversity of the Forest and provide habitat for various animal species. Many people feel that these stands should be maintained in their natural conditions to fill this role and provide for nonmarket values.

Another element in this Planning Problem is the cost, hazards, utilization factors, and environmental impacts of treating residues created by timber harvest or stand conversion Limits are needed for acceptable risks associated with residue treatments Better utilization, for firewood and other forms of energy, could aid in reducing the amount requiring disposal Disposal activities often involve the application of prescribed fire which can affect air, water quality, and soil productivity.

2. How Much Old-Growth Forest Should be Preserved?

Conflicts over the management of old-growth trees and forests have increased dramatically during the last decade. Interest has grown in preserving old growth for various reasons including· providing habitat for certain species of wildlife, maintaining the aesthetic quality of large old trees and forests, and retaining portions of the Forest in these older stages as part of the natural biological diversity of the area Some people also feel that centuries-old living trees should not be felled and converted to wood products for human use.

On the other side of this conflict is the feeling that enough old growth has already been designated for preservation, and that the remaining available stands, and the land they occupy, should be included in the base for timber management. Nearly all of the stands currently available for harvest on the Forest are in the mature or old-growth category They contain the highest volumes per acre and the highest quality wood for manufacturing Another aspect is the potential wood production that is not captured as long as these lands are occupied by slow-growing old stands. The old-growth stands generally produce little net growth, and in some cases, there is a net loss due to decay and mortality

Added to this, there is debate as to the adequacy of the Forest's inventory which surfaced through comments to the DEIS Some believe that the criteria for defining old growth is flawed; that a primary determinate should be age The specificity of the inventory is stated as being too broad to accurately differentiate "true" old growth from older, undisturbed stands of trees. The failure to come to agreement on differing criteria confounds this aspect of the old-growth question The inventory information available for the Forest was not developed to specifically identify old growth. Available data on the vegetation

condition has been used to assess the location and extent of old growth on the Forest. This data does not have the resolution to stratify stands with old-growth characteristics from other mature stands Therefore, although the majority of acres classed as mature and old growth do exhibit old-growth characteristics, some areas do not These small inclusions of other classes does not render the overall areas unsuitable as old-growth habitat.

The inventory (updated to 1985) indicates 443,000 acres of mature and old growth exist on the Forest, 99,000 acres are in areas dedicated to management that will preserve the old-growth character except for those changes resulting from natural processes (i e , Wilderness, Wild River, Research Natural Areas, and Botanical Areas); another 38,000 acres are in areas unsuitable for timber management that would not be programmed for harvest The alternatives vary by the amount of additional old growth included in land allocations that would retain the old-growth character, and by the rate of harvest of those acres that would be available for timber management.

3. How Can the Forest's Fish Habitat, Water Quality, and Soil Productivity be Maintained or Improved?

Fish habitat is highly dependent on water quality. Water temperature and sedimentation are critical to the maintenance and protection of the fisheries habitat Soil erosion, slope stability, and vegetative cover along streams are extremely important in providing for fisheries and other riparian values. Management of the soil and water resources (termed "watershed management") is closely tied with fisheries management As a result, these interrelated resources are considered in the same Planning Problem. Many people who made comments on the DEIS are concerned about fisheries and water quality.

The Siskiyou National Forest contains some of the most valuable salmon and steelhead habitat in the United States Both sport and commercial fishing interests are highly concerned with the fish production capability of rivers and streams, and feel that the Forest should be managed to enhance fish habitat and increase production. The health and productivity of fish habitat depends on good watershed management

Timber harvesting, roading, and mining activities have the potential to adversely affect fish habitat. Many feel that these activities should be precluded or curtailed on parts of the Forest to ensure protection of the fish and watershed resources. Others believe that these resources can be protected through application of available management practices without substantially reducing timber or mineral outputs.

Approximately 1,150 miles of salmonid-bearing streams, including 600 miles of suitable anadromous habitat, are administered by the Forest. With a few exceptions, most available habitat on the Forest is fully utilized by the fish that return to spawn. The quantity and quality of spawning gravel is considered adequate throughout the Forest, providing spawning habitat for production of approximately 65,000 wildlife and fish user days (WFUD's) in the sport fishery and 880,000 pounds in the commercial harvest

Management of fish habitat is the responsibility of the Forest Service, while fish populations are managed by the Oregon Department of Fish and Wildlife (ODFW) and the California Department of Fish and Game. ODFW program goals emphasize the increased production of "wild" (non-hatchery) salmonid stocks Capital expenditures for habitat improvement are the most effective means of achieving ODFW program goals in the short term. The catch attributable to Forest outputs could be increased to approximately 105,000 WFUD's and 1 3 million pounds of salmonid harvest through larger capital investments

Factors affecting the fisheries resource over which the Forest has little influence are the management of the annual fish harvest, including the off-shore catch, and the withdrawal of stream water for domestic and irrigation use The most severe withdrawals occur are on private lands in the Deer Creek and Illinois Valley.

In addition to management practices to avoid sedimentation and provide high quality water, there is also concern for maintaining or enhancing soil productivity Activities can result in soil compaction, displace-

ment, or erosion Additionally, biological, chemical, and other physical changes, such as loss of soil organics, can occur with activity Approaches to this problem range from removing land from consideration for timber harvest or mining, to applying management practices designed to protect the soil when implementing such projects

Resolution of this fish and watershed problem involves a mix of land allocation, capital investments, and application of standards and guidelines. Allocations to different Riparian management prescriptions, and the allocation of higher risk lands and inner gorge areas to Management Areas where no timber harvest is programmed, are complementary to fish and watershed resources Scheduling capital investments can be utilized for both mitigation and enhancement; and resource protection can be met through applying standards and guidelines in project phases of planning, location, design, implementation, and monitoring. The application of site-specific practices, or Best Management Practices (BMP's), can help to meet State water quality standards for protecting and maintaining the identified beneficial uses

Factors that vary by alternative include basins allocated to various Riparian prescriptions, allocations to Management Areas that have no programmed harvest, the level of capital investment, timber harvest dispersion constraints, sport fishing WFUD's, pounds of commercial catch, and sediment

4. How, and to What Extent, Should Lands in and Adjacent to River Corridors be Managed to Protect, Preserve, and Enhance Wild and Scenic River Attributes?

Parts of the Rogue and Illinois Rivers that flow through the Forest have received designation as National Wild and Scenic Rivers. Two other rivers, the Chetco and North Fork Smith, were inventoried as potential candidates to the Wild and Scenic River System. The Elk River had just recently been evaluated as eligible for potential inclusion In October, the Chetco, Elk, and North Fork Smith Rivers were designated in the Omnibus Oregon Wild and Scenic River Act of 1988. Additional information and description of the designated rivers are provided in Chapter III.

As a result of increased interest and public comment on the DEIS, several other rivers were evaluated in July 1988 for eligibility. These included the Elk, Pistol, South Fork Chetco, South Fork Coquille, South Fork Sixes, and Winchuck Rivers. Except for the Elk, the other five were determined not to be eligible for possible addition to the National Wild and Scenic River System The Elk River was determined eligible primarily for its outstandingly remarkable anadromous fishery

There are diverse opinions on the appropriate levels of use for these rivers along with management of the surrounding lands The level of use affects the amount of contact between users and has the potential to detract from the quality of the recreation experience. Activities such as timber harvest could affect the recreational setting if allowed within sight and sound of the rivers. Some feel strongly that such activities would seriously degrade the quality of the river environments, while others feel that these practices could be accomplished in ways that would be compatible with all values in the river corridors.

As a result of the Omnibus Oregon Wild and Scenic River Act of 1988, this Planning Problem now includes two elements (1) What management direction for the Recreation, Scenic, and Wild sections of the five designated rivers needs to be established or reaffirmed?, and, (2) What should management direction be for lands adjacent to Wild and Scenic River corridors?

Levels of permissible use and the distribution among various user groups is the most often cited controversy affecting management of the designated Wild and Scenic Rivers on the Forest. Use and capacity will not be addressed in this analysis A five-agency management group, including the Forest Service, is responsible for determining use capacities on the Rogue River to sustain the values for which it was nominated User capacities and distribution for the Illinois River were determined through development of the River Management Plan referenced earlier.

For this analysis, land management decisions within the actual river corridors are limited to the assignment of visual management objectives for site-disturbing activities, trail development, and the specification of Standards and Guidelines Standards and Guidelines are designed to achieve the goals and objectives of the Wild and Scenic Rivers Act

Management Plans exist for both the Rogue and Illinois Rivers However, as a result of the very recent legislation, river management plans will have to be prepared for the three new Wild and Scenic Rivers. River Management Plans are required to be developed for the Chetco, Elk, and North Fork Smith Rivers under the provisions of the Wild and Scenic Rivers Act, 1968 The management plans will state· general principles for any land acquisition which may be necessary; the kinds and amounts of public use which the river area can sustain without impact ot the values for which it was designated; and specific management measures which will be used to implement the management objectives for each of the various river segments and protection of their features Management plans for these rivers may establish varying degrees of intensity for the protection and development, based on special attributes of the rivers.

Recreational experiences and water quality and quantity can be affected by management activities adjacent to Wild and Scenic River corridors. Land management decisions for areas within the watershed, the viewshed, or corridors of the designated rivers must take into account possible repercussions on the values for which each river segments is classified

Resolution of this problem involves the recommendations for future management of the three newly designated rivers The river management plans and accompanying recommendations will be prepared later, and are not part of the Forest Plan. The key indicator for this Planning Problem, therefore, is the allocation of inventoried VQO's and other Management Areas adjacent to the river.

5. How Should Sensitive Plant Resources be Managed?

The Forest is habitat for numerous rare plants. There is a considerable amount of interest in protecting these plants from disturbance which could result from activities such as road construction, timber harvest, and mining. There is also concern that some species need protection from plant collectors Many people feel that unique habitat areas contribute to overall biological diversity and that concentrations of rare plants should be designated as Botanical areas or Research Natural Areas (RNA's); activities that could disturb plants would be precluded in these areas Others feel that the plant populations should be managed through "on-the-ground" project location and design, without removing or greatly restricting lands for timber management or mineral development.

The management of sensitive plant habitat is addressed through the alternatives by the allocation of various sites to Botanical or RNA designations. Currently there are three Botanical areas and three RNA's dedicated on the Forest. There are 24 candidate Botanical areas and four candidate RNA's under consideration in this analysis. Details of each site are provided in Appendix F.

Key indicators for the development and evaluation of alternatives are the acres allocated to these Management Areas. Sensitive plants and their habitat will also be addressed through standards to guide project design.

6. How, and to What Extent, Should Forest Scenic Values be Protected through Visual Resource Management?

As timber harvest and road construction activities occur, changes in the scenic resource become more apparent. The visual resource management issue revolves around the degree of protection scenic values are given and the costs and impacts of visual resource management on other activities. Activities that alter the vegetation can change the character of the Forest's recreational setting Many people find alteration of the natural setting objectionable and feel that the Forest should be managed to retain all, or a large

degree, of the natural forest character; and that any activities such as harvest units should be designed so they do not dominate the view from any roads, trails, or sites used by recreationists On the other side of this question are those who feel that major portions of this Forest do not warrant a high level of visual protection due to the common character of the landscape and relatively low levels of recreation use Primary concerns are the reductions in annual timber harvest and associated costs of implementing visual *management objectives*

The Forest has been inventoried according to the visual management system and stratified by potential Visual Quality Objectives (VQO's) based on the character and variety of the landscape, viewer sensitivity, and distance from the viewer The least restraining visual objective on management of National Forest land is termed Maximum Modification, which allows activities to dominate the characteristic landscape The next objective is Modification which also allows activities to be dominant to some degree Objectives of Retention and Partial Retention require activities to be subordinate to the characteristic landscape, or not visually evident to the casual Forest visitor The Preservation objective (generally used in areas not available for timber harvest) prohibits most management activities and allows for natural changes only The visual resource and inventory are explained in more detail in Chapter III.

The inventoried VQO's are used as a guideline for current management. This planning analysis considers options of adopting these inventoried objectives as standards for management on all or part of the Forest The Forest has been stratified into 44 viewsheds of contiguous areas that are viewed from specific travelways or viewpoints and would be logically managed to meet consistent objectives. These viewsheds vary in scenic qualities and type of use, and are prioritized accordingly (e.g., Oregon Caves viewshed is considered high priority).

The alternatives include options for allocation of lands to meet inventoried VQO's, including Retention and Partial Retention, by viewshed. Viewsheds not allocated to meet inventoried VQO's would be managed at the next lower objective In addition, allocations to management that have no programmed timber harvest would meet or exceed the inventoried objectives.

The key indicators used in the development and assessment of alternatives are the specific viewsheds that meet the inventoried VQO's and acres allocated that meet or exceed Partial Retention

7. How Should Wildlife Habitats on the Forest be Managed?

The Forest is inhabited by more than 250 wildlife species. Wildlife habitat management is the responsibility of the Forest Service, while populations are managed by the Oregon Department of Fish and Wildlife and the California Department of Fish and Game. In recent years, management considerations between the agencies have broadened to encompass nongame species in addition to those commonly hunted, fished, or trapped. Environmental legislation over the past two decades has continued to emphasize the cooperative relationship between the agencies and the need to provide suitable habitat that will sustain all populations

The controversy in the wildlife question is not found in the desirability of maintaining diverse and healthy populations, but in the management actions needed to accomplish this objective Many people responding to the DEIS are concerned about vegetation-altering activities, such as timber harvest, which change the character of the habitat and its ability to provide for various species Activities are often beneficial for some species and detrimental for others Populations, such as big game, benefit from increased forage produced in harvest units, while populations of species dependent on mature or old-growth forest may decline Cavity-nesting species are also impacted by removal of snags and hollow trees There is a divergence of opinion as to the appropriate balance of habitats that should be maintained, and the acceptable level of effect on timber production resulting from wildlife management prescriptions

Several wildlife species groups have been identified to address their habitat needs These groups include (1) species dependent on specialized habitat conditions, such as cavity-nesting bird populations, (2) species requiring a particular seral stage, such as grass/forb or old growth, (3) popular game species, and (4) threatened, endangered, and sensitive species Eight indicator species have been selected to represent critical habitat needs Environmental consequences for each indicator species are used to assess the effect an alternative would have on the species group Other indicators used in tracking resolution of this problem are allocations to Special Wildlife Sites, capital investments, and wildlife user days (WFUD's).

8. How Will Management Direction Affect Recreation Opportunities in the Wilderness and Unroaded Areas?

The most polarized issue addressed in this analysis involves the management direction for those areas not yet developed by roads. The Forest has 232,000 acres of Wilderness. The inventory of unroaded areas outside of Wilderness in the 1984 data base was 314,000 acres as reported in the DEIS. Since 1984, continued management under current direction and implementation of the Silver Fire Recovery Project have resulted in some road construction in the former roadless areas. Currently, there are 284,000 acres of unroaded areas outside of Wilderness; adjusted boundaries and current acreages are displayed in Appendix C This Planning Problem deals with management of the existing Wilderness and allocation and management of remaining unroaded areas.

People on both sides of the unroaded issue feel that they are continually losing ground Timber and commodity interests see the land base for production eroding as additional areas are periodically designated for uses that preclude development for commodity production Since 1978, Wilderness on the Forest has been increased from 77,000 to 232,000 acres. Many feel allocation of any additional land to uses that do not allow development would be unwarranted and unacceptable

On the other side, those who would prefer that land and forest areas remain in their natural state see options dwindle as new roads are constructed in previously undeveloped areas. Development has been deferred in these areas in recent years while various reviews have been conducted, but it seems that major portions of these areas may be roaded in the next few years if the lands are allocated to uses that include timber management. Many feel that all or part of these lands should remain undeveloped and be managed to provide benefits not available in areas where timber harvest and roading are permitted

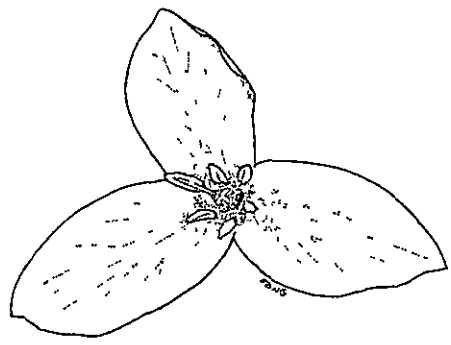
Wilderness and unroaded areas provide the only Primitive and Semi-Primitive Non-motorized recreation experiences on the Forest. Under current management direction, a great amount of the currently unroaded area is expected to be developed within the next two decades, thus leaving existing Wildernesses to supply Primitive and Semi-Primitive Non-motorized recreation. Based on projected increases in use, by the year 2020 demand is expected to exceed the capacity of the Wildernesses to provide these forms of recreational experience.

Management options in the Wildernesses range from closure of existing trails and campsites to actions that increase capacity and disperse users Trail development, maintenance, or improvement, and the use of fire as a management tool are the principal mechanisms for changing the use and capacity while maintaining opportunities for quality experiences.

The alternatives vary by the management direction and capital investment schedules for the Wildernesses Alternatives also vary by, and are evaluated by, the location and number of acres of unroaded areas allocated to management that would maintain their undeveloped status Another key indicator is the area remaining in Primitive and Semi-Primitive status The analysis of individual unroaded areas is documented in Appendix C.

In response to the DEIS, many people expressed that more recreation opportunities should be offered throughout the Forest (in addition to unroaded areas). A variety of activities should be provided to satisfy

the multiple types of public recreation They are interested in enhancing opportunities through capital investments in trails and other facilities. Many would like to see the Forest work more closely with counties and other agencies and groups to provide more recreation and tourism in the area



9. How Should Mineral Resources of the Forest be Developed in Coordination With Management of Other Resources?

Interest in developing the mineral resources of the Forest has been increasing during recent years As this interest grows, the prospect of ground-disturbing activities increases. Accompanying this is a heightened concern for environmental protection. The role of the Forest Service is to manage the surface resources by cooperating with the minerals industry in the application of mineral extraction and land restoration technology, or to recommend withdrawal of lands from mineral entry where warranted.

Minerals and mining interests are concerned about how much of the Forest will be available and accessible for development of the mineral resources. Future options could be limited by the amount of the Forest remaining unroaded, and by areas allocated to other uses not complementary to mineral development

Concern also exists for protecting resource values that may be disturbed during exploration, development, or extraction of minerals Particular concern is expressed over the potential conflict between mineral development and the protection of sensitive plants and visual quality. Some of the unusual geologic sites that are habitat for sensitive plants are also high in potential mineral values. The Forest's mineral potential and pattern of use are described in Chapter III.

The alternatives vary primarily in the number of acres allocated to uses that include road access that would result in more efficient mineral exploration or extraction, and in the emphasis placed on other resources A key indicator in resolution of this problem is the area remaining available for development with limited (i e , low and moderate) restrictions imposed by other resource considerations.

ISSUES NOT ADDRESSED IN PLANNING PROBLEMS

HERBICIDE USE

This issue is outside the scope of this analysis It will not be considered for resolution here. It has been and will continue to be dealt with in separate environmental analyses and NEPA documents at the Regional and Forest levels. Any additional consideration of this issue would be through similar processes at the Regional level, or through Forest environmental analyses tiered to the Pacific Northwest Region's FEIS for Managing Competing and Unwanted Vegetation (USDA-Forest Service, 1988c)

During implementation of the Forest Plan, timber harvest and growth will be monitored Stand condition and performance (with or without the availability of chemical release) will be evaluated and the harvest level adjusted appropriately

ROADS

The road management issue is not treated as a Planning Problem. It is, however, dealt with in each alternative through application of the Standards and Guidelines and general direction for road standards and closures. Incorporation of the Standards and Guidelines and management direction is designed to be consistent with the theme of the alternative. The Forest will continue to strive to build and maintain roads at the lowest cost, subject to meeting management objectives for the particular road Management direction, including closures, for specific roads will be determined at the project level The issue concerning roading the undeveloped areas is addressed in Planning Problem #8.

PLANNING RECORDS

AVAILABILITY

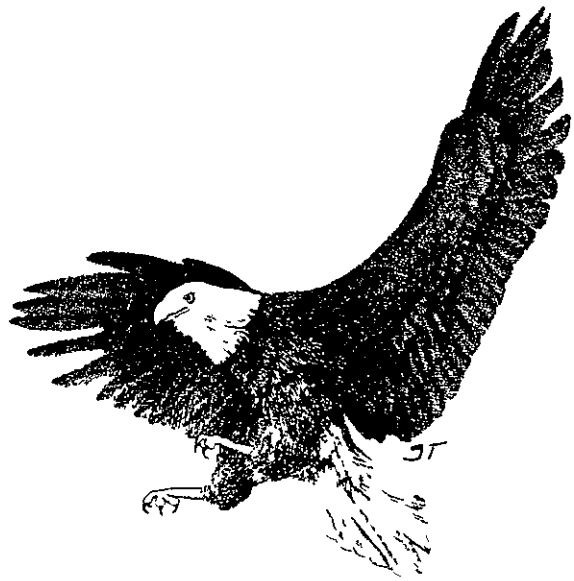
All of the documents and files that chronicle the Forest planning process, including the environmental analysis of the Siskiyou National Forest, are available for review at the Supervisor's Office in Grants Pass, Oregon These documents and files (known as "Planning Records") contain the detailed information and decisions used in developing this FEIS and Forest Plan. The planning records are referenced at appropriate points in the text and appendices of this FEIS and Forest Plan.

READING GUIDE

This FEIS is composed of four chapters (one volume) and nine appendices (two volumes). Chapter I, *Purpose of and Need for Action*, describes the issues, concerns, and opportunities (presented as Planning Problems) that this Environmental Impact Statement is designed to address. The evolution of the Planning Problems, beginning with the identification of ICO's, is detailed in Appendix A.

Alternative ways of addressing or resolving the Planning Problems are described in Chapter II (titled, *Alternatives, Including the Proposed Action*) The number of acres proposed for each Management Area, the dollars invested, and standards and guidelines are the principal means used to resolve the Planning Problems. Each Management Area has a unique prescription and set of standards and guidelines (defined in Appendix D) designed to achieve specific management objectives in an environmentally sound manner. Chapter II, therefore, describes alternative ways of managing the land to produce different mixes of goods, services, and Forest conditions relative to the Planning Problems

The land and resources, as they physically exist today, are described in Chapter III, *Affected Environment* The kind of environmental conditions or modifications necessary to satisfy current demands, wants and desires (as reflected in the Planning Problems) are discussed along with the physical capability of the Forest to achieve the necessary desired future condition



Environmental impacts on the land and resources are disclosed in Chapter IV (titled, *Environmental Consequences*) Both short- and long-term consequences that would result from the implementation of the various alternatives are presented for each component of the environment. This is the scientific and analytic portion of the FEIS

A summary of the most important environmental consequences that the public, other agencies, and decisionmaker need to be aware of in making an informed decision is presented in comparative form in Chapter II. A description of each alternative is also included It may be convenient to study only Chapters I and II to understand both the issues and alternative ways of satisfying the Planning Problems

Readers wishing to understand the basic facts and assumptions underlying the disclosures made in Chapter II should study Chapters III and IV Detailed information, including inventory information and analytic procedures employed in the analyses are presented in the appendices to the FEIS.

The reader will find it useful to consult the Management Area maps when reviewing this FEIS (a large map of each alternative was provided in the DEIS package; a few sets are still available at the Supervisor's Office). A new map showing Management Areas for the Preferred Alternative S is enclosed with the FEIS

The Land and Resource Management Plan (LRMP or Forest Plan) that accompanies this FEIS represents the implementation plan for the Preferred Alternative Information relevant to and directing management activities on the Siskiyou National Forest is compiled in the Forest Plan, along with management objectives, monitoring needs, and other pertinent aspects. This final Land and Resource Management Plan will direct the Forest's management activities for the next 10 to 15 years

Chapter II
ALTERNATIVES, INCLUDING THE PROPOSED ACTION
INTRODUCTION

This chapter is the heart of the Environmental Impact Statement. Alternative ways of managing the Forest's land and resources are described in this chapter. Outputs and environmental effects associated with the alternatives are also displayed in a comparative format to give the decisionmaker and the public a clear basis for choice among the available options A description of how the alternatives were developed, including a summary of the planning steps and analysis leading up to alternative development, is also presented in this chapter.

The alternatives considered in this Final Environmental Impact Statement display different ways of managing the lands and resources of the Siskiyou National Forest They differ from each other in the land uses and management practices that would occur on different parts of the Forest in different time periods. Each alternative is a unique combination of land allocations, management prescriptions, and activity schedules. As a result, each alternative generates a different mix of goods and services, and a different combination of resource outputs, land uses, and environmental effects.

An even distribution of reasonable alternatives, which covers a broad range of possible actions, was formulated. Alternatives were designed to explore a variety of ways to respond to the Forest's Planning Problems. From this range, the Regional Forester has a basis for selecting the alternative that comes nearest to maximizing net public benefits

There are three main parts to this chapter. First, there is a summary of the analysis that was conducted in the process of developing the alternatives (a more detailed description of this process is presented in Appendix B, Description of the Analysis Process). Next, the purpose and emphasis of each alternative is described, followed by a response to each of the Planning Problems (introduced in Chapter I). Alternatives are rigorously evaluated in the final part of the chapter, using a comparative format that examines the alternatives based on the information and analysis presented in Chapter III, Affected Environment, and Chapter IV, Environmental Consequences.

Included is information on resource outputs, environmental effects, land allocations, and economic costs and benefits for each alternative Detailed information is presented in tabular form, with narrative to describe relevant differences between the alternatives

CHANGES BETWEEN DRAFT AND FINAL

Numerous changes have occurred in this chapter as a result of public and agency comments on the DEIS, continuing management of the Forest, the 1987 fires, and Congressional designation of three Wild and Scenic Rivers in late 1988

Several changes have been made in analysis processes The calculation of nonconsumptive wildlife user days has been modified to be a function of recreational demand instead of big game forage as it was in the DEIS Acres of mineral access restrictions have been modified to correspond to revised management direction First decade board foot volume projections have been adjusted to more closely reflect the volume expected to be harvested in the first decade. Salvageable dead timber volume has been calculated from the inventory and included as a component of timber harvest projections Numerous data entries have been corrected or modified to better display the differences between alternatives or the environmental consequences associated with alternatives.

The documentation of the methods selected to accomplish the Management Requirements (MR's) has been modified to address the tradeoffs associated with the various methods instead of the sensitivity

analysis presented in the DEIS Appendix J has also been modified to discuss tradeoffs of various methods of meeting MR's, the sensitivity analysis has been relegated to the planning records

As a result of public input and management concerns over protection of the water resource and its related soil and fisheries resources, we have highlighted current management practices designed to protect and enhance water quality under "Best Management Practices" (BMP's) in Standards and Guidelines for the Forest Plan These are described in detail in Appendix F of the Forest Plan

The "Alternative at a Glance" tables that accompanied each alternative description in the DEIS have been dropped. The data is included in other tables in a comparative format.

The section "Alternatives Considered But Eliminated From Detailed Study" has been expanded to provide a better explanation of several items. It also includes discussion of some alternatives that were suggested between the Draft and Final, and alternatives fully evaluated in the Draft, but eliminated from detailed study in the Final Alternatives K-Departure and L in the DEIS have been eliminated from detailed study.

Based on public and agency comments, Alternative S was developed and is identified as the new Preferred Alternative. It is within the range of alternatives considered in the Draft.

Management Area 6, "Custodial (Roadless)," has been modified and renamed "Backcountry Recreation" to better reflect the management objectives for this prescription In addition, the individual areas under this allocation can be qualified as either motorized or non-motorized

A section has been added at the end of this chapter to relate the effects of the 1987 fires to the alternatives in this analysis.

The Omnibus Oregon Wild and Scenic Rivers Act of 1988 has implications for most of the alternatives considered in this analysis. This Act was passed by Congress just as these documents were in the final stages of preparation for printing. The need for analysis of suitability and disclosure of the effects and outputs of Forest Service recommendations on the inventoried and eligible rivers has been eliminated by the Act

A number of changes, including several mentioned in this section, are discussed in the section, "Features Common to all Alternatives."

ALTERNATIVE DEVELOPMENT PROCESS

The primary purpose of alternative development is to formulate a broad range of options as a basis for identifying the alternative that comes nearest to maximizing net public benefit (NPB) (36 CFR 219.11(f)). An analytic process is used to develop alternatives that reflect a range of resource output and expenditure levels, distributed between the minimum and maximum resource potentials identified in the analysis process (36 CFR 219 12 (e) and (f)) Alternatives are formulated in a manner that facilitates the evaluation of a number of economic parameters, including effects on costs and benefits, present net value, and analyses of opportunity costs and tradeoffs among alternatives Ultimately, and most importantly, the collection of alternatives demonstrates different ways of responding to the Planning Problems in a cost efficient manner

By managing the Forest resources in different ways, various objectives can be achieved which respond to the many issues and concerns This differing management can vary by what, where, and when it is done. The result is a combination of management activities, management areas, and schedules which define a unique combination of resource outputs and environmental conditions for each alternative The merits of an alternative are evaluated based upon the NPB that the alternative achieves, and how it responds to the public issues

Present net value (PNV) is the quantitative component of NPB. It is the discounted value of all priced benefits less all priced costs. Timber benefits and costs, quantitatively valued aspects of recreation, human use of wildlife and fisheries, and range are included in PNV calculations. It is also recognized that some values, such as the preservation of old growth and roadless areas, the protection of spotted owls and rare plants, the achievement of Retention and Partial Retention Visual Quality Objectives, and the fostering of local social stability may not be adequately represented by quantitative measures. These and others need to be taken into account while responding to issues. In addition to the measured economic benefits, the nonpriced outputs and effects, such as the protection of sensitive species and the preservation of cultural values or Research Natural Areas, are also considered in assessing the merits of an alternative.

NPB reflects both quantified and nonquantified net benefits of the alternatives and represents the overall value to the nation of all outputs and positive effects (benefits) less all of the associated inputs and negative effects (costs) of producing priced and nonpriced goods and services from National Forest lands (36 CFR 219.3). Thus, NPB represents the sum of net priced outputs and the net value of nonpriced outputs. Forest planning alternatives are formulated to examine different combinations of goods and services, both quantitatively and qualitatively valued, to find that mix which best maximizes NPB while responding effectively to public issues

DESCRIPTION OF THE ANALYSIS PROCESS

Several of the planning steps presented in Chapter I deal with the analysis process The Issues, Concerns, and Opportunities (ICO's) identified in the scoping process provide information on which resources are important to the public, and in many cases where they are located on the Forest The analysis process is designed to inventory these resources, determine their productive potential, and quantify their interrelationships. There are two major parts of the analysis process; one is the physical inventory of the Forest resources and their productive potential, the other is the identification of optional management strategies or prescriptions that may be applied to the land base. Combinations of the physical inventory (land base) and the various prescriptions are then used to form alternatives for managing the Forest. Figure II-1 illustrates the analysis process and may facilitate understanding the following discussion. The numbered references within parentheses in the text are keyed to the elements in the flowchart.

The first step in the analysis process was to collect the resource inventories (1). This information was collected on a common map base, with different map layers developed for various resources and inventory components. Inventories of the character, potentials, and limitations of the Forest were conducted. Areas of the Forest with similar physical and biological characteristics were stratified into "capability areas" (2). These homogeneous areas are expected to have a somewhat uniform response to any particular management prescription Criteria used to identify capability areas include land and vegetative characteristics, as well as unique attributes important to the resolution of issues and concerns. This phase resulted in the identification of more than 40 layers of land attribute and management opportunity delineations

The next step was to aggregate the thousands of individual areas, resulting from overlaying the capability area layers, to form a manageable number of areas with similar characteristics This resulted in the creation of 317 unique Analysis Areas (3). Each Analysis Area is composed of sites with similar vegetation and other resource characteristics, management opportunities, and responses to management activities. Analysis Areas are not geographically contiguous, but they provide a manageable number of unique types of areas on which to analyze resource allocation and scheduling options and their effects.

Any particular area often has the potential to be managed in a variety of ways to meet various resource objectives with differing degrees of responsiveness to the ICO's. To analyze and present these options, management strategies (4) were defined for 14 Management Areas, each with specific resource objectives (The individual Management Areas are defined later in this chapter and include, for example, Wilderness, Designated Wildlife Habitat, and Retention Visual categories.) Each Management Area has general

management requirements to meet the specific resource objectives and satisfy environmental concerns. Most analysis areas have the capability to meet the resource objectives of more than one Management Area For example, a particular piece of land may have the capabilities to produce the results associated with Designated Wildlife Habitat, Retention Visual, or General Forest, and would be a candidate for all three. Because of this, the aggregate of the Management Area candidates far exceeds the total Siskiyou National Forest acres.

Some elements of management direction are fixed to assure that the basic objective for each Management Area will be achieved Other elements have more flexibility while still meeting the overall objectives To analyze this potential and identify the most efficient management for each analysis area, prescription options or intensities (5) were developed within the Management Areas For example, in the Partial Retention Visual Management Area the management requirements needed to meet the visual objectives are fixed, but within these requirements several optional prescriptions for timber management were developed A mathematical estimate of the economic costs and resource yields associated with each prescription is generated to identify the most efficient prescriptions, and for scheduling activities and outputs The analysis required by 36 CFR 219 14(b), known to some as the "Stage II suitability analysis," is documented in Appendix B, "Most Efficient Intensities " The intensities identified along with other options and timing choices are used in the modeling process to find the most efficient Forest-wide solutions.

To analyze the potential land allocations to the various Management Areas, logical units of contiguous acres were mapped and termed Special Areas (6). These Special Areas were identified from the capability area mapping and from public input gathered in the scoping process. Each Special Area is a discrete unit that can be identified on the ground. Collections of these then become the Management Areas (7) which are not contiguous units, but which would be managed under the same management direction.

Several parts of the process come together in the design of alternatives (8) For each alternative, the land is assigned to Management Areas based on the specific theme and objectives for that alternative This is done by identifying those special areas which can best meet the objectives and respond to the issues while minimizing the effects on other resources. The analysis areas are then linked with the prescriptions and intensities (several choices in some cases) appropriate within the Management Areas.

The alternative designs are entered into the Forest planning model (FORPLAN) (9) along with economic benefits and costs, and any other constraints (10) needed to assure that alternative results will be feasible and environmental considerations are represented. FORPLAN is a linear programming model that is used to analyze many of the management objectives and how they interact. More detailed explanation of the FORPLAN model can be found in "FORPLAN Version 2: An Overview" (Johnson and others 1986), and a more general discussion of the use of analysis and models in forest management can be found in "Forest Management" (Davis and Johnson 1987) Given the land allocation represented by Management Areas and the possible activities represented as prescription intensities with various timing choices, the FORPLAN model can find the most efficient set of prescriptions and activity schedule for each alternative

The final step is to display the FORPLAN results (11) in a comparative format for each alternative These results include the prescriptions and land allocations, the schedule of management activities and resource outputs, and some environmental effects. Additional environmental effects are based on the FORPLAN results and are included with the effects of the alternative.

Appendix B of this FEIS describes the entire analysis process in detail, including the models which were used in the process Readers are encouraged to refer to that appendix for a more complete discussion than is presented here.

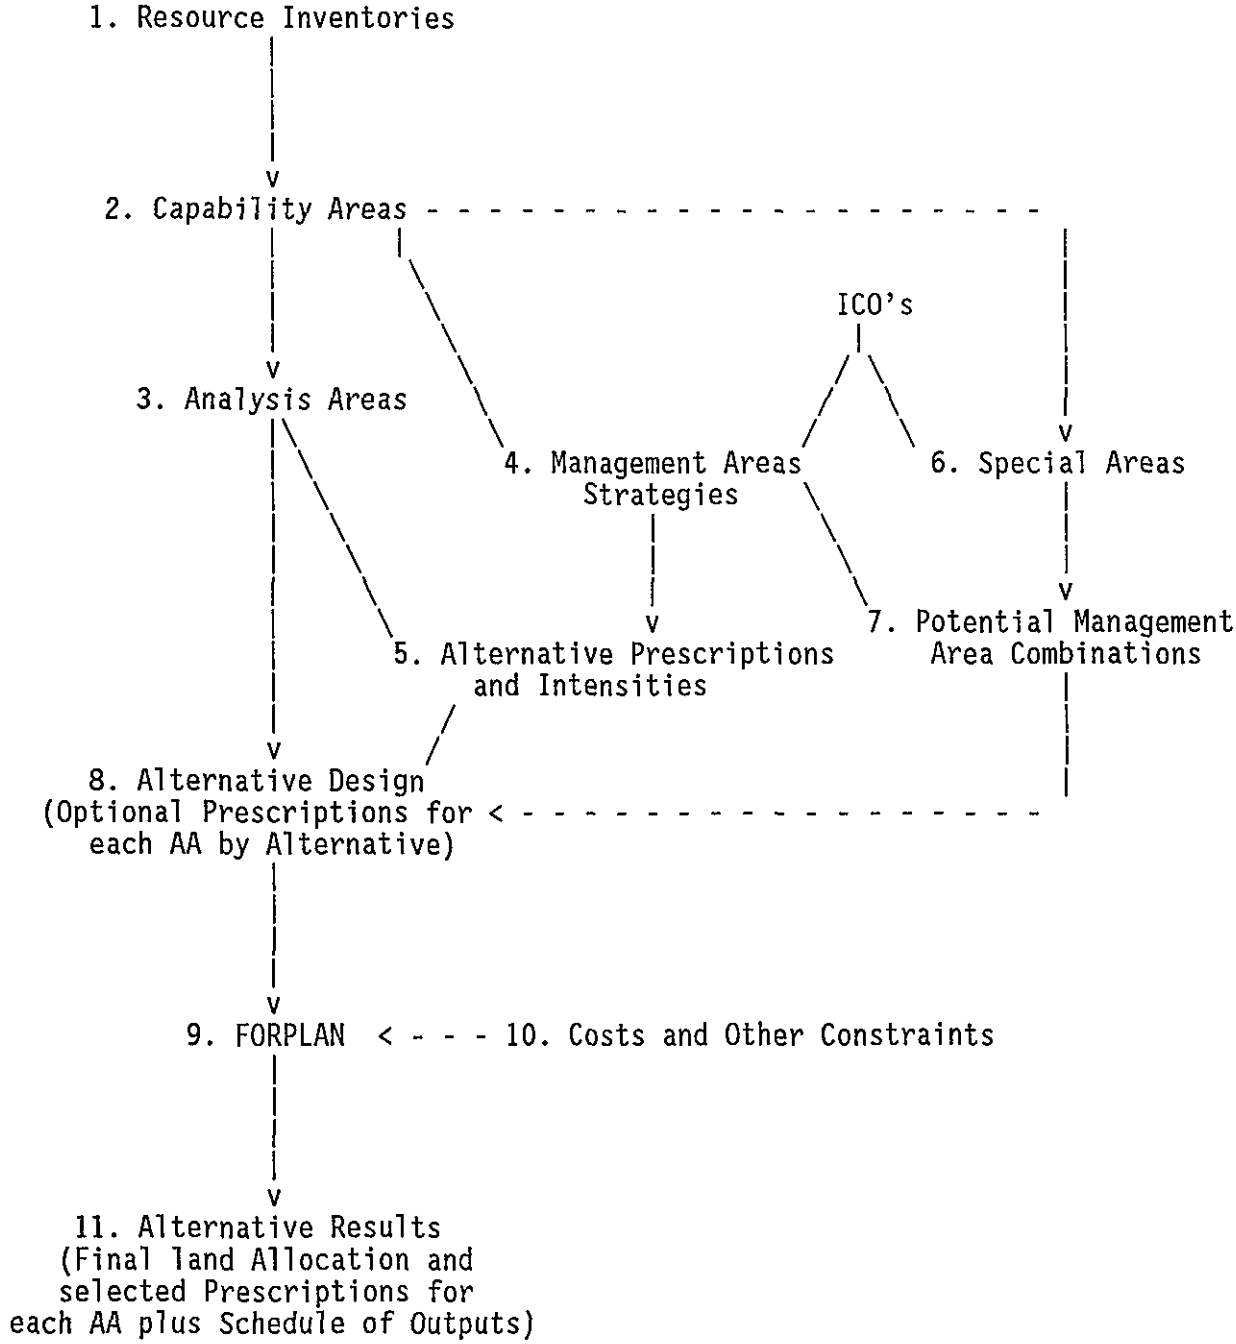

Figure II-1 Analysis Process For Alternative Development

ANALYSIS OF THE MANAGEMENT SITUATION

The analysis of the management situation was a major phase in the planning process. Results of the analysis are detailed in Appendix B, Analysis Prior to Development of Alternatives. A brief summary is presented in this chapter.

There are two primary purposes for the analysis of the management situation. First, to determine the Forest's maximum capability to produce single resources (supply potentials) that satisfy the Planning Problems, and to maximize economic efficiency Second, to assess the need to change current management direction in light of these supply potentials and their relationship to the Planning Problems

MANAGEMENT REQUIREMENTS

The Management Requirements (MR's) are designed to meet the requirements of applicable laws and regulations, specifically those of 36 CFR 219.27 NFMA regulation (36 CFR 219.12) specifies that certain MR's be included in the planning process. The methods to meet these MR's include developing standards, guidelines, and appropriate management practices for inclusion in multiple-use management prescriptions; assignment of management prescriptions and intensities containing specific practices to analysis areas in FORPLAN, and applying specific constraints in FORPLAN (see Appendix B).

The Management Requirements used in this analysis are designed to.

- Conserve soil and water resources.
- Minimize serious or long-lasting hazards from flood, wind, wildfire, erosion, or other natural physical forces.
- Reduce serious, long-lasting hazards or damage from pest organisms
- Protect riparian areas
- Maintain diversity of plant and animal communities.
- Provide adequate fish and wildlife habitat to maintain viable populations.
- Conform with multiple-use laws.
- Prevent the destruction or adverse modification of critical threatened and endangered species habitat.
- Ensure roads are designed to standards appropriate to planned uses
- Revegetate temporary roads within ten years
- Maintain air quality
- Harvest timber only on lands that can be restocked within five years after final harvest.
- Adhere to clearcut size limits

Direction has been evolving and guidance has been given to the Forest through several documents at the National and Regional levels This direction has been packaged along with supporting information in following documents issued in June 1986: *A Report on Minimum Management Requirements for Forest Planning on the National Forests of the Pacific Northwest Region, USDA Forest Service*, and, *A Background Document on the Development and Review of Minimum Management Requirements for Forest Planning on the National Forests of the Pacific Northwest Region, USDA Forest Service* The appendices of the latter document incorporate previous letters and documents containing pertinent direction. A summary of information presented in these documents is presented in Appendix J of this FEIS. Information is presented there to close the gap between the regulations and the application of MR's at the Forest level.

The discussion here concentrates on those MR's applied on the Siskiyou that (1) impose substantive standards, (2) can be incorporated in the analysis, and (3) are likely to have an impact on the analysis There are many other requirements that the Forest must meet which are not discussed here including substantive requirements that do not have significant impacts when viewed on a Forest scale, as well as procedural requirements Examples of substantive requirements that are not discussed here include those

for cultural resources, and those for threatened and endangered species These requirements are part of the Standards and Guidelines. While significant in themselves, they do not have significant affects on the Forest-wide analysis.

The MR's with significant interactions with other resources are those for mature and old-growth dependent wildlife species, dispersal of created openings, and maintenance of water quality and riparian areas along perennial streams Development of individual prescriptions and constraints to satisfy these minimum resource needs is documented in Appendix B and the Planning Records The requirements are based on guidelines in the direction documents referenced above and the Regional Guide for the Pacific Northwest Region, as amended by the Supplemental EIS for Spotted Owl Guidelines. Specific requirements for the Siskiyou were developed by the interdisciplinary team and are designed to accomplish each objective with minimum adverse impacts on other resources

Analysis of wildlife species groups found on the Forest indicates that, although a number of them require some management considerations, only those dependent on mature and old-growth habitat require modification of management that could significantly affect other resources. The indicator species for these groups are spotted owl, pine marten, and pileated woodpecker To perpetuate these species over their present range, a network of suitable habitat areas have been identified Each area would provide habitat for one pair of animals and distances between habitats would be conducive to dispersal of young. To minimize the opportunity costs to the timber program, habitat areas were collocated (more than one species in the same area) wherever possible, and areas were adjusted to lands not suitable for timber production.

Total habitat protected over time to meet the Management Requirement amounts to 159,949 acres. This includes 106,090 acres in Wilderness and other designated areas, or in areas unsuitable for timber management Only 36,712 acres are tentatively suitable for timber production. Prescription options of protecting these areas with no programmed timber harvest versus managing enough acres with a long timber rotation to provide equivalent suitable habitat were examined For this planning period, habitat areas will be designated with no programmed timber harvest This would have the least impact on the timber harvest schedule and would be the most efficient for implementation and monitoring The analysis supporting this conclusion is documented in Appendix J and in Appendix B, under DEVELOPMENT OF MANAGEMENT REQUIREMENTS. The designated habitat areas to satisfy the MR's for mature and old-growth wildlife species are included in all alternatives except the No Change Alternative (NC).

Dispersion of created openings is represented in the analysis through application of constraints on the amount of timber harvest that could occur per decade in any one planning basin (the Forest is divided into 19 planning basins, or major watersheds, for analysis purposes; these are described in Chapter III under **SOIL AND WATER**). This constraint also accomplishes the dispersion of activities to avoid concentrating the risk of soil and watershed impacts (landslides, soil erosion, and stream sedimentation) inordinately within some drainages. Openings created by timber harvest were limited to 20 percent of the suitable land base per decade by planning basin. This level of constraint was identified through iterative analysis as the point where a reduction in Forest-wide timber outputs begins to occur. While this constraint does not have a significant effect in itself, it was applied in conjunction with Riparian Prescription B, and the Standards and Guidelines which direct management practices, to accomplish the MR's for soil, water, and fish

The most critical factor for fish habitat in Siskiyou streams is summer water temperature Under current conditions, summer water temperatures reach critical thresholds for salmonid production If stream temperatures increase above these levels, salmonid production declines rapidly The Interdisciplinary Team examined various options for management of riparian areas and the associated implications for the fisheries resource Options examined range from total protection of the riparian area to allowing timber harvest without special consideration for retaining vegetation, with multiple-use prescriptions in between.

Three levels of multiple-use prescriptions were examined for the Riparian Management Area: Prescriptions A, B, and C These prescriptions varied in the amount of vegetation removal allowed, with Prescription A allowing the most removal and Prescription C the least. Stream temperature modeling was done for each of the three options using stream shading as the independent variable, and the relationship between changes in stream shading and the removal of timber from the riparian areas Prescription A would reduce shading to levels that would cause critical stream temperatures to exceed State Water Quality Standards for the established beneficial uses. The projected increase in water temperature under this prescription would have significant adverse impacts on the anadromous fisheries on most major streams on and immediately downstream of the Forest. Prescription B would maintain stream temperatures and is considered the minimum protection needed to meet the Management Requirement (MR) to protect water quality and fish habitat through management of riparian areas. This MR is met or exceeded in all alternatives.

Riparian Prescription B is the same as the current Siskiyou Riparian Policy. This 1979 policy has evolved over a number of years through incorporating results of implementation evaluations, monitoring, and application of research findings on new methods and practices The stream temperature modeling has been facilitated by work pioneered on the Siskiyou using a solar pathfinder to correlate changes in the vegetation (growth or removal) with changes in actual stream shade during critical times of the year. The riparian policy has developed with the involvement of experienced resource professionals from all disciplines and has been the object of numerous field reviews attended by professionals from all levels of the Forest Service, as well as university faculty members, representatives from the timber industry, State of Oregon personnel, and other interested publics. The Siskiyou's riparian policy for streamside management is considered state-of-the-art in multiple-use management in an area with high resource values, challenging terrain, and competing and conflicting values.

Although not Management Requirements per se, timber policy requirements are also included in most alternatives These constraints require that stands of timber shall generally have reached the culmination of mean annual increment (CMAI) prior to final harvest, and that timber harvest shall be scheduled to sustain a nondeclining yield (NDY).

Timber and economic opportunity costs associated with both timber policy constraints and implementation of the MR's are displayed in Table II-1 To establish the maximum effects of each constraint or group of constraints, FORPLAN runs are compared to a base run that has none of these constraints. The base run establishes the highest possible PNV that could be produced by the Forest without these constraints, and the associated timber outputs. With the addition of each successive constraint, PNV and first decade Allowable Sale Quantity (ASQ) are reduced. Long-Term Sustained Yield (LTSY) is also generally reduced as constraints are added with the exception of the CMAI constraint which increases LTSY. Without the CMAI constraint, stands are harvested at younger ages to sustain higher harvest levels in early decades at the expense of long-term production.

Table II-1. Summary of Effects of Timber Policy and Management Requirements on PNV (MM$) and Timber Outputs (MMCF)

Benchmark or FORPLAN Specification	PNV MM $	ASQ MMCF	LTSY MMCF
Unconstrained Base Run	2,061	74 4	56 5
With CMAI	1,994	66 4	62 7
With CMAI and NDY	1,814	39 8	58 2
CMAI and NDY plus Soil, Water, and Fish MR's	1,586	34 6	54 6
CMAI and NDY plus Wildlife MR's	1,670	37 1	55 5
All Timber Policy and MR Constraints (PNV Benchmark)	1,491	32 4	51 9

The tradeoffs associated with the MR's are determined by comparing the run including the timber policy constraints with a run including the MR's for soil, water, and fish (harvest dispersion and riparian management), with another run including the wildlife MR's, and then with a run including all of the MR's. Addition of the timber harvest dispersion and riparian management MR's reduce the ASQ by 13 percent, primarily as a result of the Riparian Management Areas The wildlife MR's reduce the ASQ by seven percent when taken alone. When all of the resource MR's are applied together, ASQ is reduced by 19 percent. It should be noted that this is not a reduction from the current situation, but from the base run The wildlife MR's are the only significant change from current management. The incremental effect of adding the wildlife MR's on top of the riparian is less than six percent

The requirements for spotted owl habitat were developed based on the direction in the Regional Guide for the Pacific Northwest Region (USDA Forest Service 1984b) as amended by the Supplement for Spotted Owl Guidelines (USDA Forest Service 1988b). The Final Supplement to the EIS (SEIS) for an Amendment to the Pacific Northwest Regional Guide was prepared in response to an appeal filed in July 1984, by the National Wildlife Federation, et al. The appellants challenged the direction in the Regional Guide for treating spotted owl habitat in Forest Planning. Appendix H of Forest Plan DEIS described the relationship of the Draft SEIS for the Regional Guide and this analysis. The Final SEIS does not substantially change the direction for the Siskiyou from the original direction in the Regional Guide (this is not true, however, for all Forests); Appendix H is dropped from this analysis, but is available in the planning records.

Appendix J was prepared in response to decisions of the Chief of the Forest Service and the Deputy Assistant Secretary of Agriculture regarding an appeal brought by the Northwest Forest Resource Council on September 18, 1986 The appeal centered on direction from the Regional Forester to incorporate Minimum Management Requirements (MMR's) into Forest Plan alternatives. Appellants requested that the appropriateness of the MR's be examined through the environmental impact statement process. Appendix J that accompanied the DEIS documented a sensitivity analysis intended to address an issue raised concerning uncertainty about the information The sensitivity analysis contained in Appendix J of the DEIS has been relegated to the planning records and replaced with the current Appendix J which presents a comparison of the opportunity costs of the various methods considered to meet the MR's.

The MR's examined in Appendix J are those for protection of fish habitat and water quality, and those designed to maintain viable populations of species using mature and old-growth conifer habitat. Alternative methods for achieving these requirements considered by the Forest Service are presented along with the opportunity costs in terms of timber and PNV. Implications associated with the alternative methods for accomplishing the MR are also presented, as well as the rationale for the method selected and relationship to the alternatives in this FEIS.

The Forest Service has attempted to base the MR's on the available scientific research, supplemented by experience and professional judgment MR's are designed to provide those minimum levels of resource protection required while minimizing the adverse impacts to other values As knowledge of these resources builds and additional research findings come to light, the Forest Service is prepared to modify management direction, including the MR's, to stay current with the state-of-the-art in forest resource management. Information on the proposed MR's was presented in the DEIS to provide reviewers the opportunity to comment on their adequacy, suggest refinements or modifications, or suggest alternative methods of meeting the requirements that may give a better balance of resource benefits. Reviewers criticized the processes used by the Forest Service to develop MR's claiming that appropriate public involvement and review processes were not followed; or simply asserted that requirements identified are either not needed, or not adequate Few substantive comments offering factual information or informed opinion on specific proposed requirements were received.

BENCHMARKS

"Benchmarks" are presented and discussed several times in this chapter The major purpose of benchmarks was to determine the maximum physical capability of the Forest to produce various resource outputs related to the Planning Problems Collectively, the benchmarks defined the range within which alternatives could be constructed (also known as "decision space"). They were also used to provide information on maximum biological potential of the Forest and the economic implications of various management strategies.

Nine benchmark levels were developed to define resource supply potentials and economic relationships on the Forest. Production capabilities were determined for a minimum level of management, for maximum output (or condition) of single resources, and for a set of multiple resource outputs that maximize present net value (NFMA regulation 219 12e) A level was also established from which the costs and effects of applying regulation and policy constraints were measured. The computer model FORPLAN was used to help determine the resource supply potentials. All benchmarks include the MR's.

Benchmark descriptions are summarized in this section A detailed discussion and the results of the benchmarks may be found in Appendix B.

Maximum Present Net Value Benchmark

This benchmark established the mix of resource uses and outputs that results in the greatest difference between total discounted costs and total discounted benefits over a 150-year planning horizon using market and assigned nonmarket values. This benchmark provides the reference point for determining economic opportunity costs in other benchmarks and alternatives

Maximum Timber Benchmark

The maximum capability of the Forest to produce timber in a manner consistent with the Management Requirements (36 CFR 219 27) was determined by this benchmark Timber production was maximized in the first decade, for fifteen decades, then "rolled over" under a "Max PNV" objective function to achieve the timber objective in a cost efficient manner The physical capabilities of the Forest to satisfy the first and last Planning Problems, concerning timber and minerals, respectively, are determined through this benchmark The initial benchmark did not include fertilization as a management practice; in response to the public review of the DEIS and additional analysis, an option on this benchmark which includes fertilization as a management practice has been developed

Maximum Visuals Benchmark

The purpose of this benchmark was to analyze the potential for producing other resource outputs and services while meeting all of the inventoried Visual Quality Objectives (VQO's) on the Forest. Maximum tradeoffs for complete resolution of Planning Problem #6 were determined through this benchmark

Maximum Unroaded Benchmark

This benchmark was designed to analyze the potential for producing other resource outputs and services while maintaining all presently unroaded areas in their unroaded condition. The maximum physical capacity of the Forest to satisfy non-motorized recreation demand (Planning Problem #8) was determined by this benchmark, as well as the Forest's ability to satisfy Planning Problem #2 concerning the preservation of old growth

Maximum Recreation Benchmark

This benchmark determined the potential for utilizing all of the land classified as Primitive (Recreation Opportunity Spectrum classification) on the Forest Recreation capacity was maximized by assigning all inventoried roadless areas to an unroaded status and allocating 25 Supplemental Resource Management Areas to a dispersed recreation emphasis The most extreme environmental consequences associated with complete resolution of Planning Problem #4, concerning Wild and Scenic Rivers, were identified through this benchmark.

Maximum Fish/Watershed Benchmark

The purpose of this benchmark was to establish the highest reasonable level of anadromous fisheries outputs Management activities designed to improve overall watershed conditions were included in this benchmark The Forest's ability to satisfy Planning Problem #3 was determined in this benchmark (although strategies for additional capital investment opportunities were identified and included in some alternatives).

Maximum Wildlife Benchmark

This benchmark was designed to achieve a desirable mixture of wildlife habitats. This benchmark emphasizes a balance of all habitat types. Planning Problems #5 and #7 were addressed through this benchmark.

Maximum Level Benchmark

This benchmark defined the minimum costs of public landownership and the resource outputs which are incidental to Forest management This benchmark served as a reference point to develop and/or test alternative outputs and costs which result from Forest Service management activities. This benchmark is displayed in order to provide a reference to the minimum level considered when a comparison of alternatives is made.

Current Direction Benchmark

This benchmark defined the level of goods and services that the Forest could produce if current management direction is followed with no budget constraint Given information from the benchmarks discussed above, the results of this benchmark served as the basis for determining the need to change management direction

RANGE OF ALTERNATIVES

The benchmarks presented in the previous section were used to develop alternatives that represent a range of resource outputs for addressing and responding to the Planning Problems Upper and lower production levels for these outputs also established the range of possible options available to the decisionmaker for resolving the Planning Problems. For example, the timber and minimum level benchmarks show that the timber base sale levels can range from a minimum of zero to a maximum of 34 million cubic feet (MMCF) per year in the first decade when timber policy constraints apply Thus, without relaxing the timber policy constraints, the most the Forest can do to satisfy the first Planning Problem is produce an average of 34 MMCF of timber per year

The degree of flexibility that the decisionmaker has in responding to the Planning Problems is referred to as "decision space." In most cases, benchmarks were not carried forward as alternatives because they were responsive to only one of several resource issues. Alternatives were designed to span the benchmark range while meeting policy constraints such as riparian protection, MR's for anadromous fish, and other multiple-resource objectives.

REQUIRED ALTERNATIVES

Based on the information generated by the analysis of the management situation, and the analytic limits and reference points identified by the various benchmarks, the Interdisciplinary Team began construction of alternatives which could be implemented on the Forest. Among the alternatives formulated were several alternatives that are required by regulation, and National and Regional direction. The required alternatives are listed and briefly described here.

- No Change. This alternative has been developed in response to decisions made regarding an appeal brought by the Northwest Forest Resource Council on May 19, 1986 The substance of the appeal was that a "true no action alternative representing current management plans" was not included in Forest Plan EIS's because the Current Direction alternative included MR's developed to implement the requirements of NFMA The No Change Alternative (NC) has been developed to represent the existing timber management plans without inclusion of measures needed to fully comply with all the provisions of NFMA and regulations promulgated by the Secretary of Agriculture to implement NFMA.

- No Action. This is the alternative of "No Action" required by the Council on Environmental Quality (CEQ) regulations (40 CFR 1502.14) and by the NFMA Planning Regulations (36 CFR 219.12 (F)) This alternative would continue the management of the Forest as defined by existing direction in approved management plans, continuation of existing policies, standards, and guidelines, and, to the extent possible, production of current levels and mixes of resource outputs. This alternative does not always show the same outputs as the current plans, however, because more recent inventories are used to predict the results of implementation. Should the decision in this action elect to continue with current direction, all MR's required by NFMA would be implemented Alternative A is the No Action Alternative in this FEIS

- Current Direction· Because the definition of no action described above is the continuation of current direction, Alternative A is also the "Current Direction" alternative in this analysis.

- Emphasis on Market Opportunities: Alternative D has an emphasis on outputs that have an established market price (e g , timber, commercial fish, developed recreation opportunities, minerals). Management for other resources will be at economically and environmentally feasible levels consistent with the emphasis on market-oriented outputs

- Emphasis on Nonmarket Opportunities: Alternative E emphasizes water, fish and wildlife, recreation, and other amenity values Management for other resources will be at economically and environmentally feasible levels consistent with the emphasis on amenity values

- Emphasis on the Current RPA Program· This alternative will determine how the current (1980) RPA program distributed to the Forests through the Pacific Northwest Regional Guide can best be implemented Alternative B is the current "RPA" program alternative in this FEIS.

- Emphasis on Nondevelopment and Intensified Management: Alternative E incorporates a large portion of the roadless areas on the Forest as undeveloped while continuing commodity production at a high level in those areas already roaded.

"DEPARTURE" ALTERNATIVES

Two alternatives (Alternatives A-Departure and B) are "departure" alternatives. They have the same land allocation and resource management prescriptions as the "parent" alternative that they are based upon. However, the timber harvest schedule has been modified to depart from nondeclining flow of timber. Management under a departure schedule would result in higher volumes of timber harvested in the next 10 to 20 years, but have lower volumes of timber available 20 to 50 years in the future.

OTHER ALTERNATIVES

Additional alternatives, including those necessary to respond to the full range of public issues, management concerns, and resource use and development opportunities, were formulated to reflect a broad range of resource outputs and expenditure levels Collectively, the alternatives satisfy 36 CFR 219.12(f)(1) which requires alternatives to "be distributed between the minimum resource potential and the maximum resource potential" in order to adequately analyze a "full range" of management options.

The design of several alternatives was the result of public input. Alternatives C, D1, G, and M were generated from information received at public meetings held at three separate locations around the Forest on November 17, 1984. Many elements of other alternatives incorporate the suggestions received during scoping prior to release of the DEIS, as well as similar comments received during the review period. Alternative S was developed following the review of the DEIS and incorporates numerous suggestions from comments on the Draft

Figure II-2 displays several key indicators that are part of the respective alternative design or results. This figure serves to illustrate the range of alternatives considered and the distribution through the decision space. Maximums and minimums for each key indicator illustrate the concept of the decision space The figure graphically demonstrates the range of options available to the decisionmaker, and the full range of alternatives considered in this FEIS.

ALTERNATIVES CONSIDERED BUT ELIMINATED FROM DETAILED STUDY

Many alternative means of addressing issues, concerns, and opportunities were considered in the preliminary stages of alternative formulation Various sets of constraints that could apply to all alternatives, as well as benchmarks and fully developed alternatives, were evaluated in the process Twelve alternatives, including administratively required alternatives, were ultimately selected for detailed study in this FEIS This section describes approaches to issue resolution that were considered, but eliminated from detailed study The purposes of these alternative approaches are described below, along with the accompanying rationale for their elimination from detailed study

DESIGNATED AREAS

Several areas of the Forest have received special designation by Congress. These include five Wild and Scenic Rivers (Rogue, Illinois, Elk, Chetco, and North Fork Smith) and five Wildernesses (Kalmiopsis, Wild Rogue, Grassy Knob, Siskiyou, and Red Buttes). Three Research Natural Areas (Coquille River Falls, Port Orford Cedar, and Wheeler Creek) and three Botanical Areas (Babyfoot, Big Craggies, and York Creek) were designated by the Chief of the Forest Service and are not subject to review in this round of Forest Planning. Although there has been considerable public debate about some of the areas, there seems to be a widespread base of support for the present designations; no alternatives were developed that recommend changes in the status of these areas.

PARK ALTERNATIVES

Several alternatives have been proposed by individuals (or groups) for areas surrounding the Rogue, Illinois, and Smith Rivers for possible designation as National Parks These alternatives were considered but eliminated from detailed study for a number of reasons

Although the CEQ regulations do provide for agencies to "include all reasonable alternatives not within the jurisdiction of the lead agency" (40 CFR 1502.14), alternatives which place lands currently administered by the Forest Service into the hands of other jurisdictions, whether public or private, were not reasonable considering the scope of this (Forest Plan) proposal. The purpose of the Forest Plan, as explained in the planning regulations, is to "provide for multiple use and sustained yield of goods and services from the National Forest System in a way that maximizes long-term net public benefits in an environmentally sound manner" (36 CFR 219.1(a)) National Parks are, by law, not managed under the principles of multiple use and sustained yield

Consideration of possible inclusion in the National Park system has been specifically assigned by Congress to the Secretary of Interior, designation of a National Park requires Congressional legislation At one time (November 4, 1985), the National Park Service suggested study of a potential "wild rivers national park" in an area encompassing the portions of the lower Rogue and Illinois Rivers, but withdrew its proposal (July 22, 1986) and has not expressed further interest. Another proposal by Oregon Natural Resources Council was examined in detail by the National Park Service's Pacific Northwest Regional Director. In a letter of October 2, 1987, Director Odegaard stated, "The Forest Service has done a thorough job of planning for their management actions in the Siskiyou area and I now see no need to pursue any additional studies " It is remote and speculative that Congress would designate a National Park in the very near future However, Congress has repeatedly urged the completion of Forest Plans. Nothing would preclude the National Park Service from preparing a legislative environmental impact statement, with Forest Service cooperation, just as nothing precludes Congress from designating a National Park in the future.

In response to public comments, several aspects of what National Parks offer the public were seriously considered by the Forest Suggestions for increased emphasis in tourism and recreation opportunities

have resulted in increased cooperative efforts with local government, State, and other Federal agencies A number of capital investment projects were developed (see the LRMP, Appendix B). Two of the alternatives developed for detailed study (Alternatives E and G) include land allocations to the Backcountry Recreation and other Management Areas that, when combined with the Wildernesses, resemble the boundaries of several National Park proposals Environmental consequences associated with those alternatives are disclosed in this EIS Complementary to park proponents' interests, considerably more unroaded area would be allocated to Backcountry Recreation in the new Preferred Alternative (S) In addition, increased emphasis was given to visual allocations along more heavily used recreation travel routes.

DEPARTURES

Departure alternatives are developed if a timber harvest schedule different from that needed to assure nondeclining yield can be used to respond to a particular issue or concern. This would allow harvesting more timber in the near future with a reduction in decades three through five. Proponents of departure scheduling suggest that the short fall in future decades could be offset by timber from private lands currently stocked with immature stands Two departure alternatives are evaluated in this FEIS, Alternative A-Departure and Alternative B. The DEIS also evaluated Alternative K-Departure based on the Preferred Alternative of the Draft. This departure option was subsequently dropped as described later in this section. A departure option for the Preferred Alternative of the FEIS has not been developed for reasons similar to those for dropping Alternative K-Departure. Other departure alternatives could have been developed and examined in detail, but none were identified that would have added to the resolution of the issues and concerns, or provided ways to better meet multiple-use objectives Additionally, there was little public mandate per response to the DEIS to create additional departure alternatives or analysis.

ALTERNATIVES WITH SHORT ROTATIONS

Use of rotations shorter than culmination of mean annual increment (CMAI) of growth for intensively managed timber stands has been suggested by individuals and organizations A variation suggested is to project short rotations for only part of the Forest (existing plantations) on a one-time-only basis. The effect of such an approach during the planning period (10 to 15 years) would be similar to that of a departure from nondeclining yield Timber would be harvested at a higher rate, relative to the suitable land base, in the near future similar to a departure; the difference being that instead of a reduction in harvest level in the future, this option would schedule stands to be harvested at ages prior to CMAI to fill in the gap and maintain nondeclining flow.

In Section 6(m) of the National Forest Management Act of 1976 requires the Forest Service to "insure that, prior to harvest, stands of trees throughout the National Forest System shall generally have reached the culmination of mean annual increment of growth..." Section 6(m) also provides "exceptions to these standards for the harvest of particular species of trees in management units after consideration has been given to the multiple uses of the forest including, but not limited to, recreation, wildlife habitat, and range .." Requirements for the exception to the CMAI standard are found in 36 CFR 219.16, "Alternatives which incorporate exceptions to these standards shall be evaluated if it is reasonable to expect that the overall multiple use objectives would be better attained."

Alternative D1 develops this option for detailed study and comparison purposes. Additional alternatives or variations of this theme, including applying short rotations to existing plantations only, were considered but eliminated from detailed study The primary effect of, and motivation for, using shorter rotations would be increased timber harvest levels. Analysis of the use of short rotations (including Alternative D1) has not clearly shown that overall multiple-use objectives would be better attained, leaving some question as to whether or not such an alternative would meet the requirements of law and regulations. NEPA provides for evaluation of a reasonable alternative even though it would necessitate Congressional action Alternative D1 evaluates the use of short rotations and provides information on the associated effects

sufficient to assess this option It also provides the basic information necessary to consider the effects of variations on the short rotation theme Developing alternatives in detail with variations of this option applied selectively to sub-strata of the Forest would not provide significant new information.

BENCHMARKS

Benchmarks (summarized in the Alternative Development Process section of this chapter, and described in detail in Appendix B) resemble alternatives in many ways. Benchmarks generally do not include integrated, multi-resource objectives, and only a limited number of environmental consequences were predicted for them They were not developed with the intent that they be implementable. Several benchmarks were modified slightly and are now included as full alternatives. Others did not help in providing a full range of outputs and effects, or could not be made implementable, and were dropped from further consideration A description of the disposition of each benchmark follows:

- Minimum Level. This benchmark proposed only maintenance of the basic resources of the Forest While it does represent an extreme point of non-use of resources, it does not satisfy many of the issues and concerns, particularly those related to developed recreation use, dispersed motorized recreation use, and timber harvest Alternative M is near this end of the nondevelopment spectrum, yet does satisfy many more of the Planning Problems.

- Maximum Present Net Value: This benchmark emphasized timber harvest activity at the expense of most other program activities Other than the rate of hardwood conversion, the results were very similar to the Max Timber benchmark.

- Current Direction This benchmark was the basis for Alternative A. It was modified slightly to include operational feasibility requirements for roading, and to achieve a representative mix of site classes during harvest activity.

- *Maximum Timber· This benchmark formed the basis for Alternative C, after the addition of operational* constraints necessary for implementation and minor allocations for other uses

- Recreation: This benchmark was modified by the addition of operational requirements Further adjustments were made which increased the outputs of fish and wildlife with little effect on recreation outputs These adjustments resulted in Alternative E, which provides high levels of recreation The Recreation benchmark was not brought forward as a separate alternative

- Wildlife· A preliminary alternative was developed based on the specifications of this benchmark It was dropped from further consideration, however, because it was similar to Alternative G and other alternatives which address options of providing a range of habitat mixes

- Fish The elements of this benchmark which contribute to high quality fish habitat were brought forward into several alternatives. The fish benchmark was not brought forward as a separate alternative.

PRELIMINARY ALTERNATIVES

The following alternatives were developed and evaluated, but subsequently dropped from detailed consideration for the reasons indicated Maps and additional information are available in the process records

- Habitat Diversity (Alternative F) This alternative was developed from the optimum wildlife habitat benchmark It was dropped from detailed study because it was similar to Alternative G which does

a better job of addressing other Planning Problems, and because Alternative M better provides for old-growth dependent species.

- Maximum Fish (Alternative H). This alternative was developed to produce high levels of fish outputs while sustaining a high to moderate level of timber production Many of the elements were duplicated in other alternatives and it was dropped from detailed study.

- Selected Amenity (Alternative I)· This alternative attempts to respond to a wide range of user groups and interests. The design of the land allocation, which was an attempt to satisfy the desire for undeveloped areas with the least impact on commodity production, concentrated the undeveloped allocations in areas unsuitable for timber. This did not result in a logical delineation to respond to Planning Problem #8 dealing with the unroaded areas, and offered little else not included in other alternatives

- Economic Efficiency (Alternative J): This alternative was intended to emphasize management options that maximize present net value It was quite similar to the Maximum Present Net Value benchmark, the Maximum Timber benchmark, and Alternative C

- Variations of Alternative K· Several minor variations of the land allocations along the northern boundary of the Kalmiopsis Wilderness were considered for Alternative K. They were dropped for the same reasons as presented above for Alternative I

DEIS ALTERNATIVES

Two alternatives developed in detail in the DEIS were eliminated from evaluation in the FEIS.

- Alternative K-Departure This alternative was developed to maintain the current level of timber outputs while managing the Forest under the land allocations of Alternative K This alternative does not offer any better way to meet multiple-use objectives and did not get significant support in the public review. Departing from nondeclining yield does not have a broad base of support, and those who do suggest departure do not support the land allocations of Alternative K

- Alternative L. This alternative received little positive support in the public review The element that was commented on favorably (retention of unroaded areas) is represented with some modification in Alternative S

ADDITIONAL WILDERNESS DESIGNATION

Another possible area for alternative development would have involved proposing additional areas for Wilderness designation. When Congress passed both the Oregon and California Wilderness Acts in 1984, it included language which stated that "the Department of Agriculture shall not be required to review the wilderness option prior to the revision of the [Forest] plans..." There has been no designation on the Forest since 1984. Alternatives such as E, G, K, M, and S provide for the option of future Wilderness designation through maintaining all or large portions of the existing inventoried roaded areas. Therefore, no alternatives proposing additional Wilderness on the Forest were considered for further analysis. Readers wanting detailed information about the unroaded areas on the Forest, and the tradeoffs involved in managing them, should refer to Appendix C.

Alternative levels of trail development are considered for the Wildernesses. Additional levels, particularly at the high end of the development spectrum, could have been considered There has been no expressed public interest for this type of development in the Wildernesses, no alternatives proposing this course of action were considered

ALTERNATIVES WITH MORE DETAILED IMPLEMENTATION

The planning process could have developed additional implementation direction for the alternatives Individual timber sales, wildlife improvement projects, and recreational developments at campgrounds could all have been planned If this additional planning had been included, however, an already complex process would have become unwieldy. The time and money required to conduct the process would have expanded dramatically, and the amount of information needed to understand the process would have increased in the same proportions. Additionally, by the time many of the projects were scheduled for implementation, site conditions and other planning particulars may have become stale

The Forest Service instead chose to make this a programmatic FEIS. Additional environmental analyses will be conducted as the decisions in this process are implemented. If a site-specific environmental analysis identifies conflicts with the decisions made in Forest planning, an amendment or supplement to the Forest Plan may be required. If the site-specific environmental analysis identifies significant adverse effects on the quality of the human environment not addressed in this analysis, a site-specific EIS would be prepared

For these reasons, the Forest chose not to include specific actions to implement most of the alternative decisions in this planning process

EVERGREEN ALTERNATIVE

This alternative was proposed by the Southern Oregon Timber Industries Association (SOTIA), and was supported by a large number of people who responded to the DEIS. It proposed a blend of land allocations generally falling between Alternatives C and K, with spotted owl habitat designated to meet MR's left in the base for the calculation of the timber Allowable Sale Quantity Most elements of this alternative are incorporated in the range of alternatives in some way. The exception is the suggestion that the Forest Service manage the designated wildlife habitat for spotted owls, but continue to count it in the base for calculation of the timber harvest level. This suggestion has been considered, but rejected on the basis that once allocated to resource management that precludes timber harvest, lands are considered unsuitable for timber production. If future analysis and decisions result in those lands becoming suitable, the harvest level could be recalculated and the Forest Plan amended

Even though the Evergreen Alternative is not developed for detailed study in its entirety, each of the elements suggested were considered in the development of Alternative S. The more significant elements that are built into Alternative S include fertilization of managed stands; a slight increase in area allocated to visual resource management objectives, added protection for the Rogue River corridor; adjusted timber harvest dispersion constraints; inclusion of the inventoried Research Natural Areas, increased recreation site and trail development; and a high level of capital investments for fish habitat

Alternative S goes beyond the recommendations in the Evergreen Alternative for some land allocations. It includes recommendations for the inventoried Botanical and Supplemental Resource Management Areas over the number recommended by the Evergreen Alternative

A number of elements are included in other alternatives and were considered as Alternative S was developed, but were not included in the alternative design The Evergreen Alternative proposes rotations shorter than CMAI While this option is evaluated in Alternative D1, the Forest Service has not incorporated it in other alternatives for reasons discussed above in the section, "Alternatives With Short Rotations " It was also suggested that wildlife habitat be designated, but counted in the base for ASQ calculations as described above. In conjunction with the Evergreen Alternative, SOTIA also suggests a number of technical changes These have been carefully evaluated and some are incorporated in Alternative S, some are not.

GREGORY ALTERNATIVE

This alternative was developed by Gregory Forest Products, Inc , of Glendale, Oregon It is based on Alternative A of the DEIS with adjustments to the land allocations and additional emphasis on intensive timber management practices The elements of this alternative are found within the range of the alternatives; several have been incorporated in newly developed Alternative S. Key suggestions for changes in the technical analysis that effect timber production were similar to those suggested by SOTIA's Evergreen Alternative Suggestions for fertilization and adjustment of the harvest dispersion constraints have been incorporated in Alternative S; others, such as short rotations or elimination of Management Area 6 have not. However, the management emphasis in Management Area 6 has been measurably changed as a result of their (and others) input. Additional suggestions are responded to more specifically in Appendix K.

STATE OF OREGON ALTERNATIVE

This alternative was developed by the State of Oregon with a public review process separate from the review conducted by the Forest Service. Compared to Alternative K, the State Alternative would: increase slightly the allocations in Backcountry Recreation Management Area, increase the visual management protection along selected travel routes and most trails; increase the Visual Quality Objective of Partial Retention as seen in the middle ground from the Rogue River to Retention, recommend the three candidate rivers for Wild and Scenic designation; approximately double the Botanical areas; allocate six high value fisheries planning basins to Riparian Prescription C; and add Supplemental Resource Management Areas to the mainstem and principal tributaries of Elk River

The State's recommendation also includes a number of technical corrections and refinements to improve the analysis and reliability of resource output projections, and emphasizes intensification of timber management for areas where the management objectives include timber production. Specific recommendations include the use of fertilization as a management practice, and earlier final harvest of the existing plantations (shorter rotations). The State Alternative would also refine the harvest dispersion constraints used in Alternative K to achieve the desired result of minimizing the risk of cumulative watershed effects, with less opportunity cost to timber.

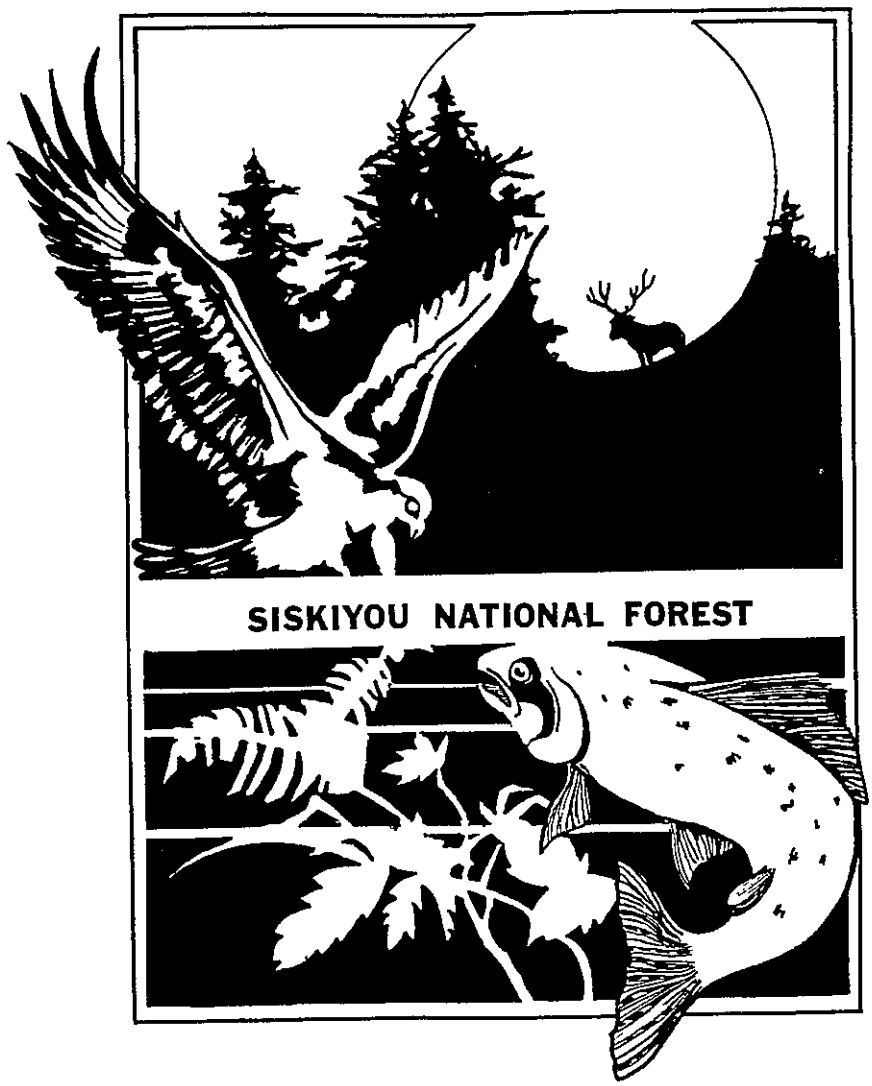
Alternative S has many similarities to the alternative recommended by the State of Oregon. Many of the recommendations are incorporated in Alternative S and only vary by degree. Alternative S, however, would substantially increase the allocations to Backcountry Recreation and the visual allocations in several areas, although it does not upgrade the inventoried Partial Retention in the Rogue River viewshed to Retention, nor does it allocate the Coquille River foreground to Retention. It would make the same refinement in the harvest dispersion constraints; include fertilization; and allocate five of the six planning basins identified in the State Alternative plus two additional to Riparian Prescription C. It would not allocate the additional Supplemental Resource Areas in the Elk River Watershed A number of technical corrections and refinements suggested by the State have been incorporated in the analysis.

Many elements of the State's recommendation have been included in the Preferred Alternative (S), and other elements are included in various forms throughout the range of alternatives The State Alternative in its original form was not developed for detailed study.

ALTERNATIVES CONSIDERED IN DETAIL

The alternatives considered in detail demonstrate different ways of managing the land and resources of the Forest Each is a combination of land uses, management practices, and activity schedules which results in a unique combination of resource outputs, land uses, and environmental conditions Each alternative has a set of goals and objectives designed to respond to the Planning Problems in a different way Table II-7 (following the presentation of alternative descriptions) summarizes the response of each alternative to all of the Planning Problems

MANAGEMENT AREAS



A critical part of each alternative design is the recommended land allocation. All National Forest System lands are assigned to several or all of the 14 Management Areas in each alternative. A Management Area is a category of land where a given prescription or set of prescriptions may be applied to meet specific management objectives (not necessarily contiguous acres). While the objectives for all Management Areas include some multiple uses, they often emphasize one or a few resources and therefore result in dominate use management for some areas. Prescriptions are management practices selected and scheduled for application on a specific area or land allocation to attain multiple use and other goals and objectives (36 CFR 219.3). The alternative design includes assignments of land areas to Management Areas, then FORPLAN is given the choice of prescriptions compatible with the Management Area to select and schedule those which can most efficiently satisfy the objectives and constraints of the alternative. In the Management Area descriptions that follow, the acres tentatively suitable for timber production are identified. It should be noted that these acres may or may not be selected for timber management in a particular alternative, and that this determination and the suitability inventory itself are subject to review at ten year intervals.

The direction for a Management Area is defined by the set of prescriptions with associated objectives, and standards and guidelines that apply to that area. Standards and guidelines deal with potentially adverse environmental effects, and attempt to mitigate them by avoiding, minimizing, or rectifying impacts. Some of these standards were developed by the Interdisciplinary Team specifically to respond to environmental conditions on the Forest. Others are adopted from the Regional Guide and the NFMA regulations (36 CFR 219 27) Additional mitigation is provided by the application of Best Management Practices (BMP's) which are described as the primary mechanism to enable the achievement of water quality standards. The specific Standards and Guidelines are presented in the Forest Plan, and in Appendix D of this FEIS in the case of those that vary from the Preferred Alternative. The BMP's can be found in Appendix F of the Forest Plan

Although many areas have multiple resource values, lands can logically only be assigned to one Management Area (each acre can only be managed under one prescription) Many overlaps occur throughout the Forest, e g , the existing Illinois Wild River runs through the Kalmiopsis Wilderness, which also includes the existing York Creek Botanical Area. In many cases, the more restrictive management prescriptions will also meet the objectives of the other areas overlapped. In our example above, the management direction for Wilderness would also be satisfactory for the Wild River and Botanical Area, however, the Wild River or Botanical Area prescriptions would not meet the requirements for Wilderness management

In order to systematically assign the land base to Management Areas, a hierarchy was developed based on the level of ground disturbance or vegetation manipulation provided for in each Management Area The Management Areas are numbered in order of increasing activity from the least ground disturbance and vegetation manipulation to the most. Management Area 1, Wilderness is the most restrictive, Management Area 14, General Forest is at the other end of the spectrum with the most road construction and timber management, and the least restrictions on mining and other activities Where alternative design results in

To analyze and evaluate alternative land allocations, it was necessary to identify logical areas that could be assigned to various Management Areas under different alternatives. Areas with attributes of significance for specific resources were mapped and labeled as "special areas" for the analysis It may be noted that there are no special areas for timber This is not an oversight, nor a de-emphasis of the timber resource All acres tentatively suitable for timber production start out in the General Forest Management Area and FORPLAN is allowed to select the prescriptions which produce the highest timber outputs, subject to basic multiple-use constraints. To develop a full range of alternatives and examine the various ways of responding to the issues, differing levels and combinations of the special areas are subtracted from the General Forest and assigned to Management Areas which emphasize other resources.

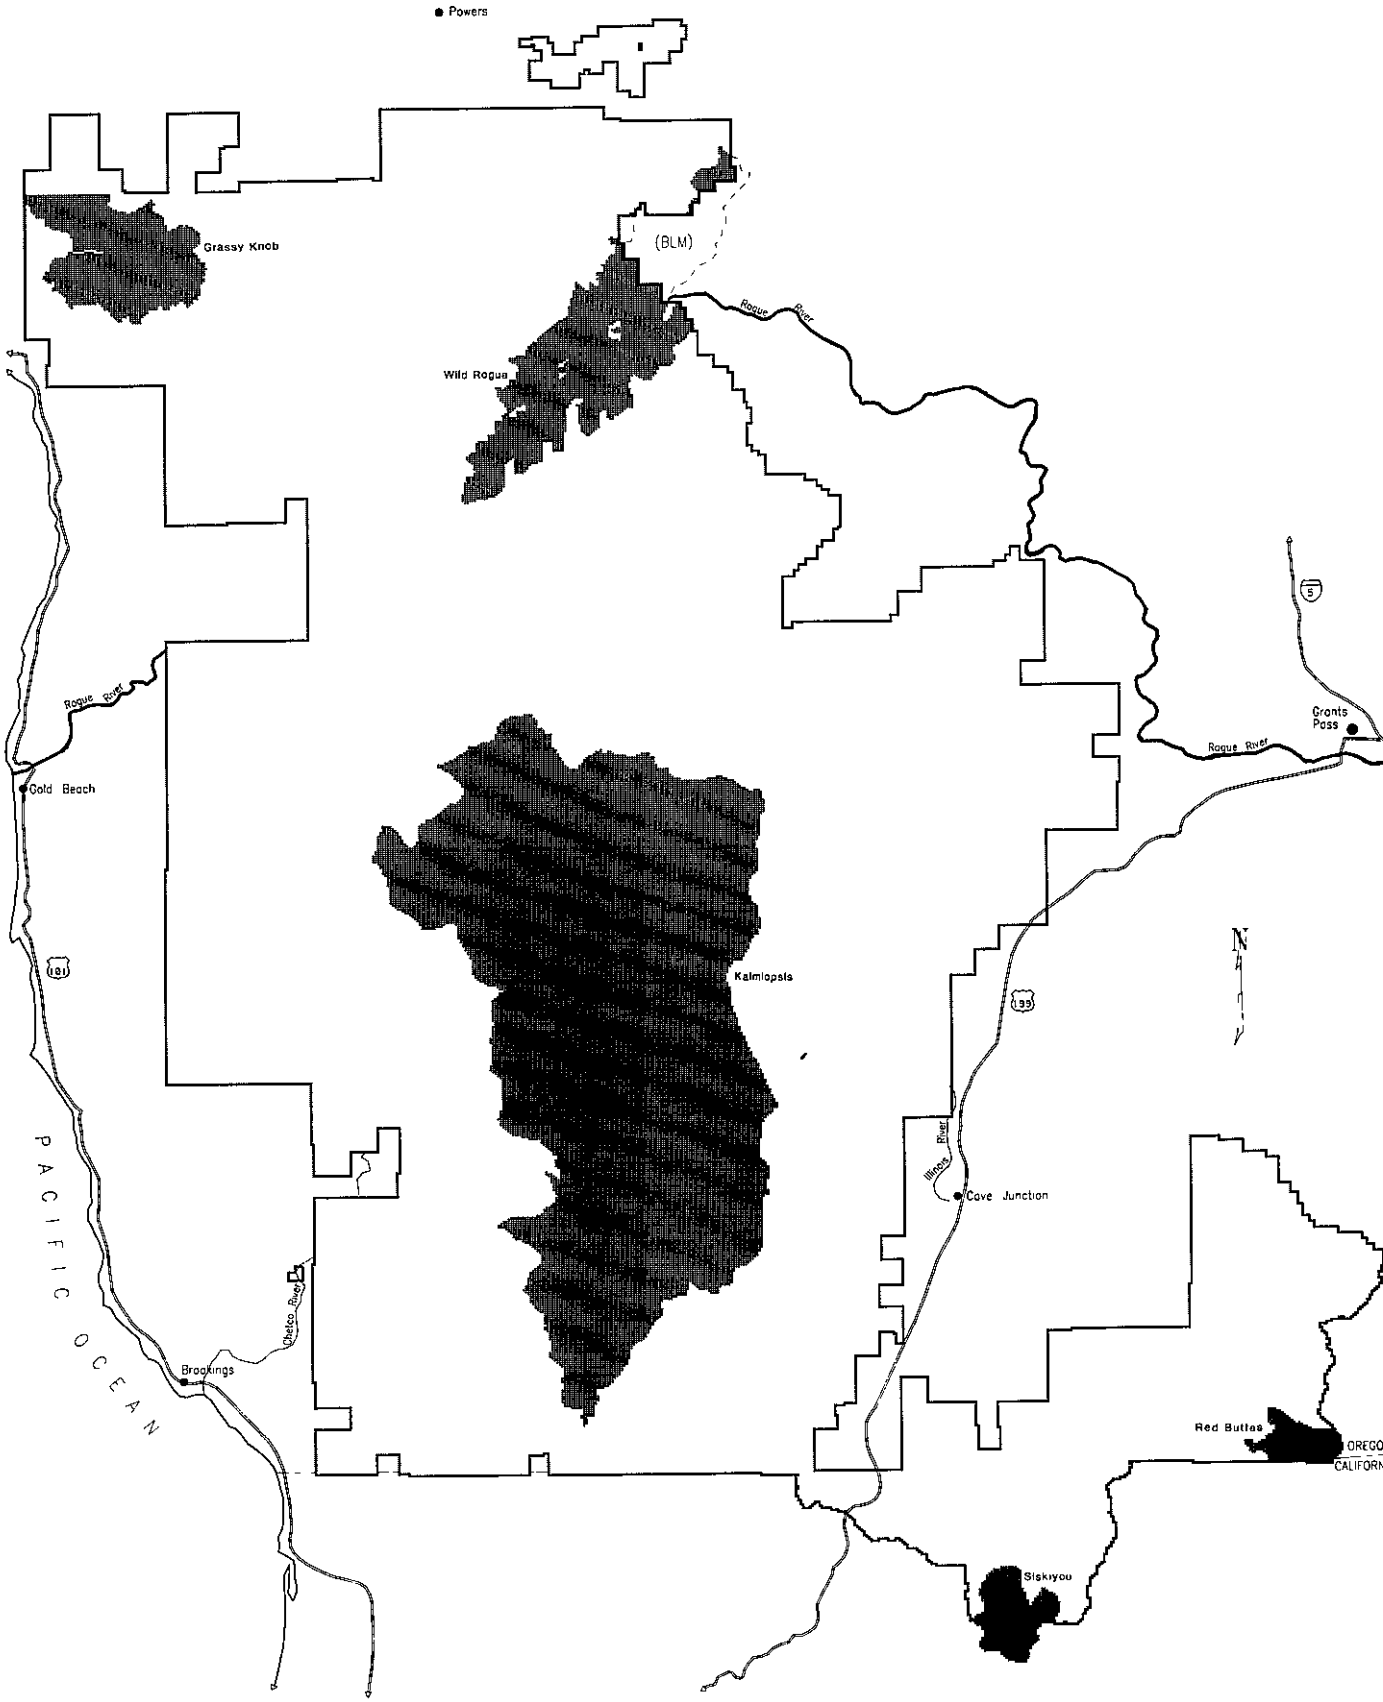


Figure II-3. Wilderness Management Area Map

MANAGEMENT AREA 1 WILDERNESS

Wilderness is essentially undisturbed area where natural processes continue with a minimum of human interference. Wildernesses are pristine, scenic landscapes that provide an opportunity for solitude. The Wildernesses on the Siskiyou are characterized by deep, rugged canyons containing clear rushing streams The steep, heavily vegetated slopes generally terminate in knife-like ridges. The areas are managed to comply with the requirements of the Wilderness Act of 1964. The size of this Management Area (232,495 acres) does not change by alternative. It consists of five Wildernesses. Kalmiopsis, Grassy Knob, and portions of Wild Rogue, Red Buttes and Siskiyou

Figure II-3 displays a map of each location, and Table II-3 shows the acres associated with each area.

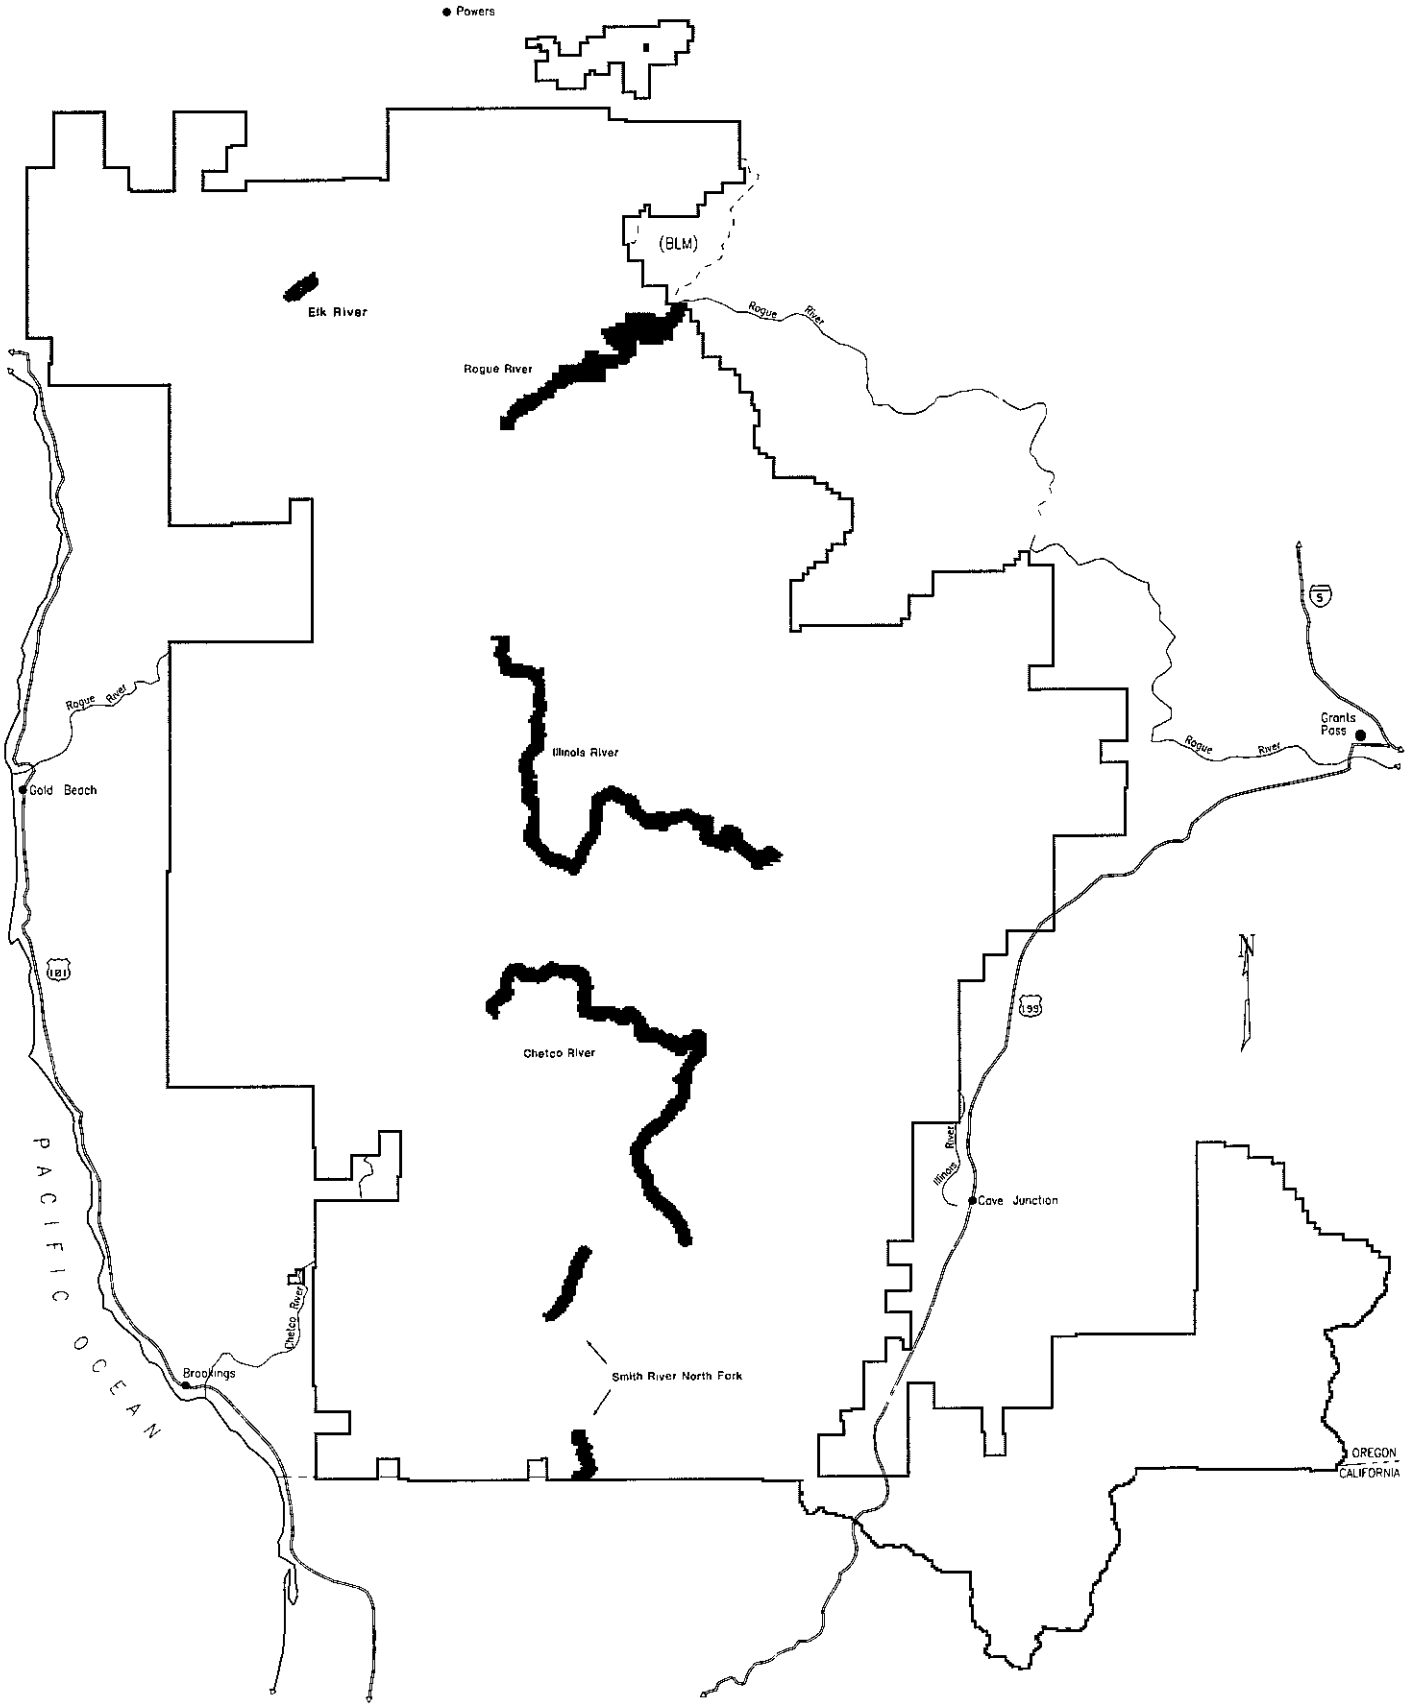

Figure II-4 Wild River Management Area Map

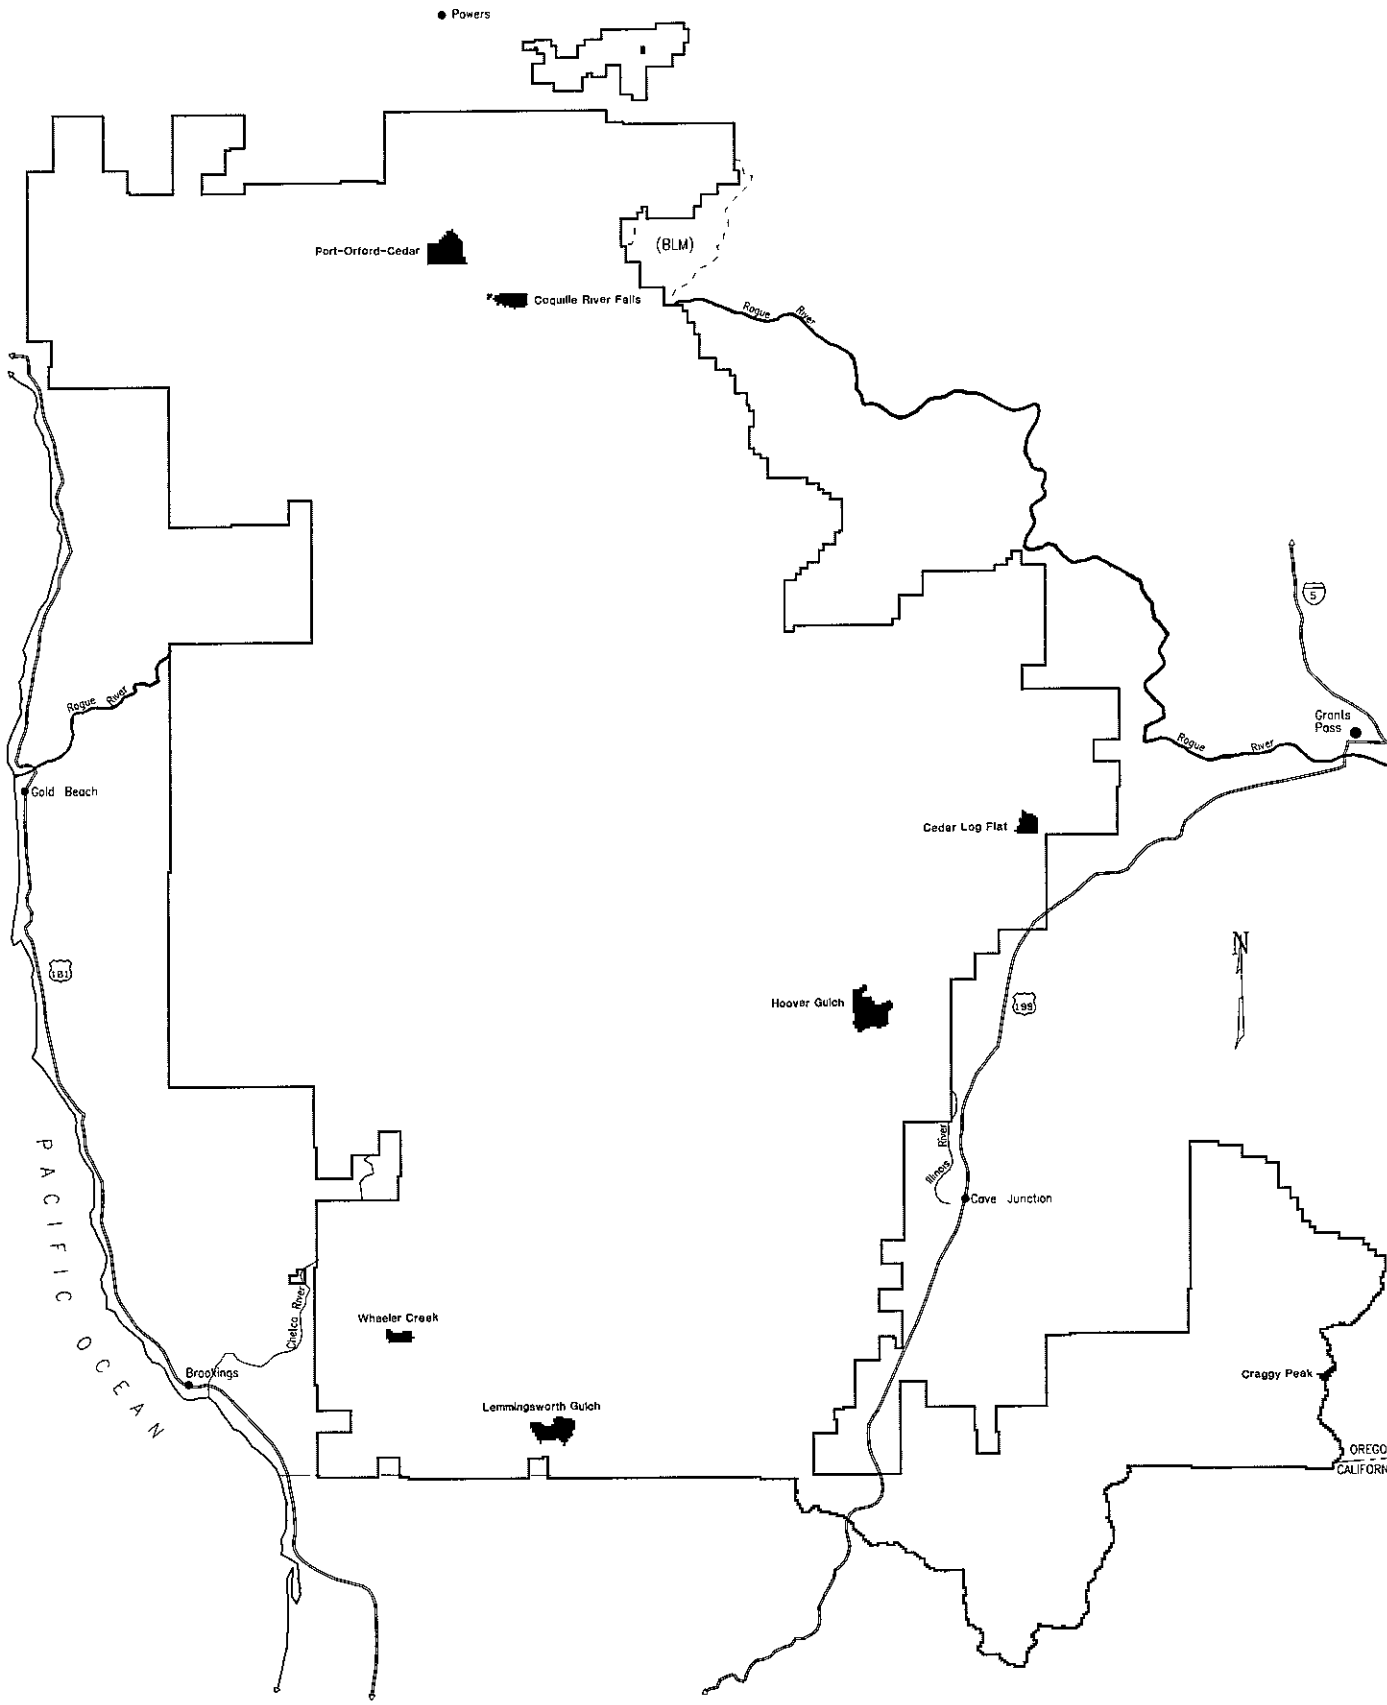
MANAGEMENT AREA 2 WILD RIVER

Management Area 2 consists of the "Wild" segments of the Rogue, Illinois, Chetco, North Fork Smith, and Elk Rivers which were designated by Congress under the National Wild and Scenic Rivers Act. The Wild designation was reserved for those rivers that are free flowing, free of impoundments, and generally inaccessible except by trail. This Management Area includes 27,128 acres of National Forest Land

Figure II-4 displays a map of each area's location, and Table II-3 shows how each river was treated by alternative Note: **The North Fork Smith, Chetco, and Elk Rivers were designated by the Omnibus Oregon Wild and Scenic River Act of 1988 following the time that the alternatives for this EIS were developed and analyzed. Any alternative selected for implementation would be modified to include all of these rivers.**



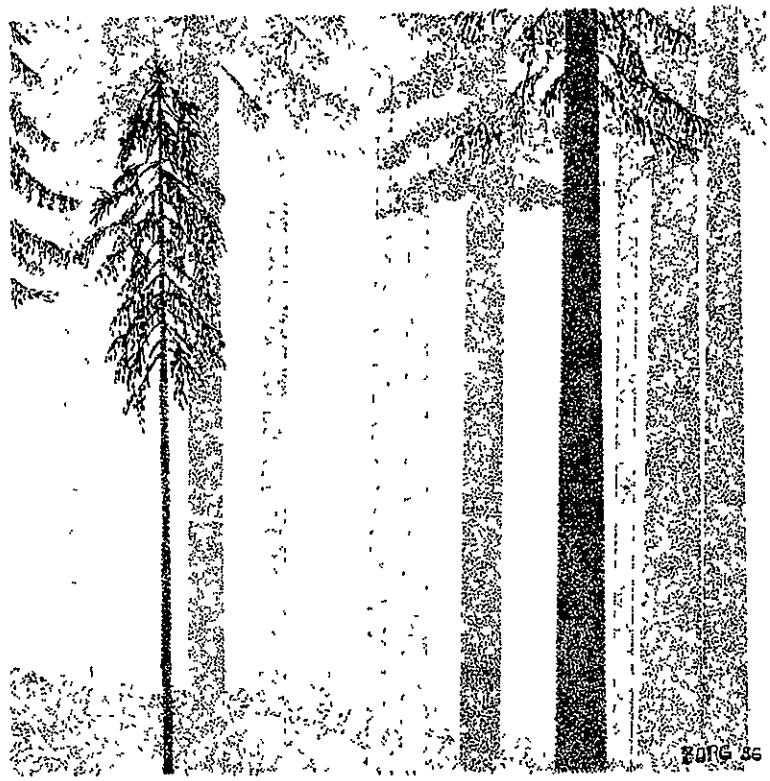


Figure II-5 Research Natural Area Management Area Map

MANAGEMENT AREA 3 RESEARCH NATURAL AREA

Management Area 3 contains distinctive natural ecosystems designated (or proposed) as part of the Research Natural Area Program for scientific and educational purposes Research Natural Areas (RNA's) are sites which typify an undisturbed aquatic or terrestrial ecosystem where natural features are preserved for scientific purposes and natural processes are allowed to dominate Three existing RNA's (Coquille River Falls, Port Orford Cedar, and Wheeler Creek) were established by the Chief of the Forest Service and remain constant at 1,957 acres in all alternatives. Four additional areas, totaling 2,799 acres (1,505 tentatively suitable timber land), are being considered for recommendation to the RNA program in this FEIS: Hoover Gulch, Lemmingsworth Gulch, Cedar Log Flat, and Craggy Peak.

Figure II-5 displays a map of each location, and Table II-3 shows the acres associated with each candidate area and how they were allocated by alternative.

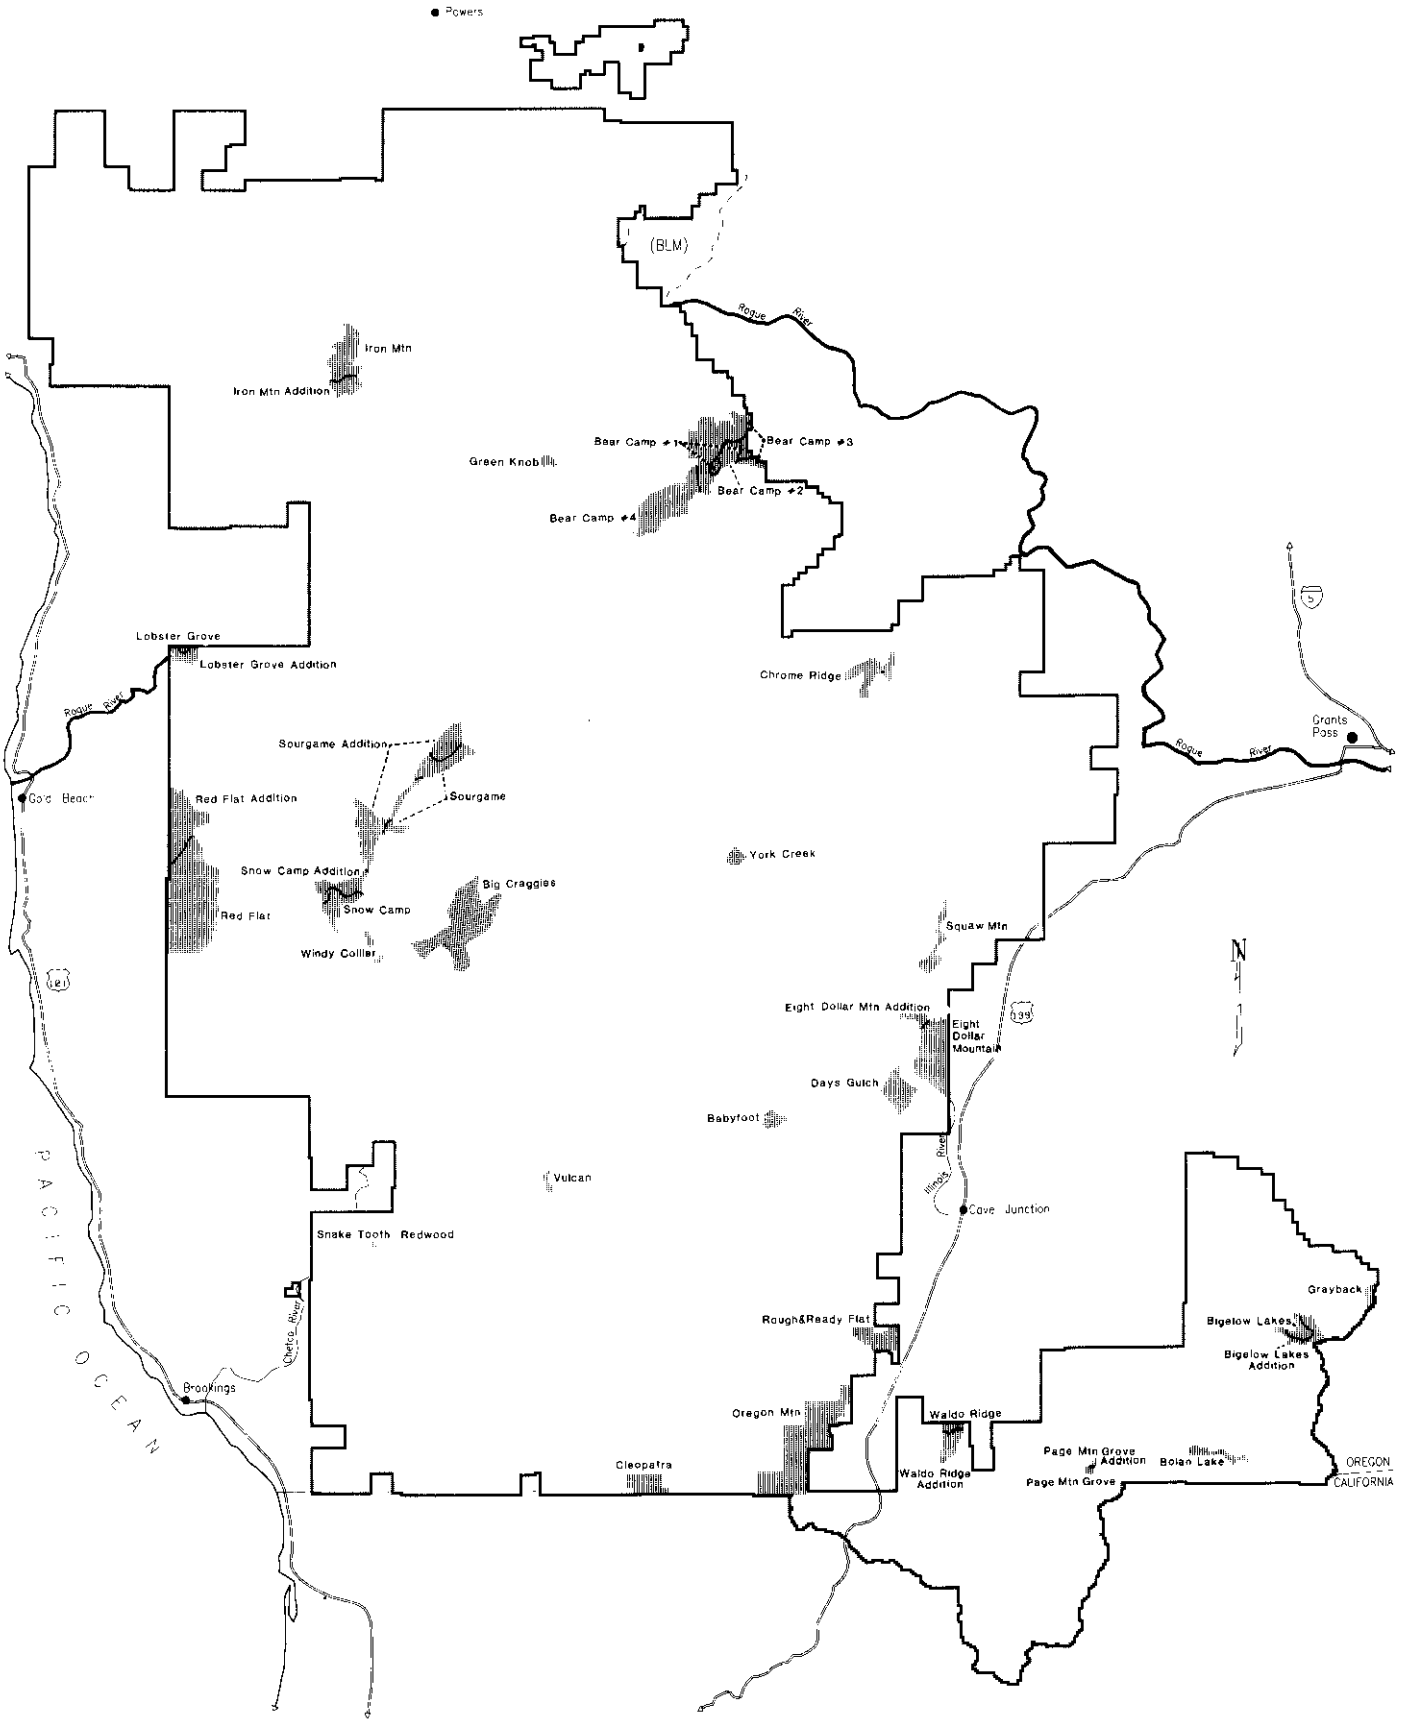

Figure II-6. Botanical Management Area Map

MANAGEMENT AREA 4 BOTANICAL

Management Area 4 includes the best representations found on the Forest of unusual plants indigenous to southwestern Oregon There are three existing Botanical Areas totaling 4,475 acres, two of which (Big Craggies and Babyfoot Lake) have portions outside of Wilderness. Nineteen additional sensitive plant areas are considered for designation in this FEIS. All 19 contain a total of 35,596 acres (16,462 acres tentatively suitable timber land). Five old-growth sites are also considered, they contain 1,321 acres (1,067 acres tentatively suitable timber land) Acres allocated to this Management Area would be managed with emphasis on the protection and enhancement of the rare plant or unique old-growth resources; other uses consistent with these goals would be allowed. These areas would not have programmed timber harvest, and other ground-disturbing or vegetation-manipulating activities may be significantly restricted

Figure II-6 displays a map of each area's location, and Table II-3 shows the acres associated with each candidate area and how they were allocated by alternative

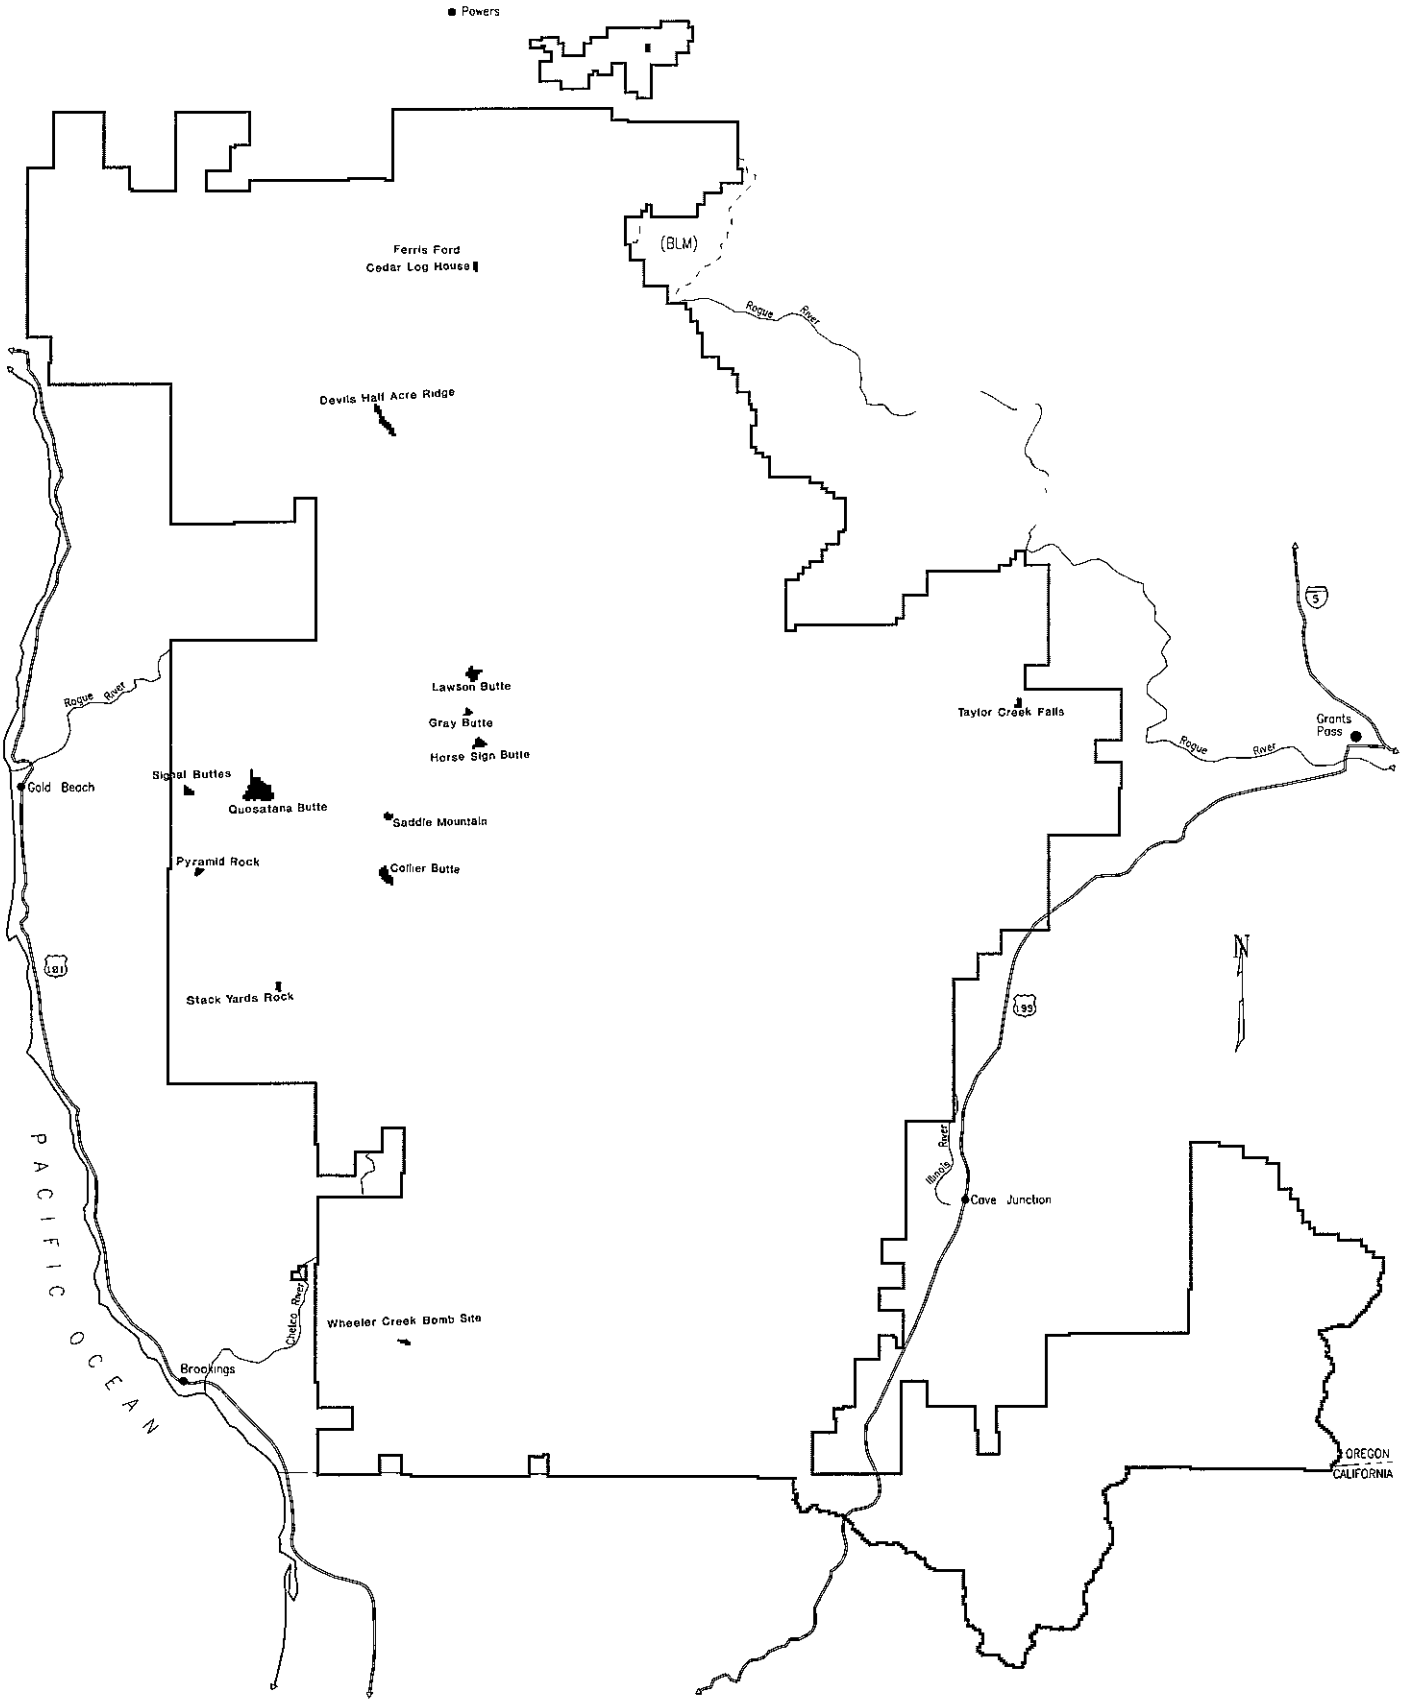

Figure II-7 Unique Interest Management Area Map

MANAGEMENT AREA 5 UNIQUE INTEREST

Management Area 5 protects significant cultural or exceptional geologic sites on the Forest. Development or vegetation manipulation for commodity production would not be allowed Cultural sites include historic structures or locations of historically significant events Geologic sites consist of prominent or unusual rock buttes or waterfalls. Thirteen such areas are considered for designation in this FEIS. Wheeler Creek Bomb Site, Collier Butte, Devils Half Acre Ridge, Gray Butte, Horse Sign Butte, Lawson Butte, Pyramid Rock, Quosatana Butte, Saddle Mountain, Signal Buttes, Stack Yards Rock, Taylor Creek Falls, and Ferris Ford Log House These areas contain 1,705 acres (766 acres tentatively suitable timber land).

Figure II-7 displays a map of each area's location, and Table II-3 shows the acres associated with each candidate area and how they were allocated by alternative

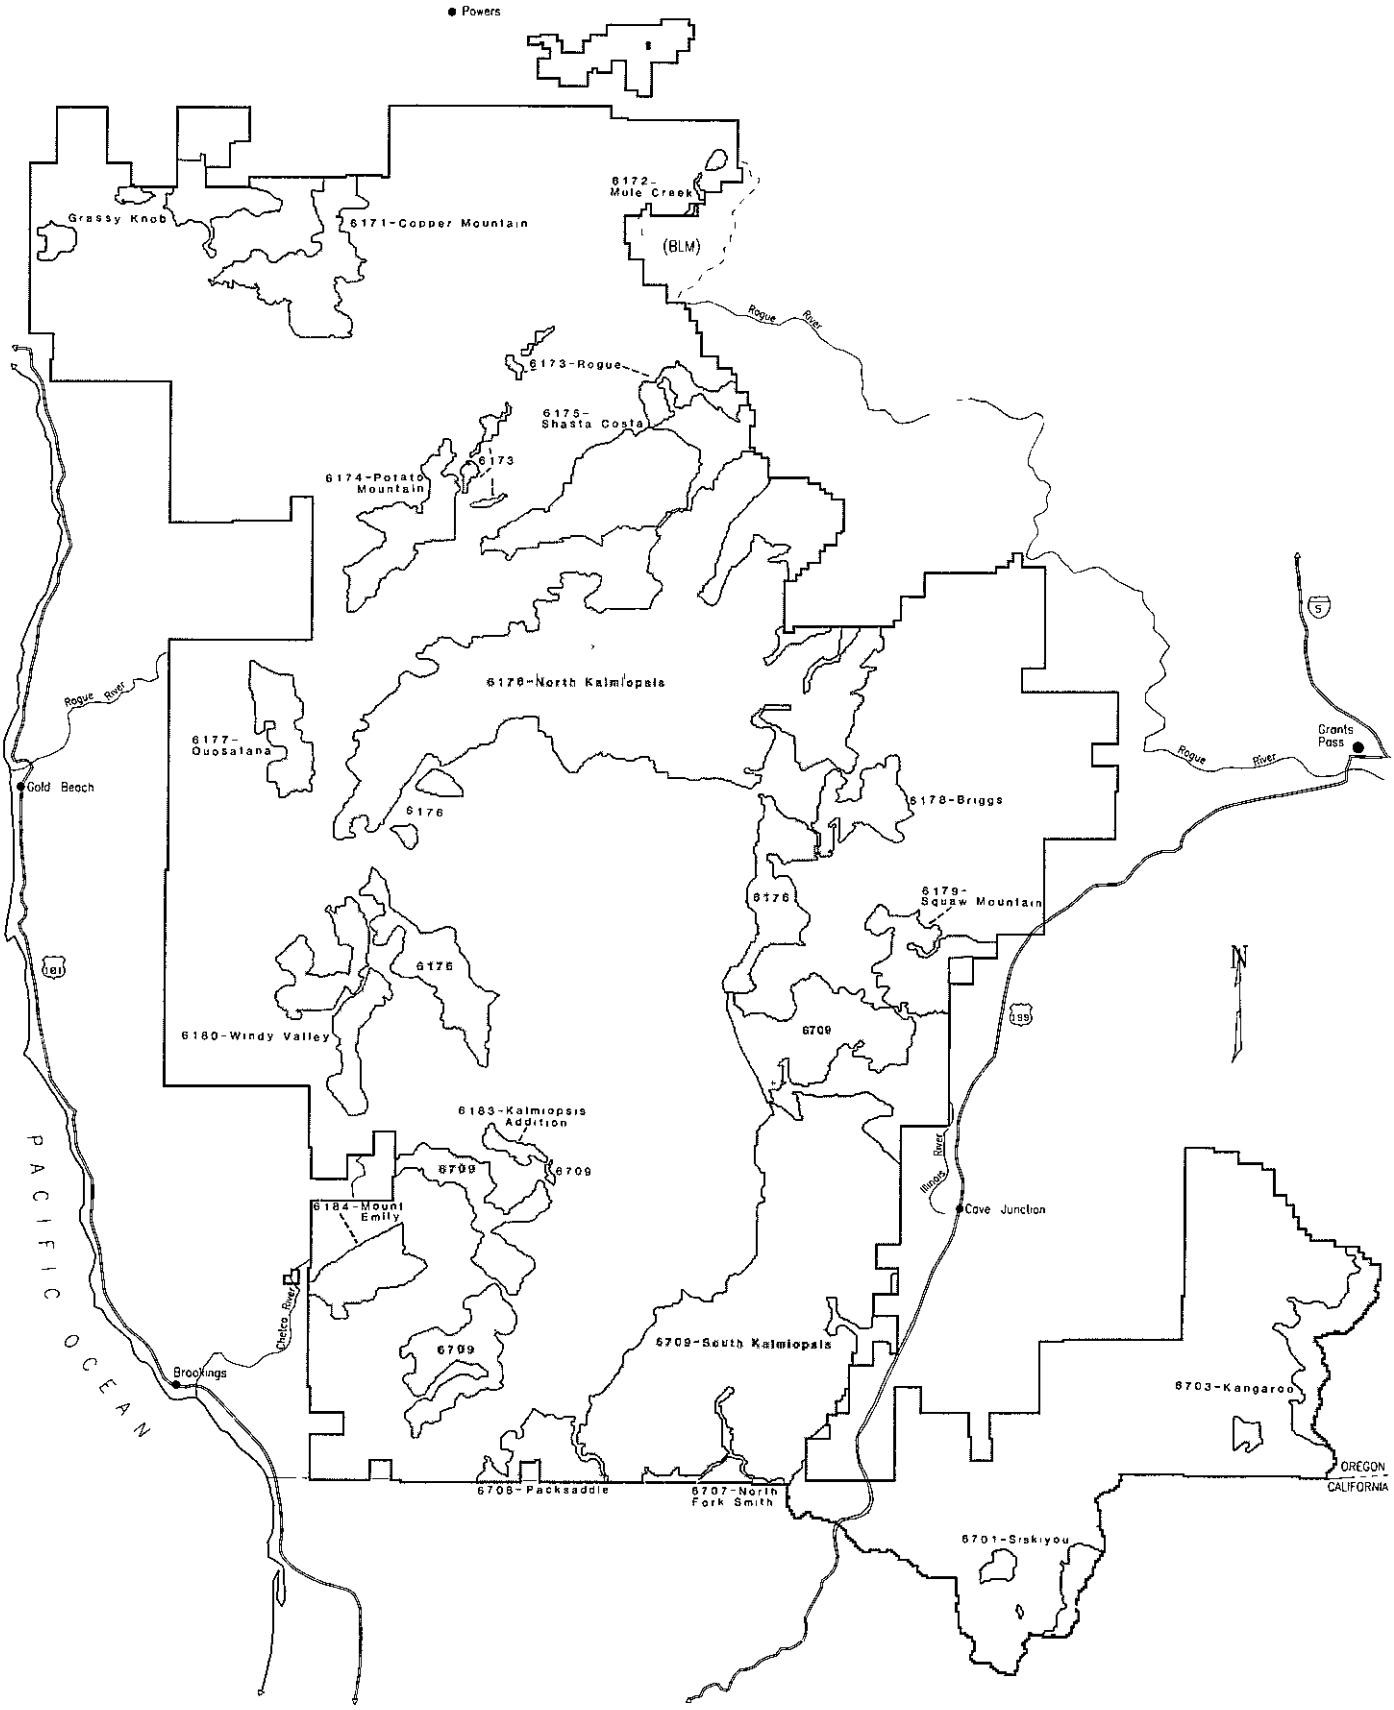

Figure II-8. Backcountry Recreation Management Area Map

MANAGEMENT AREA 6 BACKCOUNTRY RECREATION

This Management Area contains areas that will be retained in their natural state and will provide recreational and other resource opportunities associated with large unroaded areas. Candidates for Management Area 6 consist of the inventoried roadless areas on the Forest which are at least 5,000 acres in size and/or adjacent to existing Wilderness These areas are in a natural state and essentially unaffected by human activity. In areas that have been partially developed as a result of continuing management activities under current direction, a restoration program would be implemented to return the area to a near-natural condition over time Various levels of trail development are prescribed for these areas to increase recreation carrying capacity, and still maintain Primitive and Semi-primitive character. The Management Area prescription is designed to provide motorized recreation opportunities in designated areas, and in other areas to exclude the use of motorized equipment and emphasize non-motorized recreation opportunities. Eighteen areas are being considered, totaling 314,000 acres (171,844 acres tentatively suitable timber land).

Figure II-8 displays a map of the location of each, and Table II-3 shows the acres associated with each candidate area and how they were allocated by alternative

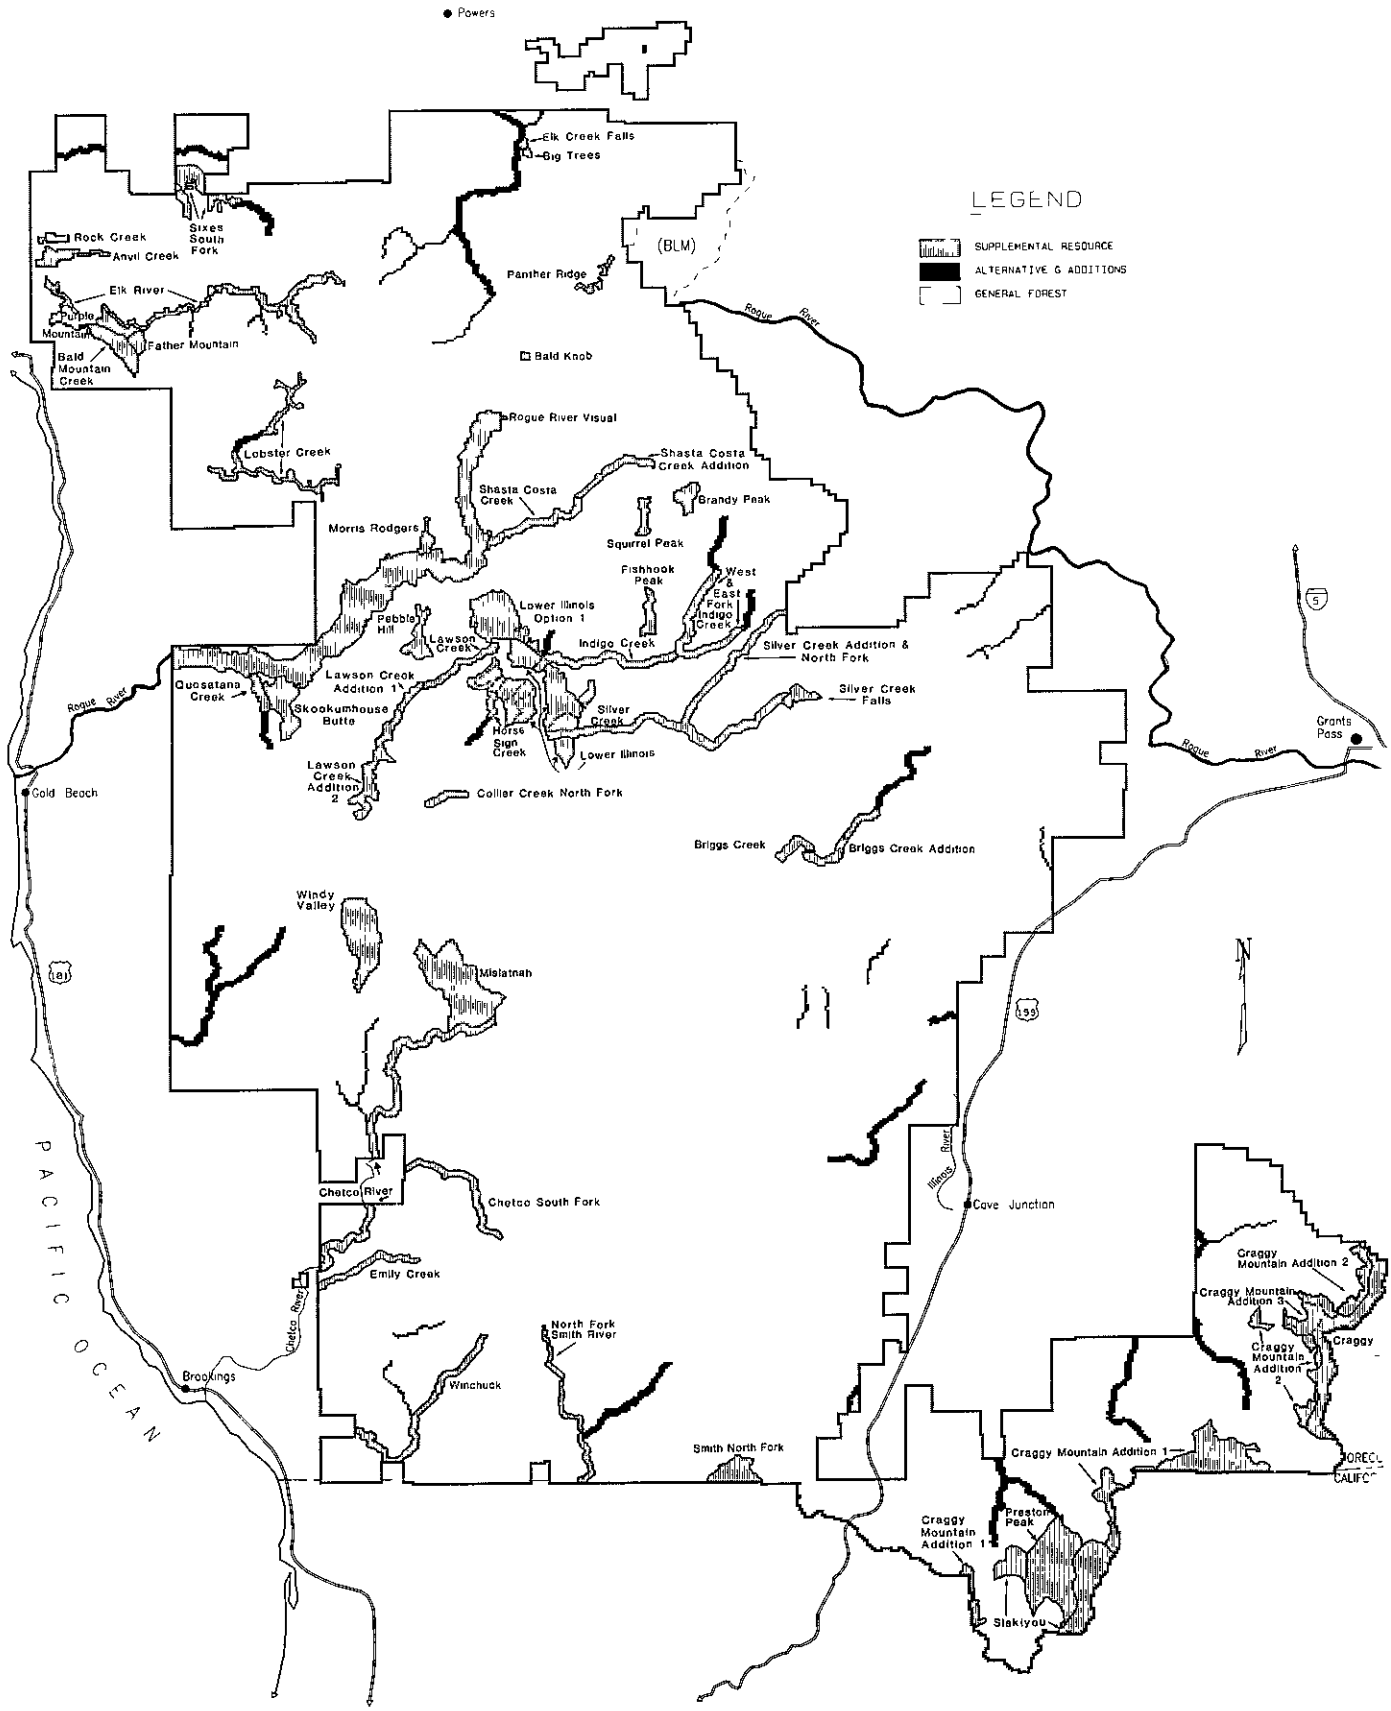

Figure II-9. Supplemental Resource Management Area Map

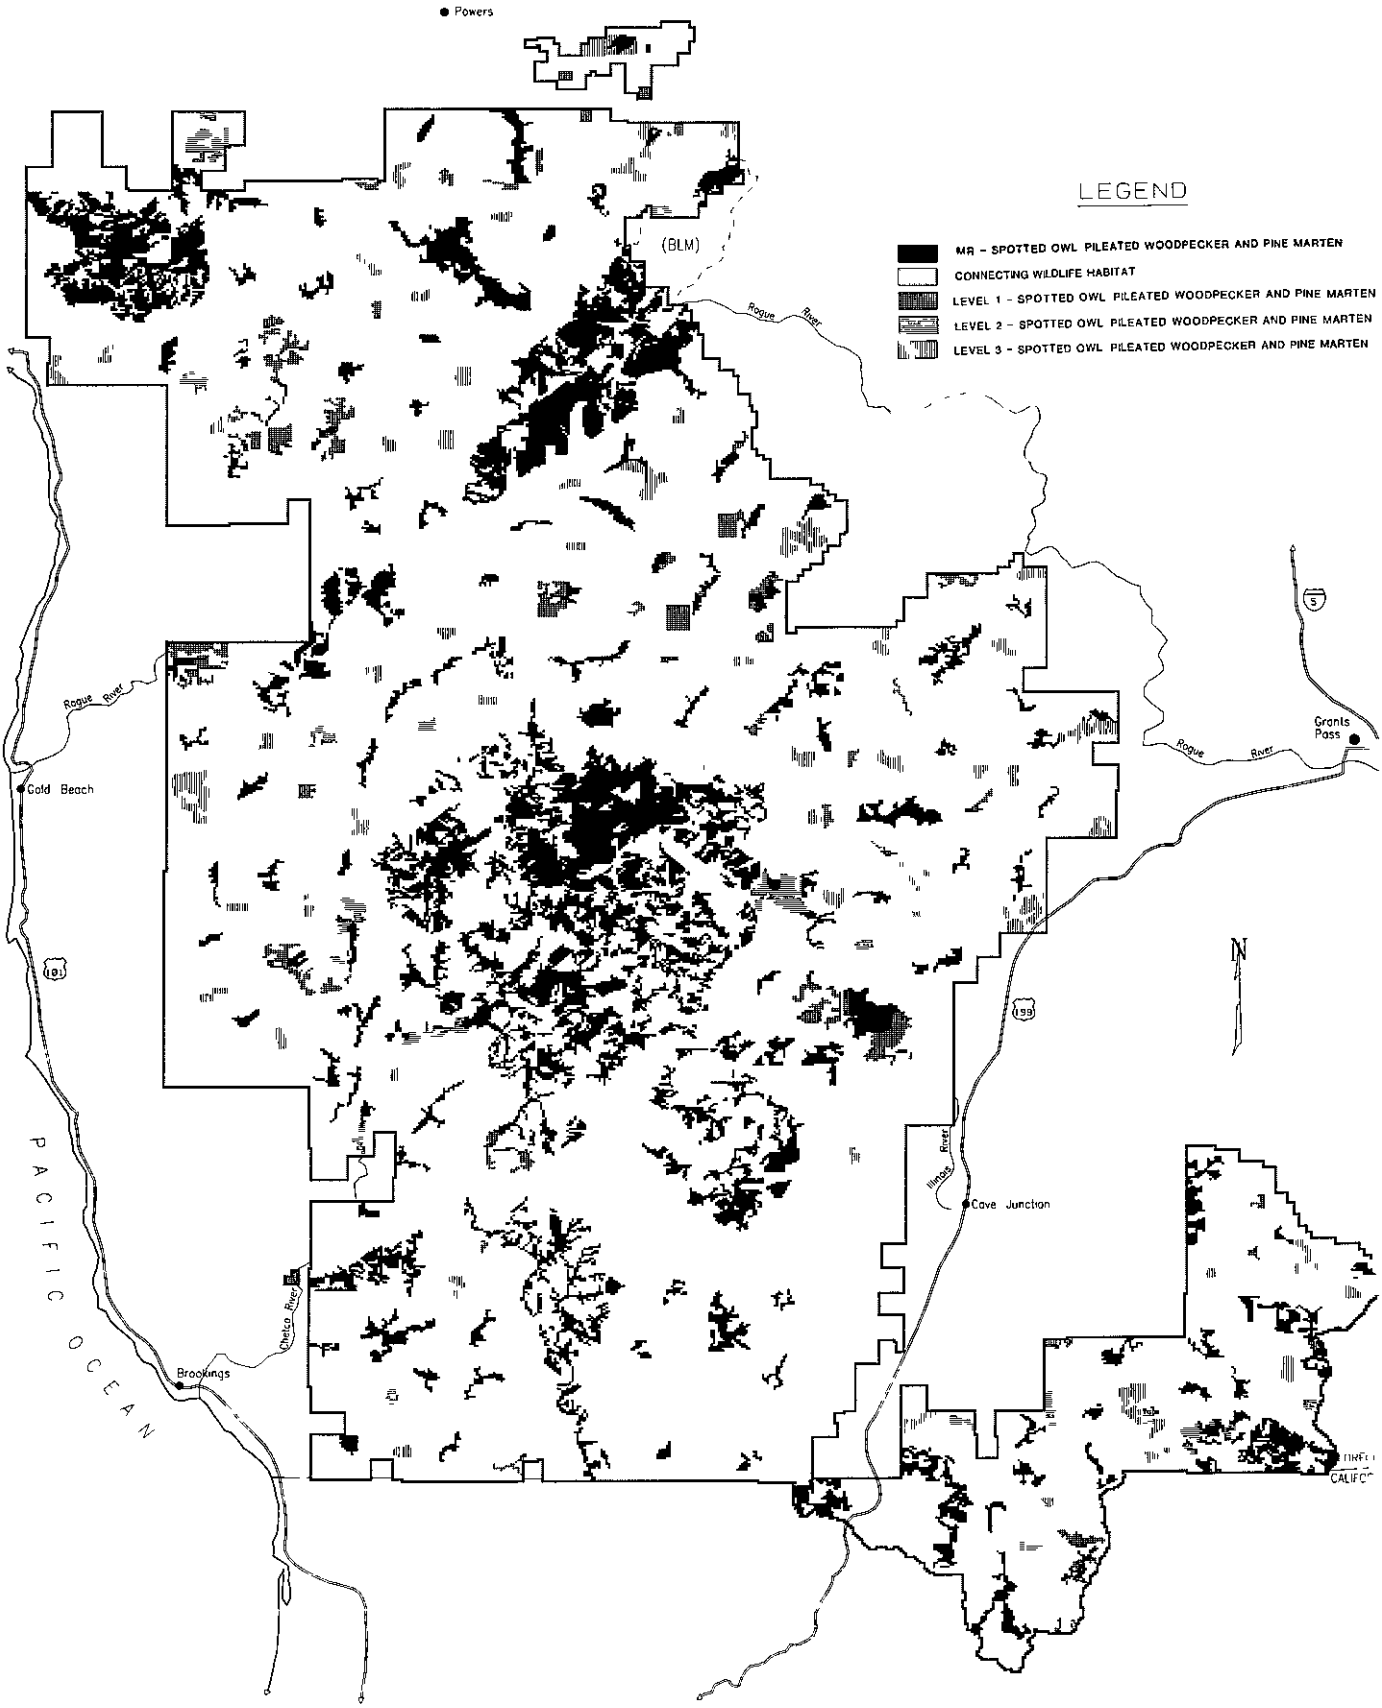
MANAGEMENT AREA 7 SUPPLEMENTAL RESOURCE

Areas considered highly productive habitat for fish or wildlife, have strong recreational attributes or values, or are necessary for the maintenance of sensitive watershed conditions are provided in this Management Area designation. Management objectives include maintenance of near-natural conditions while permitting limited levels of activity, such as through-road construction or habitat improvement projects. No timber harvest is programmed from these areas, but activity is permitted to salvage or protect stands from disease and insect infestations. These areas are considered supplemental to the Siskiyou Riparian Ecosystem Policy and other direction designed to protect or enhance water quality plus wildlife and fisheries habitat. Forty-two areas, totaling 76,281 acres (45,312 acres tentatively suitable timber land), are considered for Supplemental Resource Management Area designation in this FEIS.

Figure II-9 displays a map of each area's location, and Table II-3 shows the acres associated with each candidate area and how they were allocated by alternative



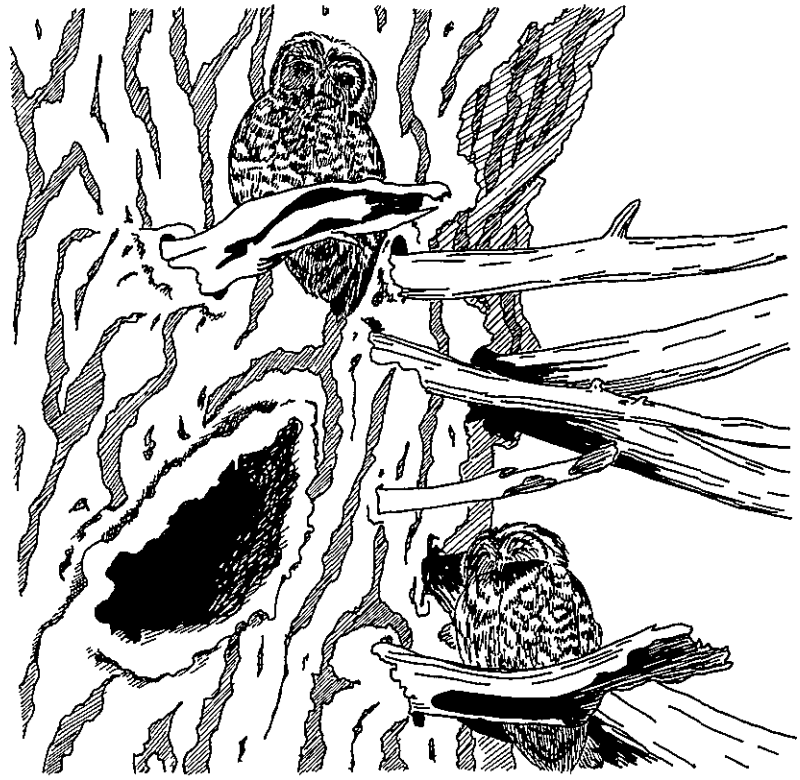


Figure II-10 Designated Wildlife Habitat Management Area Map

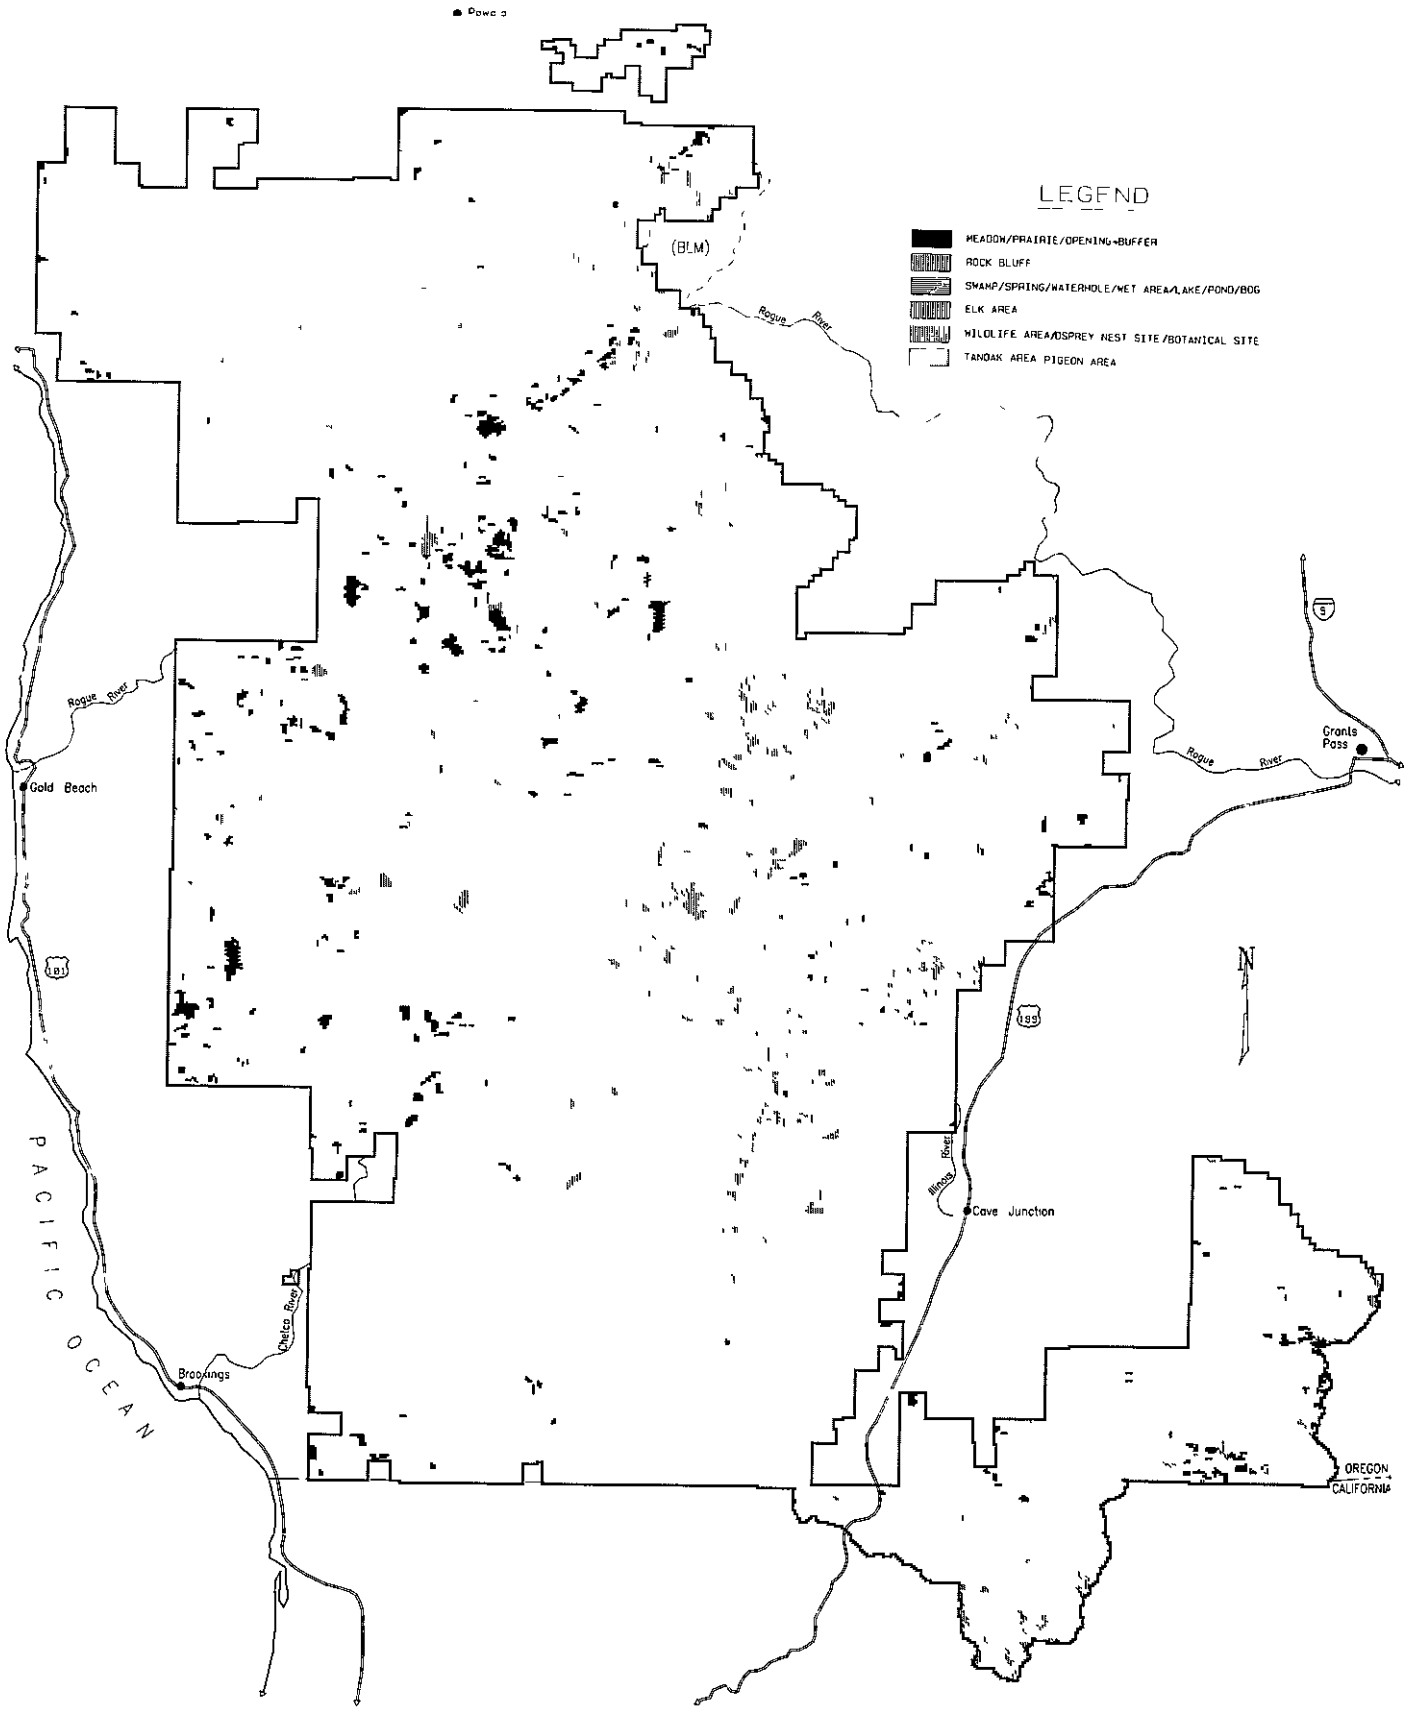
MANAGEMENT AREA 8 DESIGNATED WILDLIFE HABITAT

Management direction for this designation protects habitat for spotted owls, pileated woodpeckers, and pine martens. These three animals are indicator species for all wildlife inhabitants of mature or old-growth forests. This Management Area includes habitat needed to meet Management Requirement (MR) objectives Management direction for this designation includes requirements to maintain those mature and old-growth characteristics necessary for the sustenance of dependent wildlife species. No timber harvest activity is programmed for this area and ground-disturbing activities are limited to occasional road construction or habitat improvement projects Salvage is not permitted unless it is necessary to prevent disease or insect infestations. Total habitat protected over time to meet the Management Requirement amounts to 159,949 acres This includes 106,090 acres in Wilderness and other designated areas, or in areas unsuitable for timber management. Only 36,712 acres are tentatively suitable for timber production. Another 39,672 acres (36,911 acres of tentatively suitable timber land) are considered in some alternatives in addition to the level needed to meet MR's.

Figure II-10 displays a map of each area's location, and Table II-3 shows the acres associated with each candidate area and how they were allocated by alternative



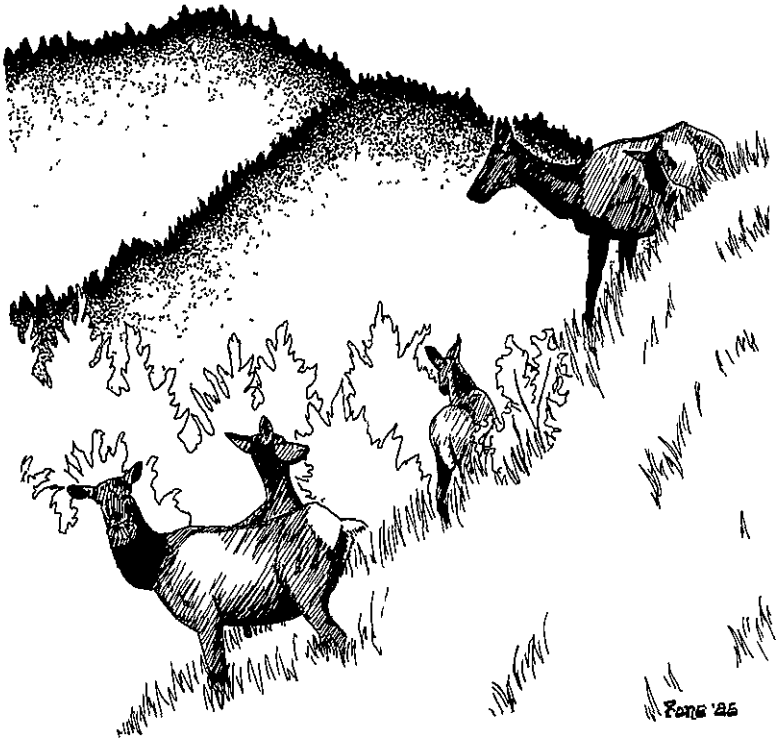


Figure II-11 Special Wildlife Site Management Area Map

MANAGEMENT AREA 9 SPECIAL WILDLIFE SITE

Management Area 9 consists of special wildlife habitat sites which are important components for overall wildlife habitat diversity Examples include meadows, lakes, tanoak stands, wet areas, rock bluffs, and other areas frequented by wildlife. Management direction for this area precludes programmed timber harvest activity but allows site-disturbing activities that are not contrary to the overall objective of preserving special wildlife habitats A total of 46,019 acres (including 13,264 acres of tentatively suitable timber land) are considered for designation in this FEIS.

Figure II-11 displays a map of each area's location, and Table II-3 shows the acres associated with each site type and how they were allocated by alternative

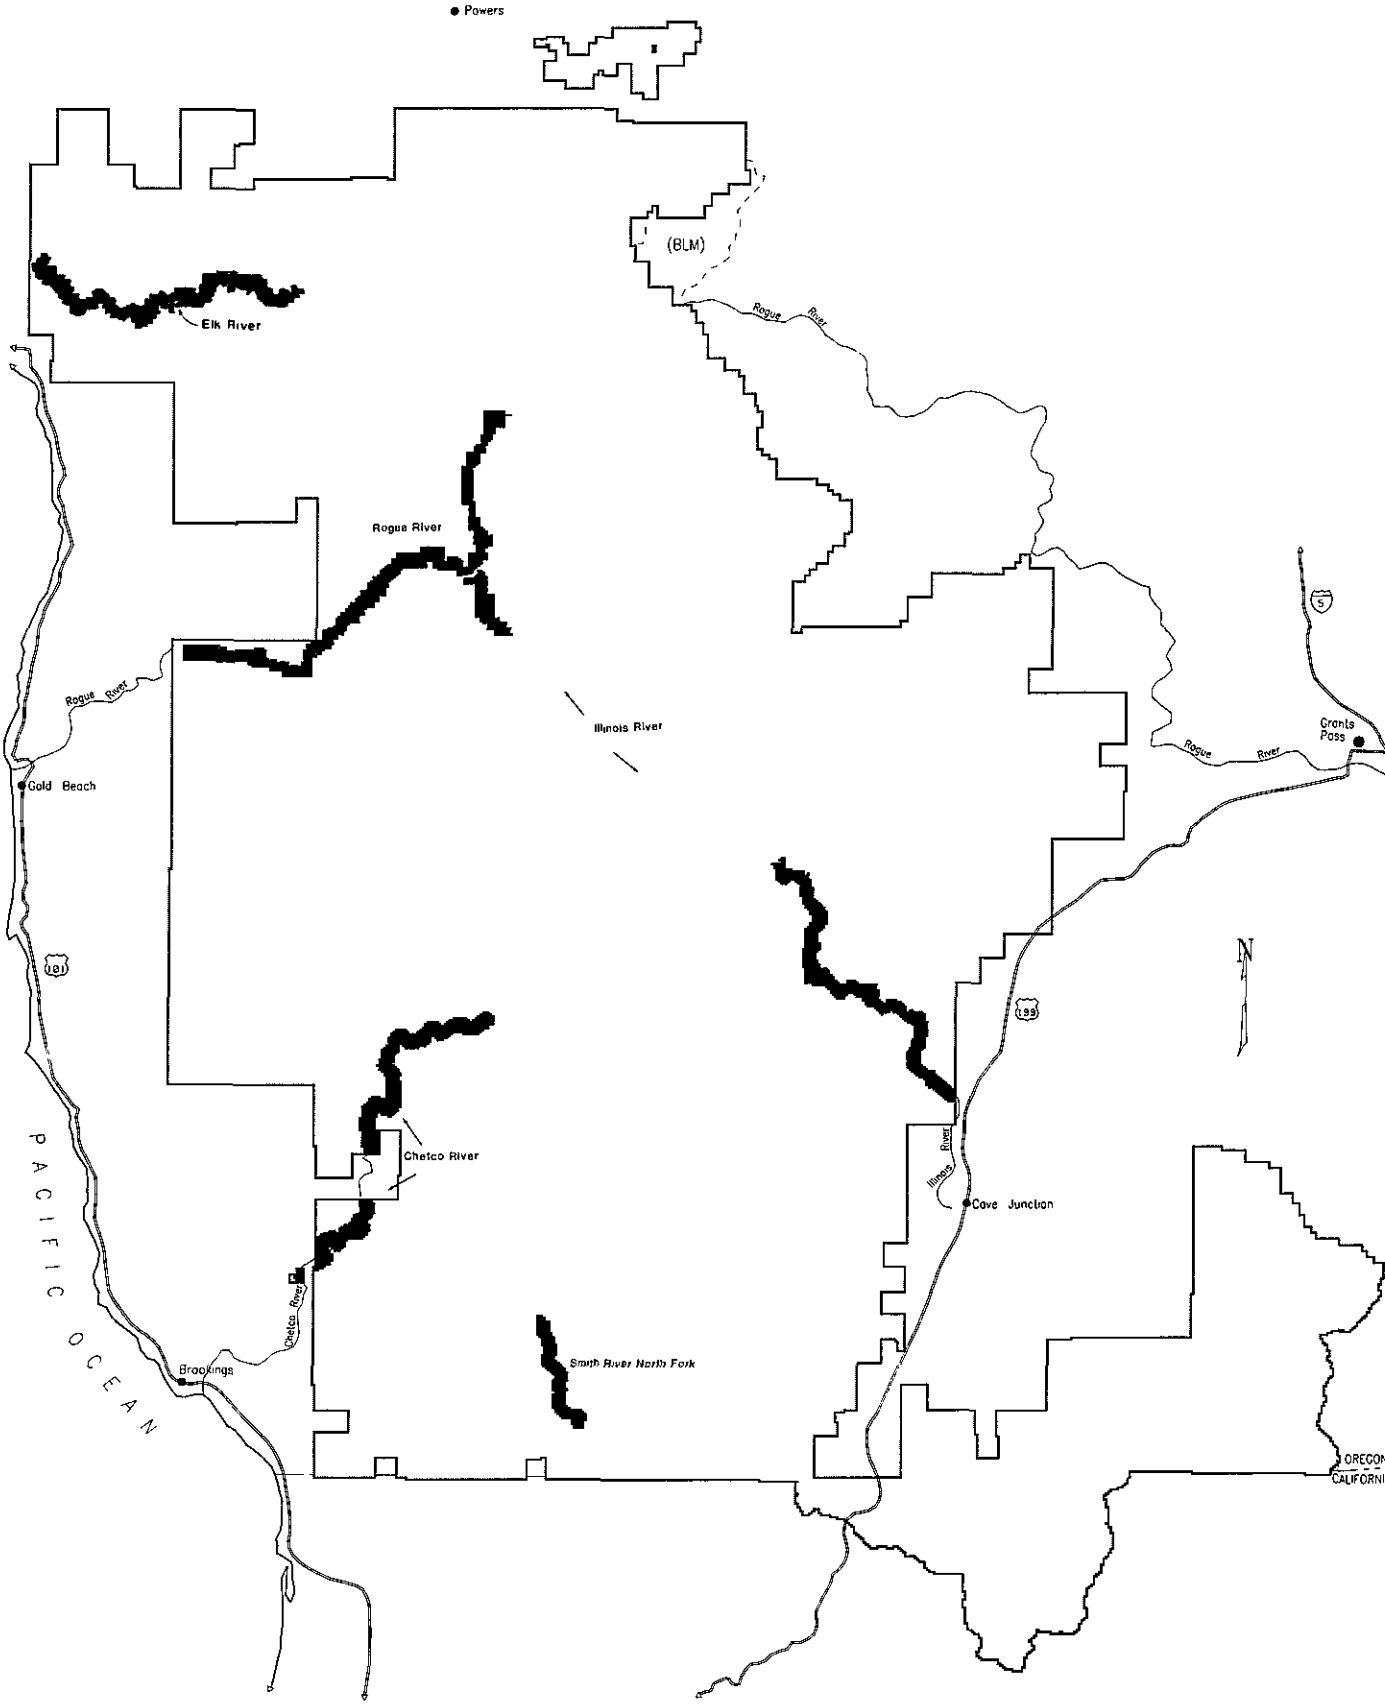

Figure II-12 Scenic/Recreation River Management Area Map

MANAGEMENT AREA 10 SCENIC/RECREATION RIVER

Management Area 10 includes segments of the Rogue, Illinois, Chetco, North Fork Smith, and Elk Wild and Scenic Rivers, and adjacent corridors of land classified as "Scenic" and "Recreational " The Chetco, North Fork Smith, and Elk were recently designated Wild and Scenic in the Omnibus Oregon Wild and Scenic Rivers Act of 1988. These areas are managed for multiple uses with emphasis on recreation and scenic quality, and protection of their "outstandingly remarkable" values. Timber management is planned at a low level where it can be accomplished consistent with meeting these other objectives. A Scenic river must be of high scenic quality, free of impoundments, and have a largely undeveloped shoreline, but can be accessed in places by roads The Recreation classification applies to those river segments which are readily accessible by public roads and have undergone substantial modification of the scenery from human causes These existing designated areas total 23,931 acres.

Figure II-12 displays a map of each area's location, and Table II-3 shows how each river was treated by alternative Note: **The North Fork Smith, Chetco, and Elk Rivers were designated by the Omnibus Oregon Wild and Scenic River Act of 1988 following the time that the alternatives for this EIS were developed and analyzed. Any alternative selected for implementation would be modified to include all of these rivers.**

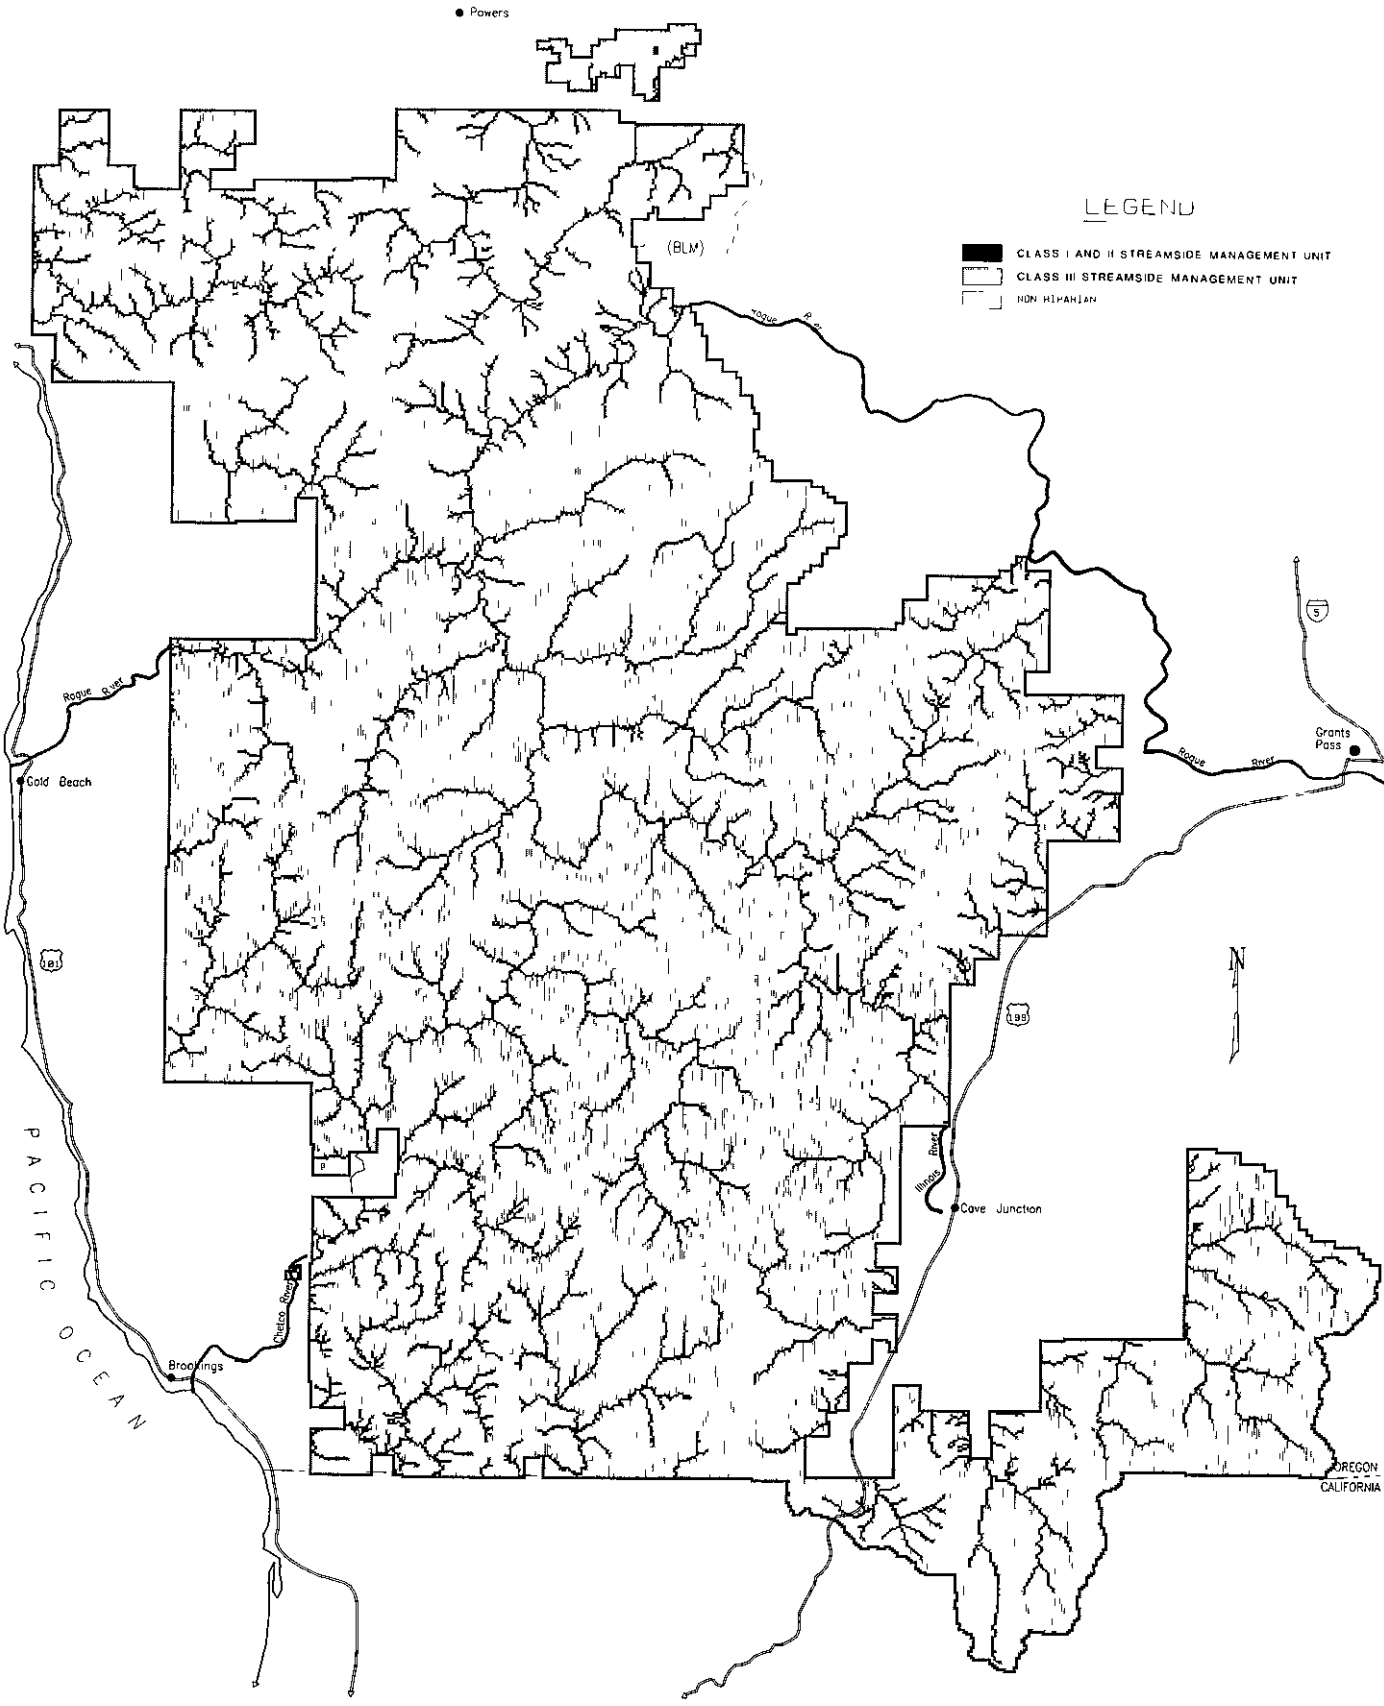

Figure II-13 Riparian Management Area Map

MANAGEMENT AREA 11 RIPARIAN

Management Area 11 contains the riparian area along perennial streams. The minimum area of consideration for management of the riparian area is 100 feet measured horizontally from each side of all Class I, II and III streams The actual width of the riparian zone is determined on the ground and varies for site-specific conditions For the purpose of this analysis, Riparian Management Areas are modeled as the area 150 feet measured horizontally from each side of all Class I and II streams, and 100 feet each side along Class III streams. There are an estimated 175,500 acres of riparian areas Forest-wide with approximately 99,000 acres tentatively suitable for timber production. Within this Management Area there are three prescription themes that are assigned to individual planning basins by alternative. Two include multiple uses with the emphasis on watershed and fisheries values and limited timber production. Prescription B is designed to manage vegetation to maintain water temperature, while Prescription C manages vegetation to reduce water temperature and improve watershed conditions over time. The third option is Minimum Level (M) which programs no timber harvest that would remove stream shade producing vegetation. While riparian areas are overlapped by Management Areas 1 through 10, they are never assigned to Management Areas 12 through 14 since this would not meet the MR's for watershed and fisheries protection.

Figure II-13 displays a map of riparian areas and Table II-3 shows the acres associated with each riparian area and the prescription by alternative

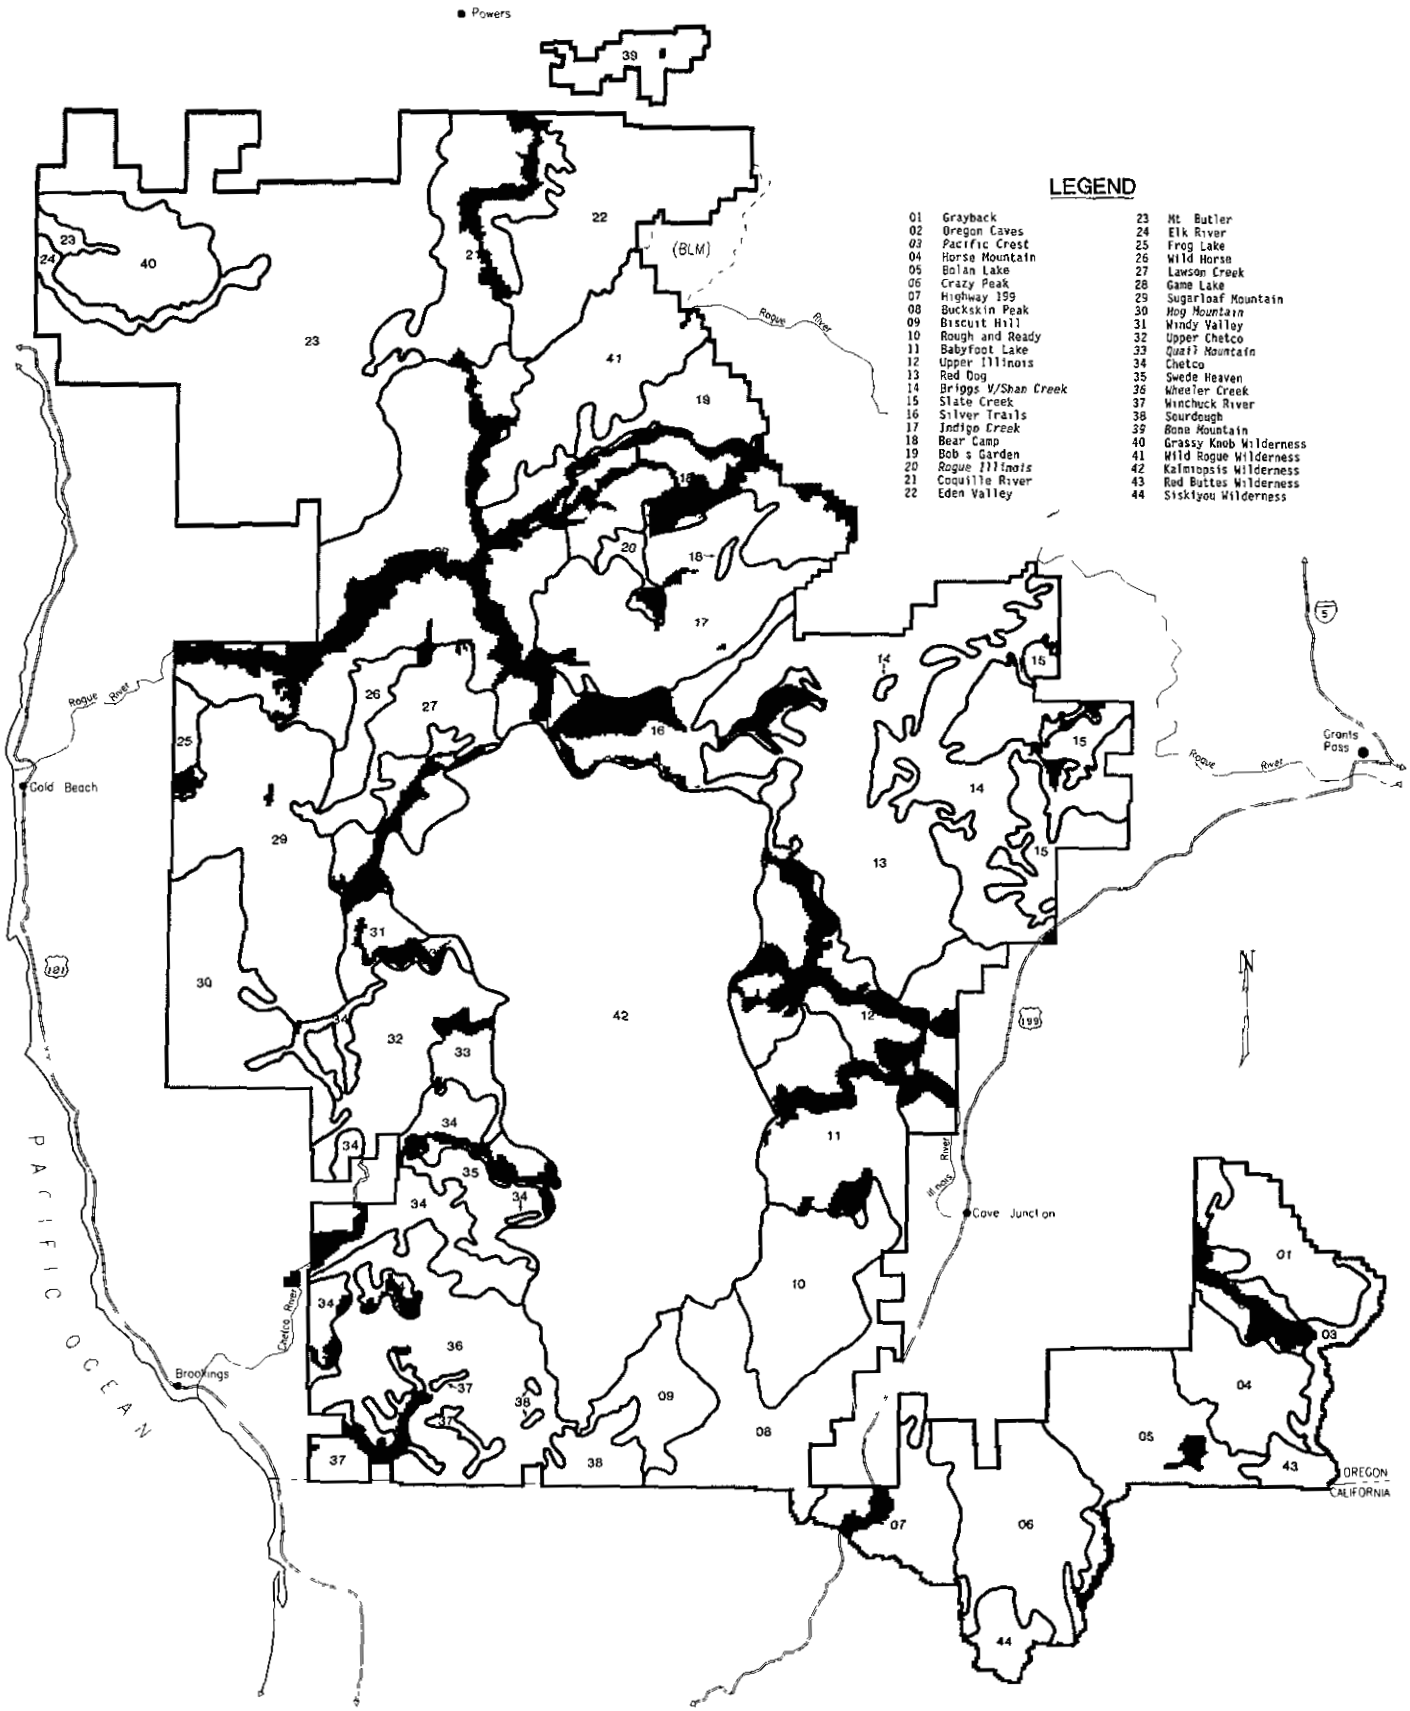

Figure II-14 Retention Visual Management Area Map

MANAGEMENT AREA 12 RETENTION VISUAL

Management Area 12 consists primarily of land that is immediately adjacent to, and visible from, major travel routes, rivers, and other high use recreation areas. The inventory also reflects viewer sensitivity to significant landscapes located along Wilderness access routes, Wild and Scenic river corridors, and in areas viewed from major recreation trails Maintenance of scenic quality is emphasized in this Management Area Timber would be produced at a low level Management activities, including timber harvest, would be designed to not be visually evident to the casual Forest visitor. There are 81,480 acres inventoried with a "Retention" Visual Quality Objective, of which 46,657 are tentatively suitable for timber production. Part or all of these acres are assigned to Retention based on the objectives of the alternative being considered.

Figure II-14 displays a map of each area's location, and Table II-3 shows the acres associated with each viewshed area and how they were allocated by alternative.

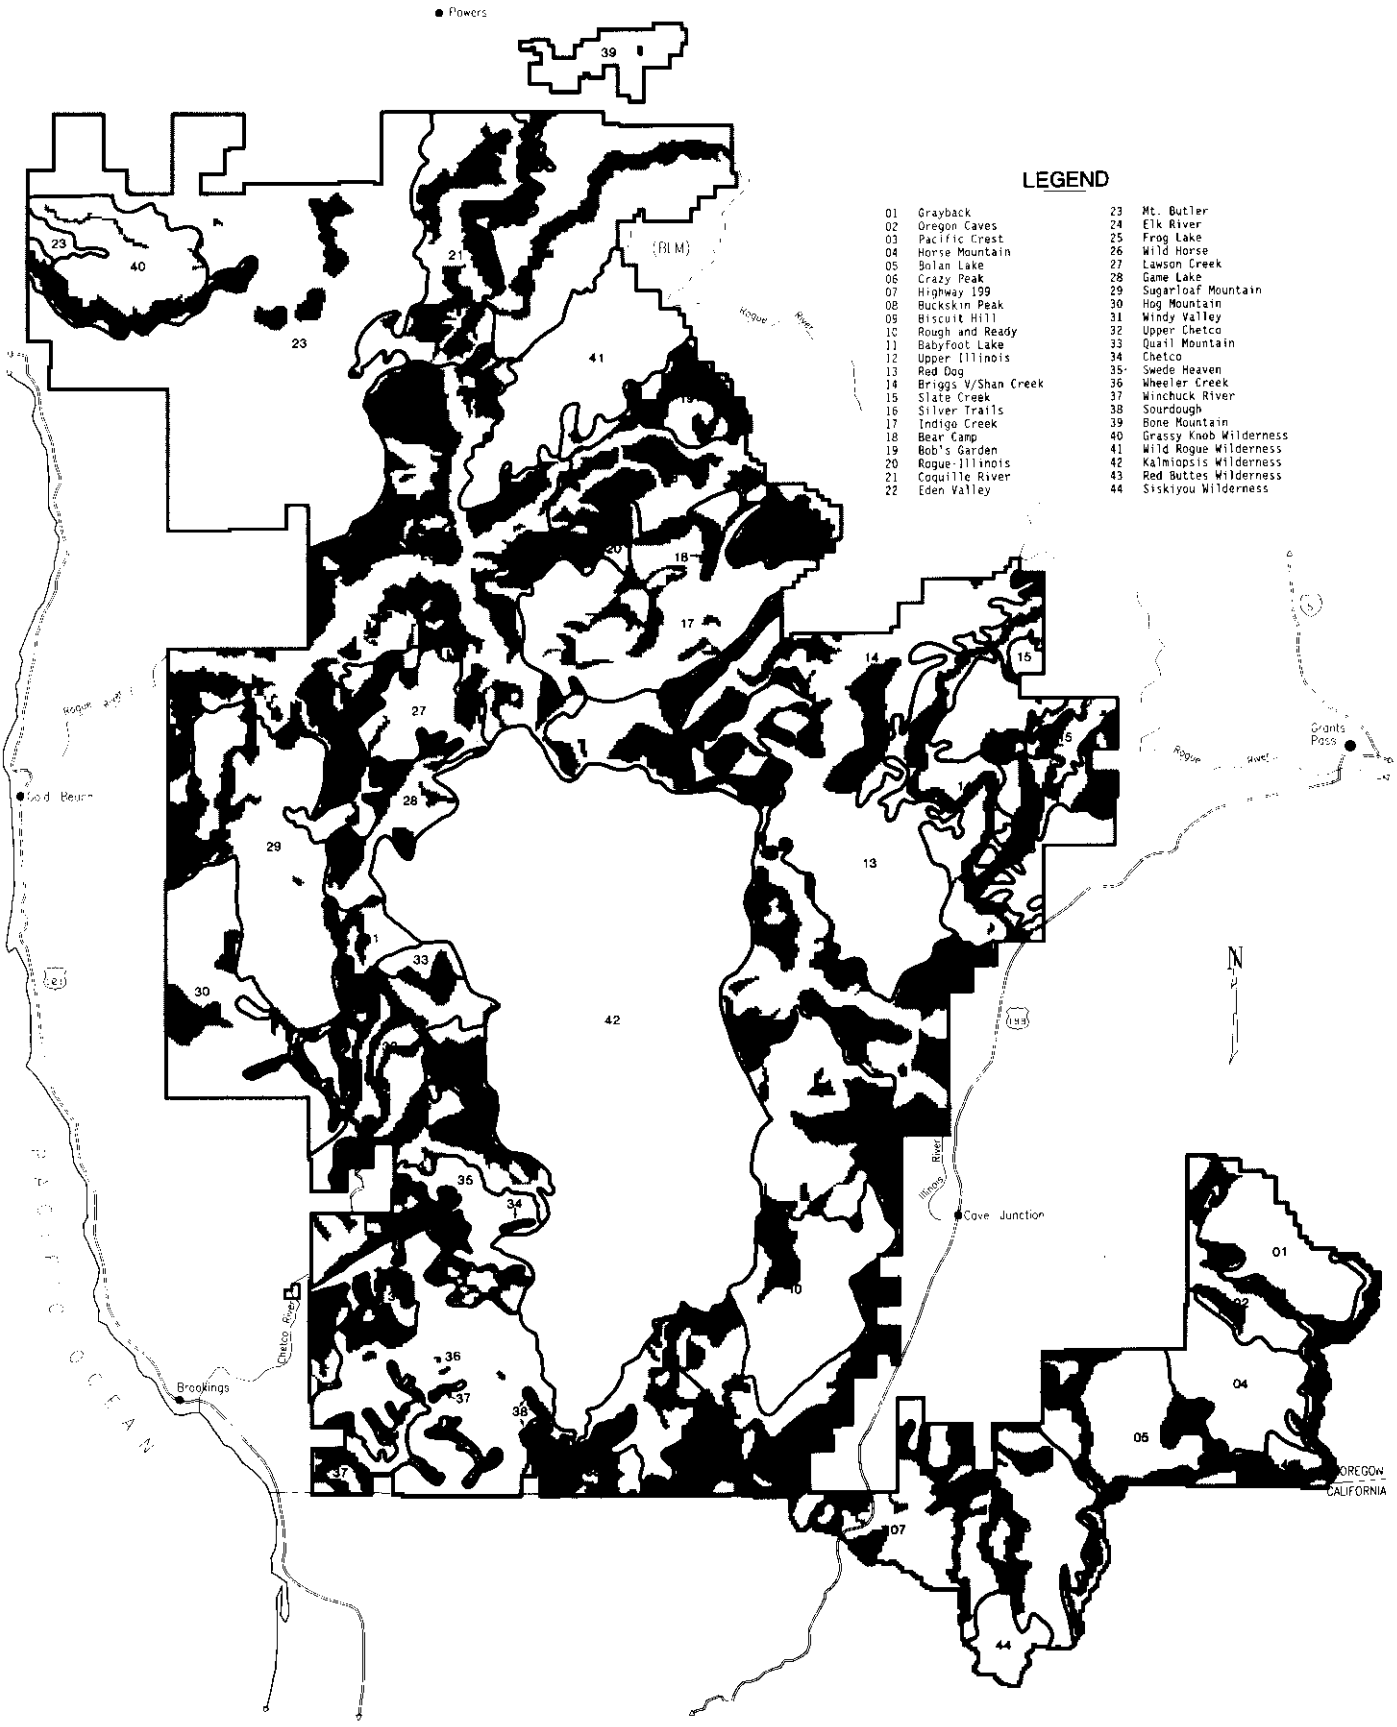

Figure II-15. Partial Retention Visual Management Area Map

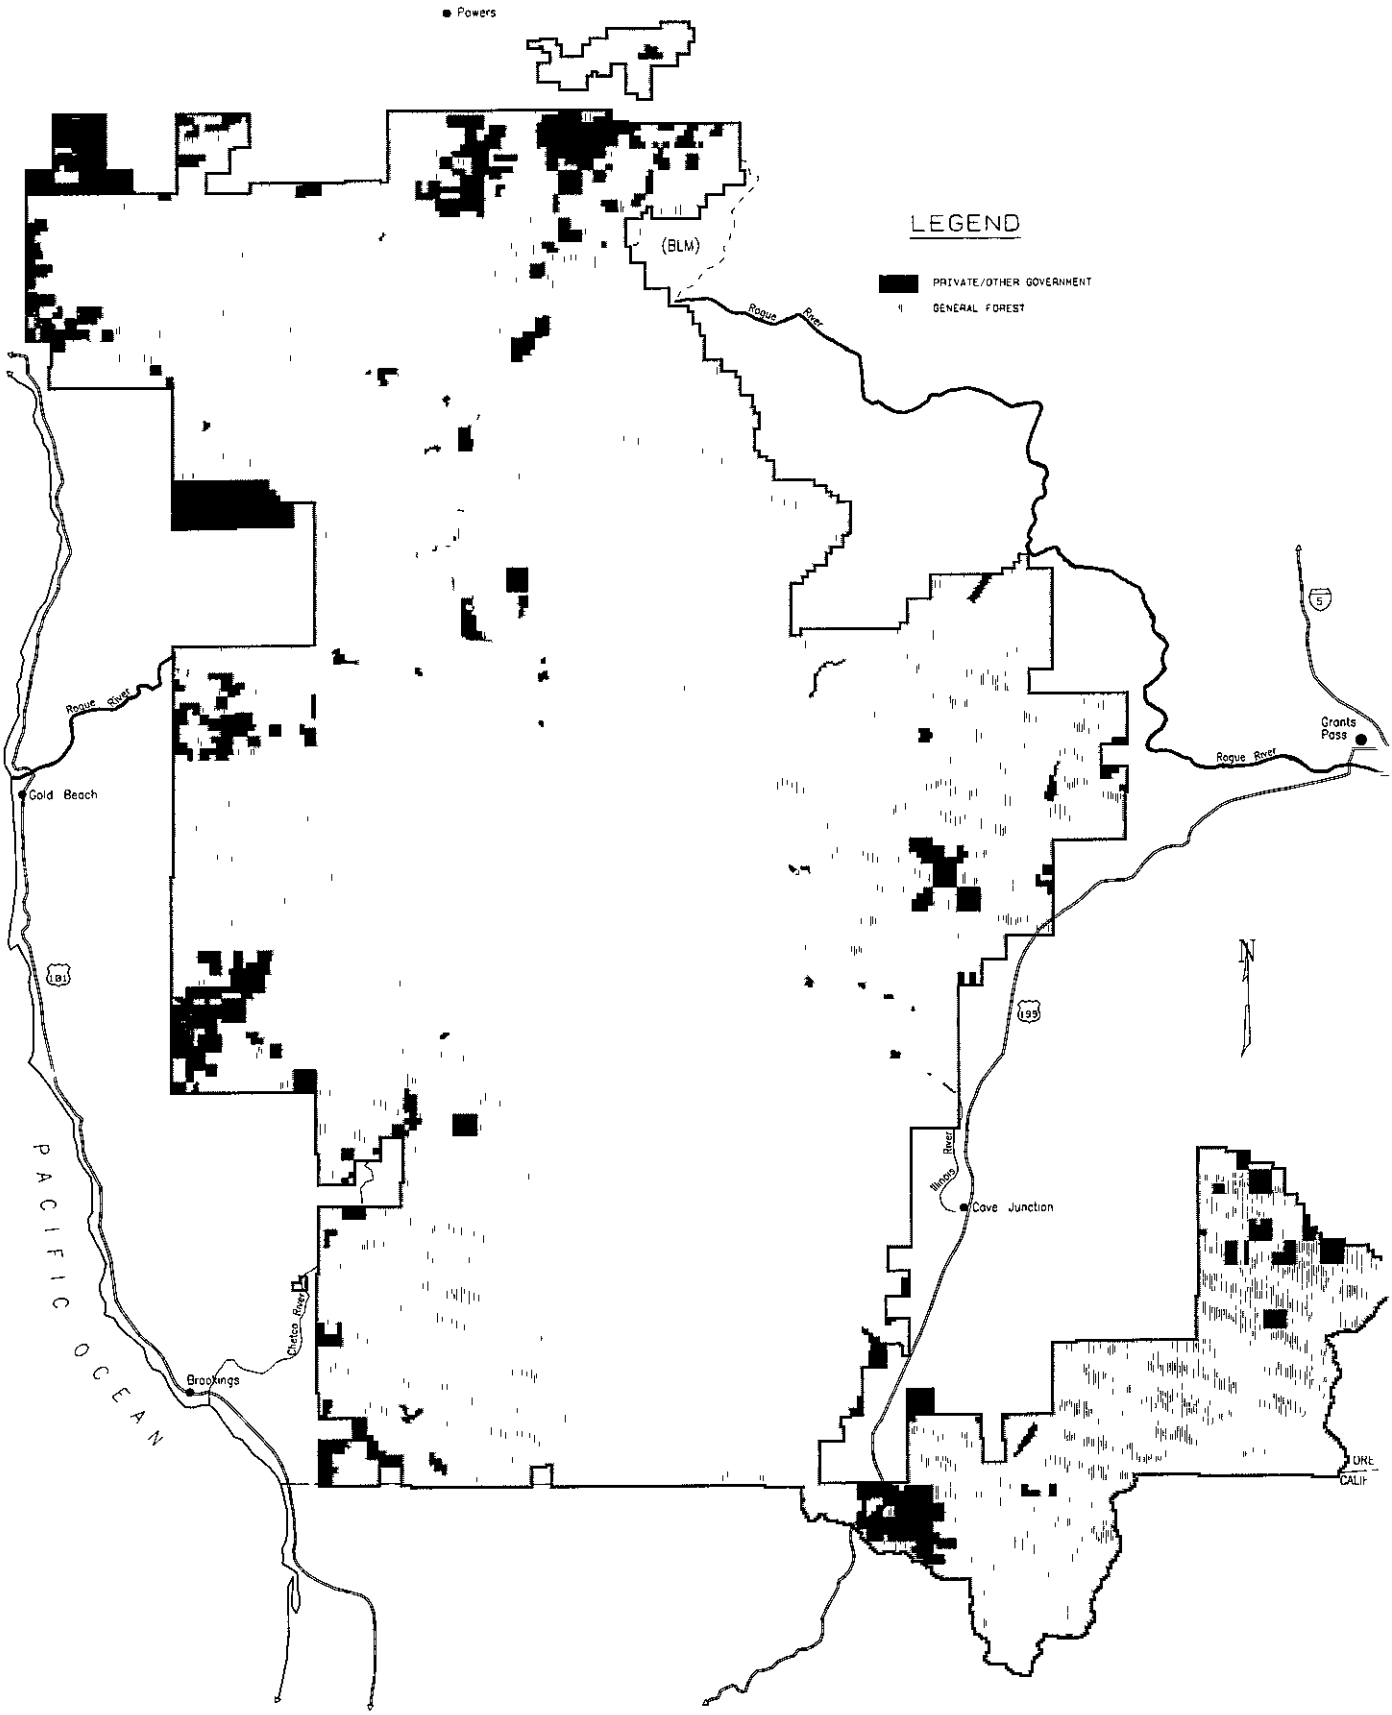
MANAGEMENT AREA 13 PARTIAL RETENTION VISUAL

Management Area 13 consists of land that is visible in the middle to background of major and secondary travel routes, rivers and other high use recreation areas The total area inventoried as Partial Retention on the Forest is 287,700 acres of which 194,190 are tentatively suitable for timber production. These areas are managed for multiple uses including recreation, timber production, and wildlife habitat There is a priority on the maintenance of scenic quality and there is a minor reduction in timber production to allow for accomplishing these visual objectives Management activities are evident, but are designed to be visually subordinate to the characteristic landscape. The assignment of part or all of the inventoried Partial Retention acres is done by viewshed and is based on the objectives of the alternative.

Figure II-15 displays a map of each viewshed's location, and Table II-3 shows the acres associated with each viewshed and how they were allocated by alternative.



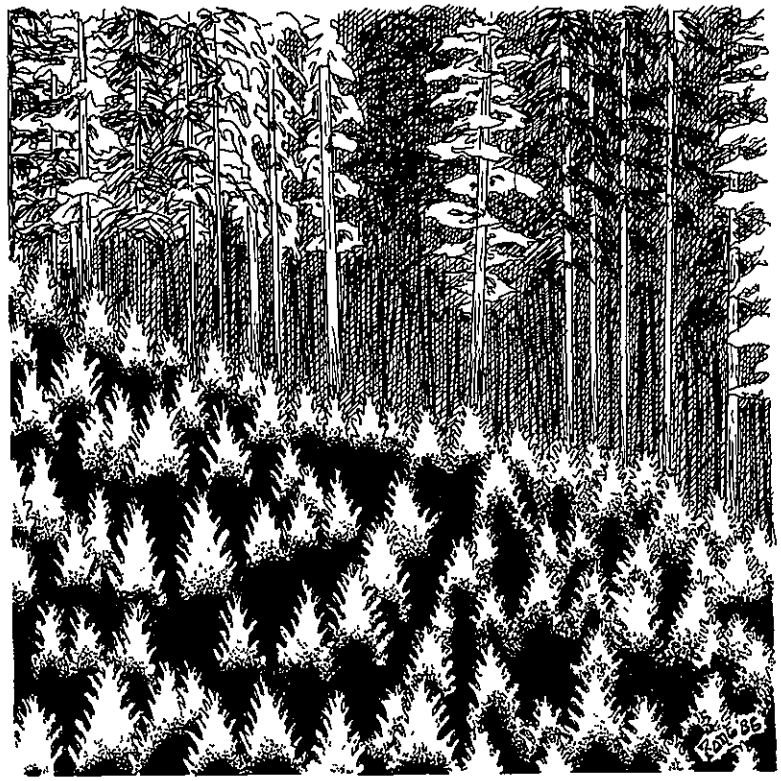


Figure II-16. General Forest Management Area Map

MANAGEMENT AREA 14 GENERAL FOREST

This Management Area includes forested land which is managed for multiple uses including timber production and the maintenance of many wildlife habitats. A number of other uses and land classifications are also included in the General Forest Management Area developed campgrounds, roads, utility corridors, cultural sites, administrative sites, and unsuitable timber land. Silvicultural activities may include timber harvest, precommercial and commercial thinning, fertilization, and reforestation. Wildlife species that use early seral stages, such as deer and elk, benefit from the mosaic of harvest units that provide forage opportunities in close proximity to hiding cover Approximately 565,000 acres of the tentatively suitable timber land could be allocated to this Management Area.

Figure II-16 displays a map of the potential General Forest land

OUTPUTS ASSOCIATED WITH ALTERNATIVES

Management of the Forest under the different alternatives will result in various land uses, resource outputs, and environmental effects Differences among alternatives generally represent the specific goals and objectives of the alternative. The causes and relationships governing the resource outputs and environmental effects are discussed in Chapter IV, Environmental Consequences. Summaries of the outputs and effects are reported in the **Comparison of Alternatives** section of this chapter and as part of the alternative description All of the significant land uses, environmental effects, and resource outputs are presented by alternative and by time period

Displayed outputs are estimates based on inventory samples and models representing the relationships of interacting factors found in the forest environment Inventory sample surveys are seldom designed to have confidence intervals tighter than plus or minus 10 percent due to the cost associated with substantially increasing the sample size for minor increases in reliability; representations in models are also never perfect This is pointed out here because outputs are often presented in a form implying precision not supported by the data While the numbers may not be precise, they are good relative projections of expected outcomes and are valid measures of comparison between alternatives. They also serve as reasonable projections for the environmental consequences displayed in Chapter IV, particularly when viewed as a relative comparison with other alternatives, including continuation of the current level of activity

FEATURES COMMON TO ALL ALTERNATIVES

Features common to all alternatives are described in the section below. (Land allocations common to all alternatives, such as existing Wilderness, RNA, and Wild and Scenic River designations were presented above and are not repeated here.) Following this section, the alternatives selected for detailed study are presented These alternatives represent a broad range within the decision space defined by the benchmarks

Timber

The final determination of timber harvest method will be made on a site-specific level for each project. All alternatives would employ combinations of the silvicultural systems applicable on this Forest Options of designing alternatives using a single system (either even-aged or uneven-aged) were not built into the alternatives due to the tremendous physical and biological variation found within the Forest and the multiple objectives associated with each alternative. Clearcut, shelterwood, seed tree, single-tree selection, and group selection harvest methods are all available tools under each alternative. The Standards and Guidelines (Chapter IV of the LRMP) indicate the system generally appropriate for given combinations of site and stand conditions, and management goals and objectives FEIS, Appendix G presents a discussion of the various systems, comparisons of their effects, and rationale for uses under different conditions. The systems indicated as most appropriate for the broad categories presented should be those most often used, however, it is not intended that other systems should not be used when site-specific conditions warrant. The final selection of a silvicultural system for a specific site is left for the silvicultural prescription. This is consistent with Criterion 6 of Section I-1 of the Standards and Guidelines in the Regional Guide for the Pacific Northwest Region (USDA Forest Service 1984b).

Logging systems will also be matched to the site specific conditions, and systems will be selected to meet the resource objectives at the least cost Specific areas suitable for only some systems have not been identified by alternative. All systems will be available, including helicopter, and will be used where appropriate The cost data used in the analysis includes allowances for this mix of logging systems in the timber program.

Timber management intensities, which define the levels of practices such as precommercial and commercial thinning, were developed to portray different investment levels and management strategies Once the allocations and constraints necessary to accomplish the objectives of the alternative were installed, the FORPLAN model was allowed to select from the full range of prescription intensities to find the most efficient level of timber management for those Management Areas with programmed timber production The solutions tend to have the same mix of intensities with a high or moderate level on medium and high sites, and moderate or extensive level on low sites.

The herbicide issue has been and will continue to be dealt with in separate environmental analyses and NEPA documents at the Regional level All alternatives in this Forest Plan EIS assume the continued use of the full range of alternative treatment methods including manual, mechanical, prescribed fire, biological, and chemical methods. If chemical tools are not available in the future it may be necessary, regardless of the alternative, to adjust projected costs or the proposed levels of timber outputs Timber stand condition and performance (with or without the availability of chemical release) will be evaluated and any needed adjustments in the harvest level made during implementation and monitoring (see Chapter V of the LRMP).

When given the option, the FORPLAN model schedules timber management on most suitable acres of the Forest; there is little potential to increase ASQ as a result of future market conditions. Two categories of land that have potential not utilized by FORPLAN are the separate suitability component (SSC) lands, and those lands currently stocked with hardwood species. The Forest Plan contains the flexibility to manage these lands under changing market conditions without amendment or revision.

The SSC lands do not have programmed timber harvest, but site specific opportunities may be scheduled in accordance with Standard and Guideline 6-2(7) of the Forest Plan. These lands (18,713 acres) are insignificant in terms of the Forest-wide analysis for timber production. They are very low site and their total potential contribution to ASQ, if all were in full yield allocations, would only be about 1 MMBF. The net effect of these lands on ASQ would be less than one percent of any alternative On the average, these lands would not be selected for timber management if entered into the FORPLAN model; however, there is considerable variation in the vegetation conditions existing on these sites. The site-by-site evaluation will provide the flexibility to take advantage of opportunities such as overstory removal harvests that require low investment and cannot be identified with the resolution of our current inventory.

Lands currently stocked with noncommercial species or hardwoods are not always selected by the FORPLAN model. Because the current ASQ is most dependent on the existing volume available, the ASQ effect of operating on these lands is negligible. Bringing these lands into production through the harvest of hardwood stands and replanting with conifers does have the potential to increase future timber outputs, and supply fuelwood or other products in the short-term. To evaluate the environmental consequences of taking advantage of such opportunities, levels of operation ranging from zero to 14,000 acres per decade were installed in the alternatives. These acres are included in the suitable land base whether selected by FORPLAN or not. Whether or not these acres will actually be treated will depend on site-specific conditions and market demand for hardwoods (see Standard and Guideline 6-13 in the Forest Plan).

Fish, Soil, and Water

Fisheries habitat capability is maintained at or above present levels in all of the alternatives. One determinant of this is the assignment of riparian management prescriptions. These prescriptions govern the amount of harvest allowed in the areas adjacent to streams (they are more fully described in Appendix B). Their effect on fish habitat is primarily through changing the quantity of stream shading, and thus effecting water temperature There are three variations of the riparian prescription. Riparian Prescription B maintains existing water temperatures. Both Riparian Prescription C and allocation to Minimum Level of management (no programmed timber harvest) would increase shade over time, resulting in cooler summer water temperatures and consequently, improve fish production. Minimum level prescription (M) applies to all riparian areas in Wilderness.

Management activities in all alternatives would be governed by Standards and Guidelines (Appendix D, and LRMP, Chapter IV) and Best Management Practices (LRMP, Appendix F) specifically designed to protect site productivity, water quality, and fisheries. Best Management Practices (BMP's) are specifically designed to protect water quality, as required by Section 208 of the Clean Water Act. General BMP's will be selected and tailored for site-specific conditions to arrive at project-level BMP's for the protection of water quality. The process and practices are discussed in the BMP Appendix (LRMP, Appendix F)

Areas which have active landslides or risk irreversible soil loss are designated unsuitable and have no programmed timber harvest

Wildlife

A number of areas are allocated to wildlife use in all of the alternatives These include. existing meadows, swamps and springs, and osprey nest sites.

The alternatives and benchmarks, except the No Change Alternative, were developed using procedures described in Chapter 3 of the Regional Guide for the Pacific Northwest Region (USDA Forest Service 1984b) as amended by the Supplement for Spotted Owl Guidelines (USDA Forest Service 1988b). Specifically, these procedures provide the direction for development of methods to achieve the Management Requirements described previously in this Chapter and in Appendices B and J

Wild and Scenic Rivers

The DEIS was designed to evaluate a range of options for designation of Wild and Scenic Rivers. As the FEIS was being prepared for printing, Congress passed the Omnibus Oregon Wild and Scenic Rivers Act of 1988. The Act designates the inventoried rivers evaluated in the DEIS (Chetco and North Fork Smith), and the Elk River which was determined to meet eligibility criteria following the release of the DEIS. Most of the alternatives as defined in this FEIS do not include management direction for these rivers under the Wild and Scenic designation Any alternative selected would be brought into compliance with the Act prior to implementation. Also as a result of this legislation, Planning Problem #4 has been modified to address management of the lands adjacent to river corridors, but not the question of recommendations for designation or further study. Appendix E, which was devoted to the detailed evaluations of the recommendations for the individual rivers, has been dropped from this FEIS; pertinent information from that appendix can be found in the Planning Record

Minerals

Mineral exploration and development would be facilitated by retaining approximately 75 percent of the Forest in an accessible category in all alternatives. The access restriction category for each Management Area is selected based upon an assessment of the effect of limitations imposed on mineral development. Since the nature and level of mineral activity can vary from casual prospecting to mine development, the actual degree of restriction would only be defined through evaluation of site-specific proposals. The Forest may make recommendations for additional withdrawal from mineral entry when mitigation of a projects effect on resource values will not reduce impacts to an acceptable level.

CHANGES BETWEEN DRAFT AND FINAL COMMON TO ALL ALTERNATIVES

Several changes in analysis processes and features common to all alternatives have occurred as a result of the review of the DEIS, or changes in circumstances which affects the analysis or decision space (Changes in the Preferred Alternative are described in a later section in this chapter) The noteworthy changes are mentioned in this section. Analysis changes are explained in more detail in Appendix B

Management Area 6 has been changed from "Custodial (Roadless)" to "Backcountry Recreation " The change in the name better reflects the management intent of these proposed allocations The Management

Area Prescription has also been revised slightly, particularly related to relaxing restraints that were applied to mineral access and motorized forms of recreation

The Standards and Guidelines pertaining to mineral development and exploration have been revised The Draft Forest Plan implied unrealistic restrictions on mineral activities. These have been revised to correspond more closely with legal authority and probable limitations on exploration and development operations where necessary to protect other resource values.

The analytical procedures used to project nongame wildlife use (measured in Wildlife/Fish User Days - WFUD's) have been modified in response to public input In the DEIS, the nongame wildlife use was assumed to be equal to the game use and was projected based on expected changes in deer habitat For this FEIS, the nongame use is projected similar to the demand for recreation assuming that the change in the level of wildlife viewing is a function of the change in the human population - not the change in wildlife habitat. An error was also identified in the calculation of deer habitat capability. Habitat capability was underestimated by about 25 percent This has been corrected and all affected tables and text have been revised. This error was consistent in all alternatives and benchmarks so relative differences remain the same

The Final Supplement to the Environmental Impact Statement (FSEIS) for an Amendment to the Pacific Northwest Regional Guide was completed in 1988. This amends the Spotted Owl Guidelines used by the Forest to define habitat needs to achieve MR's As discussed in the section on Management Requirements, the changes did not substantially affect the habitat proposed for designation on the Siskiyou. There are some minor changes in the location of habitat areas that would be incorporated in any alternative selected for implementation. Appendix H of the DEIS, which provided information on the relationship of the concurrent analyses on the Regional Guide Amendment and the Forest Plan, has been dropped from this FEIS.

In response to requests for more detailed information on implementation techniques and mitigation measures used to maintain or protect watershed values, a list of Best Management Practices (BMP's) has been prepared. The BMP's are described in Appendix F of the Forest Plan.

Continued management of the Forest under current direction and implementation of the Silver Fire Recovery Project have changed the character of some of the unroaded area originally inventoried in the RARE II process (total acres have changed from 314,000 acres to 284,000 acres since the last planning inventory update in 1984) If an alternative is selected that allocates some of the area that has been roaded or harvested to Management Area 6 (Backcountry Recreation), these areas would be managed to restore the natural character and roadless recreation opportunities.

Wildfires burned over a large part of the Forest in late 1987. The changes in environmental conditions resulting from these fires and subsequent timber salvage projects relative to the Forest Planning analysis are described in Chapter III. Though the changes in conditions do not significantly affect the analysis here or the comparison of alternatives, there is a lot of interest in the relationship of the fires to the Forest Plan. A section discussing the implications of the 1987 fires has been added at the end of this chapter, and Chapters III and IV.

A number of the changes have implications for minor inventory adjustments The 1987 fires changed the vegetation in burned areas; the intensive field work done in association with the Silver Fire Recovery Project identified additional areas unsuitable for timber management, there are new Wild and Scenic Rivers; and the revised spotted owl habitat guidelines result in an adjustment of the habitat needed for MR's. These adjustments are not accounted for in the alternative outputs and effects displayed in this FEIS. Any alternative selected for implementation would need to have these "fine tuning" adjustments made. The Forest Plan is developed from the Preferred Alternative with these adjustments

BACKGROUND ON THE NO CHANGE AND NO ACTION ALTERNATIVES

THE "NO CHANGE" ALTERNATIVE

This alternative has been developed in response to decisions made regarding an appeal brought by the Northwest Forest Resource Council on May 19, 1986 The appeal centered on a decision by the Regional Forester to "require inclusion of Minimum Management Requirements (MMR's) in the Current Direction Alternative for each Forest Plan " The substance of the appeal was that a "true no-action alternative representing current management plans" was not included in Forest Plan EIS's In response to this, a No Change alternative has been developed to represent the existing timber management plan, and consequently does not comply with all provisions of the National Forest Management Act (NFMA) and regulations promulgated by the Secretary of Agriculture to implement NFMA

The following provisions of NFMA or other laws or regulations are among those not explicitly complied with in the current timber management plan represented by the No Change Alternative:

36 CFR 219.14 - Timber resource land suitability. requires identification of lands not suited for timber production based on risk of irreversible resource damage; lack of assurance of reforestation within five years; or withdrawal by Act of Congress, Secretary of Agriculture, or Chief of Forest Service

36 CFR 219 15 - Specifies a process for choosing vegetation management practices. Also, ties to 36 CFR 219 27 which identifies required resource protection and silvicultural practices.

36 CFR 219 16 - Requires that all alternatives identify decadal timber harvest levels and long-term sustained yield levels, consistent with the requirements of the RPA program and Regional guide.

36 CFR 219.18 - Requires that Wilderness management direction be provided, including actions needed to limit or distribute visitor use and measures desirable to protect the wilderness or adjacent areas from wildfire, insects or disease

36 CFR 219 19 - Provides for viable populations of vertebrate wildlife species, the selection and monitoring of management indicator species, cooperation with wildlife management agencies, and protection of habitat critical to threatened or endangered species.

36 CFR 219 21 - Requires that recreation resources be addressed, including supply and demand of various recreation opportunities, coordination with State agencies, and off-road vehicle use

36 CFR 219.22 - Requires that mineral exploration and development in the planning area be addressed, including existing uses, the potential for future development, and access requirements.

36 CFR 219 23 - Requires full consideration of water and soil resources including estimates of current water uses, instream flow requirements, protection of water quality, watershed condition, and protection of wetland and floodplain values.

36 CFR 219 24 - Requires inventory, evaluation, and protection of cultural and historic resources, identification of opportunities for cultural resource interpretation, and coordination with other agencies

36 CFR 219.25 - Requires that Forest Plans provide for the establishment of Research Natural Areas

36 CFR 219.26 - Provides for consideration of plant and animal community diversity.

36 CFR 219.27 - Identifies specific Management Requirements to be used in the development analysis, approval, implementation, monitoring, and evaluation of forest plans for activities including; silvicultural practices, resource protection, vegetative manipulation, protection of riparian areas, protection of soil and water, and maintenance of diversity.

The Timber Management Plan upon which the No Change Alternative is based was developed in 1962. The plan was not an integrated resource plan, and consequently did not address all resource uses and outputs The original plan was based on yield tables and resource relationships which do not reflect the latest scientific techniques and information and do not reflect the standards in the NFMA regulations. Unit Plans developed during the 1970's provided new standards and management objectives which were applied to on-the-ground management. The Timber Management Plan has been amended following Congressional designations (Wilderness additions), but there has not been reconciliation of the Timber Management Plan with Unit Plan direction and requirements of NFMA.

The Timber Management Plan calculated a "Biological Potential," or the maximum amount of sustainable wood fiber obtainable by application of intensive management practices, to acres classified as commercial forest land. The needs of other forest uses are not incorporated. A "Potential Yield" was then calculated which represents the sustainable output of wood fiber available after the needs of other forest uses have been deducted from the Biological Potential. The Potential Yield of the 1962 Timber Management Plan was 191 MMBF on an annual basis. Amendments have adjusted this figure downward to 167.5 MMBF as parts of the land base have been allocated to uses that preclude timber harvest (i.e., Wilderness and Wild Rivers). Nonchargeable salvage is sold in addition to the Potential Yield since this material was not included in the yield calculations. The amount of nonchargeable salvage included in the program has been approximately 5 MMBF annually. The Potential Yield and the amount sold is displayed for each year from 1963 to 1987 in Table II-36. The Potential Yield was based primarily on the timber resource, and although there was some recognition of other forest uses, did not constitute the integrated resource management planning required by NFMA.

The other forest uses allowed for in the computation of the Potential Yield are not specifically identified. This leaves some room for speculation as to how much or what part of the current considerations for other resource management might be assumed to be represented in the Potential Yield figure. Analysis of the capability of the Forest to produce the Potential Yield of the timber management plan using the latest inventory data and timber yield tables and integrating the direction of the unit plans, as well as the requirements of all laws and regulations, indicates that the Potential Yield of 167.5 MMBF plus the nonchargeable salvage could not be maintained (salvage is included in the current inventory). Consequently the timber sale level of the timber management plan, and thus the No Change Alternative, would not be feasible under existing laws and regulations and current unit plan direction

Although the No Change Alternative is defined as carrying forward the direction and analysis (including the inventory and yield table information) from the timber management plan, the Siskiyou has used current data and the FORPLAN model to represent this alternative for evaluation and comparison purposes This is only possible because of the closeness of the timber output levels predicted by two very different analyses (The timber management plan used different yield tables with different utilization standards, different inventory data, different land stratification, different definitions for timber land suitability, and a simple formula to compute the Potential Yield.) By not including the MR for mature and old-growth wildlife habitat, it is possible to meet all other MR's and direction from unit plans, and maintain the timber outputs of the existing Timber Management Plan. This is true on the Siskiyou only because the projected timber outputs using the current analysis are not substantially different from the previous analysis.

The No Change Alternative presented in this document is formulated to maintain the timber outputs of the 1962 Timber Management Plan, but includes all of the direction in current Unit Plans. Maintaining the direction of the current Unit Plans also results in all of the MR's being met except the requirement for mature and old-growth wildlife habitat needed to comply with 36 CFR 219 19 and 36 CFR 219.27. The No Change Alternative could not be implemented or used in future management of the Forest under the Forest Plan without Congressional and/or Secretary of Agriculture action to change the law or regulations If the No Change Alternative were to be implemented without such action, the alternative would have to be amended or revised to comply with the law and regulations.

THE NO ACTION ALTERNATIVE

The Current Direction alternative (Alternative A) is the "No Action" alternative required by NEPA (40 CFR 1502 14) and NFMA (36 CFR 219 12 (f)(7)). The NFMA regulations state:

> At least one alternative shall reflect the current level of goods and services provided by the unit and the most likely amount of goods and services expected to be provided in the future if current management direction continues Pursuant to NEPA procedures, this alternative shall be deemed the "no action" alternative

Alternative A would carry forward current management direction, and is made implementable by adding the MR's necessary to comply with laws and regulations as described earlier in this chapter The levels of goods and services associated with this alternative are those most likely to be provided in the future under this direction In the case of timber outputs, this would mean a change from the 172 5 MMBF (Potential Yield plus salvage) to an ASQ of 169 6 MMBF on a non-declining yield schedule.

One additional variation is provided with Alternative A-Departure which departs from the non-declining yield policy to maintain the current level of timber outputs while installing the MR's With this alternative current management direction would continue, all laws and regulations would be complied with, and the current levels of goods and services would be expected to continue for the next two decades. The level of timber harvest would decline in the third and fourth decades to compensate for the higher level harvested in the first two decades.

THE PREFERRED ALTERNATIVE

A Preferred Alternative is identified in this chapter The selection of the Preferred Alternative was made after careful comparison of all the alternatives on the basis of their resource outputs, environmental effects, implementation costs, and the "tradeoffs" between them The Preferred Alternative was selected from all those formulated as the one which best maximized the NPB in an environmentally sound manner. Alternative K was identified as the preferred in the Draft EIS With Alternative K as a base, Alternative S was developed considering the public and other agency comments received on the DEIS After the Forest Supervisor reviewed the Interdisciplinary Team's evaluation, Alternative S was selected as the Preferred Alternative in this Final EIS.

The Preferred Alternative (S) incorporates many suggestions made by reviewers of the Draft proposal Suggestions were evaluated by the Interdisciplinary Team and incorporated where they offered methods of increasing total benefits the Forest could provide, or indicated a resource management preference having potential to further resolve public issues The more substantial elements in the formulation of Alternative S, relative to Alternative K, are described in this section

The timber harvest dispersion constraints in Alternative K were criticized as imposing an unwarranted opportunity cost to timber These constraints specific to each planning basin were designed to disperse activities over time and space, without substantially reducing the overall level of activity The specific factors for each planning basin in Alternative K ranged from 9 to 13 percent of the land base suitable for timber

to be harvested per decade Further analysis indicates that these constraints can be refined to be more specific to individual watershed conditions, better fit the present FORPLAN model formulation, and achieve the desired effect with less timber opportunity cost The factors used in Alternative S range from 7 to 17 percent for the individual planning basins.

Numerous comments were received pointing out the high values of the Forest's fishery resource which is supported by the water resource and stream habitat, and the social and economic importance of this resource to local communities Alternative S would allocate seven of the high fish value planning basins to be managed under the Riparian Prescription C, affording additional protection to the stream shade. As a result, a net improvement is projected in fish habitat capability. This is compared to only one planning basin being assigned to Prescription C in Alternative K out of a Forest total of 19 basins

Allocations to Supplemental Resource Management Areas along major streams is also increased slightly in Alternative S relative to Alternative K. This additional stream corridor protection (Lobster Creek, and East and West Fork Indigo Creeks) is in response to protection needs in specific areas indicated by the public.

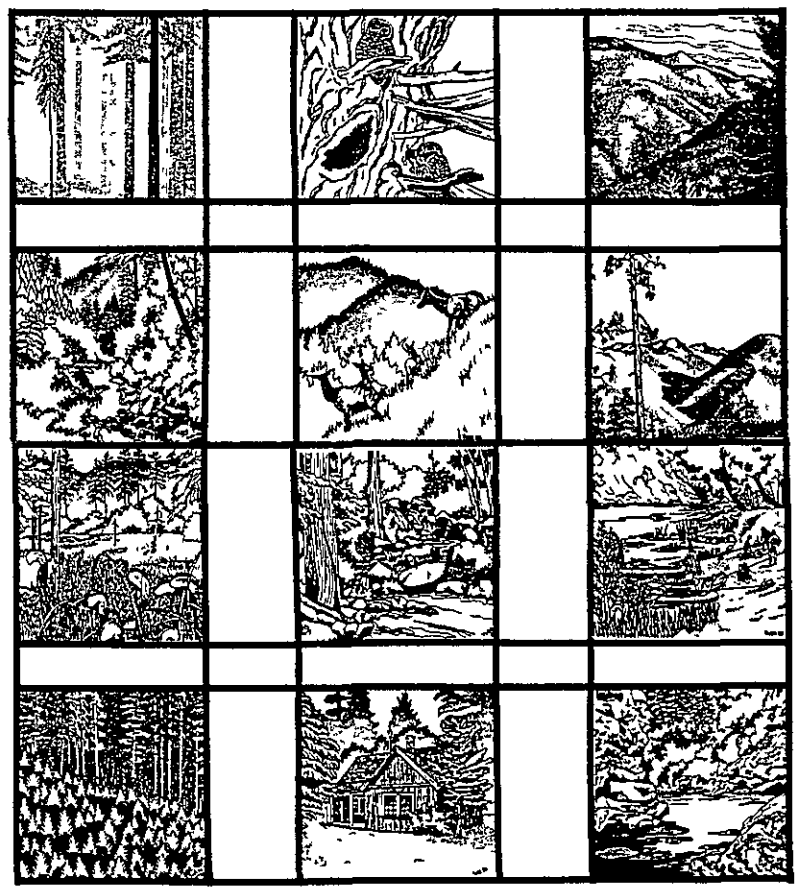
There is tremendous support for maintaining more of the Forest in an undeveloped condition to provide Primitive and Semi-primitive recreation opportunities, as well as reserves of old-growth conifer forest and other values associated with large undeveloped areas The allocations to Backcountry Recreation Management Area have been significantly increased in Alternative S. To accommodate historic use described in public comments, specific Backcountry Recreation areas would be managed for Semi-primitive Motorized recreation to allow four-wheel drive and motorbike travel on primitive roads and trails existing in these areas

A related concern raises the question of the appropriateness of intensive timber management and road development in some areas with very steep slopes and rocky soils Alternative S would designate some areas for "extensive" management; keeping them in the timber management base, but projecting a less intensive management schedule and logging by helicopter without major road development. The total area, however, is quite limited in extent.

The Siskiyou is recognized as one of the most botanically diverse and interesting Forests in the Nation. Alternative S would allocate several more Botanical Areas to management and added protection of sensitive and rare plant habitat. Detailed comments on specific areas provided the information to refine boundaries of some candidate Botanical Areas in Alternative S.

It was pointed out that fertilization is being used as a management practice on many Forests and other ownerships to increase timber yields Further analysis and results of fertilization trials indicate that fertilization is feasible on the Siskiyou. Fertilization has been included in Alternative S as a management practice to be used on intensively managed timber stands.

Alternative K reduced allocations in several areas with management emphasis on visual quality Many, including local governments and agencies, thought it went too far and failed to identify specific areas of the Forest with outstanding scenic quality or higher recreation use The allocations to Retention and Partial Retention Visual Management Areas are increased in Alternative S to include some of the specific travel corridors that have substantial recreation opportunities and scenic values.



Interest in recreation and tourism has increased in recent months. The counties in southwestern Oregon have identified "tourism" as the focus for their strategy as part of the Oregon Comeback, other reviewers point out the importance of, and potential for, the tourist industry. In response, Alternative S would program higher levels of capital investments to complement the emphasis of State and local governments and private industry. In addition, some land allocations have been increased, such as the visual and Backcountry Recreation allocations mentioned above, that are complementary to this emphasis

Interest in Wild and Scenic Rivers also increased substantially in 1988. In addition to the two inventoried rivers considered in the DEIS (North Fork Smith and Chetco), several others including the Elk River were suggested for inclusion in the National System Analysis of the attributes of the suggested new rivers to be considered indicates that only the Elk meets the eligibility requirements for Wild and Scenic designation. Alternative S would have recommended designation of the inventoried rivers and further study for the Elk -- a moot point now since all were designated in the Omnibus Oregon Wild and Scenic Rivers Act of 1988 shortly before these documents went to print.

ALTERNATIVE DESCRIPTIONS

Descriptions of the 12 alternatives considered in detail are presented in this section. Primary goals and objectives, model design, and an overview of unique environmental consequences introduce each alternative. The *goals* section describes the theme of the alternative and the specific purpose behind its formulation. The *design* section discloses those elements of the alternative that were designed and input to the model by the Forest Service. The *overview* section is a synopsis of the important results and environmental consequences that are unique to the alternative. Following this brief three-part introduction, the alternative's response to each Planning Problem is discussed in some detail.

Quantitative and qualitative summaries of the alternatives are presented in a comparative format in tables that follow this section. Appendix I contains alternative-specific tables which show the number of acres allocated to each Management Area, and the contribution each Management Area makes to the resolution of each Planning Problem. The disposition of each geographically unique land area across all alternatives is included in Table II-3, along with basic attribute information such as size and suitability of each individual area. A map of Alternative S is distributed with these documents. Maps of the other alternatives were distributed with the DEIS and are unchanged. Additional maps are available on request. (There is no map labeled for Alternative NC, but it is essentially the same as Alternative A, except it has very few acres in Management Area 8, Designated Wildlife Habitat.)

ALTERNATIVE NO CHANGE

ALTERNATIVE NO CHANGE

GOALS

The purpose of Alternative No Change (NC) is to continue the levels of goods and services as set out in plans formulated and approved prior to the passage of the National Forest Management Act, specifically the 1962 Timber Management Plan. This alternative does not comply with all provisions of NFMA and the regulations promulgated by the Secretary of Agriculture to implement NFMA, and could not be implemented or used in future management of the Forest under the Forest Plan without Congressional and/or Secretary of Agriculture action to change the law or regulations

DESIGN

Timber production would be maintained at the level of the Potential Yield of the 1962 timber management plan. Available suitable timber land inventory was updated to meet current standards The wildlife MR's, which were not required by law when previous plans were completed, are not included A moderate amount of hardwood conversion would be allowed

The full range of inventoried VQO's from the Unit Plans would be achieved Riparian areas would be managed under current Siskiyou riparian policy (Prescription B)

OVERVIEW

Alternative design specifications would have the following results Timber outputs would be sustained at 31 0 MMCF, or at the current Potential Yield level (167.5 MMBF) plus nonchargeable salvage Much of the Forest, with the exception of existing Wilderness, would eventually be roaded and developed Motorized recreation opportunities would be enhanced, as roads are constructed for timber management. Scenic quality would be high as the entire complement of inventoried VQO's from the land use plans would be allocated in all 44 viewsheds

Approximately 35 percent of the Forest's presently standing mature and old-growth would be protected in this alternative. The wildlife MR's for mature and old-growth dependent species are not included in this alternative. Big-game hunting opportunities would be maintained at a level slightly higher than currently available Fishing opportunities would be maintained

1. How Much Timber Should the Forest Produce?

Alternative NC would result in the average annual production of 31 0 MMCF (173 MMBF) of chargeable and nonchargeable timber volume per year during the first decade. Governed by a policy of nondeclining flow, average annual sale offerings would gradually increase in subsequent decades to reach the LTSY of 54 2 MMCF. Final harvest would generally occur when the timber stands reach CMAI (approximately 100 years)

Timber production would be supported by a land base of 576,000 acres (selected suitable), which includes 37,053 acres of standing hardwood. Hardwood conversion would be limited to no more than 7,500 acres per decade, subject to market conditions Final harvest would occur on an average of 4,518 acres per year during the first decade and increase to 5,572 acres per year by the fifth decade Appendix I, Table I-1 (NC) displays the Management Areas that provide timber management opportunities.

2. How Much Old-Growth Forest Should be Preserved?

Alternative NC would reserve 152,990 acres having mature and old-growth forest characteristics With the exception of the reserved areas displayed by Management Area in Appendix I, Table I-2 (NC), existing mature and old-growth would be metered out to accommodate the harvest sale schedule Of the 443,000

acres of mature and old-growth that currently exist, 394,510 would remain at the end of the first decade. Except for isolated tracts, riparian, and other small areas, all unprotected mature and old-growth would be removed by the tenth decade.

3. How Can the Forest's Fish Habitat, Water Quality and Soil Productivity be Maintained or Improved?

Management objectives for fish, water quality, and soil productivity would be designed to maintain existing conditions Land characterized by riparian vegetation would be managed to maintain water quality and fish habitat Vegetative disturbance in the riparian areas that are in the base for timber management would be controlled by Riparian Prescription B, which is designed to maintain existing water temperatures. Appendix I, Table I-3 (NC) shows how riparian habitat would be affected by the various Management Area designations

The current level of capital investment is proposed in this alternative. Approximately $451,400 per year would be spent on fish, soil and water resource projects.

4. How, and to What Extent, Should Lands In and Adjacent to River Corridors be Managed to Protect, Preserve, and Enhance Wild and Scenic River Attributes?

Management activities would be designed to protect Wild and Scenic River attributes All viewsheds surrounding the Wild and Scenic Rivers would have a natural or near-natural appearance as lands would be managed to meet their inventoried VQO's. Land within 1/4 mile of either side of the Chetco and North Fork Smith Rivers would be managed under two management areas, the interior 1/8 mile would be managed in the Supplemental Resource Management Area, while the remaining land would be allocated to its respective Wild or Scenic/Recreation Management Area

Appendix I, Table I-4 (NC) shows the number of acres within each Management Area which directly contribute to preservation and enhancement of Wild and Scenic River attributes. Those that contribute to maintenance of water quality and visual quality in Wild and Scenic River corridors are indicated

5. How Should Sensitive Plant Resources be Managed?

The variety of sensitive plants on the Forest would be managed through a number of land allocations designed with specific protection standards. Each Management Area has Standards and Guidelines (in addition to Forest-wide Standards and Guidelines) designed to protect sensitive plants endemic to the Forest (see LRMP, Chapter IV) RNA's and Botanical Management Areas would provide special emphasis to the preservation of ecotypes and sensitive plants One new RNA is proposed in current management plans in addition to the three existing areas (for a total of 3,249 acres) resulting in the preservation of 14 ecotypes No new Botanical areas would be recommended for addition to the three that presently exist (4,476 acres).

The distribution (percentages) of sensitive plant habitat in the various Management Areas is indicated in Appendix I, Table I-5 (NC) Specific descriptions and attributes of each individual site are included in Appendix F of the FEIS

6. How, and to What Degree, Should Forest Scenic Values be Protected through Visual Resource Management?

Visual management objectives would be achieved by designing activities to meet the inventoried VQO's on the entire Forest (1,092,302 acres). All (44) viewsheds considered would be governed by their respective inventoried VQO's.

Appendix I, Table I-6 (NC) shows the number of acres in each VQO category by Management Area Approximately 318,625 acres would have an unmodified appearance (Preservation). While management activities would be evident, but visually subordinate (Partial Retention) on 258,622 acres, another 72,323 acres would be managed where activities are not evident to the casual Forest visitor (Retention) The remaining area (442,732 acres) would be in Modification where management activities may dominate the characteristic landscape, but resemble naturally occurring patterns when viewed in the background

7. How Should Wildlife Habitats on the Forest be Managed?

The wildlife MR's for mature and old-growth dependent species are not included in this alternative Wildlife habitat would be managed to provide a mix of seral stages. A small number of Special Wildlife Sites (6,261 acres) are prescribed.

Appendix I, Table I-7 (NC) shows a variety of land allocations that contribute to overall wildlife habitat diversity. Standing dead trees (snags) in areas managed for timber production provide habitat capable of sustaining at least 60 percent of the maximum population of cavity-nesting birds. Approximately 54,815 acres of prime bald eagle and osprey habitat would be provided along rivers and streams that have a protected status Approximately 53 percent of the Forest (576,000 acres) would provide an adequate combination of cover and forage for deer to sustain an average herd of 30,800 animals for the first five decades.

There would be no capital investments for wildlife habitat improvements in this alternative.

8. How Will Management Direction Affect Recreation Opportunities in the Wilderness and Unroaded Areas?

None of the existing unroaded areas would be maintained in an unroaded status in this alternative. Primitive and Semi-primitive Non-motorized recreation opportunities would be provided principally in existing Wildernesses

Primitive and Semi-primitive recreational capacity would be slightly increased in the Wilderness by constructing 0 3 miles ($9,700) of trail during the first decade. Overall, 261,505 acres of unroaded Primitive and Semi-primitive recreation opportunities would be provided on the Forest Appendix I, Table I-8 (NC) shows the number of acres in each Management Area that provide unroaded Primitive and Semi-primitive recreational opportunities.

9. How Should Mineral Resources of the Forest be Developed in Coordination With Management of Other Resources?

Mineral exploration and development would be facilitated by retaining 76 percent of the Forest (825,852 acres) in an accessible category. Approximately 95 percent of accessible acres (786,041 acres) have low to moderate restrictions which would not limit mining activities. Approximately five percent (39,811 acres) have access restrictions in the high category which could make many types of mining activity uneconomical Appendix I, Table I-9 (NC) displays the level of restriction affecting acres within each Management Area. Specific Standards and Guidelines affecting mineral exploration and development are defined in Chapter IV of the LRMP for each Management Area

ALTERNATIVE A

ALTERNATIVE A

GOALS

The purpose of Alternative A is to continue management direction as set out in plans formulated and approved prior to the passage of the National Forest Management Act, and included in existing policies, standards, and guidelines. This is the "No Action" alternative required by NEPA.

DESIGN

Timber production would be maintained at the highest practical level under current land allocations and subject to nondeclining flow. Timber merchantibility standards, yield tables, and inventory data are updated to current or proposed standards. Available and suitable timber land inventory was updated to meet current standards. A moderate amount of hardwood conversion would be allowed. The wildlife MR's, which were not required by law when previous plans were completed, are included Fewer special resource areas for sensitive plants, wildlife, and fisheries would be allocated than in many of the other alternatives.

The entire complement of VQO's from the land use plans would be achieved. Visual and water quality of Wild and Scenic Rivers will be maintained. Riparian areas within lands in the timber base would be managed under current Siskiyou riparian policy (Riparian Prescription B).

OVERVIEW

Alternative design specifications would have the following results. Timber outputs would be sustained slightly below the current level. Much of the Forest, with the exception of existing Wilderness and areas without programmed timber harvest, would eventually be roaded and developed. Motorized recreation opportunities would be enhanced, as roads are constructed for timber management. Non-motorized recreation experiences would also be enhanced through trail construction in the Wildernesses.

The entire complement of inventoried VQO's from the land use plans would be allocated This includes all 44 viewsheds Scenic quality would be high

Approximately 39 percent of the Forest's presently standing mature and old-growth would be protected in this alternative Wildlife populations dependent on mature or old-growth habitat would be maintained above viable levels

Big-game hunting opportunities would be maintained at a level slightly higher than currently available Fishing opportunities would be maintained.

1. How Much Timber Should the Forest Produce?

Alternative A would result in the average annual production of 30 1 MMCF (168 MMBF) of chargeable sawtimber volume plus one percent chargeable salvage during the first decade Governed by a policy of nondeclining flow, average annual sale offerings would gradually increase in subsequent decades to reach the LTSY of 52.7 MMCF. Harvest would generally occur when the timber stands reach CMAI (approximately 100 years).

Timber production would be supported by a land base of 557,000 acres (selected suitable), which includes 37,053 acres of standing hardwood. Hardwood conversion would be limited to no more than 7,500 acres per decade, subject to market conditions. Final harvest would occur on an average of 4,505 acres per year during the first decade and increase to an average of 5,401 acres per year by the fifth decade Appendix I, Table I-10 (A, A-Departure) displays the Management Areas that provide timber management opportunities

2. How Much Old-Growth Forest Should be Preserved?

Alternative A is designed to reserve 173,754 acres having mature and old-growth forest characteristics With the exception of the reserved areas displayed by Management Area in Appendix I, Table I-11 (A, A-Departure), existing mature and old-growth would be metered out to accommodate the harvest sale schedule Of the 443,000 acres of mature and old-growth that currently exist, 392,970 will remain at the end of the first decade of harvest activity Except for isolated tracts, riparian, and other small areas, unprotected mature and old-growth would be removed by the tenth decade

3. How Can the Forest's Fish Habitat, Water Quality and Soil Productivity be Maintained or Improved?

Management objectives for fish, water quality and soil productivity would be designed to maintain existing conditions. Allocation of 327,456 acres (30 percent of the Forest) to Management Areas 1-9 which limit site-disturbing activity and preclude programmed timber harvest would protect fish and watershed values in those areas. In other areas, these values would be protected though the application of Standards and Guidelines and Best Management Practices (BMP's) The impacts of timber harvest would be mitigated by distributing activities through time and space. This is represented in the alternative design by limiting timber harvest in the model to 20 percent of each planning basin per decade.

Land characterized by riparian vegetation would be managed to maintain water quality and fishery habitat Vegetative disturbance in the riparian area in the timber base would be controlled by Riparian Prescription B Riparian Prescription B is designed to maintain existing water temperatures. Appendix I, Table I-12 (A, A-Departure) shows how riparian habitat would be affected by the various Management Area designations

The current level of capital investment is proposed in this alternative Approximately $455,100 per year would be spent on fish, soil and water resource projects.

4 How, and to What Extent, Should Lands In and Adjacent to River Corridors be Managed to Protect, Preserve, and Enhance Wild and Scenic River Attributes?

Land allocations to a variety of Management Areas would protect Wild and Scenic River attributes. All viewsheds surrounding the Wild and Scenic Rivers would have a natural or near-natural appearance as lands would be managed to meet their inventoried VQO's. Land within 1/4 mile of either side of the Chetco and North Fork Smith Rivers would be managed under two Management Areas, the interior 1/8 mile would be allocated to the Supplemental Resource Management Area, while the remaining land would be allocated to its respective Wild or Scenic/Recreation River Management Area

Appendix I, Table I-13 (A, A-Departure) shows the number of acres within each Management Area which directly contribute to preservation and enhancement of Wild and Scenic River attributes. Those that contribute to maintenance of water quality and visual quality are indicated.

5. How Should Sensitive Plant Resources be Managed?

The variety of sensitive plants on the Forest would be managed through a number of land allocations designed with specific protection standards Each Management Area has Standards and Guidelines (in addition to Forest-wide Standards and Guidelines) designed to protect sensitive plants endemic to the Forest (see LRMP, Chapter IV) RNA's and Botanical Management Areas would provide special emphasis to the preservation of ecotypes and sensitive plants. One new RNA is proposed in addition to the three existing areas (for a total of 3,249 acres) resulting in the preservation of 14 ecotypes. No new Botanical areas would be recommended for addition to the three that presently exist (4,476 acres)

The distribution (percentages) of sensitive plant habitat in the various Management Areas is indicated in Appendix I, Table I-14 (A, A-Departure). Specific descriptions and attributes of each individual site are included in Appendix F of the FEIS.

6. How, and to What Degree, Should Forest Scenic Values be Protected through Visual Resource Management?

Visual management objectives would be achieved by designing activities to meet VQO's on the entire Forest (1,092,302 acres). All (44) viewsheds considered would be governed by their respective inventoried VQO's.

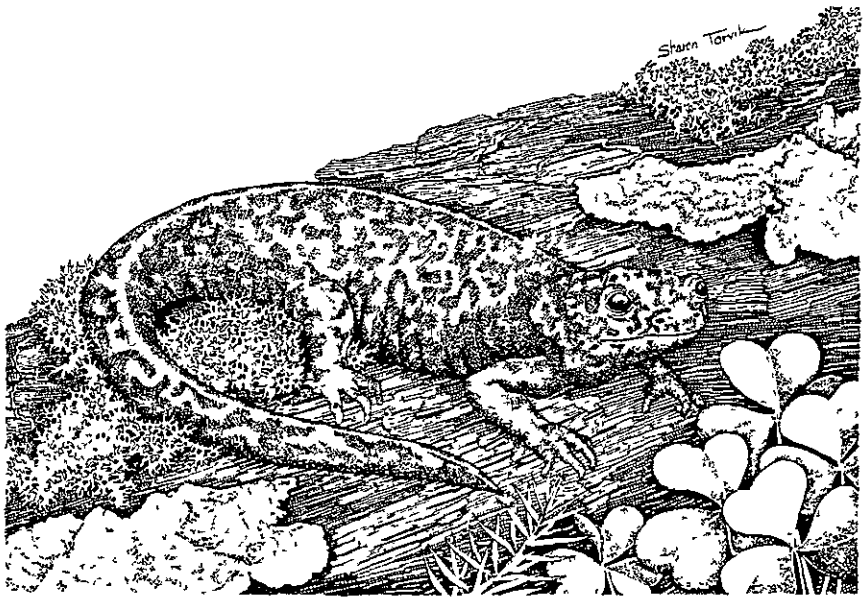
Appendix I, Table I-15 (A, A-Departure) shows the number of acres in each VQO category by Management Area. Approximately 356,603 acres would have an unmodified appearance (Preservation) While management activities would be evident, but visually subordinate (Partial Retention) on 246,281 acres, another 65,536 acres would be managed where activities are not evident to the casual Forest visitor (Retention). The remaining area (423,882 acres) would be in Modification where management activities may dominate the characteristic landscape, but resemble naturally occurring patterns when viewed in the background

7. How Should Wildlife Habitats on the Forest be Managed?

Designated Wildlife Habitat Management Areas would be allocated to meet MR's for wildlife inhabiting mature and old-growth forest A small number of Special Wildlife Sites (5,883 acres) are prescribed. In total, approximately 173,754 acres of mature and old-growth forest wildlife habitat would be maintained

Appendix I, Table I-16 (A, A-Departure) shows a variety of land allocations that contribute to overall wildlife habitat diversity. Standing dead trees (snags) in areas managed for timber production would provide habitat capable of sustaining at least 60 percent of the maximum population of cavity-nesting birds Approximately 54,719 acres of prime bald eagle and osprey habitat would be provided along rivers and streams that have a protected status Approximately 51 percent of the Forest (557,000 acres) would provide an adequate combination of cover and forage for deer to sustain an average herd size of 30,800 animals for the first five decades.

Capital investments for wildlife habitat improvements would result in higher carrying capacity for many species Approximately $56,000 per year would be prescribed to complete an average of 191 structural improvements and treat about 449 acres.



8. How Will Management Direction Affect Recreation Opportunities in the Wilderness and Unroaded Areas?

None of the existing unroaded areas would be maintained in an unroaded status in this alternative. Primitive and Semi-primitive Non-motorized recreation opportunities would be provided principally in existing Wildernesses

Primitive and Semi-primitive recreational capacity would be slightly increased in the Wilderness by constructing 0 3 miles ($9,700) of trail during the first decade. Overall, 261,505 acres of unroaded Primitive and Semi-primitive recreation opportunities would be provided on the Forest. Appendix I, Table I-17 (A, A-Departure) shows the number of acres in each Management Area that provide unroaded Primitive and Semi-primitive recreational opportunities

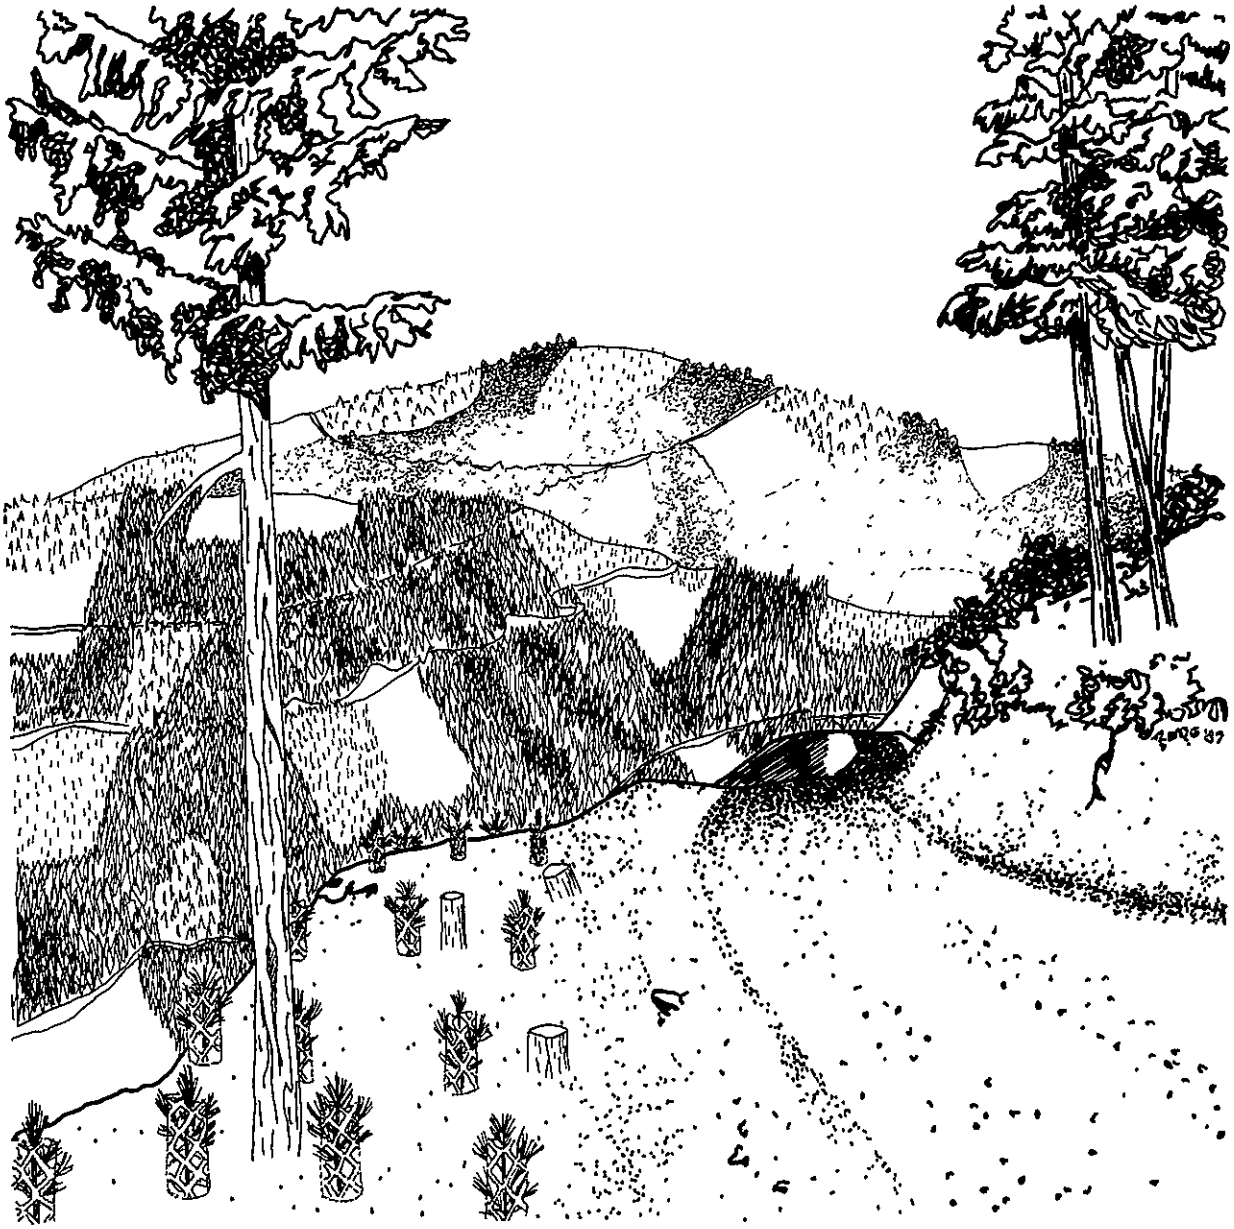
9. How Should Mineral Resources of the Forest be Developed in Coordination With Management of Other Resources?

Mineral exploration and development would be facilitated by retaining 76 percent of the Forest (825,403 acres) in an accessible category Approximately 95 percent of accessible acres (786,705 acres) have low to moderate restrictions which would not limit mining activities Approximately five percent (38,698 acres) have access restrictions in the high category which could make many types of mining activity uneconomical. Appendix I, Table I-18 (A, A-Departure) displays the level of restriction affecting acres within each Management Area. Specific Standards and Guidelines affecting mineral exploration and development are defined in Chapter IV of the LRMP for each Management Area

ALTERNATIVE A-DEPARTURE

ALTERNATIVE A-DEPARTURE

The goals and design of this alternative are identical to Alternative A with the exception of the timber harvest schedule. This alternative is designed to maintain the current level of timber output in the first two decades of the planning period, using the same land allocations as Alternative A. Departing from the nondeclining yield policy, timber outputs would decline by three percent in the third decade, and by six percent in the fourth and fifth decades. The description below includes only those planning problems where this alternative differs; other elements are identical to Alternative A.



1. How Much Timber Should the Forest Produce?

Alternative A-Departure would result in the average annual production of 31.2 MMCF (174 MMBF) of chargeable sawtimber volume plus one percent chargeable salvage during the first two decades. Departing from a policy of nondeclining flow, average annual sale offerings would gradually decline in the third decade to 30.3 MMCF, and 29 4 MMCF in the fourth and fifth decades The LTSY of 52.7 MMCF would be achieved by the eleventh decade Harvest would generally occur when the timber stands reach CMAI (approximately 100 years).

Timber production would be supported by a land base of 557,000 acres (selected suitable), which includes 38,585 acres of standing hardwood. Hardwood conversion would be limited to no more than 7,500 acres per decade, subject to market conditions. Final harvest would occur on an average of 4,697 acres per year during the first decade, increasing to 5,429 acres per year by the fifth decade Appendix I, Table I-10 (A, A-Departure) displays the Management Areas that provide timber management opportunities.

2. How Much Old-Growth Forest Should be Preserved?

Alternative A-Departure is designed to reserve 173,754 acres having mature and old-growth forest characteristics With the exception of the reserved areas displayed by Management Area in Appendix I, Table I-11 (A, A-Departure), existing mature and old-growth would be metered out to accommodate the harvest sale schedule Of the 443,000 acres of mature and old-growth that currently exist, 391,050 will remain at the end of the first decade of harvest activity Except for isolated tracts, riparian, and other areas, all unprotected mature and old-growth will be removed by the tenth decade.

ALTERNATIVE B

ALTERNATIVE B

GOALS

The purpose of this alternative is to evaluate how the current (1980) Forest and Rangeland Renewable Resources Planning Act (RPA) production targets for goods and services, as set out in the Regional Guide, can best be implemented. This alternative would meet, or attempt to meet, all assigned targets simultaneously The 1980 RPA targets emphasize high commodity production (wood fiber and fish) with *moderate levels of developed and dispersed recreation, and nongame and big-game wildlife habitat*

DESIGN

The land allocation emphasizes fish and timber. Timber production is set at the RPA target for the first two decades This would require a departure from nondeclining flow since this level cannot be sustained over the planning horizon (The base alternative is Alternative D described later in this section.) Timber outputs are allowed to drop over the third, fourth, and fifth decades, then increase in subsequent decades. A high *rate of hardwood conversion would be allowed. All MR's are included. A number of areas with special* resource values such as sensitive plants, unique ecosystems, and wildlife habitat would be allocated to Management Areas which have no programmed timber harvest.

Riparian areas in the timber base in six planning basins with high fisheries potential would be allocated to Riparian Management Prescription C; the remaining basins would be allocated to Prescription B. The full range of inventoried VQO's would be achieved only in the highest priority viewsheds.

OVERVIEW

Alternative design specifications would have the following results. This alternative is the most extreme departure of all the alternatives and would produce the highest timber output in the first two decades. Much of the Forest, with the exception of existing Wilderness and areas without programmed timber harvest, would eventually be roaded and developed. Motorized recreation opportunities would be enhanced, as roads are constructed for timber management. Non-motorized recreation experiences would also be enhanced through trail construction and reconstruction in the Wildernesses Primitive and Semi-primitive Non-motorized recreation experiences would generally be found only in the Wildernesses by the second decade. The scenic quality of the Forest would be highly modified; a natural appearance would be maintained in only the three most highly valued travel corridors and viewsheds.

Approximately 39 percent of the Forest's presently standing mature and old-growth would be protected in this alternative. Wildlife populations dependent on mature or old-growth habitat would be maintained above viable levels Big-game hunting opportunities would exceed those currently available throughout the planning period, because of the changes in the cover/forage ratio resulting from the timber harvest schedule. Fishing opportunities would be somewhat enhanced through protection of high value fish habitat and high capital investment expenditures

1. How Much Timber Should the Forest Produce?

The RPA target for timber outputs is 40 MMCF (including nonchargeable volume) per year for the first five decades. Alternative B will result in the average annual production of 36.8 MMCF (205 MMBF) of chargeable sawtimber volume plus one percent chargeable salvage, and an additional 4 MMCF of nonchargeable volume, for the first two decades. A departure from nondeclining flow policy is required because this level of output cannot be sustained beyond the second decade In the third, fourth, and fifth through seventh decades, harvest volumes would drop to 33 0 MMCF, 28.0 MMCF, and 25 MMCF, respectively Harvest volumes would begin to increase in the eighth decade, and reach LTSY (54.8 MMCF) in the tenth decade Harvest would generally occur when the timber stands reach CMAI (approximately 100 years)

Timber production would be supported by a land base of 558,000 acres (selected suitable), which includes 38,885 acres of standing hardwood. Hardwood conversion would be limited to no more than 14,000 acres per decade, subject to market conditions Final harvest would occur on an average of 5,562 acres per year during the first decade, decreasing to 4,364 acres per year by the fifth decade. Appendix I, Table I-19 (B) displays the Management Areas that provide timber management opportunities.

2. How Much Old-Growth Forest Should be Preserved?

Alternative B is designed to reserve 170,954 acres having mature and old-growth forest characteristics With the exception of the reserved areas displayed by Management Area in Appendix I, Table I-20 (B, D and D1), existing mature and old-growth would be harvested more rapidly in the first two decades of this alternative than in others Of the 443,000 acres of mature and old-growth that currently exist, 378,170 will remain at the end of the first decade of harvest activity Except for isolated tracts, riparian, and other small areas, all unprotected mature and old-growth would be removed by the tenth decade.

3. How Can the Forest's Fish Habitat, Water Quality and Soil Productivity be Maintained or Improved?

Management objectives for fish, water quality and soil productivity would be designed to maintain existing conditions Allocation of 327,456 acres (30 percent of the Forest) to Management Areas 1-9 which limit site-disturbing activity and preclude programmed timber harvest would protect fish and watershed values in those areas. In other areas, these values would be protected thought the application of Standards and Guidelines and BMP's The impacts of timber harvest would be mitigated by distributing activities through time and space This is represented in the alternative design by limiting timber harvest in the model to 20 percent of each planning basin per decade

The watershed condition would be maintained in pristine areas and improved in those areas which are now degraded Allocation of 319,749 acres (29 percent of the Forest) to Management Areas 1-9 which limit site-disturbing activity and preclude programmed timber harvest would protect fish and watershed values in those areas Land surrounding rivers and streams (13,739 acres) with exceptional salmon and steelhead rearing capabilities would be allocated to the Supplemental Resource Management Area. In other areas, these values would be protected though the application of Standards and Guidelines and BMP's The impacts of timber harvest would be mitigated by distributing activities through time and space. This is represented in the alternative design by limiting timber harvest in the model with constraints ranging from 9 to 12 percent per decade in six high fish-producing planning basins and constraints of 20 percent per decade in 12 of the 19 planning basins.

Land characterized by riparian vegetation would be managed to improve water quality and fishery habitat. Vegetative disturbance in the riparian area within the timber base would be controlled by Riparian Prescriptions B or C Prescription C would be applied on the six high fish-producing basins, it is designed to produce a 2-degree decrease in summer water temperature by the third decade Riparian Prescription B, designed to maintain existing water temperatures, is applied to the remaining basins Appendix I, Table I-21 (B) shows how riparian habitat would be affected by the various Management Area designations.

A high level of capital investment is proposed in this alternative. Approximately $650,000 per year would be spent on fish, soil and water resource projects.

4. How, and to What Extent, Should Lands In and Adjacent to River Corridors be Managed to Protect, Preserve, and Enhance Wild and Scenic River Attributes?

Land allocations to a variety of Management Areas would protect Wild and Scenic River attributes. All viewsheds surrounding the Rogue and Illinois Wild and Scenic Rivers would have a natural or near-natural appearance as lands would be managed to meet their inventoried VQO's. Land within 1/8 mile of either side of the Chetco, North Fork Smith, and Elk Rivers would be allocated to the Supplemental Resource

Management Area which minimizes site-disturbing activity. Viewsheds surrounding these rivers would not be managed to meet their inventoried VQO's, except for Partial Retention areas around the Chetco River.

Appendix I, Table I-22 (B, D and D1) shows the number of acres within each Management Area which directly contribute to preservation and enhancement of Wild and Scenic River attributes Those that contribute to maintenance of water quality and visual quality are indicated.

5. How Should Sensitive Plant Resources be Managed?

The variety of sensitive plants on the Forest would be managed through a number of land allocations designed with specific protection standards. Each Management Area has Standards and Guidelines (in addition to Forest-wide Standards and Guidelines) designed to protect sensitive plants endemic to the Forest (see LRMP, Chapter IV). RNA's and Botanical Management Areas would provide special emphasis to the preservation of ecotypes and sensitive plants. Two new RNA's are proposed in addition to the three existing areas (for a total of 3,349 acres). A total of 16 ecotypes would be preserved on the Forest Seven new Botanical areas would be recommended for addition to the three that presently exist for a total of 9,056 acres.

The distribution (percentages) of sensitive plant habitat in the various Management Areas is indicated in Appendix I, Table I-23 (B, D and D1). Specific descriptions and attributes of each individual site are included in Appendix F of the FEIS.

6. How, and to What Degree, Should Forest Scenic Values be Protected through Visual Resource Management?

Visual management objectives would be achieved by designing to meet VQO's on 473,998 acres Eight entire viewsheds (of the 44 considered) would be governed by their respective inventoried VQO's, three of which encompass heavily used recreation travel corridors. the Upper Illinois, Oregon Caves, and Highway 199

Appendix I, Table I-24 (B and D) shows the number of acres in each VQO category by Management Area. Approximately 349,707 acres would have an unmodified appearance (Preservation). While management activities would be evident, but visually subordinate (Partial Retention) on 106,123 acres, another 18,168 acres would be managed where activities are not evident to the casual Forest visitor (Retention). The remaining area (618,304 acres) would be in Modification where management activities may dominate the characteristic landscape, but resemble naturally occurring patterns when viewed in the background

7. How Should Wildlife Habitats on the Forest be Managed?

Designated Wildlife Habitat Management Areas would be allocated to meet MR's for wildlife inhabiting mature and old-growth forest. In total, over 170,954 acres of mature and old-growth forest wildlife habitat would be maintained Allocations to the Special Wildlife Site (9,195 acres), RNA's (3,349 acres), and Botanical (5,648 acres) Management Areas would contribute to overall habitat diversity, but represent relatively open vegetative types

Appendix I, Table I-25 (B and D) shows a variety of land allocations that would contribute to overall wildlife habitat diversity Standing dead trees (snags) in areas managed for timber production would provide habitat capable of sustaining at least 20 percent of the maximum population of cavity-nesting birds Approximately 48,620 acres of prime bald eagle and osprey habitat would be provided along rivers and streams that have a protected status. Approximately 51 percent of the Forest (558,000 acres) would provide an adequate combination of cover and forage for deer to sustain an average herd size of 31,300 animals for the first five decades

Capital investments for wildlife habitat improvements would result in higher carrying capacity for many species Approximately $110,000 per year would be prescribed to complete an average of 191 structural improvements and treat about 4,550 acres

8 How Will Management Direction Affect Recreation Opportunities in the Wilderness and Unroaded Areas?

None of the existing unroaded areas would be maintained in an unroaded status in this alternative. Primitive and Semi-primitive Non-motorized recreation opportunities would be provided principally in existing Wildernesses.

Primitive and Semi-primitive recreational capacity would be increased in the Wilderness by constructing 21.0 miles ($315,000) and reconstructing 7 0 miles ($111,900) of trail during the first decade. Overall, 261,485 acres of unroaded Primitive and Semi-primitive recreation opportunities would be provided on the Forest. Appendix I, Table I-26 (B) shows the number of acres in each Management Area that provide unroaded Primitive and Semi-primitive recreational opportunities.

9. How Should Mineral Resources of the Forest be Developed in Coordination With Management of Other Resources?

Mineral exploration and development would be facilitated by retaining 76 percent of the Forest (826,628 acres) in an accessible category Approximately 97 percent of accessible acres (798,248 acres) have low to moderate restrictions which would not limit mining activities Approximately three percent (28,380 acres) have access restrictions in the high category which could make many types of mining activity uneconomical. Appendix I, Table I-27 (B, D and D1) displays the level of restriction affecting acres within each Management Area Specific Standards and Guidelines affecting mineral exploration and development are defined in Chapter IV of the LRMP for each Management Area

ALTERNATIVE C

ALTERNATIVE C

GOALS

Alternative C is designed to provide the highest sustainable annual timber harvest yields (subject to nondeclining yield) from the Forest

DESIGN

Timber production would be relatively unconstrained beyond MR's, general multiple use considerations, and nondeclining flow. A high rate of hardwood conversion would be allowed The wildlife MR's are included

Only the highest priority viewsheds have VQO's allocated and in these areas, the Retention acres are reduced to Partial Retention The only acres managed for Retention would be in the designated Wild and Scenic Rivers. Riparian areas in the timber base would be managed under Riparian Prescription B.

OVERVIEW

Alternative design specifications would have the following results. This alternative would achieve current timber outputs without departing from nondeclining flow. It would achieve this by allocating the most acres to timber production, with reduced visual management and other resource allocations Much of the Forest, with the exception of existing Wilderness and areas without programmed timber harvest, would eventually be roaded and developed. Motorized recreation opportunities would be enhanced, as roads are constructed for timber management. Non-motorized recreation experiences would also be enhanced through trail construction in the Wildernesses. Primitive and Semi-primitive Non-motorized recreation experiences would generally be found only in the Wildernesses by the second decade. The scenic quality of the Forest would be highly modified in this alternative, although a near-natural appearance would be maintained in the four most heavily used travel corridors and viewsheds. Developed recreation opportunities would remain what they are today.

Approximately 37 percent of the Forest's presently standing mature and old-growth would be protected in this alternative. Wildlife populations dependent on mature or old-growth habitat would be maintained above viable levels. Big-game hunting opportunities would exceed those currently available throughout the first five planning periods, because of changes in the cover/forage ratio resulting from the timber harvest schedule Fish habitat would be managed to maintain existing capability

1. How Much Timber Should the Forest Produce?

Alternative C would result in the average annual production of 31.8 MMCF (177 MMBF) of chargeable timber volume plus one percent chargeable salvage during the first decade. Governed by a policy of nondeclining flow, average annual sale offerings would gradually increase in subsequent decades to reach the LTSY of 57.0 MMCF. Harvest would generally occur when the timber stands reach CMAI (approximately 100 years).

Timber production would be supported by a land base of 566,000 acres (selected suitable), which includes 40,704 acres of standing hardwood Hardwood conversion would be limited to no more than 14,000 acres per decade, subject to market conditions. Final harvest would occur on an average of 6,713 acres per year during the first decade, decreasing to 6,072 acres per year by the fifth decade Appendix I, Table I-28 (C) displays the Management Areas that provide timber management opportunities

2. How Much Old-Growth Forest Should be Preserved?

Alternative C is designed to reserve 166,063 acres having mature and old-growth forest characteristics. With the exception of the reserved areas displayed by Management Area in Appendix I, Table I-29 (C), existing mature and old-growth would be metered out to accommodate the harvest sale schedule Of the 443,000 acres of mature and old-growth that currently exist, 369,650 would remain at the end of the first decade of harvest activity Except for isolated tracts, riparian, and other small areas, all unprotected mature and old-growth will be removed by the tenth decade.

3. How Can the Forest's Fish Habitat, Water Quality and Soil Productivity be Maintained or Improved?

Fish habitat would be managed to maintain minimum viable population levels of native fish Allocation of 309,801 acres (28 percent of the Forest) to Management Areas 1-9 which limit site-disturbing activity and preclude programmed timber harvest would protect fish and watershed values in those areas In other areas, these values would be protected thought the application of Standards and Guidelines and BMP's The impacts of timber harvest would be mitigated by distributing activities through time and space. This is represented in the alternative design by limiting timber harvest in the model to 20 percent of each planning basin per decade.

Land characterized by riparian vegetation would be managed to improve water quality and fishery habitat Vegetative disturbance in the riparian areas in the timber base would be controlled by Riparian Prescriptions B Riparian Prescription B is designed to maintain existing water temperatures. Land surrounding two (of thirty) rivers and creeks with exceptional salmon and steelhead rearing capabilities (Lawson and Emily Creeks) would be allocated to the Supplemental Resource Management Area, where no timber harvest would occur. Appendix I, Table I-30 (C) shows how riparian habitat would be affected by the various Management Area designations

A high level of capital investment is proposed in this alternative Approximately $664,600 per year would be spent on fish, soil and water resource projects.

4. How, and to What Extent, Should Lands In and Adjacent to River Corridors be Managed to Protect, Preserve, and Enhance Wild and Scenic River Attributes?

A limited amount of protection would be afforded Wild and Scenic River values in this alternative. Viewsheds surrounding the Chetco, North Fork Smith, and Elk Rivers would not be managed to meet their inventoried VQO's, except for inventoried Partial Retention areas around the Chetco River. The influence of management activities on the Rogue and Illinois Wild and Scenic River corridors would be evident as no lands are allocated to the Retention Management Area in this alternative. Allocations to the RNA's (1,291 acres), Botanical (2,880 acres), and Designated Wildlife Habitat (7,334 acres) Management Areas would provide the only unaltered landscapes within the viewsheds of the rivers.

Appendix I, Table I-31 (C) shows the number of acres within each Management Area which directly contribute to preservation and enhancement of Wild and Scenic River attributes Those that contribute to maintenance of water quality and visual quality are indicated

5. How Should Sensitive Plant Resources be Managed?

The variety of sensitive plants on the Forest would be managed through a number of land allocations designed with specific protection standards Each Management Area has Standards and Guidelines (in addition to Forest-wide Standards and Guidelines) designed to protect sensitive plants endemic to the Forest (see LRMP, Chapter IV) RNA's and Botanical Management Areas would provide special emphasis to the preservation of ecotypes and sensitive plants Two new RNA's (Hoover Gulch and Craggy Peak) would be proposed in addition to the three existing areas (for a total of 3,349 acres) resulting in the

protection of 16 ecotypes Seven new Botanical areas would be recommended for addition to the three that presently exist for a total of 9,056 acres

The distribution (percentages) of sensitive plant habitat in the various Management Areas is indicated in Appendix I, Table I-32 (C). Specific descriptions and attributes of each individual site are included in Appendix F of the FEIS.

6. How, and to What Degree, Should Forest Scenic Values be Protected through Visual Resource Management?

This alternative would provide the most modified visual appearance of any alternative considered. Visual management objectives would be achieved by designing activities to meet VQO's on 449,093 acres Five viewsheds (of the 44 considered) in established Wildernesses would be governed by their respective inventoried VQO's, none of which encompass heavily used recreation travel corridors. Management of Forest scenic values would be limited to high recreation use travel corridors and viewsheds No viewsheds, outside of Wildernesses, would be managed to meet their respective inventoried visual objectives All inventoried Retention and Partial Retention acres in four viewsheds (Rogue-Illinois, Oregon Caves, Upper Illinois, and Chetco) would be managed for Partial Retention.

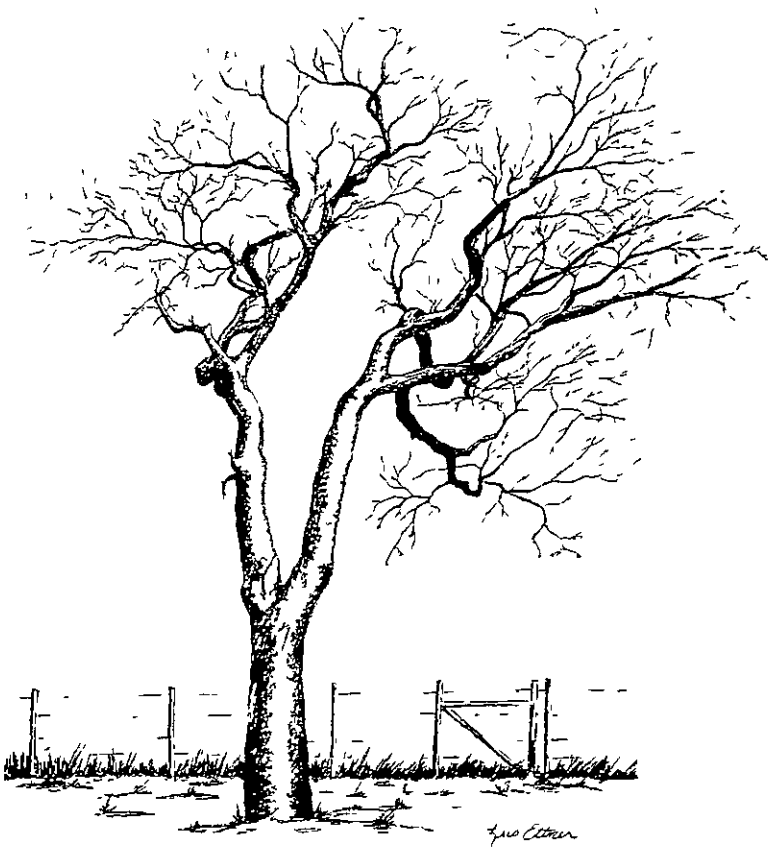
Appendix I, Table I-33 (C) shows the number of acres in each VQO category by Management Area Approximately 342,016 acres would have an unmodified appearance (Preservation) While management activities would be evident, but visually subordinate (Partial Retention) on 97,551 acres, another 9,526 acres would be managed where activities are not evident to the casual Forest visitor (Retention). The remaining area (643,209 acres) would be in Modification where management activities may dominate the characteristic landscape, but resemble naturally occurring patterns when viewed in the background.

7. How Should Wildlife Habitats on the Forest be Managed?

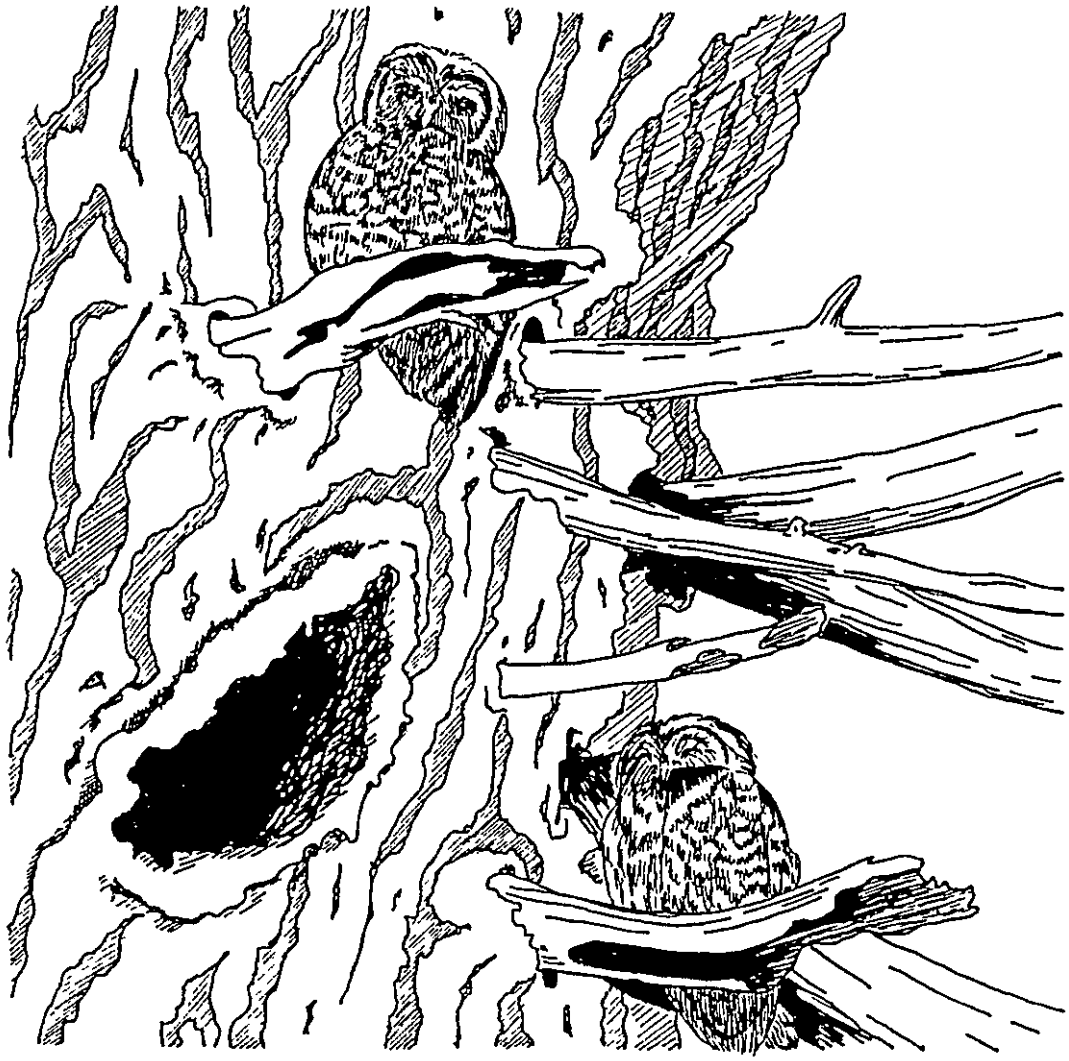
Allocations to the Special Wildlife Site (9,477 acres), RNA's (3,349 acres), and Botanical (5,648 acres) Management Areas would contribute to overall habitat diversity, but represent relatively open vegetative types Designated Wildlife Habitat (55,109 acres) Management Areas that meet MR's would be included in this alternative

Appendix I, Table I-34 (C) shows a variety of land allocations that contribute to overall wildlife habitat diversity Standing dead trees (snags) in areas managed for timber production would provide habitat capable of sustaining at least 20 percent of the maximum population of cavity-nesting birds. Approximately 48,620 acres of prime bald eagle and osprey habitat would be provided along rivers and streams that have a protected status. Approximately 52 percent of the Forest (566,000 acres) would provide an adequate combination of cover and forage for deer to sustain an average herd of 33,000 animals for the first five decades.

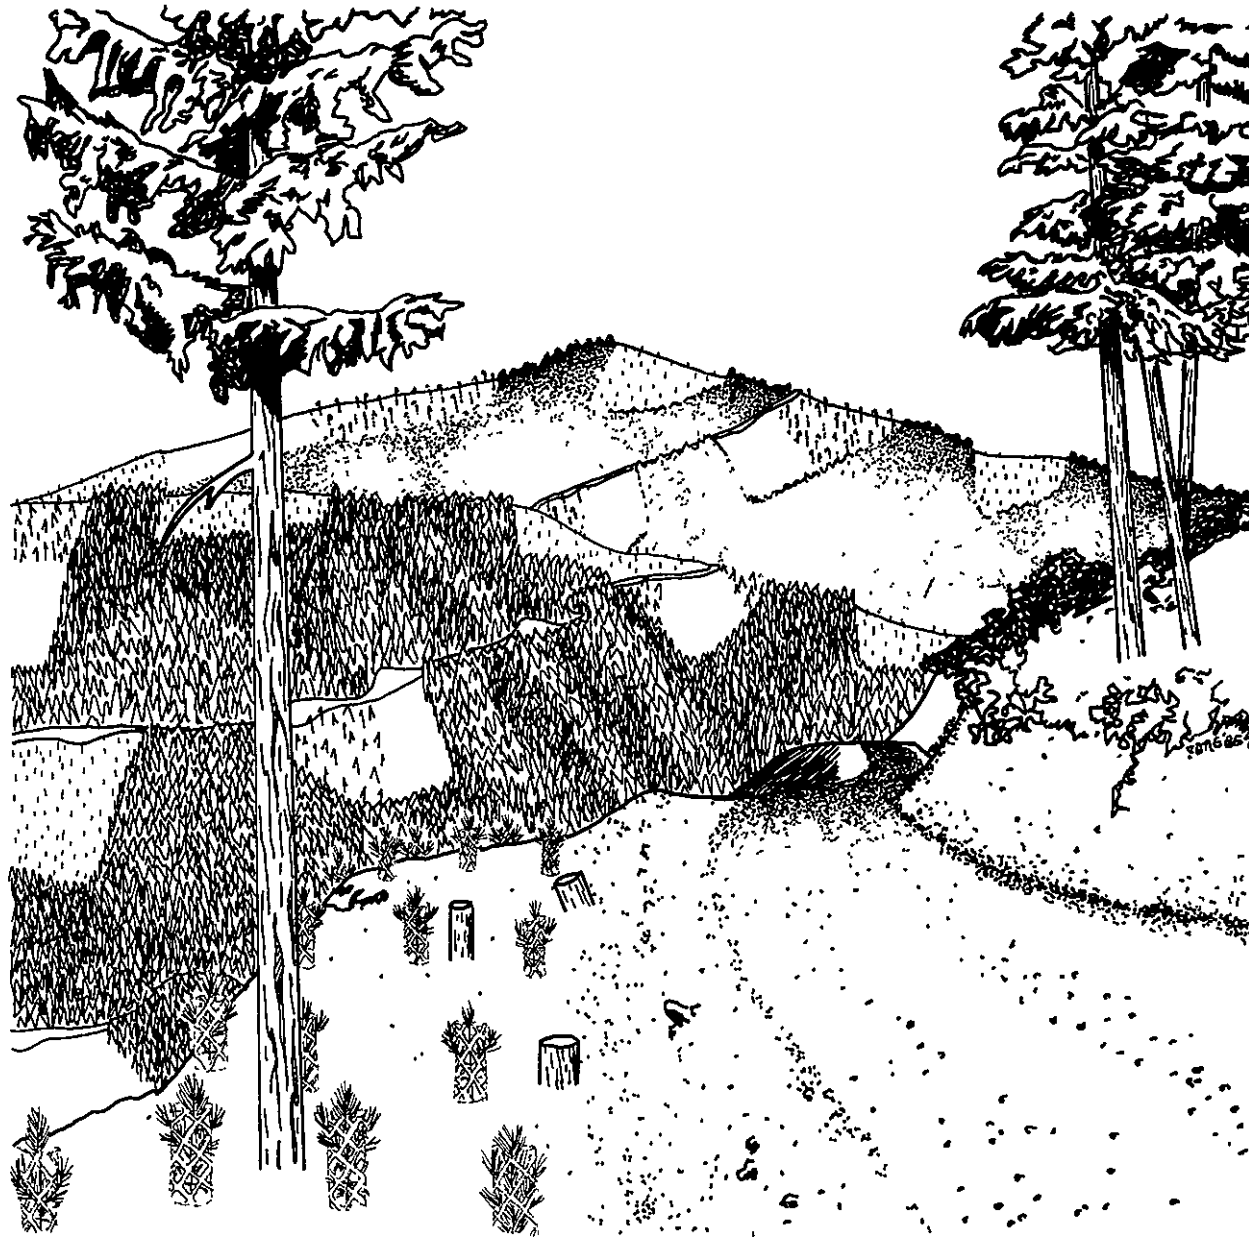
Capital investments for wildlife habitat improvements would result in higher carrying capacity for many species Approximately $56,000 per year would be prescribed to complete an average of 191 structural improvements and treat about 449 acres



8 How Will Management Direction Affect Recreation Opportunities in the Wilderness and Unroaded Areas?



None of the existing unroaded areas would be maintained in an unroaded status in this alternative Primitive and Semi-primitive Non-motorized recreation opportunities would be provided principally in the existing Wildernesses



Primitive and Semi-primitive recreational capacity would be increased in the Wilderness by constructing 47.0 miles ($757,500) and reconstructing 7 0 miles ($111,900) of trail during the first decade Overall, 263,079 acres of unroaded Primitive and Semi-primitive recreation opportunities would be provided on the Forest. Appendix I, Table I-35 (C) shows the number of acres in each Management Area that provide unroaded Primitive and Semi-primitive recreational opportunities

9. How Should Mineral Resources of the Forest be Developed in Coordination With Management of Other Resources?

Mineral exploration and development would be facilitated by retaining 76 percent of the Forest (826,967 acres) in an accessible category Approximately 98 percent of accessible acres (809,649 acres) have low to moderate restrictions which would not limit mining activities Approximately two percent (17,318 acres) have access restrictions in the high category which could make many types of mining activity uneconomical. Appendix I, Table I-36 (C) displays the level of restriction affecting acres within each Management Area. Specific Standards and Guidelines affecting mineral exploration and development are defined in Chapter IV of the LRMP for each Management Area.

ALTERNATIVE D

ALTERNATIVE D

This is the base alternative for the departure that forms Alternative B The primary objective of Alternative D is to emphasize the production of goods and services having established market prices (timber, minerals, developed recreation, and commercial fisheries). The alternative is designed to provide a balance of these commodity outputs for all resources (i.e., one commodity-producing resource is not subordinate to another). The acre allocations are the same as Alternative B, as are most other elements The primary difference is that Alternative D is subject to the nondeclining flow timber harvest constraint

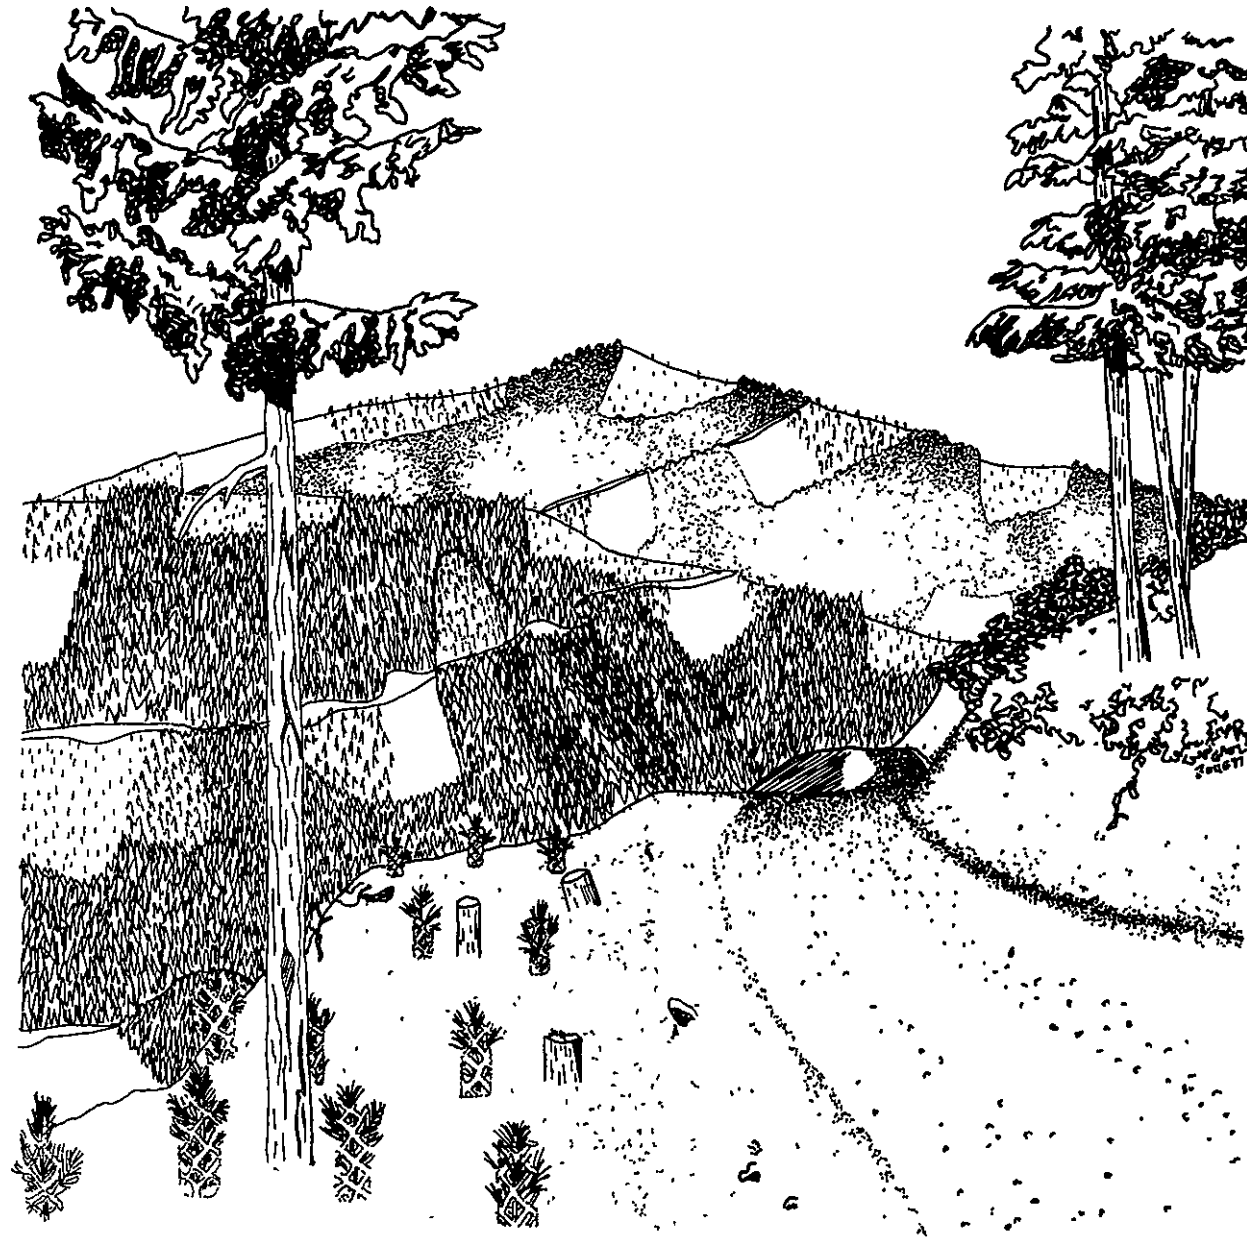
The description below includes only those Planning Problems where this alternative differs, other elements are identical to Alternative B

1. How Much Timber Should the Forest Produce?

Alternative D would result in the average annual production of 30.4 MMCF (170 MMBF) of chargeable sawtimber volume plus one percent chargeable salvage during the first decade Governed by a policy of nondeclining flow, average annual sale offerings would gradually increase in subsequent decades to reach the LTSY of 54.8 MMCF. Harvest would generally occur when the timber stands reach CMAI (approximately 100 years)

Timber production would be supported by a land base of 560,000 acres (selected suitable), which includes 40,023 acres of standing hardwood Hardwood conversion would be limited to no more than 14,000 acres per decade, subject to market conditions Final harvest would occur on an average of 5,570 acres per year during the first decade, decreasing to 5,093 acres per year by the fifth decade Appendix I, Table I-37 (D) displays the Management Areas that provide timber management opportunities

2. How Much Old-Growth Forest Should be Preserved?



Alternative D is designed to reserve 170,954 acres having mature and old-growth forest characteristics With the exception of the reserved areas displayed by Management Area in Appendix I, Table I-20 (B, D and D1), existing mature and old-growth would be metered out to accommodate the harvest sale schedule Of the 443,000 acres of mature and old-growth that currently exist, 382,580 will remain at the end of the first decade of harvest activity Except for isolated tracts, riparian, and other areas, most unprotected mature and old-growth will be removed by the tenth decade

3. How Can the Forest's Fish Habitat, Water Quality and Soil Productivity be Maintained or Improved?

Alternative D would be similar to Alternative B except capital investments would be approximately $595,600 per year spent on fish, soil and water resource projects

7. How Should Wildlife Habitats on the Forest be Managed?

This alternative is essentially the same as Alternative B except the nondeclining flow timber schedule would result in more even production of forage through time A low level of capital investment is proposed in this alternative because wildlife-related recreation is not considered a commodity. Approximately $28,000 per year would be prescribed to complete an average of 96 structural improvements and treat about 225 acres

ALTERNATIVE D1

ALTERNATIVE D1

This alternative is identical to Alternative D, except the CMAI requirement on timber harvest rotation is replaced with a provision which allows timber to be harvested as much as 20 years prior to the normal rotation age (this may not be in compliance with the intent of NFMA). The purpose of this alternative is to maintain a high level of timber output, by decreasing rotation lengths, under a nondeclining flow schedule.

Timber management activities would be intensive and apparent to the Forest visitor Trees would be smaller in diameter at the time of final harvest, and the future Forest in areas with programmed timber harvest might have more of a "tree farm" appearance than in the other alternatives.

The description below includes only those Planning Problems where this alternative differs, other resources and Forest conditions are the same as those described for Alternative D (and B)

1. How Much Timber Should the Forest Produce?

Alternative D1 would result in the average annual production of 33.2 MMCF (185 MMBF) of chargeable sawtimber volume plus one percent chargeable salvage during the first decade Governed by a policy of nondeclining flow, average annual sale offerings would gradually increase in subsequent decades to reach the LTSY of 49.0 MMCF. Harvest would generally occur an average of 20 years prior to age when stands reach CMAI *This results in an average rotation length of about 80 years for this alternative.*

Timber production would be supported by a land base of 550,000 acres (selected suitable), which includes 39,440 acres of standing hardwood. Hardwood conversion would be limited to no more than 14,000 acres per decade, subject to market conditions. Final harvest would occur on an average of 5,251 acres per year during the first decade, increasing to 5,335 acres per year by the fifth decade. Appendix I, Table I-39 (D1) displays the Management Areas that provide timber management opportunities

2. How Much Old-Growth Forest Should be Preserved?

Alternative D1 is designed to reserve 170,954 acres having mature and old-growth forest characteristics. With the exception of the preserved areas displayed by Management Area in Appendix I, Table I-20 (B, D and D1), existing mature and old-growth would be metered out to accommodate the harvest sale schedule. Of the 443,000 acres of mature and old-growth that currently exist, 383,650 would remain at the end of the first decade of harvest activity. Except for isolated tracts, riparian, and other areas, all unprotected mature and old-growth would be removed by the tenth decade.

6. How, and to What Degree, Should Forest Scenic Values be Protected through Visual Resource Management?

Appendix I, Table I-41 (D1) shows the number of acres in each VQO category by Management Area These show slight differences due to the way FORPLAN selected acres for timber harvest, however, the viewsheds allocated are the same as for Alternatives B and D

7. How Should Wildlife Habitats on the Forest be Managed?

Similar to Alternative D except the higher harvest level would result in slightly higher carrying capacity for big game, and the capital investment level would be approximately $56,000 per year prescribed to complete an average of 191 structural improvements and treat about 449 acres

Appendix I, Table I-42 (D1) shows the variety of land allocations that contribute to overall wildlife habitat diversity

ALTERNATIVE E

ALTERNATIVE E

GOALS

Alternative E emphasizes the aesthetic values of the Forest by promoting the production of goods and services that do not necessarily have established market prices (e g , soil, water, fish, recreation, and scenery).

DESIGN

Land allocations and management decisions in undeveloped areas generally favor preservation Areas with special resource values such as sensitive plants, unique ecosystems, wildlife habitat, and backcountry recreation opportunities would be allocated to Management Areas which have no programmed timber harvest. Timber would be produced on remaining lands after other resource objectives have been met No hardwood conversion would be allowed. The wildlife MR's are included

The full range of inventoried VQO's would be allocated in all viewsheds. The riparian areas would not have a programmed timber harvest, Minimum Level prescription (Prescription M) applies to all riparian areas.

OVERVIEW

Alternative design specifications would have the following results Timber management activities would be intensive and apparent to the Forest visitor on the roaded areas of the Forest However, fewer areas would be roaded than in any other alternatives, except M. Primitive and Semi-primitive Non-motorized recreation experiences would be emphasized. Many new trails would be constructed in the Wilderness and Backcountry Recreation Management Areas Developed recreation opportunities would also increase substantially over what they are today.

Forest visitors would find natural and near-natural landscapes throughout much of the Forest. All of the VQO's would be met or exceeded in this alternative.

Approximately 62 percent of the Forest's presently standing mature and old-growth would be protected in this alternative Biological diversity would be promoted through· (1) allocations to maintain older seral stages and natural processes (primarily in Wilderness, Research Natural Areas, Backcountry Recreation, Botanical, Supplemental Resource and Designated Wildlife Habitat Management Areas), and (2) management direction (Standards and Guidelines). Wildlife populations dependent on mature or old-growth habitat would be maintained at approximately three times their minimum levels Big-game hunting opportunities would decline from what they are today.

Fish habitat would be enhanced through the allocation of riparian areas to Riparian Prescription M (no timber harvest programmed), and through capital investments

1. How Much Timber Should the Forest Produce?

Alternative E would result in the average annual production of 16.2 MMCF (90 MMBF) of chargeable sawtimber volume plus one percent chargeable salvage during the first decade. Governed by a policy of nondeclining flow, average annual sale offerings would gradually increase in subsequent decades to reach the LTSY of 32.2 MMCF. Harvest would generally occur when the timber stands reach CMAI (approximately 100 years).

Timber production would be supported by a land base of 287,000 acres (selected suitable). No standing hardwoods are included in the timber base in this alternative Final harvest would occur on an average of 2,890 acres per year during the first decade, decreasing to 2,560 acres per year by the fifth decade. Appendix I, Table I-43 (E) displays the Management Areas that provide timber management opportunities.

2. How Much Old-Growth Forest Should be Preserved?

Alternative E is designed to reserve 273,070 acres having mature and old-growth forest characteristics With the exception of the reserved areas displayed by Management Area in Appendix I, Table I-44 (E), existing mature and old-growth would be metered out to accommodate the harvest sale schedule Of the 443,000 acres of mature and old-growth that currently exist, 414,100 would remain at the end of the first decade of harvest activity. Except for isolated tracts, riparian, and other small areas, all unprotected mature and old-growth would be removed by the tenth decade

3. How Can the Forest's Fish Habitat, Water Quality and Soil Productivity be Maintained or Improved?

Fish habitat would be improved through land allocations that minimize soil disturbance and reduce summer water temperatures Allocation of 642,349 acres (59 percent of the Forest) to Management Areas 1-9 which limit site-disturbing activity and preclude programmed timber harvest would protect fish and watershed values in these areas In other areas, these values would be protected thought the application of Standards and Guidelines and BMP's. The impacts of timber harvest would be mitigated by distributing activities through time and space. This is represented in the alternative design by limiting timber harvest in the model with constraints ranging from 9 to 13 percent per decade specific to each planning basin

Land characterized by riparian vegetation would be managed to improve water quality and fishery habitat. No harvest activity would occur on riparian vegetation surrounding Class I, II, and III streams in any basin. Land surrounding all 30 rivers and creeks with exceptional salmon and steelhead rearing capabilities would be allocated to the Supplemental Resource Management Area where no programmed timber management activities would occur Forest wide, approximately 175,493 acres of riparian vegetation would be protected in its existing state. Appendix I, Table I-45 (E) shows how riparian habitat would be affected by the various Management Area designations.

A low level of capital investment is proposed in this alternative. Approximately $388,300 per year would be spent on fish, soil and water resource projects.

4. How, and to What Extent, Should Lands In and Adjacent to River Corridors be Managed to Protect, Preserve, and Enhance Wild and Scenic River Attributes?

Land allocations to a variety of Management Areas would protect Wild and Scenic River attributes. All viewsheds surrounding the Wild and Scenic Rivers would have a natural or near-natural appearance as lands would be managed to meet their inventoried VQO's. Land within 1/4 mile of either side of the Chetco, North Fork Smith, and Elk Rivers would be managed under two Management Areas. The interior 1/8 mile would be allocated to the Supplemental Resource Management Area; the remaining land would be allocated to their respective Scenic/Recreation River Management Area

Appendix I, Table I-46 (E) shows the number of acres within each Management Area which directly contribute to preservation and enhancement of Wild and Scenic River attributes Those that contribute to maintenance of water quality and visual quality are indicated.

5. How Should Sensitive Plant Resources be Managed?

The variety of sensitive plants on the Forest would be managed through a number of land allocations designed with specific protection standards Each Management Area has Standards and Guidelines (in addition to Forest-wide Standards and Guidelines) designed to protect sensitive plants endemic to the Forest (see LRMP, Chapter IV). RNA's and Botanical Management Areas would provide special emphasis to the preservation of ecotypes and sensitive plants Four new RNA's are proposed in addition to the three existing areas (for a total of 4,756 acres) resulting in the protection of 25 ecotypes. Sixteen new Botanical areas would be recommended in addition to the three that presently exist for a total of 27,726 acres

The distribution (percentages) of sensitive plant habitat in the various Management Areas is indicated in Appendix I, Table I-47 (E). Specific descriptions and attributes of each individual site are included in the FEIS, Appendix F

6. How, and to What Degree, Should Forest Scenic Values be Protected through Visual Resource Management?

Visual management objectives would be achieved by designing activities to meet VQO's on the entire Forest All 44 viewsheds considered would be governed by their respective inventoried VQO's.

Appendix I, Table I-48 (E) shows the number of acres in each VQO category by Management Area. Approximately 704,686 acres would have an unmodified appearance (Preservation) While management activities would be evident, but visually subordinate (Partial Retention) on 116,281 acres, another 25,814 acres would be managed where activities are not evident to the casual Forest visitor (Retention) The remaining area (245,521 acres) would be in Modification where management activities may dominate the characteristic landscape, but resemble naturally occurring patterns when viewed in the background

7. How Should Wildlife Habitats on the Forest be Managed?

The combination of land allocations and capital expenditures prescribed in this alternative provides a wide range of effective habitat conditions. Among the significant land allocations are all the Special Wildlife Sites, and the four Supplemental Resource Management Areas with high wildlife value (Fishhook Peak, Morris Rodgers Creek, Pebble Hill, and Windy Valley) Designated Wildlife Habitat that meets MR's is prescribed along with an additional 18,086 acres of habitat that occur in small blocks and serve as "stepping stones" between a number of Designated Wildlife Habitat areas. In total, over 273,070 acres of mature and old-growth forest wildlife habitat would be maintained

Appendix I, Table I-49 (E) shows a variety of land allocations that contribute to overall wildlife habitat diversity. Standing dead trees (snags) in areas managed for timber production would provide habitat capable of sustaining at least 60 percent of the maximum population of cavity-nesting birds Approximately 58,260 acres of prime bald eagle and osprey habitat would be provided along rivers and streams that have a protected status Approximately 26 percent of the Forest (287,000 acres) would provide an adequate combination of cover and forage for deer to sustain an average herd of 21,600 animals for the first five decades.

Capital investments for wildlife habitat improvements would result in higher carrying capacity for many species. Approximately $56,000 per year would be prescribed to complete an average of 191 structural improvements and treat about 449 acres

8. How Will Management Direction Affect Recreation Opportunities in the Wilderness and Unroaded Areas?

Primitive and Semi-primitive Non-motorized recreation opportunities would be provided principally through allocation to Backcountry Recreation Management Areas, and in existing Wildernesses. Primitive and Semi-primitive recreational capacity would be increased in the Backcountry Recreation and Wilderness areas by reconstructing 18 1 miles ($25,000) of trail during the first decade. Overall, 343,498 acres of unroaded Primitive and Semi-primitive recreation opportunities would be provided on the Forest. Appendix I, Table I-50 (E) shows the number of acres in each Management Area that provide unroaded Primitive and Semi-primitive recreational opportunities.

9. How Should Mineral Resources of the Forest be Developed in Coordination With Management of Other Resources?

Mineral exploration and development would be facilitated by retaining 75 percent of the Forest (824,579 acres) in an accessible category. Approximately 93 percent of accessible acres (765,086 acres) have low to moderate restrictions which would not limit mining activities. Approximately seven percent (59,493 acres) have access restrictions in the high category which could make many types of mining activity uneconomical. Appendix I, Table I-51 (E) displays the level of restriction affecting acres within each Management Area. Specific Standards and Guidelines affecting mineral exploration and development are defined in the LRMP, Chapter IV, for each Management Area.

ALTERNATIVE G

ALTERNATIVE G

GOALS

Alternative G emphasizes the protection and enhancement of the Forest's nontimber resources. The alternative is designed to encourage the health and productivity of the Forest's water-related resources, particularly rivers and streams associated with the Illinois River drainage With the objective of maintaining the area's reputation for natural beauty and increasing recreation-oriented industries, Alternative G would preserve many existing unroaded areas and favors management governed by high VQO's.

DESIGN

Timber production would be at a moderate level. A limited amount of hardwood conversion would be allowed The wildlife MR's are included. A number of areas with special resource values such as sensitive plants, unique ecosystems, wildlife habitat, and backcountry recreation opportunities would be allocated to Management Areas which have no programmed timber harvest The full range of inventoried VQO's would be allocated for all viewsheds Riparian areas in the timber base for all planning basins would be managed under Prescription C

OVERVIEW

Alternative design specifications would have the following results Timber management activities would be intensive and apparent to the Forest visitor on the roaded areas of the forest Much of the Forest, with the exception of existing Wilderness and areas without programmed timber harvest, would eventually be roaded and developed Motorized recreation opportunities would be enhanced, as roads are constructed for timber management. Non-motorized recreation experiences would also be enhanced through trail construction in the Wilderness and Backcountry Recreation Management Areas. Forest visitors would find natural and near-natural landscapes throughout much of the Forest All of the VQO's would be met or exceeded in this alternative

Approximately 57 percent of the Forest's presently standing mature and old-growth would be protected in this alternative. Biological diversity would be promoted through: (1) allocations to maintain older seral stages and natural processes (primarily in Wilderness, RNA's, Backcountry Recreation, Botanical, Supplemental Resource and Designated Wildlife Habitat Management Areas), and (2) management direction (Standards and Guidelines) Wildlife populations dependent on mature or old-growth habitat would be maintained at approximately three times their minimum levels. Big-game hunting opportunities would decline from what they are today. Fish habitat would be enhanced through the allocation of all riparian areas to Riparian Prescription C.

1. How Much Timber Should the Forest Produce?

Alternative G would result in the average annual production of 20 5 MMCF (114 MMBF) of chargeable sawtimber volume plus one percent chargeable salvage during the first decade. Governed by a policy of nondeclining flow, average annual sale offerings would gradually increase in subsequent decades to reach the LTSY of 38 7 MMCF Harvest would generally occur when the timber stands reach CMAI (approximately 100 years)

Timber production would be supported by a land base of 406,000 acres (selected suitable), which includes 24,000 acres of standing hardwood Hardwood conversion would be limited to no more than 4,000 acres per decade, subject to market conditions. Final harvest would occur on an average of 3,495 acres per year during the first decade, decreasing to 3,095 acres per year by the fifth decade. Appendix I, Table I-52 (G) displays the Management Areas that provide timber management opportunities

2. How Much Old-Growth Forest Should be Preserved?

Alternative G is designed to reserve 253,966 acres having mature and old-growth forest characteristics With the exception of the reserved areas displayed by Management Area in Appendix I, Table I-53 (G), existing mature and old-growth would be metered out to accommodate the harvest sale schedule. Of the 443,000 acres of mature and old-growth that currently exist, 407,510 will remain at the end of the first decade of harvest activity. Except for isolated tracts, riparian, and other small areas, most unprotected mature and old-growth will be removed by the tenth decade.

3. How Can the Forest's Fish Habitat, Water Quality and Soil Productivity be Maintained or Improved?

Fish habitat would be improved through land allocations that minimize soil disturbance and reduce summer water temperatures Watershed conditions would be maintained in pristine areas and improved in those areas presently degraded Allocation of 557,681 acres (51 percent of the Forest) to Management Areas 1-9 which limit site-disturbing activity and preclude programmed timber harvest would protect fish and watershed values in those areas In other areas, these values would be protected thought the application of Standards and Guidelines and BMP's The impacts of timber harvest would be mitigated by distributing activities through time and space This is represented in the alternative design by limiting timber harvest in the model with constraints ranging from 9 to 13 percent per decade specific to each planning basin

Land characterized by riparian vegetation would be managed to improve water quality and fishery habitat Vegetative disturbance in the riparian area in the timber base would be controlled by Riparian Prescription C. Prescription C would be applied on all Class I, II, and III streams; it is designed to produce a two-degree decrease in summer water temperature by the third decade Land surrounding all 30 rivers and creeks with exceptional salmon and steelhead rearing capabilities would be allocated to the Supplemental Resource Management Area with no programmed timber harvest Appendix I, Table I-54 (G) shows how riparian habitat would be affected by the various Management Area designations.

A low level of capital investment is proposed since most fish habitat needs would be satisfied through land allocations. Approximately $429,200 per year would be spent on fish, soil and water resource projects.

4. How, and to What Extent, Should Lands In and Adjacent to River Corridors be Managed to Protect, Preserve, and Enhance Wild and Scenic River Attributes?

Land allocations to a variety of Management Areas would protect Wild and Scenic River attributes. All viewsheds surrounding the rivers would have a natural or near-natural appearance as lands would be managed to meet their inventoried VQO's Land within 1/4 mile of either side of the Chetco, North Fork Smith, and Elk Rivers would be managed under two Management Areas. The interior 1/8 mile would be allocated to the Supplemental Resource Management Area, while the remaining land would be allocated to their respective Recreation and Scenic Management Area

Appendix I, Table I-55 (G) shows the number of acres within each Management Area which directly contribute to preservation and enhancement of Wild and Scenic River attributes. Those that contribute to maintenance of water quality and visual quality indicated

5. How Should Sensitive Plant Resources be Managed?

The variety of sensitive plants on the Forest would be managed through a number of land allocations designed with specific protection standards Each Management Area has Standards and Guidelines (in addition to Forest-wide Standards and Guidelines) designed to protect sensitive plants endemic to the Forest (see LRMP, Chapter IV). RNA's and Botanical Management Areas would provide special emphasis to the preservation of ecotypes and sensitive plants Four new RNA's are proposed in addition to the three

existing areas (for a total of 4,756 acres) resulting in the protection of 25 ecotypes. Twenty-five new Botanical areas would be recommended for addition to the three that presently exist for a total of 39,001 acres.

The distribution (percentages) of sensitive plant habitat in the various Management Areas is indicated in Appendix I, Table I-56 (G) Specific descriptions and attributes of each individual site are included in the FEIS, Appendix F.

6. How, and to What Degree, Should Forest Scenic Values be Protected through Visual Resource Management?

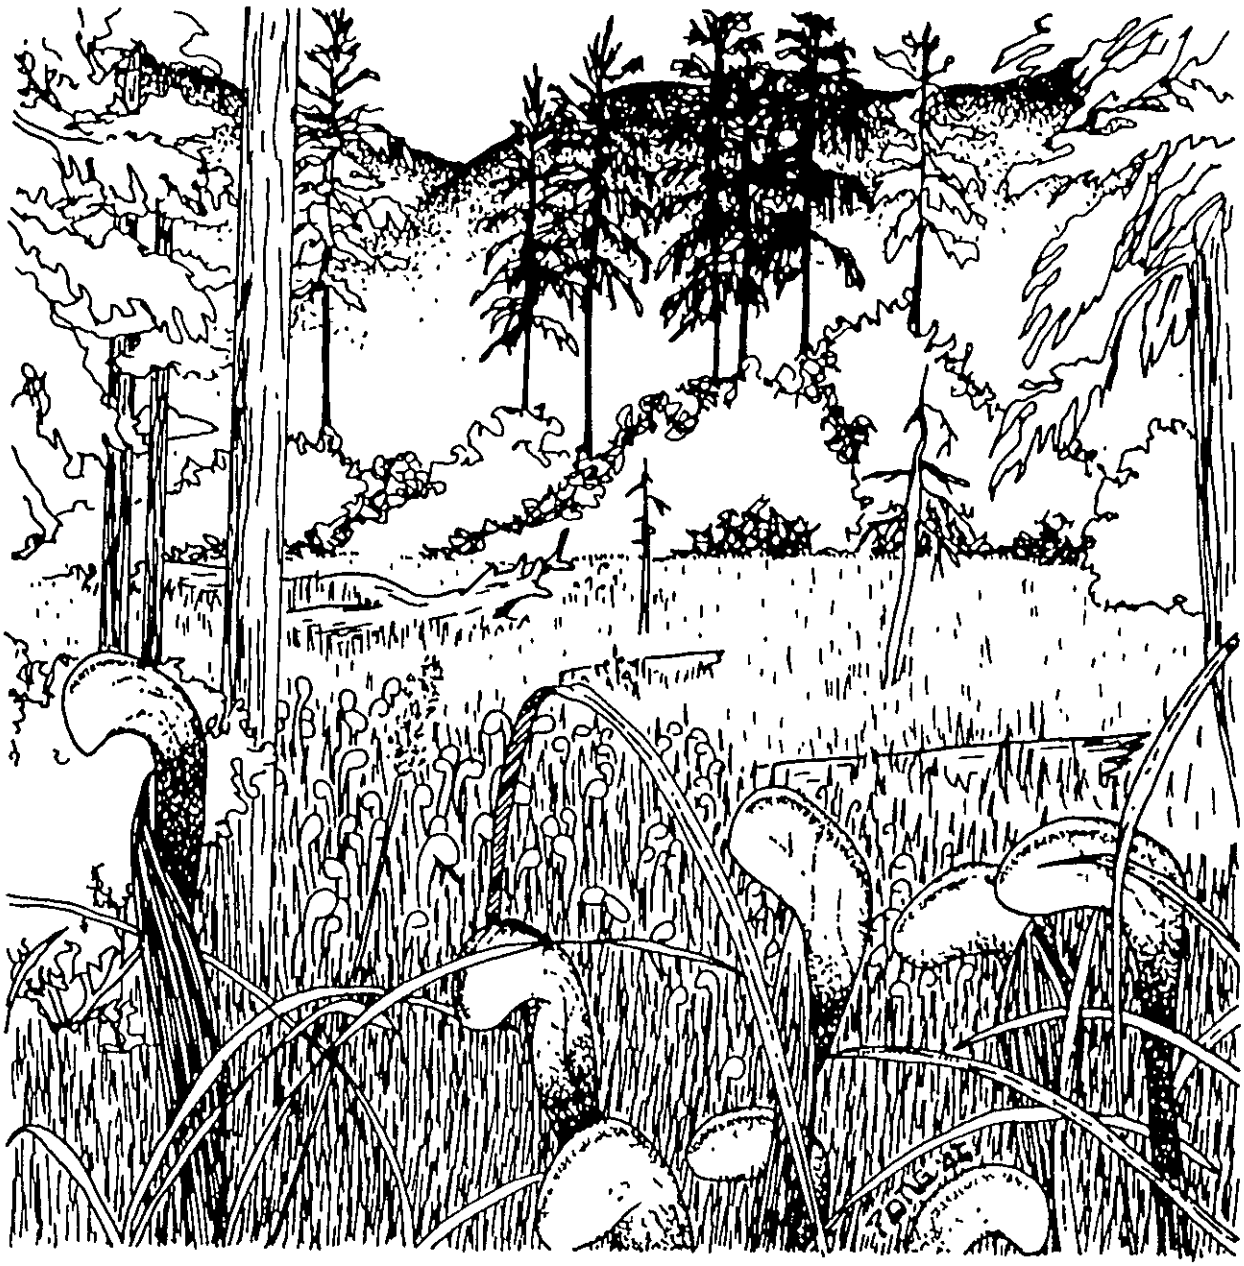
Visual management objectives would be achieved by designing activities to meet the VQO's on the entire Forest. All 44 viewsheds considered would be governed by their respective inventoried VQO's.

Appendix I, Table I-57 (G) shows the number of acres in each VQO category by Management Area Over 584,952 acres would have an unmodified appearance (Preservation) While management activities would be evident, but visually subordinate (Partial Retention) on 164,680 acres, another 31,309 acres would be managed where activities are not evident to the casual Forest visitor (Retention). The remaining area (311,361 acres) would be in Modification where management activities may dominate the characteristic landscape, but resemble naturally occurring patterns when viewed in the background

7. How Should Wildlife Habitats on the Forest be Managed?

The combination of land allocations and capital expenditures prescribed in this alternative would provide a wide range of effective habitat conditions Among the significant land allocations are all the Special Wildlife Sites (8,640 acres) and the four Supplemental Resource areas with high wildlife value (Fishhook Peak, Morris Rodgers Creek, Pebble Hill, and Windy Valley) Designated Wildlife Habitat Management Areas that exceed MR's by 57,000 acres are proposed along with an additional 18,086 acres of habitat that occur in small blocks and serve as "stepping stones" between individual Designated Wildlife Habitat Areas In total, 253,966 acres of mature and old-growth forest wildlife habitat would be maintained.

Appendix I, Table I-58 (G) shows a variety of land allocations that would contribute to overall wildlife habitat diversity Standing dead trees (snags) in areas managed for timber production would provide habitat capable of sustaining at least 60 percent of the maximum population of cavity-nesting birds. Approximately 58,260 acres of prime bald eagle and osprey habitat would be provided along rivers and streams that have a protected status. Approximately 37 percent of the Forest (406,000 acres) would provide an adequate combination of cover and forage for deer to sustain an average herd of 24,500 animals for the first five decades



Capital investments for wildlife habitat improvements would result in higher carrying capacity for many species Approximately $56,000 per year would be prescribed to complete an average of 191 structural improvements and treat about 449 acres.

8. How Will Management Direction Affect Recreation Opportunities in the Wilderness and Unroaded Areas?

Primitive and Semi-primitive Non-motorized recreation opportunities would be provided principally through allocation to Backcountry Recreation Management Areas, and in existing Wildernesses. Primitive and Semi-primitive recreational capacity would be increased in the Backcountry Recreation and Wilderness areas by constructing 21 5 miles ($336,000) and reconstructing 7.0 miles ($59,500) of trail during the first decade. Overall, 342,490 acres of unroaded Primitive and Semi-primitive recreation opportunities would be provided on the Forest Appendix I, Table I-59 (G) shows the number of acres in each Management Area that provide unroaded Primitive and Semi-primitive recreational opportunities.

9. How Should Mineral Resources of the Forest be Developed In Coordination With Management of Other Resources?

Mineral exploration and development would be facilitated by retaining 75 percent of the Forest (824,343 acres) in an accessible category Approximately 89 percent of accessible acres (732,177 acres) have low to moderate restrictions which would not limit mining activities Approximately 11 percent (92,166 acres) have access restrictions in the high category which could make many types of mining activity uneconomical. Appendix I, Table I-60 (G) displays the level of restriction affecting acres within each Management Area Specific Standards and Guidelines affecting mineral exploration and development are defined in the LRMP, Chapter IV, for each Management Area

ALTERNATIVE K

ALTERNATIVE K

GOALS

The purpose of Alternative K is to address the desires of a wide range of user groups and interests, while continuing to supply goods and services vital to the maintenance of local and National economic development Achievement of the objective requires that the Forest capitalize on the multi-product nature of land allocations that minimize tradeoffs between goods and services

DESIGN

Timber production would be at a moderate to high level. A moderate amount of hardwood conversion would be allowed. The wildlife MR's are included A number of areas with special resource values such as sensitive plants, unique ecosystems, wildlife habitat, and backcountry recreation opportunities would be allocated to Management Areas which have no programmed timber harvest

The full range of inventoried VQO's would be allocated in the high priority viewsheds Some of the moderate priority viewsheds would have the inventoried Retention areas allocated to Partial Retention. The prescription for riparian areas in the timber base would be Prescription C in one planning basin, the remaining planning basins would be allocated to Prescription B.

OVERVIEW

Alternative design specifications would have the following results. Timber outputs would be sustained at approximately 90 percent of the current level Much of the Forest, with the exception of existing Wilderness and areas without programmed timber harvest, would eventually be roaded and developed Motorized recreation opportunities would be enhanced, as roads are constructed for timber management. Non-motorized recreation experiences would also be enhanced through trail construction in the Wilderness and Backcountry Recreation Management Areas. Viewsheds most important to recreational use would be maintained in a natural or near-natural condition

Approximately 42 percent of the Forest's presently standing mature and old-growth would be protected in this alternative Biological diversity would be promoted through: (1) allocations to maintain older seral stages and natural processes (primarily in Wilderness, RNA's, Backcountry Recreation, Botanical, Supplemental Resource and Designated Wildlife Habitat Management Areas); and (2) management direction (Standards and Guidelines). Wildlife populations dependent on mature or old-growth habitat would be maintained above viable levels Big-game hunting opportunities would be similar to those currently available Fish habitat would be enhanced through the allocation of one high value fisheries basin to Riparian Prescription C, and through a high level of capital investments

1. How Much Timber Should the Forest Produce?

Alternative K would result in the average annual production of 27 8 MMCF (155 MMBF) of chargeable sawtimber volume plus one percent chargeable salvage during the first decade. Governed by a policy of nondeclining flow, average annual sale offerings would gradually increase in subsequent decades to reach the LTSY of 48 8 MMCF. Harvest would generally occur when the timber stands reach CMAI (approximately 100 years).

Timber production would be supported by a land base of 529,000 acres (selected suitable), which includes 34,838 acres of standing hardwood Hardwood conversion would be limited to no more than 7,500 acres per decade, subject to market conditions Final harvest would occur on an average of 4,520 acres per year during the first decade, decreasing to 4,217 acres per year by the fifth decade Appendix I, Table I-61 (K) displays the Management Areas that provide timber management opportunities

2. How Much Old-Growth Forest Should be Preserved?

Alternative K is designed to reserve 184,690 acres having mature and old-growth forest characteristics With the exception of the reserved areas displayed by Management Area in Appendix I, Table I-62 (K), existing mature and old-growth would be metered out to accommodate the harvest sale schedule Of the 443,000 acres of mature and old-growth that currently exist, 392,230 would remain at the end of the first decade of harvest activity. Except for isolated tracts, riparian, and other small areas, all unprotected mature and old-growth would be removed by the tenth decade

3. How Can the Forest's Fish Habitat, Water Quality and Soil Productivity be Maintained or Improved?

Fish habitat would be improved through land allocations that minimize soil disturbance and reduce summer water temperatures Watershed conditions would be maintained in pristine areas and improved in those areas presently degraded Allocations of 375,380 acres (34 percent of the Forest) to Management Areas 1-9 which limit site-disturbing activity and preclude programmed timber harvest would protect fish and watershed values in those areas. In other areas, these values would be protected though the application of Standards and Guidelines and BMP's The impacts of timber harvest would be mitigated by distributing activities through time and space This is represented in the alternative design by limiting timber harvest in the model with constraints ranging from 9 to 13 percent per decade specific to each planning basin

Land characterized by riparian vegetation would be managed to improve water quality and fishery habitat Vegetative disturbance in the riparian area in the timber base would be controlled by Riparian Prescriptions B or C Prescription C would be applied on the Elk/Sixes watershed basin; it is designed to produce a two-degree decrease in summer water temperature by the third decade. Riparian prescription B, designed to maintain existing water temperatures, is applied in the remaining basins Appendix I, Table I-63 (K) shows how riparian habitat would be affected by the various Management Area designations.

A high level of capital investment is proposed in this alternative Approximately $589,800 per year would be spent on fish, soil and water resource projects.

4. How, and to What Extent, Should Lands In and Adjacent to River Corridors be Managed to Protect, *Preserve, and Enhance Wild and Scenic River Attributes?*

Land allocations to a variety of Management Areas would protect Wild and Scenic River attributes in both established and eligible Wild and Scenic Rivers. All viewsheds surrounding Rogue and Illinois Wild and Scenic Rivers would have a natural or near-natural appearance as lands would be managed to meet their inventoried VQO's Land within 1/8 mile of either side of the Chetco and North Fork Smith Rivers would have allocations to minimize site-disturbing activities and maintain river values. Viewsheds surrounding the rivers would not be managed to meet their inventoried VQO's, except for Partial Retention areas around the Chetco River

Appendix I, Table I-64 (K) shows the number of acres within each Management Area which directly contribute to preservation and enhancement of Wild and Scenic River attributes. Those that contribute to maintenance of water quality and visual quality are indicated.

5. How Should Sensitive Plant Resources be Managed?

The variety of sensitive plants on the Forest would be managed through a number of land allocations designed with specific protection standards Each Management Area has Standards and Guidelines (in addition to Forest-wide Standards and Guidelines) designed to protect sensitive plants endemic to the Forest (see LRMP, Chapter IV) RNA's and Botanical Management Areas would provide special emphasis to the preservation of ecotypes and sensitive plants Four new RNA's are proposed in addition to the three

existing areas (for a total of 4,756 acres) resulting in the protection of 25 ecotypes. Eight new Botanical areas would be recommended for addition to the three that presently exist for a total of 10,689 acres.

The distribution (percentages) of sensitive plant habitat in the various Management Areas is indicated in Appendix I, Table I-65 (K) Specific descriptions and attributes of each individual site are included in the FEIS, Appendix F

6. How, and to What Degree, Should Forest Scenic Values be Protected through Visual Resource Management?

Visual management objectives would be achieved by designing activities to meet VQO's on 560,822 acres Nine viewsheds (of the 44 considered) would be governed by their respective inventoried VQO's, four of which encompass heavily used recreation travel corridors: the Upper Illinois, Rogue-Illinois, Oregon Caves, and Highway 199

Appendix I, Table I-66 (K) shows the number of acres in each VQO category by Management Area Approximately 402,268 acres would have an unmodified appearance (Preservation). While management activities would be evident, but visually subordinate (Partial Retention) on 145,436 acres, another 15,118 acres would be managed where activities are not evident to the casual Forest visitor (Retention) The remaining area (529,480 acres) would be in Modification where management activities may dominate the characteristic landscape, but resemble naturally occurring patterns when viewed in the background

7. How Should Wildlife Habitats on the Forest be Managed?

The combination of land allocations and capital expenditures prescribed in this alternative would provide a wide range of effective habitat conditions. Among the significant land allocations would be all the Special Wildlife Sites, and three of the four Supplemental Resource areas with high wildlife value (Fishhook Peak, Morris Rodgers Creek, Pebble Hill, and Windy Valley) Designated Wildlife Habitat Management Areas would be allocated to meet MR's for wildlife inhabiting mature and old-growth forest along with an additional 18,086 acres of habitat that occur in small blocks and serve as "stepping stones" between individual Designated Wildlife Habitat Management Areas. In total, 184,690 acres of mature and old-growth forest wildlife habitat would be maintained

Appendix I, Table I-67 (K) shows a variety of land allocations that contribute to overall wildlife habitat diversity. Standing dead trees (snags) in areas managed for timber production would provide habitat capable of sustaining at least 60 percent of the maximum population of cavity-nesting birds. Approximately 52,062 acres of prime bald eagle and osprey habitat would be provided along rivers and streams that have a protected status Approximately 48 percent of the Forest (529,000 acres) would provide an adequate combination of cover and forage for deer to sustain an average herd of 28,000 animals for the first five decades.

Capital investments for wildlife habitat improvements would result in higher carrying capacity for many species Approximately $56,000 per year would be prescribed to complete an average of 191 structural improvements and treat about 449 acres.

8. How Will Management Direction Affect Recreation Opportunities in the Wilderness and Unroaded Areas?

Primitive and Semi-primitive Non-motorized recreation opportunities would be provided principally through allocation to Backcountry Recreation Management Areas, and capital investments in existing Wildernesses. Primitive and Semi-primitive recreational capacity would be increased in the Backcountry Recreation and Wilderness areas by constructing 15 0 miles ($255,500) and reconstructing 7.0 miles ($59,500) of trail during the first decade Overall, 269,500 acres of unroaded Primitive and Semi-primitive

recreation opportunities would be provided on the Forest. Appendix I, Table I-68 (K) shows the number of acres in each Management Area that would provide unroaded Primitive and Semi-primitive recreational opportunities

9. How Should Mineral Resources of the Forest be Developed in Coordination With Management of Other Resources?

Mineral exploration and development would be facilitated by retaining 76 percent of the Forest (826,109 acres) in an accessible category. Approximately 93 percent of accessible acres (768,115 acres) have low to moderate restrictions which would not limit mining activities Approximately seven percent (57,994 acres) have access restrictions in the high category which could make many types of mining activity uneconomical. Appendix I, Table I-69 (K) displays the level of restriction affecting acres within each Management Area. Specific Standards and Guidelines affecting mineral exploration and development are defined in the LRMP, Chapter IV, for each Management Area

ALTERNATIVE M

ALTERNATIVE M

GOALS

Alternative M emphasizes preservation and natural processes rather than human use of the Forest's resources It would preserve the remaining natural areas on the Forest, and emphasizes old-growth wildlife habitat, and the preservation of old-growth timber stands

DESIGN

Timber production would be subordinate to other resource allocations Areas managed for timber production would have a minimum rotation length of 250 years. New access roads would not be built No hardwood conversions would be allowed. Riparian areas would not have programmed timber harvest. The wildlife MR's are included. Areas with special resource values such as sensitive plants, unique ecosystems, wildlife habitat, and backcountry recreation opportunities would be allocated to Management Areas which have no programmed timber harvest The full range of inventoried VQO's would be allocated in all viewsheds

OVERVIEW

Alternative design specifications would have the following results Management activities would be much less apparent to the Forest visitor in this alternative than in any of the other alternatives Forest visitors would find natural landscapes throughout all of the Forest All of the VQO's would be met or exceeded. Less of the Forest would be accessible by vehicle, as some existing roads would be closed to protect wildlife, and no new roads would be constructed All of the existing unroaded and undeveloped areas would remain in a roadless condition

Trees would be harvested at an average age of 250 years, instead of 80-100 years as in the other alternatives. Forest timber outputs would be less than 20 percent of what they are today. Approximately 25 percent more old-growth timber would exist at the end of the planning period (fifteenth decade) than is in existence now

Recreation would not be emphasized Some new trails would be constructed in the Kalmiopsis and Wild Rogue Wildernesses No trail construction would occur in the unroaded areas. Developed recreation opportunities would be decreased substantially over what they are today, as the little-used sites would be closed

Approximately 65 percent of the Forest's presently standing mature and old-growth would be protected in this alternative Wildlife populations dependent on mature or old-growth habitat would be maintained at almost four times their minimum levels Big-game hunting opportunities would decline by almost 60 percent from what they are today Stream temperatures would be cooler, and fish habitat would be enhanced, although access for fishing would be more limited

1. How Much Timber Should the Forest Produce?

Alternative M would result in the average annual production of 6 1 MMCF (34 MMBF) of chargeable sawtimber volume plus one percent chargeable salvage during the first decade Governed by a policy of nondeclining flow, average annual sale offerings would remain constant over the entire planning horizon Harvest would generally occur when the timber stands reach age 250

Timber production would be supported by a land base of 207,000 acres (selected suitable), which includes no acres of standing hardwood Final harvest would occur on an average of 754 acres per year during the first decade, increasing to 820 acres per year by the fifth decade Appendix I, Table I-70 (M) displays the Management Areas that provide timber management opportunities

2 How Much Old-Growth Forest Should be Preserved?

Alternative M is designed to reserve 289,633 acres displayed by Management Area in Appendix I, Table I-71 (M) having mature and old-growth forest characteristics Of the 443,000 acres of mature and old-growth that currently exist, 435,460 would remain at the end of the first decade of harvest activity With the long rotation, this alternative would reproduce stands with old-growth characteristics for a portion of their life span even in the areas with programmed timber harvest A total of 542,800 acres would exhibit old-growth characteristics by the end of the planning horizon due to maturation of such stands into an old-growth condition

3 How Can the Forest's Fish Habitat, Water Quality and Soil Productivity be Maintained or Improved?

Fish habitat would be improved through land allocations that minimize soil disturbance and reduce summer water temperatures. Watershed conditions would be maintained in pristine areas and improved in those areas presently degraded Allocations of 670,117 acres (61 percent of the Forest) to Management Areas 1-9 which limit site-disturbing activity and preclude programmed timber harvest would protect fish and watershed values in those areas In other areas, these values would be protected though the application of Standards and Guidelines and BMP's The impacts of timber harvest would be mitigated by distributing activities through time and space This is represented in the alternative design by limiting timber harvest in the model with constraints ranging from 9 to 13 percent per decade specific to each planning basin.

Land characterized by riparian vegetation would be managed to improve water quality and fishery habitat No harvest activity would occur on riparian vegetation surrounding Class I, II, and III streams in any basin Land surrounding all 30 rivers and creeks with exceptional salmon and steelhead rearing capabilities would be allocated to the Supplemental Resource Management Area where no programmed timber management activities would occur Forest wide, approximately 175,493 acres (100 percent) of riparian vegetation would be protected in its existing state. Appendix I, Table I-72 (M) shows how riparian habitat would be affected by the various Management Area designations

A low level of capital investment is proposed in this alternative since most fish habitat needs would be satisfied through land allocations Approximately $387,100 per year would be spent on fish, soil and water resource projects

4. How, and to What Extent, Should Lands In and Adjacent to River Corridors be Managed to Protect, Preserve, and Enhance Wild and Scenic River Attributes?

Land allocations to a variety of Management Areas would protect Wild and Scenic River attributes All viewsheds surrounding the rivers would have a natural or near-natural appearance as lands would be managed to meet or exceed their inventoried VQO's Land within 1/4 mile of either side of the Chetco, North Fork Smith, and Elk Rivers would be managed under two Management Areas, the interior 1/8 mile is allocated to a Supplemental Resource Management Area, while the remaining land would be allocated to the respective Scenic/Recreation River Management Area

Appendix I, Table I-73 (M) shows the number of acres within each Management Area which directly contribute to preservation and enhancement of Wild and Scenic River attributes Those that contribute to maintenance of water quality and visual quality are indicated.

5 How Should Sensitive Plant Resources be Managed?

The variety of sensitive plants on the Forest would be managed through a number of land allocations designed with specific protection standards Each Management Area has Standards and Guidelines (in addition to Forest-wide Standards and Guidelines) designed to protect sensitive plants endemic to the

Forest (see LRMP, Chapter IV). RNA's and Botanical Management Areas would provide special emphasis to the preservation of ecotypes and sensitive plants Four new RNA's are proposed in addition to the three existing areas (for a total of 4,756 acres) resulting in the protection of 25 ecotypes Twenty-five new Botanical areas would be recommended for addition to the three that presently exist for a total of 39,001 acres.

The distribution (percentages) of sensitive plant habitat in the various Management Areas is indicated in Appendix I, Table I-74 (M). Specific descriptions and attributes of each individual site are included in the FEIS, Appendix F.

6. How, and to What Degree, Should Forest Scenic Values be Protected through Visual Resource Management?

Visual management objectives would be achieved by designing to meet the inventoried VQO's on the entire Forest. All 44 viewsheds considered would be governed by their respective inventoried VQO's.

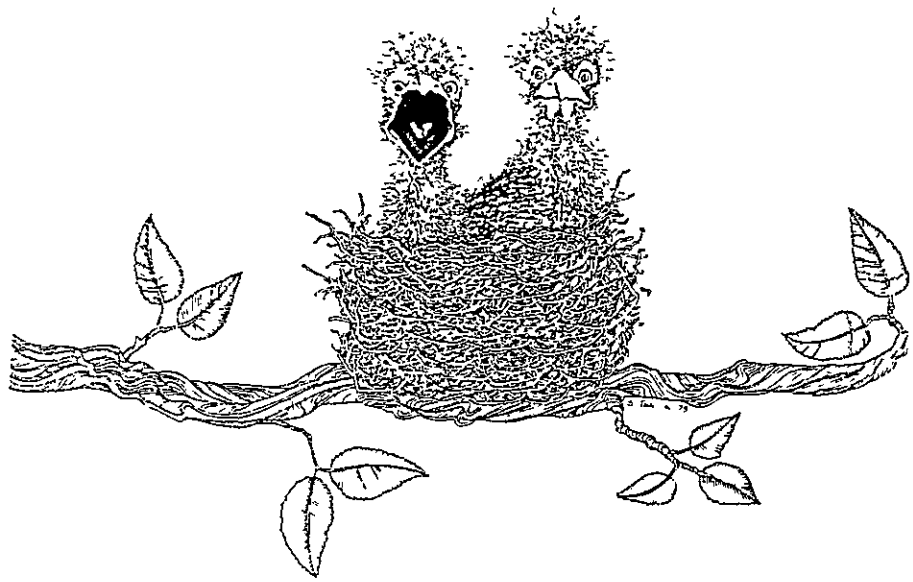
Appendix I, Table I-75 (M) shows the number of acres in each VQO category by Management Area. Approximately 726,256 acres would have an unmodified appearance (Preservation). While management activities would be evident, but visually subordinate (Partial Retention) on 109,448 acres, another 23,329 acres would be managed where activities are not evident to the casual Forest visitor (Retention). The remaining area (233,269 acres) would be in Modification where management activities may dominate the characteristic landscape, but resemble naturally occurring patterns when viewed in the background

7. How Should Wildlife Habitats on the Forest be Managed?

Among the significant land allocations would be all the Special Wildlife Sites (7,029 acres) and the four Supplemental Resource Areas with high wildlife value (Fishhook Peak, Morris Rodgers Creek, Pebble Hill, and Windy Valley). Designated Wildlife Habitat Management Areas that exceed MR's by 57,000 acres are proposed along with an additional 18,086 acres of habitat that occur in small blocks and serve as "stepping stones" between individual Designated Wildlife Habitat areas In total, 289,633 acres of mature and old-growth forest wildlife habitat would be maintained.

Appendix I, Table I-76 (M) shows a variety of land allocations that would contribute to overall wildlife habitat diversity. Standing dead trees (snags) in areas managed for timber production would provide habitat capable of sustaining at least 60 percent of the maximum population of cavity-nesting birds. Approximately 58,260 acres of prime bald eagle and osprey habitat would be provided along rivers and streams that have a protected status. Early seral stage habitat and big-game forage would decline substantially. Approximately 19 percent of the Forest (207,000 acres) would provide a combination of cover and forage for deer to sustain an average herd size of 16,700 animals for the first five decades

Capital investments for wildlife habitat improvements would result in higher carrying capacity for many species Approximately $56,000 per year would be prescribed to complete an average of 191 structural improvements and treat about 449 acres.



8 How Will Management Direction Affect Recreation Opportunities in the Wilderness and Unroaded Areas?

Primitive and Semi-primitive Non-motorized recreation opportunities would be provided principally through allocation to Backcountry Recreation Management Areas, and in existing Wildernesses. Primitive and Semi-primitive recreational capacity would be increased in the Backcountry Recreation and Wilderness areas by constructing 21 5 miles ($336,000) and reconstructing 7.0 miles ($59,500) of trail during the first decade. Overall, 347,400 acres of unroaded Primitive and Semi-primitive recreation opportunities would

be provided on the Forest. Appendix I, Table I-77 (M) shows the number of acres in each Management Area that provide unroaded Primitive and Semi-primitive recreational opportunities.

9. How Should Mineral Resources of the Forest be Developed In Coordination With Management of Other Resources?

Mineral exploration and development would be facilitated by retaining 75 percent of the Forest (824,271 acres) in an accessible category Approximately 91 percent of accessible acres (746,649 acres) have low to moderate restrictions which would not limit mining activities. Approximately 9 percent (77,622 acres) have access restrictions in the high category which could make many types of mining activity uneconomical. Appendix I, Table I-78 (M) displays the level of restriction affecting acres within each Management Area. Specific Standards and Guidelines affecting mineral exploration and development are defined in the LRMP, Chapter IV, for each Management Area

ALTERNATIVE S

ALTERNATIVE S

GOALS

The purpose of Alternative S is to achieve a balanced program of resource management, address the desires of a wide range of user groups and interests, maintain a healthy ecosystem for the future, and continue to supply goods and services vital to the maintenance of local and National economies Achievement of the objective requires that the Forest capitalize on the multi-product nature of land allocations that minimize tradeoffs between goods and services.

DESIGN

This alternative is designed in response to public input Innumerable suggestions from agencies, groups, and individuals have helped guide the design and various aspects of Alternative S

Timber production would be at a moderately high level. A limited amount of hardwood conversion would be allowed. Fertilizer would be applied to increase yields from specific areas managed for timber production. The wildlife MR's are included A number of areas with special resource values such as sensitive plants, unique ecosystems, wildlife habitat, and backcountry recreation opportunities would be allocated to Management Areas which have no programmed timber harvest

The full range of inventoried VQO's would be allocated in the high priority viewsheds Some of the moderate priority viewsheds would have the inventoried Retention areas allocated to Partial Retention. The prescription for riparian areas in the timber base in seven planning basins would be Prescription C; the remaining basins would be allocated to Prescription B

OVERVIEW

Alternative design specifications would have the following results Timber outputs would be sustained at approximately 95 percent of the current level A little over one-half of the Forest land area would eventually be roaded and developed Motorized recreation opportunities would be enhanced, as roads are constructed for timber management Non-motorized recreation experiences would also be enhanced through trail construction in the Wilderness and Backcountry Recreation Management Areas. Viewsheds most important to recreational use would be maintained in a natural or near-natural condition A high level of recreation capital investments reflects increased partnerships with counties, other local agencies and groups

Approximately 45 percent of the Forest's presently standing mature and old-growth would be protected in this alternative Biological diversity would be promoted through. (1) allocations to maintain older seral stages and natural processes (primarily in Wilderness, RNA's, Backcountry Recreation, Botanical, Supplemental Resource and Designated Wildlife Habitat Management Areas), and (2) management direction (Standards and Guidelines). Wildlife populations dependent on mature or old-growth habitat would be maintained above viable levels. Big-game hunting opportunities would be similar to those currently available.

Fish habitat would be enhanced through the allocation of high value fisheries to Riparian Prescription C, limitations on the amount of timber harvest within each watershed basin by decade; through capital investments, and soil and water Standards and Guidelines.

1. How Much Timber Should the Forest Produce?

Alternative S would result in the average annual production of 29 MMCF (162 MMBF) of chargeable sawtimber volume plus one percent chargeable salvage during the first decade. Governed by a policy of

nondeclining flow, average annual sale offerings would gradually increase in subsequent decades to reach the LTSY of 48 MMCF. Harvest would generally occur when the timber stands reach CMAI (approximately 100 years)

Timber production would be supported by a land base of 505,000 acres (selected suitable), which includes 34,624 acres of standing hardwood. Hardwood conversion would be limited to no more than 7,500 acres per decade, subject to market conditions. Final harvest would occur on an average of 4,790 acres per year during the first decade, decreasing to 4,268 acres per year by the fifth decade Appendix I, Table I-79 (S) displays the Management Areas that provide timber management opportunities

2. How Much Old-Growth Forest Should be Preserved?

Alternative S is designed to reserve 198,097 acres having mature and old-growth forest characteristics With the exception of the reserved areas displayed by Management Area in Appendix I, Table I-80 (S), existing mature and old-growth would be metered out to accommodate the harvest sale schedule. Of the 443,000 acres of mature and old-growth that currently exist, 391,758 would remain at the end of the first decade of harvest activity. By the tenth decade, all unprotected mature and old-growth would be removed.

3. How Can the Forest's Fish Habitat, Water Quality and Soil Productivity be Maintained or Improved?

Fish habitat would be improved through land allocations that minimize soil disturbance and reduce summer water temperatures Watershed conditions would be maintained in pristine areas and improved in those areas presently degraded. Allocation of 464,730 acres (43 percent of the Forest) to Management Areas 1-9 which limit site-disturbing activity and preclude programmed timber harvest would protect the fish and watershed values in those areas In other areas, these values would be protected though the application of Standards and Guidelines and BMP's The impacts of timber harvest would be mitigated by distributing activities through time and space This is represented in the alternative design by limiting timber harvest in the model with constraints ranging from 7 to 17 percent per decade specific to each planning basin.

Land characterized by riparian vegetation would be managed to improve water quality and fishery habitat. Vegetative disturbance in the riparian area within lands in the timber base would be controlled by Riparian Prescriptions B or C. Prescription C would be applied on the Elk/Sixes, Lobster, Lower Rogue, Indigo, Silver, Pistol, and Lower Chetco basins, it is designed to produce a two-degree decrease in summer water temperature by the third decade Riparian prescription B, designed to maintain existing water temperatures, is applied in the remaining basins. Appendix I, Table I-81 (S) shows how riparian habitat would be affected by the various Management Area designations

A high level of capital investment is proposed in this alternative Approximately $581,000 per year would be spent on fish, soil and water resource projects

4 How, and to What Extent, Should Lands In and Adjacent to River Corridors be Managed to Protect, Preserve, and Enhance Wild and Scenic River Attributes?

Land allocations to a variety of Management Areas would protect Wild and Scenic River attributes. All viewsheds surrounding the rivers would have a natural or near-natural appearance as lands would be managed to meet their inventoried VQO's

Both the North Fork Smith and Chetco Rivers have a 2-mile segment designated "Scenic" in the recently passed Act which are carried as "Wild" in this alternative. In each case the Forest reviewed classification and concluded areas meet "Wild" status (see FEIS, Chapter III, Wild and Scenic Rivers). This alternative protects the inventoried values in the interim until further analysis or river management plans indicate another course of action is appropriate

Appendix I, Table I-82 (S) shows the number of acres within each Management Area which directly contribute to preservation and enhancement of Wild and Scenic River attributes. Those that contribute to maintenance of water quality and visual quality are indicated.

5. How Should Sensitive Plant Resources be Managed?

The variety of sensitive plants on the Forest would be managed through a number of land allocations designed with specific protection standards Each Management Area has Standards and Guidelines (in addition to Forest-wide Standards and Guidelines) designed to protect sensitive plants endemic to the Forest (see LRMP, Chapter IV). Research Natural Areas (RNA's) and Botanical Management Areas would provide special emphasis to the preservation of ecotypes and sensitive plants. Four new RNA's are proposed in addition to the three existing areas (for a total of 4,754 acres) resulting in the protection of 25 ecotypes. Nineteen new Botanical areas would be recommended for addition to the three that presently exist for a total of 19,262 acres.

The distribution (percentages) of sensitive plant habitat in the various Management Areas is indicated in Appendix I, Table I-83 (S). Specific descriptions and attributes of each individual site are included in the FEIS, Appendix F.

6. How, and to What Degree, Should Forest Scenic Values be Protected through Visual Resource Management?

Visual management objectives would be achieved by designing to meet VQO's on 657,193 acres. Twelve viewsheds (of the 44 considered) would be governed by their respective inventoried VQO's, four of which encompass heavily used recreation travel corridors Management of Forest scenic values would be designed to complement high recreation use travel corridors and viewsheds The high priority viewsheds that would be managed to meet or exceed their respective inventoried visual objectives are: Upper Illinois, Rogue-Illinois, Oregon Caves, Highway 199, Game Lake, Bolan Lake, and Rough and Ready.

Appendix I, Table I-84 (S) shows the number of acres in each VQO category by Management Area. Approximately 487,540 acres would have an unmodified appearance (Preservation) While management activities would be evident, but visually subordinate (Partial Retention) on 148,397 acres, another 21,256 acres would be managed where activities are not evident to the casual Forest visitor (Retention). The remaining area (435,109 acres) would be in Modification where management activities may dominate the characteristic landscape, but resemble naturally occurring patterns when viewed in the background

7. How Should Wildlife Habitats on the Forest be Managed?

The combination of land allocations and capital expenditures prescribed in this alternative would provide a wide range of effective habitat conditions Designated Wildlife Habitat Management Areas would be allocated to meet MR's for wildlife inhabiting mature and old-growth forest All Special Wildlife Sites (Management Area 9) would be allocated, including more than 15,000 acres of mature and old-growth forest habitat These old-growth sites within Management Area 9 are small areas not suitable for timber management, they serve as "stepping stones" between a number of Designated Wildlife Habitat areas In total, 198,097 acres of mature and old-growth forest wildlife habitat would be maintained through the tenth decade.

Appendix I, Table I-85 (S) shows a variety of land allocations that contribute to overall wildlife habitat diversity. Standing dead trees (snags) in areas managed for timber production would provide habitat capable of sustaining at least 60 percent of the maximum population of cavity-nesting birds. Approximately 53,995 acres of prime bald eagle and osprey habitat would be provided along rivers and streams that have a protected status Approximately 46 percent of the Forest (505,000 acres) would provide an adequate

combination of cover and forage for deer to sustain an average herd of 28,500 animals for the first five decades

Capital investments for wildlife habitat improvements would result in higher carrying capacity for many species A minimum of $123,000 per year would be prescribed to complete an average of 418 structural improvements and treat about 983 acres.

8 How Will Management Direction Affect Recreation Opportunities in the Wilderness and Unroaded Areas?

Primitive and Semi-primitive Non-motorized recreation opportunities would be provided principally through allocation to Backcountry Recreation Management Areas, and in existing Wildernesses. The Backcountry Recreation Management Areas include: (1) Primitive and Semi-primitive recreation opportunities in non-motorized areas and (2) Semi-primitive recreation opportunities in areas with some primitive roads and trails which allow motorized use.

Primitive and Semi-primitive recreational capacity would be increased in the Backcountry Recreation and Wilderness areas by constructing 69.5 miles ($483,800) and reconstructing 24 miles ($109,500) of trail during the first decade. Overall, 293,500 acres of unroaded Primitive and Semi-primitive recreation opportunities would be provided on the Forest. Appendix I, Table I-86 (S) shows the number of acres in each Management Area that provide unroaded Primitive and Semi-primitive recreational opportunities.

9. How Should Mineral Resources of the Forest be Developed in Coordination With Management of Other Resources?

Mineral exploration and development would be facilitated by retaining 75 percent of the Forest (822,972 acres) in an accessible category Approximately 92 percent of accessible acres (754,532 acres) have low to moderate restrictions which would not limit mining activities. Approximately 8 percent (68,440 acres) have access restrictions in the high category which could make many types of mining activity uneconomical Appendix I, Table I-87 (S) displays the level of restriction affecting acres within each Management Area Specific Standards and Guidelines affecting mineral exploration and development are defined in the LRMP, Chapter IV, for each Management Area.

MANAGEMENT AREA ASSIGNMENTS

Table II-2 displays the proposed allocation of land to Management Areas under each alternative The Management Areas are numbered in order of increasing activity from the least ground disturbance and vegetation manipulation to the most. Where alternative design results in overlaps, the acres are assigned to the more restrictive Management Area (lower number) This precludes double counting and assures that each acre will have only one set of management direction

The organization of the alternatives in Table II-2 is also by the level of ground disturbance or vegetation manipulation expected The alternatives are arranged in order of decreasing selected suitable timber land This organization is intended to array the alternatives from the most vegetation manipulation to the least (i.e., from the least preservation to the most)

Table II-3 is a complete listing of all the "Special Areas" used in the assignment of lands to Management Areas during the alternative development process The concept of Special Areas was developed to identify logical areas with attributes of significance to specific resources that could be assigned to various management options through the range of alternatives. The definition of Special Areas runs parallel with the definition of Management Areas. The Special Areas are the existing or candidate areas that are used as the building blocks to create the land allocations by Management Area Each Special Area is a discrete unit that can be identified on the ground. Collections of these then become the Management Area which may be scattered over the Forest, but would be managed under the same management direction. This table can be used to determine the assignments of special areas that went into the formulation of each alternative.

With all of the potential land allocations and myriad of existing and candidate areas, overlaps between Special Areas are numerous Because of the system for dealing with overlaps (as mentioned above in the description of Table II-2 above), the acres listed for the assigned Special Areas will seldom add up to the Management Area acres. The General Forest (Management Area 14) is not a composite of specific areas, but consists of all land on the Forest not allocated for other purposes, and therefore does not have Special Areas. A full range of alternatives was developed by assigning differing levels and combinations of the special areas to be subtracted from General Forest. The table lists the total acreage of each Special Area and the acres within the area which would otherwise be tentatively suitable for timber production.

Specific recreation sites and trails on the Forest, and their treatment in the alternatives, are listed in Table II-4.

The following explanation of the table headings may facilitate the use of the table:

- "MA No " is the assigned Management Area number associated with the Special Areas that follow.

- "Name of MANAGEMENT AREA/Special Area" is the management area name with the associated Special Area name following.

- "Area NF (Acres)" is the acreage in the Special Area.

- "Area T.Suit (Acres)" is the tentatively suitable for timber acreage.

- "Alternative Selection" indicates whether a Special Area is in a particular alternative. The Special Areas selected are marked by an X if they were selected for the alternative.

Table II-2. Acreage in Management Areas (Alternatives are ranked in order by decreasing amount of vegetative manipulation expected)

Management Area No.-Name	ALTERNATIVE											
	No Change	C	D	B	A-Departure	A No Action	D1	K	S	G	E	M
1-Wilderness	232,495	232,495	232,495	232,495	232,495	232,495	232,495	232,495	232,495	232,495	232,495	232,495
2-Wild River	3,120	2,043	2,043	2,043	3,120	3,120	2,043	2,043	5,029	3,120	3,120	3,120

1/ The Omnibus Oregon Wild and Scenic Rivers Act of 1988 designated the Chetco, North Fork Smith, and Elk Rivers Any alternative selected would be brought into conformance with the Act.

2/ The following LEGEND applies to the "Alternative Selection" of Riparian.

B = Riparian B Rx
C = Riparian C Rx
M = Minimum Level Rx
M = Minimum Level Rx
7 = 7% Basin Constraint
9 = 9% Basin Constraint
0 = 10% Basin Constraint
1 = 11% Basin Constraint
2 = 12% Basin Constraint
3 = 13% Basin Constraint
4 = 14% Basin Constraint
5 = 15% Basin Constraint
6 = 16% Basin Constraint
8 = 17% Basin Constraint
T = 20% Basin Constraint
N = N/A Basin Constraint

SUMMARY OF ALTERNATIVE OUTPUTS, EFFECTS, ACTIVITIES, AND COSTS

Table II-5 displays the significant land uses, environmental effects, and resource outputs of the alternatives It lists the outputs and/or effects quantitatively by decade. The organization of the alternatives in Table II-5 is also by the level of ground disturbance or vegetation manipulation expected. The alternatives are arranged in order of decreasing selected suitable timber land. This organization is intended to array the alternatives from the most vegetation manipulation to the least (i.e , from the least preservation to the most).

Table II-6 displays the significant land uses, environmental effects and resource outputs of the alternatives. It is a qualitative comparison of the alternatives It is a product of the professional judgement of the ID team. The organization of the alternatives in Table II-6 is also by the level of ground disturbance or vegetation manipulation expected The alternatives are arranged in order of decreasing selected suitable timber land. This organization is intended to array the alternatives from the most vegetation manipulation to the least (i e., from the least preservation to the most).

Table II-7 summarizes in a comparative format the response of each alternative to the individual Planning Problems This table tries to capture in a very brief format the key differences between the alternatives It is based on measurable outputs, but indicates the relative differences without relying solely on the numbers. The alternatives are arranged in order of decreasing selected suitable timber land. This organization is intended to array the alternatives from the most vegetation manipulation to the least (i.e , from the least preservation to the most)

Table II-6. Qualitative Resource Outputs and Environmental Effects (by decreasing amount of vegetative manipulation expected)

Resource Outputs and Environmental Effects	ALTERNATIVE					
	No Change (NC)	C	D	B	A-Departure	A
Air Quality.	Moderate temporary adverse impact.	High adverse impact exceeds baseline.	High adverse impact.	Moderately high adverse impact.	Same as NO CHANGE Alternative.	Same as NO CHANGE Alternative.
Visual Character of the Forest.	Range from natural appearing to modified.	Primarily modified visual character.	Same as Alternative C.	Same as Alternative C.	Same as NO CHANGE Alternative.	Same as NO CHANGE Alternative.
Changes in Recreational Use Patterns.	No changes anticipated. Some increase in Wild & Scenic.	Possible increase in use of developed sites and Wilderness.	Some increase in Wilderness use may occur.	Same as Alternative D.	Same as NO CHANGE Alternative.	Same as NO CHANGE Alternative.
Accessibility for Exploration of Mineralized Areas.	Moderately accessible.	Most accessible.	Second most accessible.	Same as Alternative D.	Same as NO CHANGE Alternative.	Same as NO CHANGE Alternative.
Energy: Fuelwood for Domestic Use.	Moderate availability.	Same as NO CHANGE Alternative.	Same as NO CHANGE Alternative.	Greatest availability.	Same as NO CHANGE Alternative.	Same as NO CHANGE Alternative.
Small Hydroelectric Sites.	Slightly less restrictive than normal development.	Roading would allow normal development.	Slightly less restrictive than Alternative C.	Same as Alternative D.	Same as Alternative C.	Same as Alternative C.
Requirements.	Moderate demand for fossil fuels.	Slightly greater demand than NO CHANGE Alternative.	Slightly less demand than NO CHANGE Alternative.	Greatest demand for fossil fuels.	Slightly greater demand than NO CHANGE Alternative.	Slightly less demand than Alternative D.
Effects on Ongoing Economic Trends: Changes in Employment Opportunities.	Significant increase in jobs in lumber, wood products, & service sectors.	Same as NO CHANGE Alternative.	Same as NO CHANGE Alternative.	Significant but temporary increase in jobs in lumber, wood products, & service sectors.	Same as Alternative B.	Same as NO CHANGE Alternative.

Table II-6. Qualitative Resource Outputs and Environmental Effects (by decreasing amount of vegetative manipulation expected) (Cont'd)

Resource Outputs and Environmental Effects	ALTERNATIVE					
	No Change (NC)	C	D	B	A-Departure	A
Effects of Ongoing Economic Trends: Changes in Lifestyles.	More opportunities for jobs, hunting, firewood gathering & motorized recreation. Less opportunity for roadless rec. & undisturbed scenery.	Same as NO CHANGE Alternative.	Same as NO CHANGE Alternative.	Same as NO CHANGE Alternative but more opportunity for fish.	Same as NO CHANGE Alternative.	Same as NO CHANGE Alternative.
Community Cohesion.	Conflicts within communities are accelerated due to reduction of MR's for old-growth indicator species.	Community conflicts increased.	Same as Alternative C.	Same as Alternative C.	Same as Alternative C.	Conflicts within communities are not accelerated.
Historic and Cultural Resources.	Much inventory & evaluation of sites. Greater chance of site damage due to ground-disturbing activities.	Same as NO CHANGE Alternative.	Same as NO CHANGE Alternative.	Same as NO CHANGE Alternative.	Same as NO CHANGE Alternative.	Same as NO CHANGE Alternative.
Research Values.	Opportunities for research dealing with natural ecosystems reduced.	Same as NO CHANGE Alternative.	Same as NO CHANGE Alternative.	Same as NO CHANGE Alternative.	Same as NO CHANGE Alternative.	Same as NO CHANGE Alternative.
Threatened and Endangered Species.	Old-growth habitat for indicator species is not protected.	All present habitat maintained; exceeds eagle recovery needs.	Same as Alternative C.	Same as Alternative C.	Same as Alternative C.	Same as Alternative C.

Table II-6. Qualitative Resource Outputs and Environmental Effects (by decreasing amount of vegetative manipulation expected) (Cont'd)

Resource Outputs and Environmental Effects	ALTERNATIVE					
	No Change (NC)	C	D	B	A-Departure	A
Game Populations and Distributions.	Populations slightly higher than present situation.	Same as NO CHANGE Alternative.	Same as NO CHANGE Alternative.	Same as NO CHANGE Alternative.	Same as NO CHANGE Alternative.	Same as NO CHANGE Alternative.
Nongame Species: Populations, Distributions.	Long-term habitat reduced below MR levels for old-growth dependent species.	Habitat maintained at MR levels or above.	Same as Alternative C.	Same as Alternative C.	Same as Alternative C.	Same as Alternative C.
Plant Diversity.	Diversity maintainable.	Potential for maintaining diversity lowered.	Same as Alternative C.	Same as NO CHANGE Alternative.	Same as NO CHANGE Alternative.	Same as NO CHANGE Alternative.
Wild and Scenic River Eligibility.	The Omnibus Oregon Wild and Scenic River Act of 1988 designated the Chetco, Elk, and North Fork Smith Rivers as National Wild and Scenic Rivers. As a result, the inventoried Wild and Scenic Rivers would be treated the same for all alternatives.					

Table II-6. Qualitative Resource Outputs and Environmental Effects (by decreasing amount of vegetative manipulation expected) (Cont'd)

Resource Outputs and Environmental Effects	ALTERNATIVE					
	D1	K	S	G	E	M
Air Quality.	Same as Alternative B.	Produces moderate adverse impact.	Same as Alternative K.	Low adverse impact.	Same as Alternative G.	Negligible adverse impact.
Visual Character of the Forest.	Same as NO CHANGE Alternative.	Modified natural appearance in recreation corridor.	Natural, or near natural appearance in sensitive viewsheds.	Maintenance of existing visual character.	Same as Alternative G.	Improves visual quality over time.
Changes in Recreational Use Patterns.	Same as Alternative D.	None expected.	Some increase in Wild & Scenic, otherwise no change.	Same as Alternative S.	Same as Alternative S.	None Expected.
Accessibility for Exploration of Mineralized Areas.	Same as NO CHANGE Alternative.	Same as NO CHANGE Alternative.	Same as NO CHANGE Alternative.	Least accessible.	Same as NO CHANGE Alternative.	Same as Alternative G.
Energy: Fuelwood for Domestic Use.	High availability.	Same as NO CHANGE Alternative.	Same as NO CHANGE Alternative.	Least availability.	Same as Alternative G.	Same as Alternative G.
Small Hydroelectric Sites.	Same as Alternative D.	Same as Alternative C.	Same as Alternative C.	Much more restrictive than Alternative C.	Same as Alternative G.	Greatly more restrictive than Alternative C.
Requirements.	Somewhat less demand than Alternative B.	Somewhat less demand than Alternative A.	Slightly greater demand than Alternative K.	Somewhat greater demand than Alternative E.	Somewhat greater demand than Alternative M.	Least demand for fossil fuels.
Effects of Ongoing Economic Trends: Changes in Employment Opportunities.	Same as Alternative D.	A few more jobs in lumber, wood products, trade, & service sectors.	Same as Alternative K.	Decrease in jobs in lumber, wood products, trade & service sectors.	Significant decrease in jobs in products, trade, & service sectors.	Same as Alternative E.

Table II-6. Qualitative Resource Outputs and Environmental Effects (by decreasing amount of vegetative manipulation expected) (Cont'd)

Resource Outputs and Environmental Effects	ALTERNATIVE					
	D1	K	S	G	E	M
Effects on Ongoing Economic Trends: Changes in Lifestyle.	Same as NO CHANGE Alternative.	Intermediate opportunities for jobs, hunting, firewood gathering, and motorized recreation. Less opportunity for roadless recreation. More opportunity for fishing.	More opportunity for jobs, hunting, firewood gathering, motorized, and roadless recreation. More opportunity for fishing. Less opportunity for undisturbed scenery.	More opportunities for viewing undisturbed scenery, fishing, & roadless recreation. Less opportunity for hunting, firewood gathering, & motorized recreation.	Same as Alternative G.	Same as Alternative G.
Community Cohesion.	Same as Alternative C.	Same as Alternative A.	Same as Alternative A.	Same as Alternative C.	Same as Alternative C.	Same as Alternative C.
Historic and Cultural Resources.	Same as NO CHANGE Alternative.	Moderate levels of disturbance and evaluation of sites.	Same as Alternative K.	Little disturbance or evaluation of sites.	Same as Alternative G.	Same as Alternative G.
Research Values.	Same as NO CHANGE Alternative.	Opportunities for research dealing with natural ecosystems maintained.	Same as Alternative K.	Same as Alternative K.	Same as Alternative K.	Opportunities for research dealing with natural ecosystems enhanced.
Threatened and Endangered Species.	Same as Alternative C.	Same as Alternative C.	Same as Alternative C.	Same as Alternative C.	Same as Alternative C.	Same as Alternative C.

Table II-6. Qualitative Resource Outputs and Environmental Effects (by decreasing amount of vegetative manipulation expected) (Cont'd)

Resource Outputs and Environmental Effects	ALTERNATIVE					
	D1	K	S	G	E	M
Game Populations and Distributions.	Same as NO CHANGE Alternative.	Slightly lower than present situation.	Same as NO CHANGE Alternative.	Populations lower than present situation.	Same as Alternative G.	Populations significantly lower than present situation.
Nongame Species: Populations, Distributions.	Same as Alternative C.	Same as Alternative C.	Same as Alternative C.	Habitat maintained above MR levels.	Same as Alternative G.	Population in old-growth and mature conifer habitat highly benefited; other habitat substantially lower
Plant Diversity.	Same as Alternative C.	Same as NO CHANGE Alternative.	Same as NO CHANGE Alternative.	Same as NO CHANGE Alternative.	Same as NO CHANGE Alternative.	Same as NO CHANGE Alternative.
Wild and Scenic River Eligibility.	The Omnibus Oregon Wild and Scenic River Act of 1988 designated the Chetco, Elk, and North Fork Smith Rivers as National Wild and Scenic Rivers. As a result, the inventoried Wild and Scenic Rivers would be treated the same for all alternatives.					

Table II-7. Comparison of Planning Problem Response by Alternative (by decreasing amount of vegetative manipulation expected)

Planning Problem	Outputs or Effects to be Measured	ALTERNATIVE NO CHANGE	C	D	B (RPA)
1. How much timber should the Forest produce?	A. Selected Suitable Forest Land Base (Commercial Forest Land)	Ranked highest selected acreage: 576,000 acres.	Ranked 2nd in selected acreage: 566,000 acres. 10,000 acres less than NO CHANGE.	Ranked 3rd in selected acreage: 560,000 acres. 16,000 acres less than NO CHANGE.	Ranked tied-4th in selected acreage: 558,000 acres. 18,000 acres less than NO CHANGE.
	B. Comparison with RPA target ASQ.	5.8 MMCF less than RPA.	5.0 MMCF less than RPA. Highest non-departure output. Meets current level.	6.4 MMCF less than RPA.	Cuts 36.8 MMCF, with strong departure, to meet RPA and State goals. Note drop in ASQ in the 5th decade.
	C. ASQ - 1st Decade	Ranked 5th	Ranked 3rd	Ranked 6th	Ranked 1st
	D. ASQ - 5th Decade	Ranked 3rd	Ranked 2nd	Ranked 4th	Ranked 9th
	E. LTSY.	Ranked 4th	Ranked 1st	Rank tied	Rank tied
2. How much old-growth forest should be preserved?	A. Total Area of old growth, plant & wildlife habitat.	The 41% of Forest now in old growth declines to 17% at 5th decade, eventually down to 14%.	5th decade same as NO CHANGE, but in long-term reduces down to 15%.	5th decade old growth declines to 18%, but in long-term reduces down to 16%.	5th decade old growth declines to 16% and remains at 16% in the long-term.
	B. Pairs of Spotted Owls.	Largest reduction, 32 pairs accommodated out of 153 pairs. (This is less than MR.)	Large reduction down to 86 pairs by 5th decade.	Large reduction down to 89 pairs by 5th decade.	Large reduction down to 81 pairs by the 5th decade.
3. How can the Forest's fish habitat, water quality, and soil productivity be maintained or improved?	A. Percent change in fish habitat capability for 3 anadromous salmonid indicator species.	Current situation; 5th decade 14% increase over 1st decade.	2% increase 1st decade over NO CHANGE; 3% increase 5th decade over NO CHANGE.	3% increase 1st decade over NO CHANGE; 9% increase 5th decade over NO CHANGE.	8% increase 1st decade over NO CHANGE; 17% increase 5th decade over NO CHANGE.
	B. Mean percent change in accelerated sediment first five decades.	2% more than A.	Highest yield; 14% more than A.	3% more than A.	2nd highest production; 5% more than A.
4. How, and to what extent, should lands in and adjacent to river corridors be managed to protect, preserve, and enhance Wild & Scenic River attributes?	A. Inventoried Wild & Scenic River allocation.	The Omnibus Oregon Wild and Scenic River Act of 1988 designated the Chetco, Elk, and North Fork Smith Rivers as National Wild and Scenic Rivers. As a result, the inventoried Wild and Scenic Rivers would be treated the same for all alternatives.			
	B. Viewshed allocation within and adjacent to Wild & Scenic boundaries.	Maintains inventoried visual objectives in all river (designated and inventoried) viewsheds.	Reduced level of VQO in all river viewsheds. North Fork Smith reduced to modified forest setting.	Maintains inventoried VQO's on Rogue and Illinois. Does not maintain VQO's on N.F. Smith and Chetco, except PR objectives on Chetco.	Same as D.
5. How should the sensitive plant resource be managed?	A. Botanical areas.	Maintains 3 existing areas.	10 areas protected; several lower priority areas with minimal resource conflicts; acreage in Botanical Areas doubles.	Same as C.	Same as C.
	B. Cells filled by RNA's.	11 cells filled.	14 cells filled.	Same as C.	Same as C.

Table II-7. Comparison of Planning Problem Response by Alternative (by decreasing amount of vegetative manipulation expected) (Cont'd)

Planning Problem	Outputs or Effects to be Measured	ALTERNATIVE NO CHANGE	C	D	B (RPA)
6. How should Forest scenic values be protected and to what degree?	A. Visual Quality Objectives (VQO): Preservation (P) Retention (R) Partial Retention (PR) General Forest (M)	Maintains current visual inventory in all viewsheds.	Shift towards modified end of values: increases M (45%); increases P (7%), decreases R (87%) and PR (62%) from NO CHANGE.	Similar to C. But not as much: increases M (40%); increases P (10%), decreases R (75%) and PR (59%) from NO CHANGE.	Same as D.
	B. Level of Visual Quality allocation in high use, recreation viewsheds.	Maintains inventoried level.	No high use, recreation viewsheds would be governed by their inventoried VQO's.	Offers inventoried VQO in 3 viewsheds. Reduced protection in other high use, recreation viewsheds.	Same as D.
7. How should wildlife habitats on the Forest be managed?	A. Percent of snag level for maximum woodpecker population.	Harvested stands snag habitat at 60% level. Populations Forest-wide reduce to 75% over time.	Harvested stands snag habitat at 20% level. Populations Forest-wide reduce to 45% over time.	Same as C.	Same as C.
	B. Black-tailed deer habitat capability.	Average capability during first 5 decades is about 9% more than existing.	Average capability during first 5 decades is 17% more than existing.	Average capability during first 5 decades is about 11% more than existing.	Same as D.
	C. Area allocated to special wildlife sites.	Lowest acreage; includes wildlife areas and meadows, but no buffers.	Slightly more acreage than NO CHANGE. Includes meadow buffers, special wildlife areas not included.	Same as C.	Same as C.
	D. Acres of hardwoods converted first decade.	Up to 750 acres annually.	Up to 1,400 acres annually.	Same as C.	Same as C.
8. How will management direction affect recreation opportunities in the wilderness and unroaded areas?	A. Area allocated to: Primitive Non-Motor. Semi-primitive N-M. Primitive WRS Semi-primitive WRS	No primitive non-motorized acreage; 29,000 ac. semi-primitive non-motorized. Wilderness primitive and semi-primitive acreage at 113,000 ac. and 119,000 ac. respectively.	Same as NO CHANGE.	Similar to NO CHANGE; 2,000 ac. reduction in wilderness primitive acreage.	Same as D.
	B. Opportunity for unroaded recreation.	Unroaded recreation opportunities lost over-time, down to 6.2 MRVD in 5th decade (6.5 MRVD loss).	Same as NO CHANGE. Loss offset by aggressive trail construction program in wilderness.	Same as C. Except loss offset by slightly less aggressive trail construction program in wilderness.	Same as C.
9. How should mineral resources of the Forest be developed in coordination with management of other resources?	A. Known and potential mineral area withdrawn or restricted from mineral entry.	Ranked 7th for minerals access. High access restrictions on 40,000 ac. Represents existing condition.	Ranked 1st for minerals access. High access restrictions on 17,000 ac.	Ranked tied-2nd for minerals access. High access restrictions on 28,000 ac.	Same as Alternative D.
		All alternatives have 268,000 acres of withdrawn land, including 34,000 acres with high mineral potential.			

Table II-7. Comparison of Planning Problem Response by Alternative (by decreasing amount of vegetative manipulation expected) (Cont'd)

Planning Problem	Outputs or Effects to be Measured	ALTERNATIVE A-Departure	A (No Action)	D1	K
1. How much timber should the Forest produce?	A. Selected Suitable Forest Land Base (Commercial Forest Land)	Ranked tied-4th in selected acreage: 558,000 acres. 18,000 acres less than NO CHANGE.	Ranked 6th in selected acreage: 557,000 acres. 19,000 acres less than NO CHANGE.	Ranked 7th in selected acreage: 550,000 acres. 26,000 acres less than NO CHANGE.	Ranked 8th in selected acreage: 529,000 acres. 47,000 acres less than NO CHANGE.
	B. Comparison with RPA target ASQ.	5.6 MMCF less than RPA. Designed to meet current level of output.	6.7 MMCF less than RPA. Reflects current land management direction.	3.6 MMCF less than RPA. Unique - 2nd decade shorter rotation. Exceeds NFMA requirements for CMAI.	9.0 MMCF less than RPA.
	C. ASQ - 1st Decade.	Ranked 4th - 1st decade.	Ranked 7th - 1st decade.	Ranked 2nd - 1st decade.	Ranked 9th - 1st decade.
	D. ASQ - 5th Decade.	Ranked 6th - 5th decade.	Ranked 5th - 5th decade.	Ranked 1st - 5th decade.	Ranked 8th - 5th decade.
	E. LTSY.	Rank tied-5th for LTSY.	Rank tied-5th for LTSY.	Ranked 7th for LTSY.	Ranked 8th for LTSY.
2. How much old-growth forest should be preserved?	A. Total Area of old-growth, plant & wildlife habitat.	Similar to D.	Same as A-Departure.	Similar to B.	18% remains at 5th decade; 17% remains long-term.
	B. Pairs of Spotted Owls.	Reduction down to 90 pairs by 5th decade.	Same as A-Departure.	Similar to B, reduction to 80 pairs by 5th decade.	Reduction down to 93 pairs by 5th decade.
3. How can the Forest's fish habitat, water quality, and soil productivity be maintained or improved?	A. Percent change in fish habitat capability for 3 anadromous salmonid indicator species.	Same as NO CHANGE.	Same as NO CHANGE.	1% increase 1st decade over NO CHANGE; 9% increase 5th decade over NO CHANGE.	Same as NO CHANGE.
	B. Mean percent change in accelerated sediment first five decades.	2% more than A.	Current situation.	Same as A.	15% less than A.
4. How, and to what extent, should lands in and adjacent to river corridors be managed to protect, preserve, and enhance Wild & Scenic River attributes?	A. Inventoried Wild & Scenic River allocation.	The Omnibus Wild and Scenic River Act of 1988 designated the Chetco, Elk, and North Fork Smith Rivers as National Wild and Scenic Rivers. As a result, the inventoried Wild and Scenic Rivers would be treated the same for all alternatives.			
	B. Viewshed allocation within and adjacent to Wild & Scenic boundaries.	Same as NO CHANGE.	Same as NO CHANGE.	Same as D.	Visual objectives reduced on inventoried rivers.
5. How should the sensitive plant resource be managed?	A. Botanical areas.	Same as NO CHANGE.	Same as NO CHANGE.	Same as C.	11 priority areas protected (11,000 acres).
	B. Cells filled by RNA's.	Same as NO CHANGE.	Same as NO CHANGE.	Same as C.	25 cells filled.

Table II-7. Comparison of Planning Problem Response by Alternative (by decreasing amount of vegetative manipulation expected) (Cont'd)

Planning Problem	Outputs or Effects to be Measured	ALTERNATIVE			
		A-Departure	A (No Action)	D1	K
6. How should Forest scenic values be protected and to what degree?	A. Visual Quality Objectives (VQO): Preservation (P) Retention (R) Partial Retention (PR) General Forest (M)	Slight change from NO CHANGE: increases P (12%), decreases R (9%), PR (5%), and M (4%) from NO CHANGE.	Same as A-Departure.	Same as D.	Some increases on P and M end of values: increases P (26%), increases M (20%); consequently decreases R (79%) and PR (44%) from NO CHANGE.
	B. Level of Visual Quality allocation in high use, recreation viewsheds.	Same as NO CHANGE.	Same as NO CHANGE.	Same as D.	Offers inventoried VQO's in 4 high use, recreation viewsheds. Reduced protection in the other viewsheds.
7. How should wildlife habitats on the Forest be managed?	A. Percent of snag level for maximum woodpecker population.	Harvested stands snag habitat same as NO CHANGE. Populations Forest-wide reduce to 76% over time.	Same as A-Departure.	Similar to C.	Harvested stands snag habitat same as NO CHANGE. Populations Forest-wide same as A-Departure.
	B. Black-tailed deer habitat capability.	Same as NO CHANGE.	Average habitat capability during first 5 decades is 8% more than existing.	Average habitat capability during first 5 decades is 12% more than existing.	Average habitat capability during first 5 decades is about 1% below existing.
	C. Area allocated to special wildlife sites.	Same as NO CHANGE.	Same as NO CHANGE.	Same as C.	All habitat sites included.
	D. Acres of hardwoods converted first decade.	Same as NO CHANGE.	Same as NO CHANGE.	Same as C.	Same as NO CHANGE.
8. How will management direction affect recreation opportunities in the wilderness and unroaded areas?	A. Area allocated to: Primitive Non-Motor. Semi-primitive N-M. Primitive WRS Semi-primitive WRS	Same as NO CHANGE.	Same as NO CHANGE.	Same as D.	4,000 ac. increase in primitive and semi-primitive non-motorized areas over NO CHANGE. Wilderness primitive and semi-primitive same as NO CHANGE.
	B. Opportunity for unroaded recreation.	Same as NO CHANGE.	Same as NO CHANGE.	Same as C.	Similar to C: 1.3 MRVD increase in 5th decade from NO CHANGE, loss offset by moderate trail construction in wilderness.
9. How should mineral resources of the Forest be developed in coordination with management of other resources?	A. Known and potential mineral area withdrawn or restricted from mineral entry.	Ranked tied-5th for minerals access. High access restrictions on 39,000 ac.	Same as A-Departure.	Same as Alternative D.	Ranked 8th for minerals access. High access restrictions on 58,000 ac.
		All alternatives have 268,000 acres of withdrawn land, including 34,000 acres with high mineral potential.			

Table II-7. Comparison of Planning Problem Response by Alternative (by decreasing amount of vegetative manipulation expected) (Cont'd)

Planning Problem	Outputs or Effects to be Measured	ALTERNATIVE S	G	E	M
1. How much timber should the Forest produce?	A. Selected Suitable Forest Land Base (Commercial Forest Land)	Ranked 9th in selected acreage: 505,000 acres. 71,000 acres less than NO CHANGE.	Ranked 10th in selected acreage: 406,000 acres. 170,000 acres less than NO CHANGE.	Ranked 11th in selected acreage: 287,000 acres. 289,000 acres less than NO CHANGE.	Ranked lowest in selected acreage: 207,000 acres. 369,000 acres less than NO CHANGE.
	B. Comparison with RPA target ASQ.	7.8 MMCF less than RPA. Outputs designed to be between Alts. K and G.	16.3 MMCF less than RPA.	20.6 MMCF less than RPA.	30.7 MMCF less than RPA. Unique - Rotations extended to 250 years.
	C. ASQ - 1st Decade.	Ranked 8th - 1st decade.	Ranked 10th - 1st decade.	Ranked 11th - 1st decade.	Ranked 12th - 1st decade.
	D. ASQ - 5th Decade.	Ranked 7th - 5th decade.	Ranked 10th - 5th decade.	Ranked 11th - 5th decade.	Ranked 12th - 5th decade.
	E. LTSY.	Ranked 9th for LTSY.	Ranked 10th for LTSY.	Ranked 11th for LTSY.	Ranked 12th for LTSY.
2. How much old-growth forest should be preserved?	A. Total Area of old-growth, plant & wildlife habitat.	19% at 5th decade; 18% in the long-term.	3rd highest residual; 23% at 5th decade. 23% in the long-term.	18% at the 5th decade; 25% in the long-term.	Greatest old growth acreage; 33% at 5th decade; 27% in long-term .
	B. Pairs of Spotted Owls.	4th highest amount of spotted owl pairs at 5th decade, with 97 pairs.	3rd highest amount of spotted owl pairs at 5th decade, with 107 pairs.	2nd highest most spotted owl pairs accommodated. 129 owl pairs at end of 5th decade.	Most spotted owl pairs accommodated. 140 pairs at end of 5th decade. 13 pairs below current (approx 153).
3. How can the Forest's fish habitat, water quality, and soil productivity be maintained or improved?	A. Percent change in fish habitat capability for 3 anadromous salmonid indicator species.	3% increase 1st decade over NO CHANGE; 4% increase 5th decade over NO CHANGE.	4% increase 1st decade over NO CHANGE; 12% increase 5th decade over NO CHANGE.	4% increase 1st decade over NO CHANGE; 11% increase 5th decade over NO CHANGE.	Same as G.
	B. Mean percent change in accelerated sediment first five decades.	12% more than A.	3rd lowest; 35% less than A.	2nd lowest yield; 46% less than A.	Lowest yield; 81% less than A.
4. How, and to what extent, should lands in and adjacent to river corridors be managed to protect, preserve, and enhance Wild & Scenic River attributes?	A. Inventoried Wild & Scenic River allocation.	The Omnibus Oregon Wild and Scenic River Act of 1988 designated the Chetco, Elk, and North Fork Smith Rivers as National Wild and Scenic Rivers. As a result, the inventoried Wild and Scenic Rivers would be treated the same for all alternatives.			
	B. Viewshed allocation within and adjacent to Wild & Scenic boundaries.	Maintains inventoried VQO's on all five designated Wild and Scenic Rivers.	Backcountry Recreation allocation would upgrade inventoried visual objectives.	Visuals upgraded through management of Backcountry Recreation areas under Preservation objectives.	Extended rotations and "no harvest" on old-growth maintains Retention and Preservation over Plan life
5. How should the sensitive plant resource be managed?	A. Botanical areas.	Protection of 22 important sites; 19,300 acres in total.	Highest acreage protected. All 25 areas protected; 39,000 acres in total.	Second highest protection. 18 areas protected; 27,700 acres in total; moderate and high priorities.	Same as G.
	B. Cells filled by RNA's.	Same as K.	Same as K.	Same as K.	Same as K.

Table II-7. Comparison of Planning Problem Response by Alternative (by decreasing amount of vegetative manipulation expected) (Cont'd)

Planning Problem	Outputs or Effects to be Measured	ALTERNATIVE S	G	E	M
6. How should Forest scenic values be protected and to what degree?	A. Visual Quality Objectives (VQO): Preservation (P) Retention (R) Partial Retention (PR) General Forest (M)	Increases in P end of values: increases P (53%); decreases R (71%); PR (43%) and M (2%) from NO CHANGE.	Shift towards Preservation end of values: increases P (84%); decreases R (57%), PR (36%), and M (30%) from NO CHANGE.	Similar to G, almost double Preservation end of values: increases P (121%), correspondingly decreases R (64%), PR (55%) and M (45%) from NO CHANGE.	More than doubles Preservation end of values: increases P (128%); correspondingly decreases R (68%), PR (58%), and M (47%) from NO CHANGE.
	B. Level of Visual Quality allocation in high use, recreation viewsheds.	VQO's would be met on 4 high use, recreation viewsheds. Reduced protection in other high use, recreation viewsheds.	All viewsheds will be governed by their inventoried VQO's.	Same as G.	Meets and exceeds inventoried level.
7. How should wildlife habitats on the Forest be managed?	A. Percent of snag level for maximum woodpecker population.	Harvested stands snag habitat same as NO CHANGE. Populations Forest-wide reduce to 79%.	Harvested stands snag habitat same as NO CHANGE. Populations Forest-wide reduce to 83% over time.	Harvested stands snag habitat same as NO CHANGE. Populations Forest-wide reduce to 86% over time.	Harvested stands snag habitat same as NO CHANGE. Populations Forest-wide same as E over time.
	B. Black-tailed deer habitat capability.	Average habitat capability during first 5 decades is about 1% above existing.	High capability reduction: 13% average decrease first 5 decades.	High capability reduction: 24% average decrease first 5 decades.	Highest reduction in habitat capability, average 41% first 5 decades.
	C. Area allocated to special wildlife sites.	Same as K, plus dispersed old growth.	Same as K.	Same as K.	Same as K.
	D. Acres of hardwoods converted first decade.	Same as NO CHANGE.	Up to 400 acres annually.	No conversion of hardwoods.	Same as E.
8. How will management direction affect recreation opportunities in the wilderness and unroaded areas?	A. Area allocated to: Primitive Non-Motor. Semi-primitive N-M. Primitive WRS Semi-primitive WRS	9,000 ac. increase in primitive and 23,000 ac. increase in semi-primitive non-motorized areas over NO CHANGE. Wilderness primitive and semi-primitive same as NO CHANGE.	Primitive non-motorized increases 12,000 ac. and semi-primitive non-motorized increases 69,000 ac. over NO CHANGE. Wilderness primitive and semi-primitive same as NO CHANGE.	Primitive non-motorized increases 14,000 ac. and semi-primitive non-motorized increases 68,000 ac. over NO CHANGE. Wilderness primitive and semi-primitive same as NO CHANGE.	Primitive non-motorized increases 14,000 ac. and semi-primitive non-motorized increases 72,000 ac. over NO CHANGE. Wilderness primitive and semi-primitive same as NO CHANGE.
	B. Opportunity for unroaded recreation.	9.4 MRVD increase in 5th decade from NO CHANGE; loss offset by aggressive trail construction program in wilderness.	5th decade 9.4 MRVD more than NO CHANGE. Moderate trail construction program in Wilderness provides additional capacity.	5th decade 9.4 MRVD more than NO CHANGE.	5th decade 9.4 MRVD more than NO CHANGE. Moderate trail construction program in wilderness provides additional capacity.
9. How should mineral resources of the Forest be developed in coordination with management of other resources?	A. Known and potential mineral area withdrawn or restricted from mineral entry.	Ranked 10th for minerals access. High access restrictions on 68,000 ac.	Ranked 12th for minerals access. High access restrictions on 92,000 ac.	Ranked 9th for minerals access. High access restrictions on 59,000 ac.	Ranked 11th for minerals access. High access restrictions on 78,000 ac.
		All alternatives have 268,000 acres of withdrawn land, including 34,000 acres with high mineral potential.			

COMPARISONS OF THE ALTERNATIVES CONSIDERED IN DETAIL

This section presents comparisons of the alternatives by environmental component The land allocations and descriptions by Planning Problem were presented in the previous section. Much of the data in the preceding tables is also pertinent to the following comparisons. The discussion here includes resource outputs, environmental effects, and costs and benefits presented in a comparative format with explanation of some of the more significant differences between alternatives. This section also presents the analysis of the tradeoffs among the alternatives

CULTURAL RESOURCES

As production-oriented resource outputs (such as timber harvest levels) change by alternative, the cultural resource requirements of inventory, evaluation, protection, mitigation, and monitoring vary quantitatively.

Alternatives E, G, and M favor the least production and development oriented approach to land management and therefore trigger few ground-disturbing activities within the Siskiyou National Forest. The primary project type requiring cultural resource involvement under these alternatives is road building. For every planned length of new road construction, adequate cultural resource survey work must be undertaken. In relative terms, these alternatives result in low costs for cultural resource compliance work, as listed above, due to low levels of production. These alternatives favor preservation of archaeological and historic sites, but provide little opportunity for locating new sites or conducting data recovery projects, such as excavation.

Alternatives K and S call for moderate levels of production. With the introduction of land-disturbing activities, cultural resource inventories and subsequent evaluation of any sites discovered are required. Protection, mitigation, and monitoring of any site determined eligible to the National Register of Historic Places is provided through consultation with the State Historic Preservation Office. Funding, commensurate with the degree of cultural resource compliance work required, is at a level between those alternatives listed above and below.

Alternatives NC, A, A-Departure, B, C, D, and D1 would permit the highest levels of production among the range of alternatives. Consequently, the costs of cultural resource compliance measures identified above are higher for these alternatives than the others. The potential to identify new sites is the greatest under these alternatives, as is the likelihood of damaging cultural evidence.

Figure II-17 displays the acres by alternative in Management Areas which permit ground disturbing activities, and the acres that have high or moderate probability for containing cultural resources, as determined by the Forest's Sample Survey Design. The Management Areas considered are: Riparian, Retention Visual, Partial Retention Visual, and General Forest. Figure II-18 displays the high probability acres for cultural resource sites within these Management Areas, by alternative.

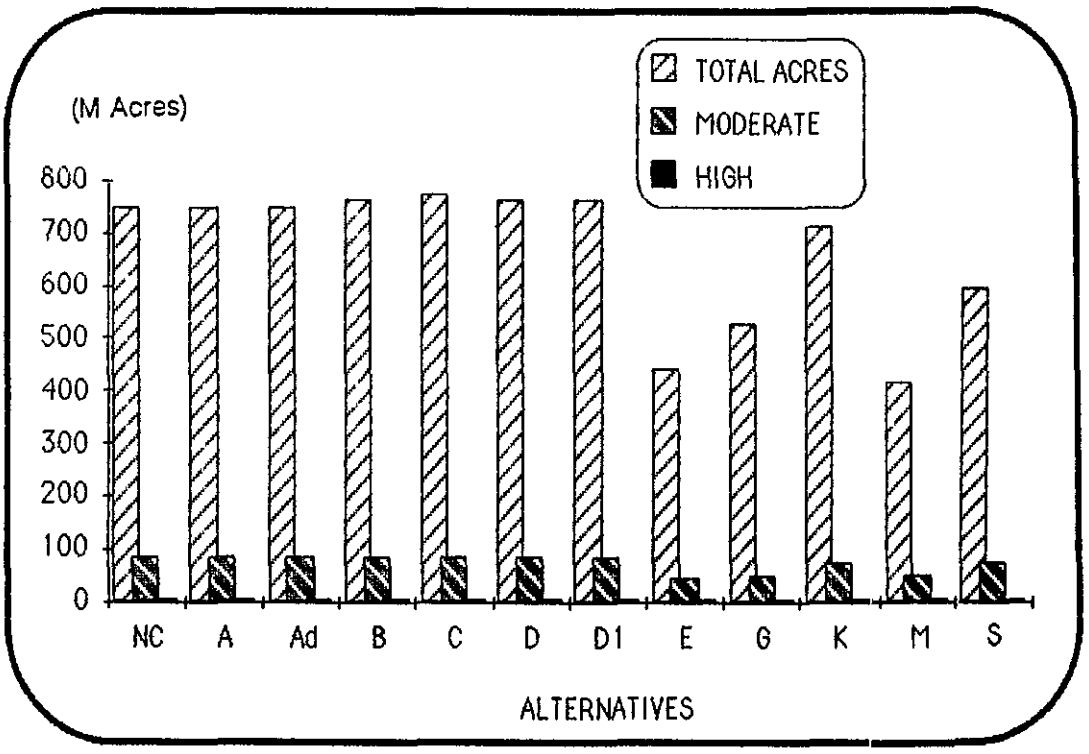

Figure II-17 The Area Under Management Allowing Ground Disturbance by Cultural Site Potential (M Acres), by Alternative

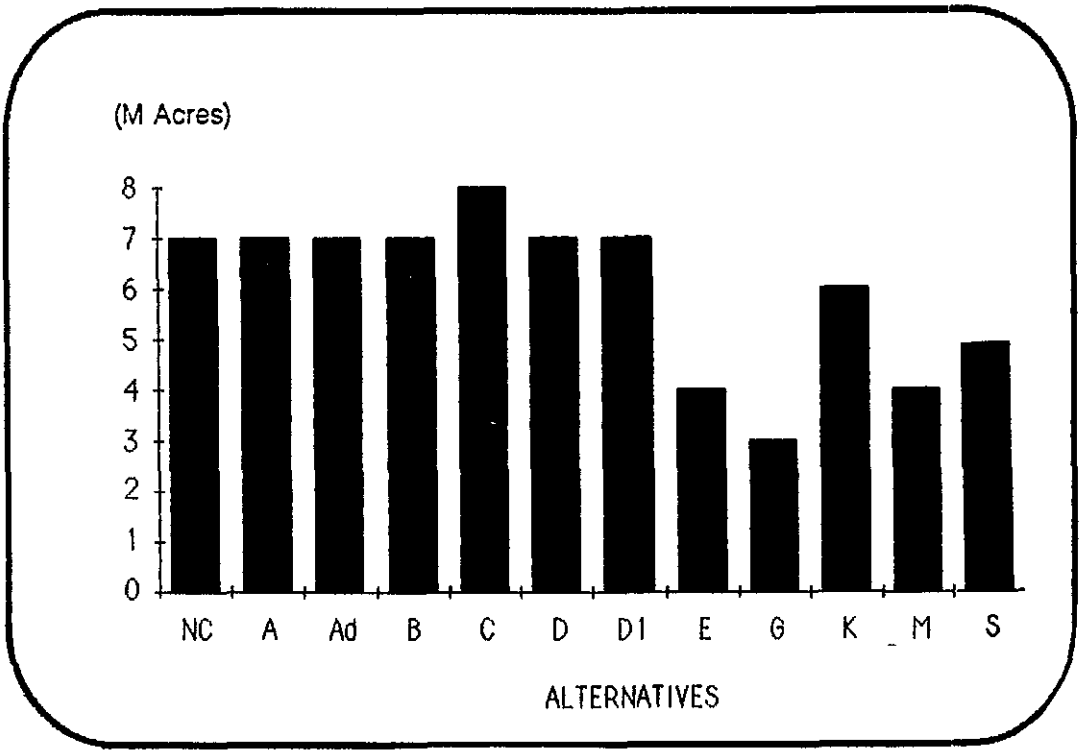

Figure II-18. High Probability Area for Cultural Resource Sites in Management Areas Allowing Ground Disturbance (M Acres), by Alternative

ENERGY

FUELWOOD

Current Direction could continue to produce about 49,000 cords of fuelwood per year during the first decade Alternative B would produce the highest volume of fuelwood of any of the alternatives considered, about 22 percent more than currently. Alternative S, the Preferred Alternative, would produce about eight percent less than Current Direction. At 78 percent less than Current Direction, Alternative M would produce the fewest cords of fuelwood. Projected cords of fuelwood available in decades one, two, and five by alternative, are displayed in Table II-5.

HYDROPOWER

The comparison of alternatives relative to potential hydropower development focuses on access The access and restrictions on access associated with the alternatives are discussed under the heading **"MINERAL DEPOSITS"** in this section The reader is referred there as the implications for hydropower development would be similar

ENERGY REQUIREMENTS

The energy required to continue with current direction is about 4,293,102 BTU's per decade. The alternatives range from the high of Alternative B (20 percent more than Current Direction) to the low of Alternative M (76 percent less) with the Preferred Alternative about 5 percent less.

The energy required to implement the alternatives (Table II-8) has been broken down by activities as a percent of the total for each alternative, and the total relative energy requirement of each alternative is displayed as a percent of the requirement for Current Direction.

Table II-8 Percentage of Each Alternative's Energy Requirement by Activity, and Comparison of Alternative Totals as Percent of Current Direction

	Alternative (Percent)											
Activities	NC	A	A-Dep	B	C	D	D1	E	G	K	M	S
Timber Harvest	87	87	87	88	86	86	86	83	85	86	74	88
Biomass Extraction	0	0	0	0	0	1	0	0	0	0	0	0
Range	0	0	0	0	0	0	0	0	0	0	0	0
Recreation	4	4	4	4	4	4	4	8	6	5	18	5

Minerals Extraction (Non-fuel)	1	1	1	0	0	1	1	0	0	0	0	0
Road Construction	7	7	7	7	8	7	7	7	7	7	4	7
Fire Management	1	1	1	1	2	2	1	2	2	2	4	2
Percent of Alternative A - Current Direction	102	100	103	120	107	101	110	70	70	92	24	95

MINERAL DEPOSITS

The geologic potential for locatable (hardrock) minerals and leasable (oil, gas and geothermal) energy resources has been evaluated Accessibility restraints for National Forest lands have also been reviewed. When considered together, potential and accessibility restrictions tend to indicate the potential for development of the mineral and energy resources

The land area accessible to mineral exploration, development, and extraction with limited (low or moderate) restrictions is shown for each alternative in Figure II-19 (The definitions of the restriction categories and discussion of mineral potential are found in Chapters III and IV, MINERAL DEPOSITS.) As less acres are withdrawn from mineral entry, or as fewer areas receive high accessibility restrictions, the area remaining for mineral activities would be greater. Approximately three-fourths of the National Forest is now available for mineral and energy development with varying degrees of restriction In addition, nearly three-fourths of the area available for mineral entry has low access restrictions

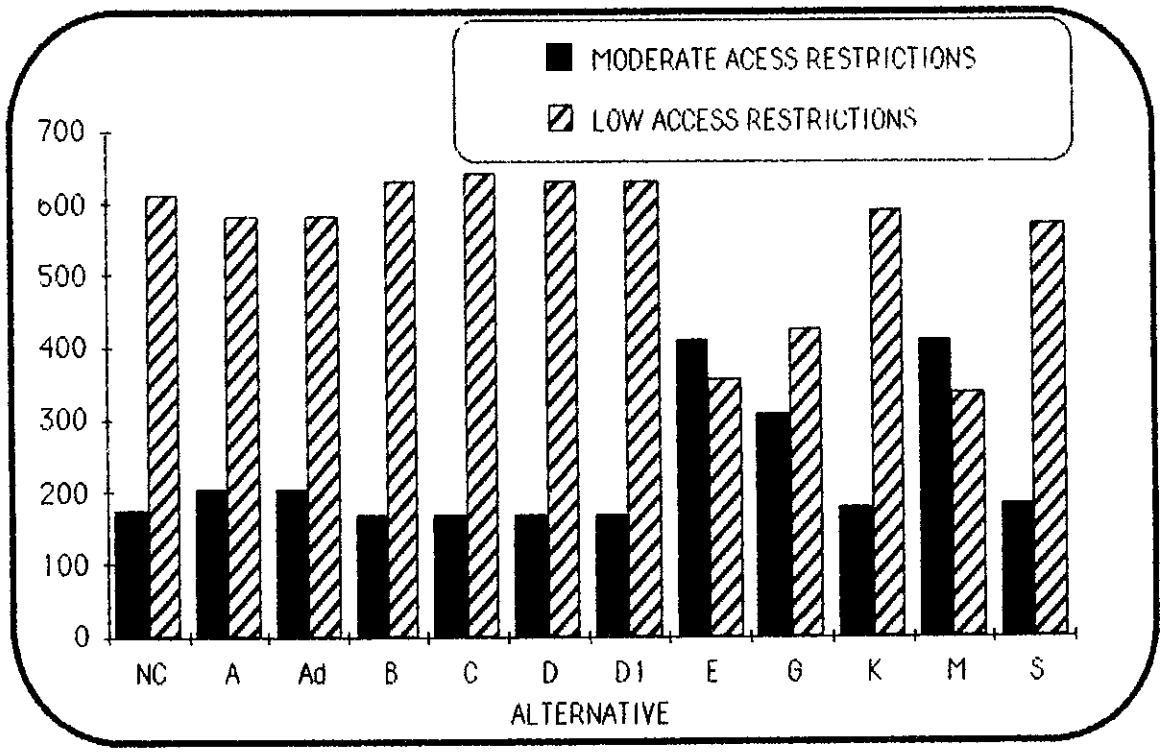

Figure II-19 Land Area Accessible to Mineral Exploration, Development and Extraction with Limited (Low or Moderate) Restrictions (M Acres)

IMPROVEMENTS

ROADS

Miles of new road construction are projected with the FORPLAN model based on the acres scheduled for harvest The model does not have the spatial resolution to exactly portray the roading program needed to support the timber harvest scheduled in any particular decade. This is due to the variability in the mix of harvest areas scheduled requiring new roads versus those that are accessed by existing roads, and to the situations where initial entry into an area may require more road per acre harvested than subsequent entries when units may be harvested along previously constructed roads The estimates of road construction miles balance out over the first few decades and the total road system projected is accurate, however the miles projected in any one decade may not be adequate to support the timber program. The pattern projected by the model generally underestimates the miles of road needed in the first two or three decades and overestimates the miles needed in subsequent decades The projected miles are presented here for comparison purposes; actual miles needed for implementation of any alternative may be more than those shown.

Alternatives NC, A, A-Departure, B, C, D, and D1 would provide the greatest amount of new roads with the addition of approximately 1,550 miles. The most mileage constructed during the first decade would be under Alternative C. Alternative M plans no new road construction. Table II-9 compares construction under each alternative. In the long-term, Alternative C would provide a total road system of 4,222 miles, while Alternative M would leave the road system at the existing 2,645 miles. Alternatives A, A-Departure, B, C, D, and D1 would include the highest non-timber-sale road mileages (for recreation, mining, etc.).

Table II-9. Miles of Road Construction 1/ 2/

	Miles				
Alternative	Decade 1 Built 3/	Built to Complete System	Non-Timber Sale	System Ultimate Road System	Decade 95 Percent Complete
NC, A, and A-Departure	230	1,545	(47)	4,190	7
B	277	1,553	(47)	4,198	6
C	308	1,577	(44)	4,222	5
D and D1	271	1,555	(48)	4,200	5
E	110	665	(7)	3,310	5
G	142	963	(11)	3,608	7
K	206	1,433	(32)	4,078	8
M	0	0	(0)	2,645	0
S	228	1,343	(32)	3,988	7

1/ Does not include temporary roads which will be reclaimed after use and which serves a single use
2/ Fiscal Years 80 through 84 averaged 49 6 miles per year of new road construction
3/ Roading estimates are based on FORPLAN modeling and may underestimate the road construction needed to support the timber outputs scheduled for early decades (see discussion in Appendix B)

Road reconstruction would be highest in Alternatives C and D1; while Alternative M would have the need for the least. Table II-10 includes comparisons of Decades 1, 5, 10, and 15 road reconstruction needs by alternative This comparison indicates that all alternatives have a general upward trend in the amount of miles reconstructed per year

Table II-10 Miles of Road Reconstruction 1/

Alternative	Decade (Miles/Year)			
	1	5	10	15
NC and A	146	163	132	166
A-Departure	147	164	132	178
B	167	167	169	169
C	172	178	166	179
D	156	158	167	168
D1	172	174	192	194
E	82	87	95	97
G	101	106	119	115
K	131	137	146	140
M	23	23	20	36
S	135	138	146	144

1/ Fiscal Year 1980 through 1984 averaged 112 miles per year of reconstruction

Tables II-11 and II-12 display the availability of the road system for public use at the end of the first decade and the long-term availability when the road system is complete. Alternative C would provide the most road network for public and commercial users. In the first decade, Alternative C would provide 2,576 miles of road for general public use; of this amount 1,235 miles would be suitable for passenger car use, and 1,341 miles would be suitable for high ground-clearance vehicles only. Also in the first decade, road closures would be highest in Alternative E with 733 miles and lowest in Alternatives NC and A with 347 miles. In the long-term road system the highest amount of closure occurs in Alternative K with 1,385 miles; the lowest amount closed is in Alternative M with 529 miles. Alternative B would provide the highest mileage available for passenger car users in both the first decade and the long-term road system with 1,613 and 2,012 miles respectively. Alternative G would provide the least mileage available for passenger car users in both the first decade and the long-term road system with 916 and 932 miles respectively. In the first decade, the highest amount of road suitable for high clearance vehicles occurs in Alternative G with 1,388 miles; the lowest amount suitable would be in Alternative E with 619 miles. In the long-term road system, the highest and lowest alternatives suitable for high clearance vehicles are Alternatives C and E, respectively.

Table II-11. First Decade Availability of Roads for Public Use (Miles)

Alternative	Miles				
	End of First Decade	Closed 1/	Available For Public Use 2/	Suitable For Passenger Cars	Suitable for High Clearance Vehicles Only
NC, A and A-Departure	2,875	347	2,528	1,245	1,283
B	2,922	368	2,554	1,613	941
C	2,953	377	2,576	1,235	1,341
D and D1	2,916	362	2,554	1,511	1,043
E	2,755	733	2,022	1,403	619
G	2,787	483	2,304	916	1,388
K	2,851	649	2,202	1,396	806
M	2,645	529	2,116	1,057	1,059
S	2,873	662	2,211	1,401	810

1/ May not be the same road from decade to decade, or year to year
2/ Only a portion suitable for passenger cars, all suitable for high ground-clearance vehicles (those which can travel over objects four inches high)

Table II-12 Long-term Availability of Roads for Public Use (Miles)

	Miles				
Alternative	Long-term	Closed 1/	Available for Public Use 2/	Suitable for Passenger Cars	Suitable for High Clearance Vehicles Only
NC, A, and A-Departure	4,190	871	3,319	1,632	1,687
B	4,198	878	3,320	2,012	1,308
C	4,222	885	3,337	1,456	1,881
D and D1	4,200	875	3,325	1,962	1,363
E	3,310	1,092	2,218	1,572	646
G	3,608	977	2,631	932	1,699
K	4,078	1,385	2,693	1,727	966
M	2,645	529	2,116	1,057	1,059
S	3,988	1,330	2,658	1,701	957

1/ May not be the same road from decade to decade, or year to year
2/ Only a portion suitable for passenger cars, all suitable for high ground-clearance vehicles (those which can travel over objects four inches high)

Alternative M would require the fewest dollars from timber purchaser credit allowances to be used for reconstruction activities during the first decade $599,000 per year. The greatest amount of timber purchaser credit during the first decade would be required in Alternative C with $6,869,000 per year for road construction and reconstruction. Road-related capital investments would be the highest in Alternative B during the first decade with $1,360,000 per year needed; the lowest would be in Alternative M with $165,000 per year (used for reconstruction and structure replacements). Alternative B, during the first decade, would require the most road maintenance work with $4,351,000 needed per year; the lowest amount ($1,421,000 per year) would be required in Alternative M. Table II-13 displays the projected expenditures for construction, reconstruction, and maintenance and indicates the amounts that would be funded from timber sale sources and from appropriated allocations

Table II-13. First Decade Annual Road Costs (M $) 1/

	Miles				
	Timber Purchaser Credit			Maintenance	
Alternative	Construction	Reconstruction	Road Capital Investment 2/	Timber Sale	Allocated
NC, A, and A-Departure	1,809	4,316	853	2,401	1,043
B	1,967	4,658	1,360	3,131	1,220
C	2,098	4,771	1,044	2,683	1,070
D	1,860	4,351	1,092	2,598	1,151
D1	1,969	4,782	1,167	2,775	1,091
E	762	2,527	657	1,320	1,159
G	989	3,053	634	1,695	880
K	1,460	4,081	956	2,307	1,108
M	0	599	165	440	981
S	1,566	4,189	654	2,417	1,060

1/ Roading estimates are based on FORPLAN modeling and may underestimate the road construction needed to support the timber outputs scheduled for early decades (see discussion in Appendix B)
2/ This includes road construction and reconstruction work, road-related recreation and water quality improvement work, and supplementation of timber sale road work

TRAILS

Potential trail improvements are identified in Table II-4; this table identifies those existing and planned trails selected for reconstruction or construction under each management alternative. The existing 450-mile trail system would be expanded the most under Alternative S, which would add 130 miles over the next three decades for a total of 580 miles. The added mileage is nearly equally split between Wilderness and non-Wilderness areas. Alternative C would add the most mileage to the Wilderness trail system with 92 miles. Alternative E would add the least mileage to the system with 32 miles; all of these miles are outside Wildernesses and the construction could span five decades. Alternative S would provide the greatest amount of additional non-Wilderness trails with 68 miles of construction All alternatives provide for some reconstruction work to bring trails up to standard, Alternative E would provide none in Wilderness. In total, Alternative S would reconstruct the most (63 miles) with about two-thirds in non-Wilderness

In the first decade, Alternative S would add the highest mileage to the trail system with 86 miles. Alternative C would have the most reconstruction (47 miles) in the first decade for Wilderness, and the 35 miles reconstruction in Alternative S is the most in the first decade for non-Wilderness. Long-term and first decade construction and reconstruction comparisons are shown in Table II-14

Table II-14. Miles of Trail Construction and Reconstruction 1/

	Wilderness (Miles)		Non-Wilderness (Miles)		
Alternative	Construction	Reconstruction	Construction	Reconstruction	Decade Work Complete
NC, A, and A-Departure	24 0 (0 3)	14 0 (0 0)	33 1 (0 0)	31 3 (11 0)	3
B	81 0 (21 0)	16 0 (7 0)	7 0 (5 0)	6 0 (3 0)	4
C	92 0 (47 0)	16 0 (7.0)	7 0 (5 0)	9 0 (3.0)	2
D and D1	81 0 (21 0)	16 0 (7 0)	7 0 (5 0)	6 0 (3 0)	4
E	0 0 (0 0)	0 0 (0 0)	32 1 (14 1)	28 3 (28 3)	5
G	39 5 (21 5)	11 0 (7 0)	45 1 (6 3)	31 3 (8 0)	4
K	50 5 (15 0)	16 0 (7 0)	44.1 (5 0)	37 3 (0 0)	3
M	40 5 (21 5)	11 0 (7.0)	45 1 (6 3)	31 3 (8 0)	4
S	62 0 (42 0)	16.0 (8 0)	67 8 (44 5)	47 1 (35 0)	3

1/ First decade construction and reconstruction miles shown in parentheses

First decade investments in trails would be the highest with Alternative S at $1,269,300, as would be expected from its highest construction mileage (86 miles). The next highest would be in Alternative C with $1,017,700. During the first decade, Alternatives NC, A, and A-Departure would require the least with $84,000 needed for construction and reconstruction work. Trail maintenance cost during the first decade ranges from $1,461,500 in Alternative S down to $1,226,600 in Alternatives NC, A, and A-Departure Table II-15 displays first decade trail costs

Table II-15. First Decade Trail Costs (M $)

	Trail Costs (M $) 1/		
Alternative	Construction	Reconstruction	Maintenance
NC, A, and A-Departure	9 7	74 3	1,226 6
B, D, and D1	357 5	192 4	1,309 0
C	863 3	154 4	1,400 0
E	165 2	82 4	1,253 7
G and M	420 5	125 0	1,313 4
K	298 0	59 5	1,288 0
S	888 3	381 0	1,461 5

1/ Used for construction or reconstruction of trails, trail bridges, or trailheads

Tables II-16 and II-17 display the availability of trails for public use during the first decade and the long-term respectively. These tables assume no additional restrictions on pack and saddle or motorized users. In the first decade, Alternative S will provide the most trail access with 537 miles in the total system Alternatives NC, A, and A-Departure would provide the least amount of trail access with 450 miles (present mileage). In Wilderness during the first decade, Alternative C would provide the most mileage with 264 miles, the present access would be retained in Alternatives NC, A, A-Departure, and E during this period in Wilderness. Except for Alternative S (with about 40 miles more), during the first decade there is little difference between alternatives for non-Wilderness trails. In the long term, Alternative S would provide the most trail access (580 miles), exceeding the next highest by some 31 miles (Alternative C) While Alternative E would provide the least trail access with 482 miles

Table II-16. First Decade Availability of Trails for Public Use (Miles) 1/

		Wilderness (Miles)		Non-Wilderness (Miles)		
Alternative	End of First Decade Trail System	Hiker	Pack and Saddle	Hiker	Pack and Saddle	Motorized
NC, A, and A-Departure	450	217	204	233	200	171
B, D, and D1	476	238	225	238	205	176
C	502	264	251	238	205	176
E	452	217	204	247	214	185
G and M	478	239	226	239	206	177
K	470	232	219	238	205	176
S	537	259	246	278	245	216

1/ Assumes no additional restrictions on pack and saddle or motorized users

Table II-17. Long-term Availability of Trails for Public Use (Miles) 1/

		Wilderness (Miles)		Non-Wilderness (Miles)		
Alternative	Ultimate Trail System (Miles)	Hiker	Pack and Saddle	Hiker	Pack and Saddle	Motorized
NC, A, and A-Departure	507	241	228	266	233	204
B, D, and D1	538	298	285	240	207	178
C	549	309	296	240	207	178

K	544	267	254	277	244	215
S	580	279	266	301	268	239

1/ Assumes no additional restrictions on pack and saddle or motorized users

DEVELOPED RECREATION SITES

Table II-4 displays the availability of developed recreation sites and the recreation projects selected for each management alternative. Table II-18 summarizes the management status for existing and potential recreation sites by alternative. The development scale of existing sites would be retained the most under Alternatives NC, A, A-Departure, and C with 46 sites, and retained the least under Alternatives B, D, and D1 with 42 sites A total of seven sites, including the four presently closed sites, would not be identified as usable with Alternatives B, D, and D1. Alternatives NC, A, A-Departure, K, and S would also not reopen the existing four closed sites; while Alternatives C, E, G, and M would reopen those four sites Alternative C would provide for no new construction Alternatives G and M would construct the most new recreation sites for public use (15). The most sites opened would be 65 under Alternatives G and M. The least amount of sites opened (47) would be under Alternatives A and A-Departure

Table II-18 Number of Recreation Sites by Status and Alternative1/

	Number of Sites					
Alternative	Development Scale Retained	Closed	Upgraded 2/	Closed Site Reopened	New Construction	Total Open
NC, A, and A-Departure	46	(4)	0	0	1	47
B, D and D1	42	(7)	1	0	7	50
C	46	(0)	0	4	0	50
E	45	(0)	1	4	7	57
G	43	(0)	3	4	15	65
K	43	(4)	3	0	7	53
M	43	(0)	3	4	15	65
S	43	(4)	4	0	9	56

1/ Includes developed sites and minimum developed sites (formalized dispersed sites)
2/ Minimum developed site(s) identified for reconstruction to a developed site(s)

Recreation site capital investments and maintenance needs for the first decade are displayed in Table II-19. Investment costs would be the highest under Alternative S with $2,236,000 average per year, partially due to increased size or higher level of development for some sites (e.g , flush toilets, showers) Alternative C would be the lowest with no capital investments When maintenance is included, these alternatives retain their respective high and low positions Recreation site maintenance costs for Alternatives NC, A, A-Departure, and C would be the lowest during the first decade; Alternatives B, D, and D1 would be the next lowest for this period Maintenance cost in Alternative S would be the highest with $862,800, which is slightly higher than the group containing Alternatives E, G, K, and M During the first decade, only Alternative S has rehabilitation work planned

Table II-19 First Decade Recreation Site Costs (M $)

	Costs (M $)		
Alternative	New Construction	Rehabilitation	Maintenance
NC, A, and A-Departure	590 0	0	783 8
B, D, and D1	233 0	0	695 2
C	0 0	0	783 8
E	233 0	0	842 8
G and M	802 4	0	842 8
K	212 4	0	842 8
S	2,326 0	910 0	862 8

WILDLIFE AND FISH HABITAT IMPROVEMENT

Structural improvements for wildlife are incorporated with fish improvements in Table II-20, and the capital investments for structural improvements for wildlife and fish are found in Table II-21 All alternatives would provide 1,910 wildlife structures (primarily nest structures) within the first decade, except Alternatives D and S which would provide 960 and 4,180 structures respectively. Consequently, the first decade capital investments are the same under all alternatives, except Alternative D which is half of the others and Alternative S which is over twice as much as the others

The most structural improvements for fish (log weirs, ladders, etc.) as well as nonstructural improvements (erosion control, vegetative planting, etc) during the first decade, would occur in Alternatives B, K, and S with 5,300 structures. The least amount would occur in Alternatives NC, A, and A-Departure, providing 350 structures less than the next higher group The other alternatives (C, D, D1, E, G, and M) range from 3,790 to 3,940 structures. The first decade capital investments in fish structural improvements fall into the same groupings, with the high of $3,500,000, the low of $1,750,000, and the mid-range of $2,270,000 to $2,600,000 Investments are projected to continue at the same rate in future decades resulting in a constant level of wildlife structures and approximately double the number of fish structures existing through future decades

Table II-20 Number of Wildlife and Fish Habitat Structural Improvements 1/

	Number of Structures			
	Decade 1 Construction		Long-term Inventory	
Alternative	Wildlife 2/	Fish	Wildlife 2/	Fish
NC, A, and A-Departure	1,910	3,440	1,910	6,880
B and K	1,910	5,300	1,910	10,600
C, G, and M	1,910	3,940	1,910	7,880
D	960	3,790	960	7,580
D1 and E	1,910	3,790	1,910	7,580
S	4,180	5,300	4,180	10,600

1/ These have varying lengths of useful life (maximum of 20 years)
2/ Most of the improvements are nest structures (95 percent) which are replaced in conjunction with meadow improvements, the remainder are water-related, 4,490 acres per decade of nonstructural improvements (meadow rehabilitation) in all alternatives except D and S, which would be 2,245 and 9,830 acres per decade respectively

Table II-21 Wildlife and Fish Habitat Structural Improvements Capital Investments

	Decade 1 (M $)		Long-term (M $/Decade)	
Alternative	Wildlife 1/	Fish 2/	Wildlife 1/	Fish 2/
NC, A, and A-Departure	107	2,270	107	2,270
B and K	107	3,500	107	3,500
C, G, and M	107	2,600	107	2,600
D	54	2,500	54	2,500
D1 and E	107	2,500	107	2,500
S	234	3,500	234	3,500

1/ An additional $453,000 per decade for nonstructural improvements applies to all alternatives, except, B is $993,000, D is $226,500, and S is $996,000 per decade
2/ Approximately 10 percent of fish improvements actually consist of nonstructural work

WILDERNESS AND ROADLESS AREAS

The effects of management on the Wilderness vary through the range of alternatives Effects are projected from management directly affecting designated Wildernesses (primarily trail construction) and from management activities on lands that are adjacent to Wildernesses (primarily timber harvest and road construction). The effects on the Wildernesses are demonstrated in the fluctuations in the Wilderness Recreation Spectrum (WRS) classes and in the variations in allocation to Backcountry Recreation Management Areas These figures are displayed in Tables II-22 and II-23.

When ranked according to the beneficial value to the existing and potential Wilderness resource (which includes undeveloped areas retaining wilderness characteristics), the alternatives are listed from most to least value in the order shown below.

1 M
2 E
3. G
4. S
5. K
6 NC, A, and A-Departure
7. B, D, and D1
8. C

Table II-22 Wilderness Recreation Spectrum Acreages (M Acres), by Alternative

	Alternative (M Acres)							
WRS Class	NC, A, and A-Dep	C	B, D, and D1	E	G	K	M	S
Primitive	21	21	24	21	25	29	20	29
Pristine	93	93	90	93	88	85	93	85
Semi-Primitive	119	119	119	119	119	119	119	119

Table II-23. Backcountry Recreation Management Area Allocations (M Acres), by Alternative

	Alternative (M Acres)							
Management Area	NC, A, and A-Dep	C	B, D, and D1	E	G	K	M	S
Backcountry Recreation	0	0	0	301	150	14	297	108

The approximate acres remaining roadless at the end of decades one, two, and five are summarized in Table II-24. The acres are the decade total of the 18 roadless areas by alternative The estimates are made with the assumptions displayed prefacing Table C-3 in Appendix C.

Table II-24. Roadless Area Remaining at the End of Decades 1, 2, and 5 (Thousands of Acres), by Alternative

	Area Remaining End of Decade (M Acres)1/		
Alternative	1	2	5
A, A-Dep, and NC	102	90	85
B, C, D, and D1	86	74	69
E and M	284	284	284
G	186	173	173
K	109	97	92
S	135	126	126

1/ Minimum criteria is 5,000 unroaded contiguous acres or adjacent to designated Wilderness

Alternatives M and E are almost identical with regard to their benefit to the Wilderness resource. Trail construction would be limited so that effects on the Primitive character of the Kalmiopsis Wilderness are minimized. Management intent would be to maintain the existing trail systems within the designated Wildernesses and concentrate efforts toward construction of new trail systems in the areas allocated to Backcountry Recreation In both of these alternatives, all of the unroaded areas would be allocated to Backcountry Recreation so that the effects of management on lands adjacent to the designated Wildernesses are minimized and Wilderness potential of these areas are retained for at least another decade The total area, including Wilderness, that remains in an undeveloped, natural setting exceeds a half million acres in these alternatives

Alternative G would implement plans for new trail construction in the designated Wildernesses which would have some effect on the Pristine character of the Kalmiopsis Wilderness. Trail construction would also be programmed in the Wild Rogue Wilderness in Alternative G. Much of the former North Kalmiopsis Roadless Area is allocated to Backcountry Recreation Alternative G, while allocating 150,000 acres to Backcountry Recreation, retains through the first decade approximately 186,000 acres in a roadless condition In addition to existing Wilderness, this would result in over 400,000 acres remaining in roadless condition at the end of the first decade While allocated Backcountry Recreation area is considerably less than in Alternative E and M, most are located adjacent to existing Wildernesses and provide similar benefits through minimizing adjacent land management effects.

Alternative S would implement plans for new trail construction in the Kalmiopsis, Wild Rogue, and Grassy Knob Wildernesses (approximately 62 miles) which would have some effect on the Pristine (trailless) character of the Kalmiopsis Wilderness. Of 42,000 acres allocated to Backcountry Recreation in the North Kalmiopsis roadless area, a large portion lies contiguous to the north boundary of the Kalmiopsis Wilderness in the lower reaches of Silver and Lawson Creeks and the Wild section of the Illinois River Alternative S would allocate approximately 108,000 acres (portions of eight roadless areas) to Backcountry Recreation Combined with existing Wilderness, over 360,000 acres would remain in a roadless condition after the first decade. As with the above alternatives, the Backcountry Recreation areas in Alternative S are predominately located adjacent to existing Wildernesses, benefits would be similar but at a lesser scale

Alternative K would implement a moderate program of trail construction (approximately 50 miles) in the Kalmiopsis and Wild Rogue Wildernesses The Pristine character of the Kalmiopsis would be affected. This alternative would allocate approximately 14,000 acres to Backcountry Recreation This area consists of portions of two unroaded areas which are beneficial to the Wilderness resource primarily due to their location adjacent to the Kalmiopsis Wilderness Some Primitive opportunities are maintained in the area

located in lower Silver Creek north of the Wilderness. The effects of management on adjacent lands on the quality of wilderness recreation experiences would be more pronounced under these alternatives. Approximately 340,000 acres would remain in an unroaded condition after the first decade.

Alternatives NC, A, and A-Departure would maintain the Forest's current management direction for Wilderness management. Trail construction is proposed in the Kalmiopsis Wilderness (approximately 24 miles), which would affect the Pristine (trailless) character of the Wilderness There is no trail construction proposed in the Wild Rogue or Grassy Knob Wildernesses. There would be no allocations to Backcountry Recreation in these alternatives, so that the wilderness potential of any of the unroaded areas would not be maintained. Management activities on lands adjacent to designated Wilderness would affect both the Primitive character (in the Kalmiopsis) and the quality of recreation experiences in areas of the Wilderness where these activities are evident Approximately 330,000 acres, including existing Wilderness, would remain unroaded after the first decade. Development of the North Kalmiopsis roadless area would affect approximately 4,000 acres of currently inventoried Primitive area in the Kalmiopsis Wilderness. Wilderness character would be maintained within the boundary; however, the type of experiences provided would be Semi-primitive rather than Primitive.

Alternatives B, C, D, and D1 would have the same effect on the Wilderness resource and the Forest's Wilderness potential Under these alternatives, an aggressive program of trail construction would be implemented Management intent would be to provide additional recreation opportunities in Wilderness in order to offset the loss of similar opportunities in General Forest The Pristine (trailless) character of the Kalmiopsis Wilderness would be affected (reduced by approximately 11,351 acres) These alternatives would not allocate any of the unroaded areas to Backcountry Recreation so the wilderness character of the areas would be lost The majority of these areas would be allocated to General Forest management and the influence of management activities on adjacent Wildernesses is expected to be greater under these alternatives Approximately 320,000 acres would remain in an unroaded condition after the first decade.

WILD AND SCENIC RIVER

The Forest now has five Wild and Scenic Rivers. the Rogue, Illinois, Chetco, North Fork Smith, and Elk Rivers The question of designation is no longer relative. The inventoried and eligible Chetco, North Fork Smith, and Elk Rivers were designated through the Omnibus Oregon Wild and Scenic Rivers Act of 1988 The effects of management on the Wild and Scenic River resource would vary according to alternative emphasis. When alternatives are ranked according to their complement to the Wild and Scenic River resources and "outstandingly remarkable" attributes, they list from most to least as follows:

1 E and M
2 G
3. S
4 NC, A, and A-Departure
5. K
6. B, D, and D1
7. C

Alternatives E and M are similar in that the effects of the land allocations would be very nearly the same Alternative M would be more beneficial to the Wild and Scenic River resource due to extended harvest rotations (250 years) and limiting harvest activities to previously roaded areas. A more natural-appearing Forest landscape would be expected over time as a result. The significant difference between E and M, in this respect, is that areas allocated to management under Partial Retention and General Forest would have shorter rotations (130 and 100 years, respectively), so that reductions to the character of the landscape would be expected. Both alternatives would allocate all of the Forest's unroaded areas to

Backcountry Recreation. Several of the unroaded areas are in river corridors and would maintain the natural character of the landscape.

Alternative G would retain the natural or near-natural character of the river corridors through the allocation of adjacent viewsheds to a full range of visual management. Adjacent viewsheds would be allocated to visual management resulting in the maintenance of the natural or near-natural character of the landscape Allocations to Backcountry Recreation of two unroaded areas within the upper and lower reaches of the Illinois River would directly benefit the recreation settings The inventoried foreground Retention area along the Recreation and Scenic portions of the Rogue River would not have programmed timber harvest; the vegetative character of the river would be protected. Other allocations within the river corridors that would benefit the resource include Designated Wildlife Habitat and Supplemental Resource Management Areas

Alternative S would retain the natural or near-natural character of the river corridors through the allocation of adjacent viewsheds to a full range of visual management Adjacent viewsheds within these river corridors would be allocated to visual management resulting in the maintenance of the natural or near-natural character of the landscape. Allocations to Backcountry Recreation would directly benefit the recreation setting within the upper and lower portions of the Illinois as well as portions of the Chetco, North Fork Smith, and Elk Rivers The inventoried foreground Retention area along the Recreation and Scenic portions of the Rogue River would not have programmed timber harvest; the vegetative character of the river would be protected. Other allocations within the river corridors that would benefit the resource include Designated Wildlife Habitat and Supplemental Resource Management Areas

Alternatives NC, A, and A-Departure would maintain the natural or near-natural character of the river corridors primarily through the allocation of all inventoried visual objectives in the adjacent viewsheds. This would be expected to maintain the natural or near-natural appearance of the landscape character The viewshed adjacent to the last six miles of the Wild section of the Illinois River would be allocated to the Supplemental Resource Management Area which has no programmed timber harvest

The benefits of Alternative K would be similar in effect to those described in Alternatives NC, A, and A-Departure, although allocations to Backcountry Recreation are added. The most significant allocation to Backcountry Recreation is the viewshed adjacent to the last six miles of the Wild section of the Illinois River which would be maintained in an unroaded condition. The natural or near-natural character of the river corridors would be maintained through the allocation of adjacent viewsheds to visual management. The viewsheds adjacent to the Chetco River would be managed for a reduced level of Visual Quality Objectives resulting in a near-natural or modified landscape Viewsheds adjacent to the North Fork Smith and Elk Rivers would be expected to remain in a natural or near-natural condition.

Alternatives B, D, and D1 would have the same effect on the Wild and Scenic River resource. The quality of recreation settings currently available would be reduced due to the absence of visual management in the adjacent viewsheds Partial Retention schemes would be applied to the Rogue-Illinois viewshed which would allow management within the viewshed adjacent to the last six miles of the Wild section of the Illinois River.

Alternative C would have the most dramatic effect on the character of the river corridors Recreation settings would be affected by the change in allocations to lower visual management objectives in the Rogue and Illinois River corridors. The viewsheds adjacent to the North Fork Smith and Elk River corridors would be allocated to General Forest Development activities in the viewshed adjacent to the last six miles of the Wild section of the Illinois would be obvious.

SOIL AND WATER

SEDIMENT

Increased turbidity or sediment in streams and rivers supporting beneficial uses of water provides an indicator of potential adverse effects resulting from either natural conditions or management activities. For each alternative, the amount of accelerated sediment would vary directly with the amount of road construction and timber harvest, as modified by the accompanying mitigation measures provided through Standards and Guidelines and Best Management Practices (Forest Plan, Appendix F).

Figure II-20 compares the mean decade percent change (first five decades) in potential accelerated sediment to the projected continuing implementation of current management direction (Alternative A). In comparison to Alternative A, Alternatives NC, A-Departure, B, C, and D would result in greater amounts of sediment, with Alternative C being the most significant increase. Alternative D1 is equivalent to Alternative A outputs. Alternatives K and S are considerably less Sediment produced by Alternatives E, G, and M are significantly less than current rates All alternatives, however, would have some degree of programmed activity, and thereby would have from slight to moderately large increases in potential sediment over background levels

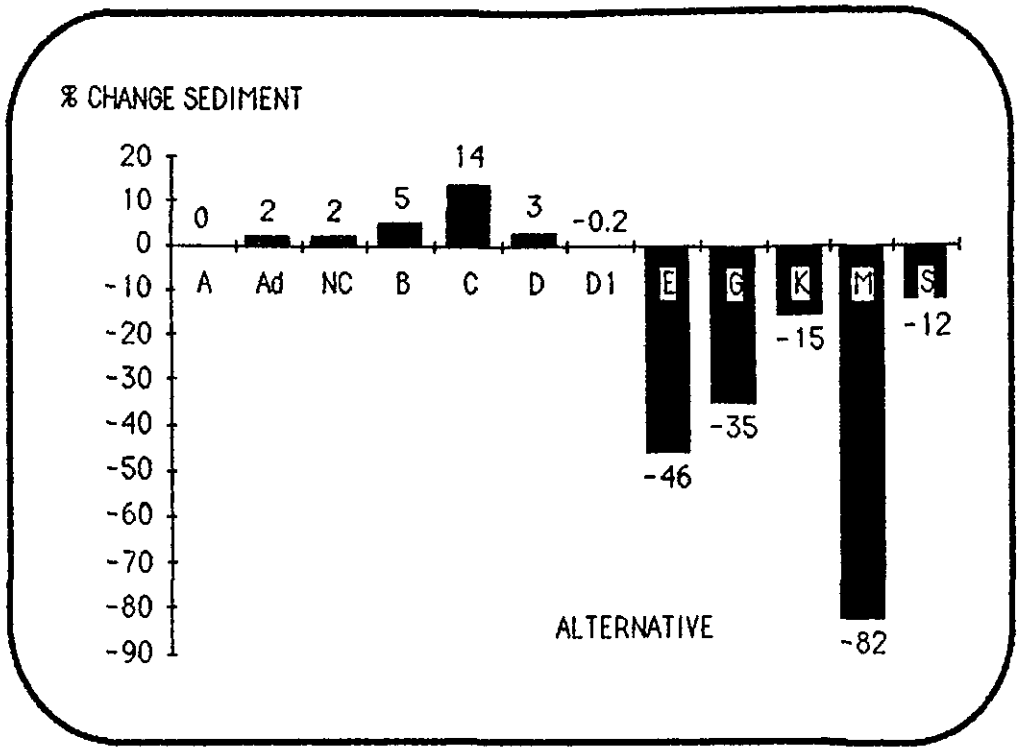

Figure II-20. Mean Percent Change in Estimated Accelerated Sediment Compared to Current Program (Alternative A), by Alternative

Figure II-21 compares the mean decade (first through fifth decades) estimated potential accelerated sediment, by alternative. The bar graph displays the quantity of sediment that would be produced by the management activity, taking into account the accompanying mitigation measures proposed for each alternative.

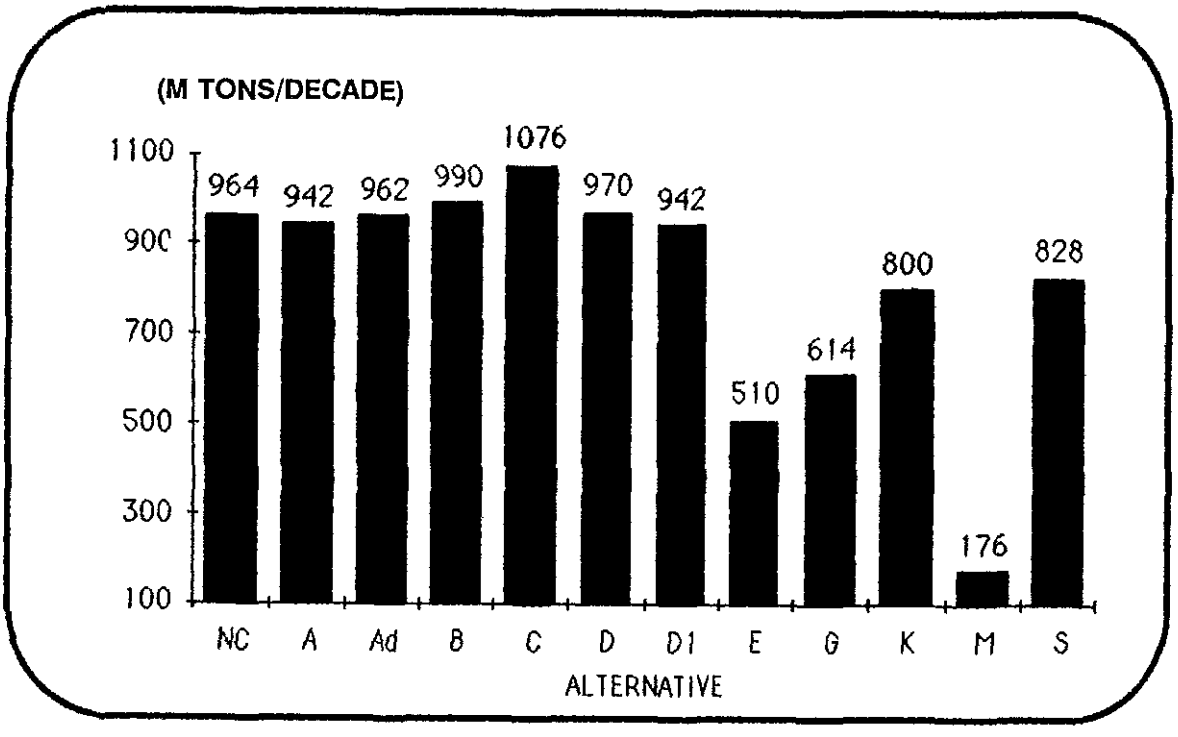

Figure II-21. Estimated Accelerated Sediment by Alternative - Mean Decades 1-5

CUMULATIVE EFFECTS

Cumulative watershed effects for both sedimentation and stream temperature increases may occur if management activities are not adequately dispersed in watersheds through time and space Rice (1980) discusses the issue of cumulative effects and supports the simple distribution of harvest as a mitigation of cumulative effects. "The problem of synchronization of effects should be addressed by dispersing watershed disturbances as greatly as feasible in time and space A more elegant approach to the problem cannot be supported by current knowledge concerning the propagation of flow or sediment in steep, rough, natural channels."

Figure II-22 compares the mean planning basin variation (coefficient of variation) for accelerated sediment for the first through fifth decades. Smaller values indicate a more even flow of sediment over the first five planning decades, while larger values indicate a greater variability in accelerated sediment delivery Smaller values in the variation of sediment over the first five decades indicate a greater dispersal of sediment over time and space with lower peaks and less potential for cumulative effects.

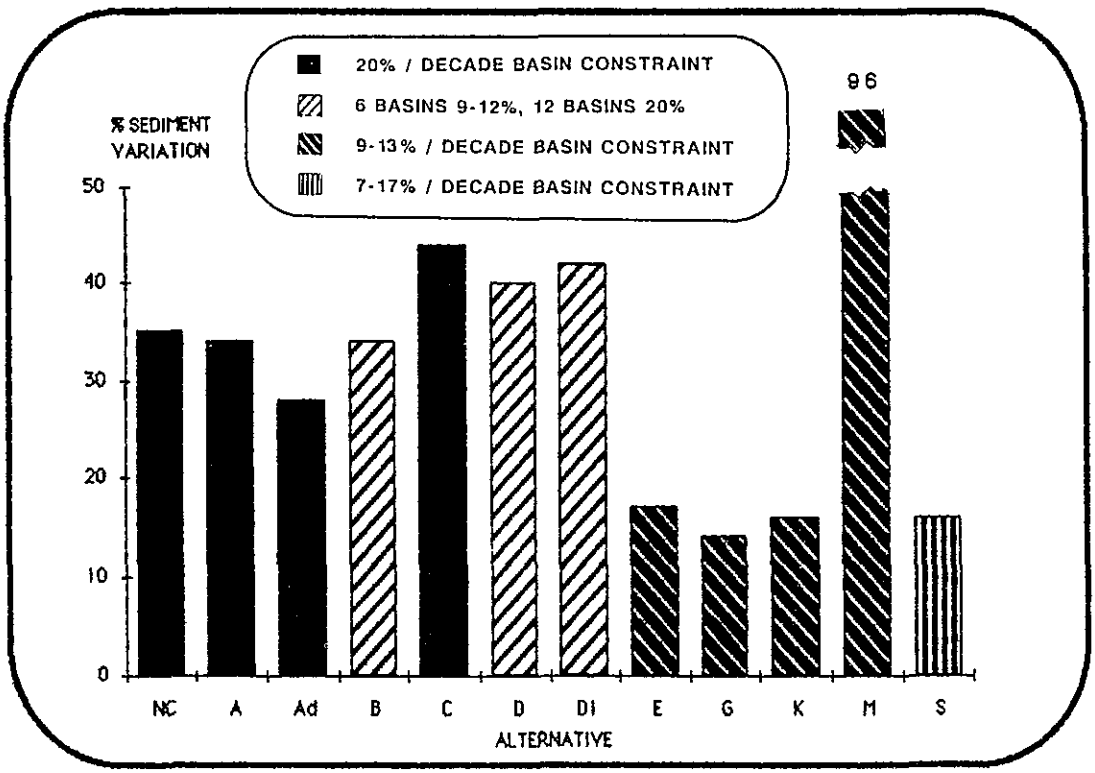

Figure II-22 Comparison of Mean Basin Variation in Accelerated Sediment by Alternative

The variation in projected accelerated sediment over the first five decades is limited for Alternatives E, G, K, and S, ranging from 14 to 17. Each of these alternatives is modeled with basin-specific timber harvest dispersion constraints of 9-13 percent (7-17 percent for Alternative S). These constraints limit the acres scheduled for harvest in any one decade to a percentage of the suitable acres in the planning basin with the objective of distributing activities, and thus effects, between the basins and through time for each basin

Although Alternative M also provides for the same decade limit, the average variation in accelerated sediment over the first five decades is nearly double However, the average variation for this alternative is not a good measure of increased potential for cumulative effects since the total amount of sediment produced is very small, even with the extreme variation, the peaks would be insignificant.

The variation in projected accelerated sediment over the first five decades ranges from 28 to 44 percent for Alternatives NC, A, A-Departure, and C. These alternatives are modeled with harvest dispersion constraints of 20 percent per decade for each basin Utilization of this basin constraint results in a less uniform scheduling of timber harvest and associated roading by basin and, thereby, greater variability in accelerated sediment is projected with higher peaks and greater potential for cumulative effects

The variation in projected accelerated sediment over the first five decades ranges from 35 to 42 percent for Alternatives B, D, and D1. For six basins, these alternatives are modeled with 9-12 percent per decade basin limit on activity acres. A 20 percent limit for the remaining twelve basins is used. The increased variation in accelerated sediment is due, in part, to more sediment being produced in the basins containing the 20 percent limit versus that being produced in the basins containing the 9-12 percent basin constraint

The potential for cumulative effects by Planning Basin is discussed under the **FISH** section in Chapter IV.

SEDIMENT AND BENEFICIAL USES

The amount of accelerated sediment and its potential risk to the beneficial uses of water, including public and domestic water supply, irrigation, wildlife, fisheries, boating, water contact recreation, visual quality, and navigation, vary by alternative The potential effects of sediment and stream temperature changes on the beneficial uses for each planning basin are discussed under the FISH section of Chapter IV (as are the definitions for "risk") For Alternative C, the estimated risk to beneficial uses ranges from moderate adverse to negligible and is about equally distributed between minor adverse and negligible. For Alternatives B, D, and D1, the estimated risk of sediment on the beneficial uses of water ranges from moderate adverse to negligible, the majority of estimated risks are negligible.

For Alternatives NC, A, and A-Departure, the estimated risk of sediment on the beneficial uses of water ranges from minor adverse to negligible; the majority of estimated risks are negligible. For Alternatives K and S, the estimated risk of sediment on the beneficial uses of water also ranges from minor adverse to negligible, however, nearly 90 percent of the estimated risks are negligible.

Alternative E, G, and M also have a negligible risk of sediment on the beneficial uses of water. The lower levels of timber harvest and roading activity in these alternatives allow for the current background level of sediment to be lowered over time Alternative M proposes the least timber harvest and roading activity.

WATER TEMPERATURE

Increased water temperatures during the summer may result from removing the vegetation shading streams and rivers Table II-3 shows the allocation of various planning basins by each alternative to Riparian Prescriptions B and C. The goal is to maintain water temperature for all planning basins allocated to Riparian Prescription B, and reduce it by up to two degrees Fahrenheit by the end of the third planning decade for all planning basins allocated to Riparian Prescription C. Alternatives that allocate planning basins to Riparian Prescription C provide a means of reducing stream water temperature within planning basins containing critical fisheries where there has been a net loss of stream shading due to past management The effect of increased stream temperature on the resident and anadromous fishery is discussed in the **FISH** section of this chapter

WATERSHED IMPROVEMENT

The amount of proposed soil and water resource improvement varies by alternative as shown below in Figure II-23 Alternatives that propose a greater rate of timber harvest would also result in greater financing for watershed improvement, since the funding for approximately 60 percent of the work is tied to timber harvest activity and volume of harvest

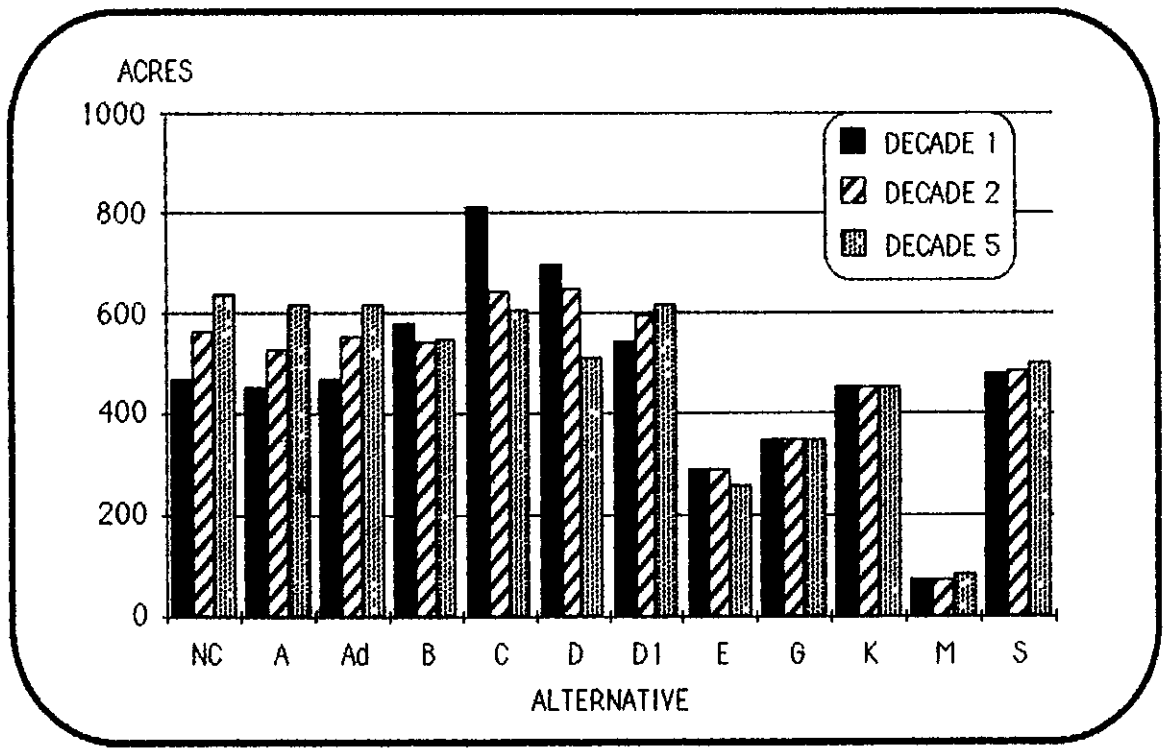

Figure II-23. Annual Acres of Improved Watershed Condition for Decades One, Two, and Five by Alternative

WATER YIELD

When compared to the total water yield for each planning basin, the increased water yield resulting from the removal of only a small percentage of mature forest is not significant. The water yield increase is gradually diminished each year as other vegetation grows on the site and the area is reforested, until returning to preharvest levels after 20 years See Chapter IV, ENVIRONMENTAL EFFECTS UNCHANGED BY ALTERNATIVES, for more detail

SITE PRODUCTIVITY

Considerable research suggests that nutrient reserves, organic residues, and soil physical properties are critical elements of the ecosystem that must be managed to ensure long-term productivity All alternatives contain Standards and Guidelines that provide for maintaining soil physical properties; all alternatives but NC, A, and A-Departure contain Standards and Guidelines to retain on-site large woody material for maintenance of a healthy forest ecosystem Alternatives NC, A, and A-Departure contain Standards and Guidelines of current direction established and documented under plans listed in Appendix D which provide for maintaining soil physical properties, but do not contain specific direction for large woody material management. See Chapter IV, SOIL AND WATER and RELATIONSHIP BETWEEN SHORT-TERM USE AND LONG-TERM PRODUCTIVITY sections for additional discussion.

FIRE

The interactions of fire, both managed (prescribed fire, i.e., slash burning and wildlife habitat improvement burning) and unmanaged (wildfire), with Forest resources and land allocations will depend upon its frequency, intensity, and duration on the site The ability of the fire management organization to physically deal with fire, in particular wildfire, is influenced by land allocations and associated Standards and Guidelines A well dispersed array of land allocations would be more difficult to manage than a limited number of land allocations consolidated in general areas Management complexity is generated by the individual fire management prescriptions developed to support the specific resource management objectives, and the activities permitted within each land allocation The array of management activities and uses of Forest resources portrayed in the range of alternatives will compound the management complexities associated with various key elements of the fire protection program, such as prevention, suppression, and fuels management.

PREVENTION

Increased recreation opportunities and timber harvest activities will add to the risk of human-caused fires. No specific numbers are available to determine the actual amount of increase, however, as activities increase, the risk of an ignition (start of a fire) also increases.

The range of alternatives provide a broad spectrum of recreational opportunities. In alternatives such as B, C, and D, areas not presently accessible would become available for recreation use as the road network expands during the course of timber harvest activities Forest recreationists, in many cases, would follow the expanding road system into areas not previously available for motorized recreation The increased recreation use and shifting recreation load would raise the risk of a human-caused wildfire in these areas

Dispersed recreation opportunities, such as those emphasized or enhanced in Alternatives E, G, K, M, and S would present a larger problem than developed recreation With dispersed recreation, the Forest visitor uses unimproved areas, which presents a greater risk of wildfire than use in developed areas

Motorized recreation, which is affected by the miles of roads open to such use, will also compound the fire prevention problem Prevention efforts will be further complicated by motorcycle and all-terrain-vehicle (ATV) users who will continue to use the many miles of unmaintained roads for recreational purposes

The prevention of industrial operations fires is a major portion of the wildfire prevention program throughout the range of alternatives The higher levels of timber activity in Alternatives NC, A, B, and C, for example, would increase the chances of an operations fire to a much greater degree than Alternatives E, G, and M The problem would increase by the fifth decade as the acreage involved in timber harvest increases in conjunction with the addition of commercial thinning activities (Table II-25)

Table II-25. Expected Annual Harvest Acres, by Alternative

	Decade (Acres Harvested)	
Alternative	1	5
NC	4,518	9,840
A	4,505	9,988
A-Departure	4,697	10,160
B	5,562	9,504
C	6,713	10,132
D	5,570	9,589
D1	5,251	9,450
E	2,890	6,603
G	3,495	7,325
K	4,934	8,800
M	754	2,147
S	4,790	9,363

SUPPRESSION

Two levels of fire protection are incorporated into the range of alternatives Alternatives NC, A, and A-Departure represent no change from the base fire planning organization The protection level for the remainder of the alternatives reflects a high degree of fire management efficiency A detailed discussion of the levels of protection analyzed for the Forest Planning process is presented in Appendix B.

The primary effect of the protection level on Forest resources such as fish, wildlife, water, recreation, timber, and facilities (improvements) is to establish a balance between suppression costs incurred while protecting resources and the damages to resources associated with wildfire occurrence.

All Forest resources will be affected by a catastrophic wildfire. These have occurred in the past and will occur on infrequent occasions in the future, regardless of the alternative The expected frequency of occurrence of a wildfire of 300 acres or larger is once every seven years.

Fire suppression effectiveness will be affected by the acres harvested in the various alternatives, the acres of hardwood stands converted to conifer production, and the resultant fuels treatment activities, which provide a diversity or mosaic of fuels The increasing diversity, coupled with fuels management practices will produce a fuels mosaic composed of recently treated harvest units, plantations, pole stands, mature timber, and old-growth timber While having average rates of spread similar to the current situation, the future fuels mosaic will have lower fuel loadings, resulting in fires of generally lower intensity and more efficient fireline construction rates This will equate to less acres burned, lower suppression costs, and lower resource damage per fire.

All alternatives, except Alternatives E, G, and M, would result in at least half of the Forest being affected by the development of a broad fuels mosaic by the end of the tenth decade. Alternative C would develop the most extensive mosaic and would complete it by the end of the eighth decade Alternative M, on the other hand, would only affect 38 percent of the Forest and the mosaic would be completed by the end of the seventh decade High percentages, 75 to 90 percent, of the mosaics in Alternatives NC, A, A-Departure, E, G, K, and S would be completed by the end of the seventh decade (Table II-26).

Table II-26 Fuels Mosaic Development through Timber Harvest Activities

Alternative	Time Mosaic Completed (Decade)	Affected Forest (Percent)
NC, A, A-Departure, D and D1	10	70
B	9	70
C	8	71
E	10	40
G	10	48
K	10	65
M	7	38
S	10	55

The miles of road available for immediate fire suppression access, as well as the miles of closed road that could be opened quickly in a fire emergency, will have a major influence on the type and amount of fire suppression forces maintained on the Forest. In alternatives such as NC, A, A-Departure, and D, which are well-roaded, a fire organization emphasizing ground forces supported by limited aerial forces would be most appropriate On the other hand, in alternatives such as E and M, a more equal balance between ground forces and aerial forces would be appropriate (Table II-27).

Table II-27 Road Available for Fire Access in Decade 1 (Miles)

	Miles	
Alternative	Open	Closed
NC, A, and A-Departure	2,528	347
B	2,254	368
C	2,576	377
D and D1	2,554	362
E	2,022	733
G	2,304	483
K	2,202	649
M	2,116	529
S	2,211	662

FUELS TREATMENT

Fuels treatment would vary throughout the range of alternatives from two important aspects (1) the activity fuels program, i e , slash or brush disposal (BD); and (2) the treatment of natural fuels

The amount of activity fuels treatment is dependent upon the acres of timber harvested. During the first decade, Alternatives B, C, and D would generate the greatest BD workload. However, by the fifth decade, the heaviest workload would fall in Alternatives NC, A, A-Departure, and C Alternative M would produce the lightest BD workload over the range of alternatives (Table II-28)

Table II-28. Expected Annual Harvest Acres Requiring Fuels Treatment, by Alternative

	Decade (Acres Requiring Treatment) 1/	
	1	5
NC	3,386	5,886
A	3,379	5,886
A-Departure	3,523	5,964
B	4,172	5,329
C	5,035	6,178
D	4,178	5,618
D1	3,938	5,647
E	2,168	3,537
G	2,621	4,154
K	3,556	4,996
M	566	1,146
S	3,593	5,239

1/ The acres treated assumes that 75 percent of the final harvest removal acres and 40 percent of the commercial thinned acres would require some form of hazard reduction work to meet resource management objectives

Three levels of natural fuels treatment are fixed into the range of alternatives. Alternatives NC, A, and A-Departure are fixed at 60 acres per year and represent no major effort at natural fuels treatment Alternative B (250 acres per year) reflects the 1980 RPA outputs (USDA 1984a). The remainder of the alternatives reflect a fixed value of 400 acres per year.

Most land allocations support use of prescribed fire as a tool to manage the accumulation of natural fuels Wilderness areas allow for the use of both planned and unplanned ignitions (See Table II-29).

The effects of the prescribed fire program will depend on factors such as size of area treated, fuel loading, and current weather conditions Accumulated fuels will be consumed by prescribed fire, reducing the severity and impacts of future fires. In addition to reducing fire hazards, low-intensity prescribed fires would increase forage for big game by removing tall, dense vegetation and encouraging earlier stages of forb and low shrubs. Palatability of forage would also be increased Prescribed fire increases both vegetative and animal diversity along with increases in populations of animal species that prefer early seral stages. The variety of fuels profiles on the Forest would be further enhanced by treating fuels complexes which have experienced 70 years of fire exclusion

Other important effects will be on air, soil, and water quality Alternatives such as B, C, and D, which utilize prescribed fire to the greatest extent, would have the greatest impact, while Alternative M, which makes the least use of prescribed fire, would have only minor impacts.

Table II-29 Prescribed Fire Ignition Strategies for Siskiyou National Forest Wildernesses

	Wilderness (Fire Ignition Strategy 1/)				
Alternative	Kalmiopsis	Wild Rogue	Grassy Knob	Siskiyou	Reb Buttes
NC, A, and A-Departure, E and M	4	4	4	5	1
B, C, D, and D1	2	1	4	5	1
G, K, and S	3	2	4	5	1

1/ Strategy 1 Planned ignitions only
Strategy 2 Planned ignitions supplemented by unplanned ignitions at Fire Intensity Level (FIL) 1
Strategy 3 Planned ignitions supplemented by unplanned ignitions at any FIL in the Pristine and Primitive (WRS) sections
Strategy 4 No planned or unplanned ignitions, fire exclusion
Strategy 5 Planned and unplanned ignitions

VEGETATION

Plant diversity has been defined variously. Many accepted quantitative definitions include the number of different species within an area and their relative abundance For example, an area with 10 different species with 10 individuals per species is considered to be more diverse than an area with 10 different species with one individual per species It is difficult to quantify the diversity of a given area and yet more difficult to predict what changes will occur, and how these changes would or should be influenced by management

Plant diversity is not static; change is inevitable For instance, control of wildfire is a major cause of change in plant community composition Ponderosa pine is not as common now on the Siskiyou as it once was. The lack of wildfire in the last few decades has left it at a competitive disadvantage. White fir, however, thrives in the absence of fire. Similarly, the application or lack of application, of management tools can be used to manipulate species composition to favor particular species or increase diversity.

Tree diversity will be maintained under all alternatives, although some fluctuations will occur in relative abundance. Although tree seedlings of various commercial species are presently not planted in the same proportions as they exist in natural stands prior to harvest, current practices are tending in that direction. Some species are given special attention Douglas-fir and sugar pine are tied to a tree improvement program Special efforts are made to plant both redwood and Brewer spruce on the sites they were removed from and onto sites identified as having the potential to grow them In fact, Brewer spruce, an indigenous tree species present on both commercial and reserved Forest lands, is being monitored to insure that it remains a viable species on commercial sites; seed is also being collected for use in reforestation Another concern is Port-Orford-cedar Because it can be killed by an introduced root disease, it will be monitored both locally and species wide Management direction designed to control the spread of the disease is included in the Standards and Guidelines governing all alternatives (LRMP, Chapter IV).

For species other than trees, the maintenance of diversity may require active management For sensitive species, alternatives with high rates of harvest and disturbance may require timely acquisition of management information, such as existing population density and sensitivity to change Alternatives E and M would leave more area undisturbed and more options open. However, species that require disturbance, such as fire, for their survival may be at risk. Alternatives E through S would tend to "preserve" diversity As mentioned, some species may require disturbance, and although these alternatives give us time, information will still be needed to assure the viability of all species, particularly sensitive species

HARDWOOD CONVERSION

Hardwood stands provide habitat diversity They are thought to be important for small mammals and birds; acorns from tanoak, one of the major hardwood species, are a staple for deer and elk They also play an important ecological role The high demand for nutrients by hardwood stands tends to slow nutrient loss after a disturbance, and their leaves quickly decompose in the winter, recycling what they have taken up The net result often enhances productivity

Alternatives B, C, D, and D1 would allow significant acres of hardwoods (14,000) to be converted to conifer plantations in the first decade Actual acres converted would depend on market conditions. Alternative A, A-Departure, K, and S would allow a moderate level of conversion the first decade (7,500 acres). Alternative G would allow a low level (4,000 acres), Alternatives NC, E, and M would not allow any

OLD GROWTH

Old-growth stands would provide the bulk of the timber harvest in the early decades in all alternatives. The rate at which old-growth stands would be harvested would serve as an indicator of the rate at which standing inventory deductions occur Departure alternatives would accelerate this rate of reduction, in comparison to their nondeclining yield counterparts. In general, old growth would be harvested more quickly under Alternatives NC, A, A-Departure, B, C, D, D1, K, and S. Under Alternative M, lands suitable for the production of timber would be managed on an old-growth rotation (250 years)

In all alternatives, some mature and old-growth forests would be maintained in the sense that they are located on lands unsuitable or unavailable for timber harvest, reserved as designated wildlife habitat, or where long rotations are established in visually sensitive areas. Mature and old growth in these categories is as low as 153,000 acres in Alternative NC, which does not meet MR's for wildlife. In alternatives with wildlife MR's, minimum levels of mature and old-growth forest would be maintained at 166,000 acres in Alternative C and would range up to 290,000 acres in Alternative M. Acres of mature and old-growth forest projected to be harvested from suitable timber lands during the first five decades are shown in Table II-30 Acres of old growth remaining are displayed by decade by alternative in Table II-31.

By the tenth decade, old-growth habitat would decline between 61 and 73 percent under Alternatives NC, A, A-Departure, B, C, D, D1, K, and S. Although still significant, reductions in old growth under Alternatives E and G would be less, 29 and 46 percent, respectively. Reduction in old growth would only be 13 percent under Alternative M (Table II-32).

By the tenth decade, old-growth habitat will be at its lowest ebb under all alternatives, old growth would occupy between 10 and 31 percent of the Forest land base, depending on the alternative. Under all alternatives, some presently young or mature timber stands would be located in areas where timber harvest is not permitted Because these stands will reach the old-growth successional stage by the fifteenth decade, the percent of old growth will actually show an increase by that time A comparison of the old-growth component as a percent of the total Forest is displayed by decade, by alternative, in Table II-32

Table II-30. Mature and Old-Growth Forest Planned for Harvest per Decade, by Alternative (Acres)

	Decade (Acres)				
Alternative	1	2	3	4	5

S	36 0	31 3	26 2	21 6	19 1	14 2	22 4

SUCCESSIONAL STAGES

Under all alternatives except M, the greatest change would occur in the old-growth stage which presently occupies 36 percent of the Forest land base, but which would decline significantly The proportions of mature and young forest would fluctuate significantly throughout the planning period under all alternatives except M, due mostly to the Forest's uneven distribution of stand age classes. Tables II-33 and II-34 demonstrate the progression of environmental consequences in the fifth and tenth decades, respectively, which would occur as old-growth stands are converted to managed stands (100-year rotations)

Seral stage proportions on the Siskiyou vary widely by planning basin Predictably, planning basins which are predominantly Wilderness or unroaded contain rather high proportions of old growth and low proportions of early seral stages If future timber harvests are distributed evenly, according to the amount of land allocated to timber production in each planning basin, each seral stage could be maintained at a minimum proportion of four or five percent within the non-Wilderness planning basins (Grass/Forb and Low Shrub grouped together)

1/ Contains serpentine/peridotite areas, rock outcrops, and hardwood stands.

TIMBER

The implications of the alternatives on timber resource management can best be understood by examining a few parameters of acre allocations and scheduled outputs. Measures of the availability of the land base to produce timber are provided by examining the acres allocated to prescriptions that include timber management. The management areas with programmed timber are: General Forest, Partial Retention Visual, Retention Visual, Riparian, and Scenic/Recreation River. The General Forest prescription provides for the highest level of timber outputs, subject to broad multiple-use constraints. The other prescriptions emphasize management for nontimber resource values (such as visual quality or riparian and watershed values) and have reduced levels of timber output. The acres allocated to these prescriptions are displayed for each alternative in Table II-3, and are illustrated by Figure II-24.

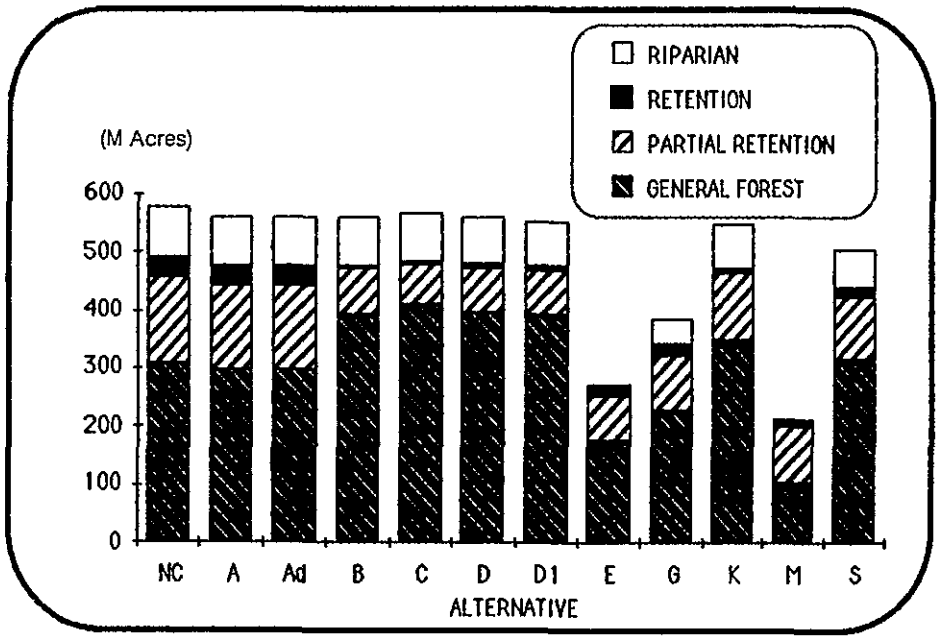

Figure II-24. Acres with Programmed Timber Harvest (M Acres)

The important timber outputs that can be used to gauge the alternatives are: first decade Allowable Sale Quantity (ASQ) and Long-Term Sustained Yield (LTSY). Both are expressed in terms of annual timber volume output. These outputs are also displayed for each alternative in Table II-5, and are illustrated by Figure II-25. Table II-35 includes timber resource management information about present and future timber production.

The analysis and projections for future timber outputs use cubic volume measure. Historic volumes and volumes projected for harvest by alternative in the next decade are also displayed in board foot measure It is expected that there will be a transition from using board foot measure to cubic measure, both within the Agency and within the timber industry, in the next decade Volumes are displayed in board foot measure for the first decade only. In the future, the board feet expected to be harvested will vary as the size of the specific stands harvested varies Board foot measure of volume harvested is expected to decline over the next few decades as the average diameter of the stands harvested decreases, even though the volume in cubic measure may be the same. For example, Alternative A projects harvest at 30.1 MMCF per year on a non-declining flow schedule, but this same volume measured in board feet could range from approximately 170 MMBF in the first decade to less than 150 MMBF by the fifth decade as the relationship of board feet to cubic feet declines with the harvest of smaller material This trend would occur under any alternative except Alternative M.

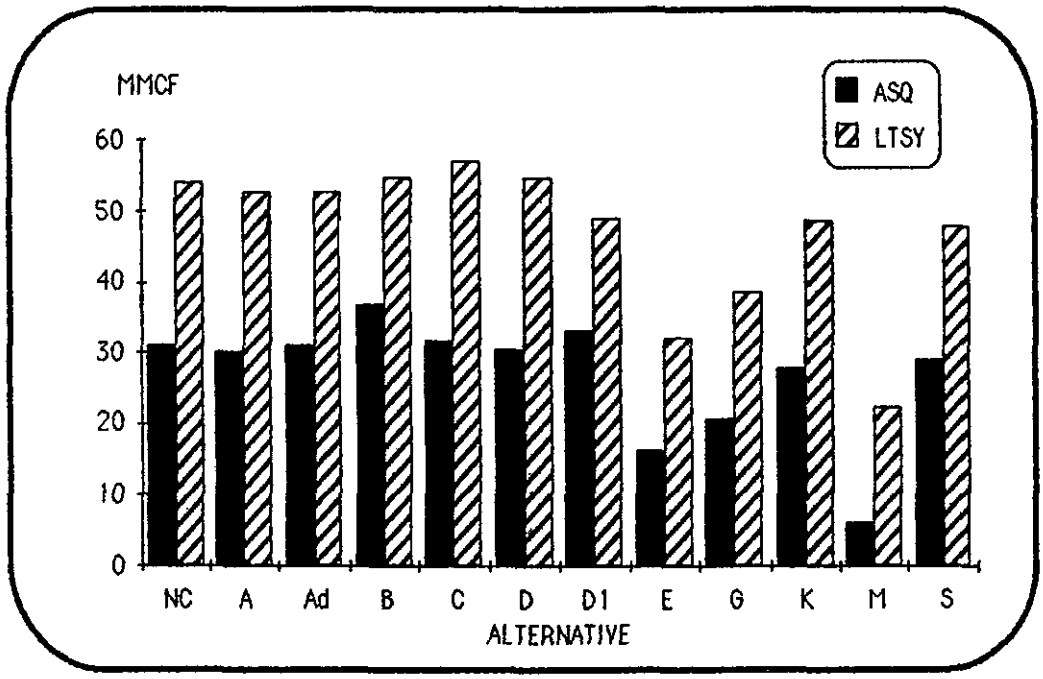

Figure II-25. Annual Timber Volume Output for ASQ (First Decade) and LTSY by Alternative (MMCF)

Suitable area declines from Alternative NC to A to D1 to K to S due to allocation of lands where programmed timber harvest is excluded (Management Areas 1-9). The amount of suitable area continues to decline from Alternative S to G to E to M

First decade ASQ and LTSY are also generally proportionate to suitable acres. Exceptions occur for the first decade ASQ where a departure harvest schedule exists (A-Departure and B) or where the rotation length is shortened (Alternative D1). Alternative NC is also different since timber production is set at the level of the 1962 Timber Management Plan LTSY would generally be reached in the ninth or tenth decade except in Alternative M where the LTSY would not be reached until after the fifteenth decade.

The net growth in year 2030 is also proportionate to the amount of suitable acres. The net growth per acre varies due to the differences in age class distribution on different site classes Those alternatives that harvest large areas early (such as C, D, and B) have large per acre growth rates due to conversions of hardwoods and slow-growing old-growth stands to thrifty growing young stands The alternatives that do not develop unroaded areas (Alternatives G, E, and M) also have high proportionate growth rates. This is due to leaving the mature stands in the unroaded areas out of the base The areas already accessed have a much higher balance of acres in younger age classes with high per-acre growth

The display of regeneration harvest acres generally varies with the harvest level. Those alternatives that have a higher harvest level have more acres harvested The amount of hardwood conversion also influences the amount of harvest acres Alternative C has the highest amount of hardwood conversions while Alternatives G, E, and M have no hardwood conversions planned.

The percentage of the potential timber yield available from the selected suitable land is a function of land allocation Those acres allocated to General Forest are managed for full yield. The Partial Retention Visual Management Area would produce less than full yield, but greater than 50 percent yield. The Riparian and Retention Management Areas would produce less than 50 percent yield

1/ Tentatively suitable for timber lands for all alternatives: 624,240 acres
2/ Harvest in Decade 15 is 28 percent of long-term sustained yield (LTSY).
3/ Some acres shown as clearcut acres may be seedtree, shelterwood, or selection treatments depending upon site specific prescription. Refer to Appendix G for more details.

Harvests scheduled in riparian areas are shown as selection harvest (column 22) All other harvests are shown as acres clearcut, however, actual selection of a harvest method will be on a site-specific basis (refer to Appendix G) and some of these acres may be shelterwood, seed tree, or selection harvests

Most of the alternatives are designed to produce timber on a nondeclining harvest schedule The projected LTSY with applied timber management is higher than the harvest level that can be maintained by the existing stands, as they are metered out to last until the regenerated stands become available for harvest. The harvest schedules would generally remain constant over the first several decades, and then increase about the eighth or ninth decade as managed timber stands become available for harvest.

Exceptions to this pattern are Alternatives A-Departure and B which depart from the nondeclining even-flow policy. These alternatives are designed to meet specific outputs in the short term Alternative B starts with the same initial acreage allocation as Alternative D, but, with the departure schedule, would meet the RPA timber goals for two decades and then drop to a low of 25 MMCF in the fifth, sixth, and seventh decades before climbing up toward LTSY. Alternative A-Departure would continue timber outputs at approximately the current level for the next two decades, and then drop to a low of 29 4 MMCF in the middle decades.

Alternative D1 is unique (in General Forest areas) in that it would provide rotations (i.e., time span from plantation establishment to harvest and establishment of a new plantation) two decades shorter than those allowed by other alternatives. With the exception of the rotation lengths, this alternative is the same as Alternative D. Alternative D1's rotation for high and medium site General Forest areas would be approximately 80 years This may not meet the NFMA requirement that, prior to harvest, stand growth shall generally have reached the culmination of mean annual increment (CMAI); minimum rotations would be one or two decades shorter than the time required for culmination of 95 percent of mean annual increment.

Alternative M is also unique, requiring minimum rotation lengths of 250 years on all lands where timber harvest is allowed These acres are listed as General Forest, but the yield tables and timber outputs would be reduced accordingly. In addition, no new roads would be constructed, and only those areas accessible by existing roads would be planned for timber management

The effects of the alternatives on management of the timber resource would primarily be the result of the allocations of land to uses that either reduce or do not provide for timber harvest. This would be mitigated to some extent by providing intensive timber management regimes on those acres remaining available for timber production To optimize the timber production aspects of each alternatives objectives, practices such as precommercial and commercial thinning, tree planting, improvement of genetic stock, and animal damage control are planned in various combinations. Treatment schedules are also designed to provide the highest outputs achievable for the existing inventory structure. The analysis and development of these regimes are described in *Managed Yield Tables For the Siskiyou National Forest* (Craig 1984).

Another way of intensifying production on available acres would be to shorten the minimum rotation length as described for Alternative D1 above. This would provide a higher level of timber output (Alternative D1, at 33 2 MMCF, versus Alternative D at 30 4 MMCF), but as mentioned, may not meet the requirement of NFMA. The option of using short rotations to increase timber outputs is discussed in more detail in the section, **ALTERNATIVES CONSIDERED BUT ELIMINATED FROM DETAILED STUDY** in this chapter.

Developing prescriptions that allow timber harvesting in areas that are allocated to the protection or management of other resources is also a form of minimizing the effects of such allocations on the management of the timber resource As examples· allocations emphasizing visual quality have prescriptions that allow timber harvesting at the highest rates that can be maintained while still meeting the objectives for visual management; riparian areas would also produce varying levels of timber, according to the alternative's Riparian Prescription and land allocations Alternatives E and M would not allow harvest from streamside areas; the remaining alternatives, however, would all provide for limited harvest of timber within the riparian area -- subordinate to the management objectives for the riparian,

fisheries, and watershed resources Alternative G would allow a low level of harvest Alternatives NC, A, A-Departure, C, and K would allow timber harvesting at or near the highest level that could be maintained while protecting fish and watershed values. Alternatives B, D, D1, and S would provide intermediate levels of timber harvest in riparian areas, with prescriptions assigned to individual basins so as to correspond to the themes of the alternatives

Historical Perspective

The Forest has historically supplied significant volumes of timber for harvest. The current Timber Management Plan was completed in 1962 and established an annual potential yield of 190 9 MMBF Amendments have adjusted the potential yield to account for changes in the land base, primarily wilderness additions Table II-36 displays the potential yield as amended, and the net chargeable volume sold and harvested by year from 1963 to 1987.

Table II-36. Siskiyou National Forest Timber Harvest Record 1963 to 1987 (MMBF)

	MMBF		
Fiscal Year	Potential Yield	Volume Sold	Volume Harvested
1963	190 9	287 4	168 4

TOTALS	4,633 1	4,454 9	4,234 3

1/ Includes transition quarter
2/ Volume sold reflects a buy-out adjustment of -412 5 MMBF

Examining the events over a recent decade (1975-1984) may add some perspective and contribute to understanding the effects of changes in the timber outputs. Events and actions within the Forest Service, and within the industry, are of interest

During this period, purchasers annually bought an average of 174 4 MMBF and cut an average of 128.3 MMBF (net merchantable) The reason the amount of timber harvested was less than the amount of timber sold involves the recession A severe depression of the housing market and a general slowdown in the economy sent demand and prices for lumber and plywood crashing in 1980. Many purchasers had a considerable volume of high priced timber under contract on the Forest at the time This impact was felt on the Siskiyou in two ways. First, timber harvest declined, in 1982 only 39 4 MMBF (all products) were cut on the Forest. Second, purchasers tried to stay competitive by harvesting their less expensive timber For example, in 1982, the average bid price for timber on the Forest was 129 dollars per MBF (all products), while the average price paid for timber cut on the Forest was 82 dollars per MBF (all products).

The average potential yield, for the Forest from 1975 through 1984 was 179 5 MMBF (chargeable sawtimber volume), as prescribed in the 1962 Timber Management Plan. Actual annual sell level for the same period, was only 170.1 MMBF (chargeable sawtimber volume) The difference between potential and actual sell was due primarily to injunctions involving the RARE II Roadless Areas which prevented the Forest from offering a number of fully prepared sales during the period In addition, several deficit sales late in the period failed to sell. In 1985, potential yield was reduced to 167.5 MMBF following passage of the Oregon and California Wilderness Acts of 1984. If current direction were to continue, the 1962 Timber Management Plan would have to be adjusted downward again to reflect the Wild and Scenic River corridors designated under the Omnibus Oregon Wild and Scenic River Act of 1988

A comparison of the past timber program and the projections for each of the alternatives is presented in Table II-37. The effect of implementing the Forest Plan depends on whether the events of the past decade continue or change. The ASQ of the Preferred Alternative (S) represents the amount of timber that could be sold in the decade (in any given year sales can exceed or fall short of the ASQ, but the cumulative total for the decade may not be exceeded). This maximum was represented by the potential yield in the current Timber Management Plan, approved in 1962. During the 1975-84 period, the Forest sold about 95 percent of the potential yield under the current Timber Management Plan. Barring unforeseen circumstances such as inadequate funding by Congress or litigation, the Forest Service expects to achieve 100 percent of the ASQ in the new Forest Plan

On the Siskiyou National Forest in 1985, Purchasers returned 412.5 MMBF under the Federal Timber Contract Payment Modification Act. This net merchantable sawtimber volume, with an average bid value of 632 dollars per MBF, was bought out at a rate of 16 dollars per MBF under the terms of the Act Also, the Forest Service implemented regulations in 1982 that require shorter term sales and more up-front money to curb the incentive to hold timber for speculation (which was a major contributing factor to the large backlog of high-priced stumpage resulting in the buy-out legislation). While harvest was very low in the early 1980's, the average annual harvest has experienced an upswing since 1986 (Table II-36) Purchasers are expected to harvest approximately what is sold under the Preferred Alternative of the Forest Plan.

Compared to the potential yield in the current Timber Management Plan, the Current Direction Alternative (A) represents only a three percent decrease in chargeable sawtimber outputs. The Preferred Alternative (S) amounts to a seven percent decrease. Compared to the actual harvest in the 1975-84 period, the Preferred Alternative represents an increase of 18 percent. Since receipts are based on cut, this equates to a 2.1 million dollars projected annual increase in county receipts, and a potential increase of 270 jobs

Table II-37. Comparison of First Decade Timber Outputs by Alternative

Timber Output Component	1975-1984 Annual Average Sold	Cut	Existing '62 TM Plan No Change	ALTERNATIVE No Action	A-Departure	B	C	D	D1	E	G	K	M	S
CHARGEABLE (MMBF)

1/ No Change figure is Potential Yield, others are ASQ
2/ TSPQ does not include convertible products.

Mills in Coos, Curry, Jackson, and Josephine Counties are expected to face a fluctuating timber supply over the next 30 years. Projections indicate that the supply of non-National Forest stumpage will drop for the next 10 years. The projected supply for the following 10 years is not of sufficient magnitude to satisfy potential consumption needs (as postulated in Chapter III). Therefore, alternatives containing National Forest harvest flows that counterbalance changes in non-National Forest supply could have the beneficial effect of mitigating the total timber supply over time Different alternatives then have different levels of projected supply within the four-county area (Table II-38)

Table II-38. Total Projected Four-County Timber Supply by Alternative and Estimated Demand (MMCF/Decade)

	Historical	Projected Supply by Decade (MMCF/Decade)		
Alternative	1980-1984	1989-1998	1999-2008	2009-2018
Volume Other than Siskiyou National Forest	1,447	1,966	1,352	1,939
Total Volume by Alternative, including Siskiyou National Forest (Arranged by Increasing Volume for the First Decade)				
M	1,606	2,027	1,413	2,000
E	1,606	2,128	1,514	2,101
G	1,606	2,171	1,557	2,144
K	1,606	2,244	1,630	2,217
S	1,606	2,250	1,636	2,223
A	1,606	2,267	1,653	2,240
D	1,606	2,270	1,656	2,243
NC	1,606	2,276	1,662	2,249
A-Departure	1,606	2,278	1,664	2,242
C	1,606	2,284	1,670	2,257
D1	1,606	2,292	1,684	2,271
B	1,606	2,334	1,720	2,269
Estimated Demand, All Ownerships				
Low Projection		2,056	2,282	2,282
High Projection		2,282	2,506	2,506

Two projections of estimated demand of wood by local mills are made. The lower projection is 2,058 MMCF in 1990 increasing to 2,282 MMCF in the year 2000. The high end projection estimates 2,282 MMCF of wood will be processed in 1990 with 2,506 MMCF being processed in the year 2000

In the first decade, Alternatives B, C, and D1 would meet or exceed anticipated log consumption needs using the high end of the range for consumption as developed in Chapter III. Alternatives NC, A, D, S, and K would almost meet the projected consumption while Alternatives E, G, and M would fall short of the projected log needs. In the second and third decade, no alternative would meet the anticipated log consumption needs for the local area of influence at the lowest level of projected demand. Alternative B would come the closest to meeting the projected needs with a total supply of 1,720 MMCF per decade

Using the low end of the range of projected consumption, all alternatives except Alternative M would exceed the projected log needs for the four-county area of Coos, Curry, Josephine, and Jackson Counties for the first decade In the second and third decades, no alternative would exceed the lower limit of demand for log consumption.

As discussed earlier, the departure alternatives (Alternative B and A-Departure) would have decreases in timber production in future decades while the other alternatives would maintain or increase their timber outputs. The departure alternatives respond to the projected downfall in timber supply in the first, second, and third decades from other ownerships The potential of the Forest to supply timber limits the extent to which the Siskiyou National Forest can respond to the projected shortage of logs

It is important to recognize other options for harvest scheduling, such as a departure beginning in the second decade. However, the time span for implementation of this plan is 10 years Management has the option to depart from evenflow harvest to respond to supply conditions in future plans as well as in the present planning effort

Comparison to Oregon Department of Forestry Goals

The Forestry Program For Oregon - An Action Program for the Eighties (Oregon State Board of Forestry 1982) updates the 1977 Forestry Program for Oregon (FPFO) which includes goals for timber production from the National Forests that correspond to State of Oregon objectives. The goals have been revised by the Oregon Department of Forestry (ODF) to correspond with the current land classifications on the Forest (letter of April 2, 1985, in the Planning Records) The revised projections indicate goals for timber outputs of 40.7 MMCF for the first decade; 39.1 MMCF for the second decade; and a decline in the third and fourth decades to 36.5 MMCF and 37.2 MMCF, respectively; it then increases to 40 MMCF or more for the remaining decades

These projections are not directly comparable to the results of the current analysis, due to differences in yield tables, inventory data, and reduced yields on acres where nontimber values are emphasized. For example, the State projections do not include harvest dispersion requirements or reduced yields in riparian areas. Installing these requirements in our analysis results in a 15 percent change in the timber harvest level. Alternative B appears to come the closest to meeting the State goals, producing 36.8 MMCF ASQ (40.5 MMCF when nonchargeable volume is included) for the first and second decades. However, this is a departure alternative and would not meet the goals in future decades.

The ODF also has identified objectives for land allocation, intensive management, and community stability. Table II-39 (developed by the ODF) displays the FPFO objectives and the standards of the ODF by which to measure how well Forest Plan FEIS alternatives meet their objectives. The alternatives are displayed according to whether they meet both the objective and the State standard (level 1); fit with the objective, but do not meet the State standard (level 2), or meet neither the objective nor the State standard (level 3). The listing of alternatives in this display was revised based on ODF review of the DEIS. Alternative C is the only alternative which meets the compatibility standards for all three objectives.

Table II-39. Relationship of the Proposed Action and Alternatives to the Basic Objectives of the Forestry Program for Oregon

Basic Objective	Proposed Action and Alternatives			Discussion
	Level 1 1/	Level 2 2/	Level 3 3/	
1. To maintain the maximum potential commercial forest land base consistent with other resource uses while assuring environmental quality.				Oregon Dept. of Forestry has stated the Forestry Program for Oregon acknowledges the need for minimum levels of environmental protection. While the ODF believes that some
ODF Standard: Alternatives are compatible with objective if the acres suitable for timber management meet or exceed the suitable land base used in the maximum PNV benchmark run, constrained by MR's.		NC, A, A-Dep, B, C, D, D1	E, G, K, M, S	MR's may unnecessarily restrict timber management, they suggest use of the maximum PNV with MR's benchmark as the best available land base standard for comparison.
2. To identify and implement economically feasible levels of intensive forest management required to achieve cost-effective growth and harvest.				The Oregon Dept. of Forestry defines the full timber yield constrained by a 95 percent culmination of mean annual increment. Again, using the MR constrained acres as a standard does not
ODF Standard: An alternative is compatible with the objective if the number of acres allocated to full timber yield in the alternative equals 90 percent or more of the number of acres allocated to the full timber yield in the PNV Benchmark.		C	NC, A, A-Dep, B, D, D1, E, G, K, M, S	mean the ODF approves of all MR strategies. The maximum PNV benchmark identifies the economically feasible levels of intensive forest management for this analysis.
3. To maintain community stability by remaining flexible for increases in future harvest levels that would offset projected shortages.				The Forestry Program addresses timber harvest scheduling and the resulting effects on local communities and the economy of the State. For most Oregon National Forests, the ODF has stated
ODF Standard: An alternative is compatible with this objective if the number of jobs and income levels and payments to counties meets or exceeds the current direction levels of these during the first decade.		NC, A, A-Dep, B, C, D, D1	E, G, K, M, S	that departure from non-declining evenflow will be necessary to maintain overall economic stability as private industrial harvests inevitably decline. The three parameters listed will be measured to determine how each alternative maintains, improves, or decreases economic stability. The ODF believes that although the Current Direction alternative on some Forests may not actually represent the existing situation, it provides the best available basis for comparison.

1/ Meets share of FPFO target level and is compatible with basic objective.
2/ Is compatible with the basic objective but does not meet target level.
3/ Does not meet target level and is not compatible with the basic objective.

SENSITIVE PLANTS AND RESEARCH NATURAL AREAS

The following discussion explains how sensitive plants and Research Natural Areas are treated in the various alternatives In response to Planning Problem #5, "How should sensitive plant resources be managed?," land allocations for Botanical and Research Natural Areas range from none to inclusion of all candidate areas Two other Planning Problems peripherally addressed are #2, "How much old-growth forest should be preserved?," and #9, "How should mineral resources of the Forest be developed in coordination with management of other resources?"

SENSITIVE PLANTS

Well over 1,000 plant species are known to exist on the Siskiyou National Forest. Most species are relatively common and widespread. However, over 60 plants are classified as sensitive by the Forest Service, and require protection or management to maintain species viability.

The two methods of managing sensitive plant resources are protection and Standards and Guidelines. Protection involves designation of specific sites as Botanical areas Important concentration areas of sensitive or rare plants are logical candidates for designation. Certain areas on the Forest, such as Eight Dollar Mountain, are more unique than others The Forest's 24 candidate Botanical areas for sensitive plants and old growth are described in detail in Appendix F.

Twenty-two candidate areas would be designated as Botanical Areas in Alternatives G and M. All or portions of 19 Botanical Areas would be designated in Alternative S; these areas present a cross section of the best sensitive plant habitat and old-growth groves the Forest has to offer, from Mountains Eight Dollar and Grayback, to Lakes Bolan and Vulcan, Groves Page and Lobster. Fifteen areas would be included with Alternative E. Alternative K would install eight of the best candidate areas. These eight sites represent a good cross section of habitat types, ranging from Iron Mountain in the northern part of the Forest to Eight Dollar Mountain in the east central, to Bigelow Lakes in the southeast. Alternatives B, C, D and D1 include seven candidate areas, most of these areas were not selected on a priority basis, but more so based on their occurrence on serpentine sites which have little tradeoff relative to the inventoried timber resource. However, Eight Dollar Mountain, the most important botanical site on the Forest, would be designated in these alternatives No candidate areas would be designated with Alternatives NC, A, and A-Departure Botanical Areas are illustrated in Figure II-6 and general alternative groupings are listed in Table II-40. A detailed display of allocations by alternative is contained in Appendix F.

Table II-40. Proposed Botanical and Research Natural Areas, by Alternative (three existing Botanical Areas encompass 4,474 acres [75 percent within the Kalmiopsis Wilderness], three existing RNA's encompass 1,957 acres)

Proposed Botanical and Research Natural Areas		Alternative					
		NC, A, and A-Dep	B,C,D,D1	E	G and M	K	S
Sensitive Plant	Number of Areas	--	6	12	19	5	14
	Acres	--	4,517	22,636	33,932	6,044	13,901
Old Growth	Number of Areas	--	1	3	3	3	5
	Acres	--	64	530	594	170	1,257
Research Natural Area	Number of Areas	1	2	4	4	4	4
	Acres	1,290	1,391	2,797	2,797	2,797	2,649

Forest-wide Standards and Guidelines will govern timber harvesting, road building, mining activities, and livestock grazing in candidate areas not selected in a given alternative. This is also true for non-candidate areas where sensitive or rare plants are more widely dispersed.

Potential conflicts between mining activities and sensitive plants exist under any alternative. These conflicts will be handled on a case-by-case basis and mitigated in the operating plans required for any major mineral activity. Sensitive plant species may also be impacted during road construction or maintenance. Alternative M, with no new roads, would have little or no risk, while Alternatives NC, A, A-Departure, B, C, D, and D1 would have a high probability of affecting some sensitive plants.

An Eight Dollar Mountain Consensus Group, composed of private citizens, The Nature Conservancy, and public agencies with land management responsibilities on the mountain, was formed in 1984 In April 1986, this group published a final report, *Eight Dollar Mountain Coordinated Management Framework*. The group considered five alternative approaches for management of the Mountain. These approaches have all been considered during the Forest Planning process and are represented in our range of alternatives for the Forest Plan The participants (Forest Service, Bureau of Land Management, Josephine County, Oregon Division of State Lands, The Nature Conservancy, and Eight Dollar Mountain Landowners Association) have developed a MOU agreement (Memorandum of Understanding) to manage the mountain in compliance with the Framework (see Appendix F and Planning Records for more information)

RESEARCH NATURAL AREAS (RNA'S)

A system of Research Natural Areas (RNA's) has been set up throughout the Pacific states to preserve representatives of plant communities RNA's are examples of typical natural ecosystems, reserved for scientific and educational use Many plant communities are not yet represented by RNA's The Siskiyou presently has three RNA's Four additional areas on the Siskiyou have been proposed by Forest Service researchers and others for inclusion into the RNA system (Dyrness and others 1975) Research Natural Areas are illustrated in Figure II-5 See Appendix F for descriptions of individual areas

Only Hoover Gulch RNA would be recommended in Alternatives NC, A, and A-Departure; this area was proposed as an RNA in the Chetco-Grayback Land Management Plan (Unit Plan). Alternatives B, C, D, and D1 would recommend Craggy Peak and Hoover Gulch. All four RNA's would be recommended with Alternatives E, G, K, M, and S, these are the only alternatives that would fulfill the cell needs for Research Natural Areas (Dyrness and others 1975). The Cedar Log Flat and Lemmingsworth Gulch areas also contain a number of sensitive plant species General alternative groupings are listed in Table II-40 A detailed display of allocations by alternative is contained in Appendix F.

AIR QUALITY

Air quality on the Forest and surrounding urban areas will be affected by the array of forest resource management activities proposed through the range of alternatives, particularly prescribed fire operations Prescribed burning is an essential tool of forest management; carried out properly, its benefits far exceed any adverse side effects, including smoke contamination

The only Air Quality Related Value (AQRV) that will be significantly impacted is visibility--and this impact will be temporary Those alternatives which use prescribed fire extensively (e g , Alternatives B, C, and D) would have a greater probability of impacting visibility than alternatives such as E, G, or M, which would have a lower level of prescribed fire use

Estimates of total suspended particulate (TSP) production exceed the 1979 baseline value of 7,300 tons in six of the alternatives Alternative C could exceed the baseline during the first decade. By the fifth decade, Alternatives NC, A, A-Departure, B, and D1 could exceed the baseline. All of the TSP estimates displayed in Table II-41 include the application of current smoke reduction techniques

The largest contribution to TSP production will come from the broadcast burning of final harvest units and the burning associated with the hazard reduction efforts in commercial thinning operations The hardwood conversion program, which is not included in all alternatives, would be the second largest contributor to TSP, followed by the burning of landing piles and road right-of-way piles The TSP production associated with the treatment of natural fuels will not be a major factor in annual TSP production

Table II-41. Expected Annual Production of Total Suspended Particulates (TSP), by Alternative.

	Decade 1		Decade 5	
Alternative	Tons of TSP	Percent Change from 1979 Baseline	Tons of TSP	Percent Change from 1979 Baseline
NC	4,307	-41	7,545	+03
A	4,280	-42	7,545	+03
A-Departure	4,445	-39	7,631	+04
B	5,804	-21	7,649	+05
C	9,159	+25	6,703	-08
D	7,265	-01	5,892	-19
D1	5,386	-26	7,554	+03
E	2,771	-63	3,330	-55
G	3,344	-55	3,913	-47
K	4,430	-39	5,663	-23
M	748	-90	1,093	-85
S	4,579	-37	5,218	-29

TSP emissions in local urban areas will be influenced by the burning of firewood obtained from the National Forest Firewood is largely produced as a by-product of the timber harvest operations. Alternatives B, C, and D1 would have the greatest opportunity to affect local air quality, while Alternatives E and M would have the least projected impact The use of the logging residues as firewood will reduce potential emissions on the Forest by 20 to 30 percent. A relevant and important consideration, this use transfers a portion of the emissions problem to urban areas already impacted by air quality problems during the winter months The burning of the residues in wood stoves and fireplaces, however, produces 55 to 60 percent less emissions than burning the same material in the Forest (Table II-42)

Table II-42 Annual Particulate Production from Firewood Versus Forest Residues for Decade 1

Alternative	Firewood Production (M Cords)	Equivalent Residues (Tons)1/	Wood stove TSP Production (Tons) 2/	Field TSP Production (Tons) 3/
NC	52	62,400	878	1,560
A	49	58,800	826	1,470
A-Departure	51	61,200	860	1,530
B	60	72,000	1,012	1,800
C	53	63,600	894	1,590
D	51	61,200	860	1,530
D1	55	66,000	927	1,650
E	28	33,600	472	840
G	35	42,000	590	1,050
K	44	52,800	742	1,320
M	11	13,200	185	330
S	45	54,000	759	1,350

1/ One cord equals 2,400 pounds
2/ Emission rate of 28 1 lbs/ton for wood stoves (Duncan and others 1979)
3/ Emission rate of 50 lbs/ton for field conditions (Ward and others 1976)

Wildfire smoke will also affect air quality and air quality-related values throughout the array of alternatives. Since the occurrence of wildfires is a random event in both time and space, the severity of the air quality impact will vary depending upon fire intensity, fuel type and conditions, size of the fire, and meteorological conditions. Wildfires, and lightning fires in Wilderness that are managed as prescribed fires, are not considered in TSP production estimates.

Forest protection efforts would occasionally be hampered by smoky conditions. The visibility from fixed detection points (lookout towers) would be reduced and aerial detection capabilities restricted, increasing the probability of a wildfire being undetected for a period of time. This could lead to more costly wildfires relative to fire suppression costs and resource damage. Wildfire smoke would add to already existing smoky conditions, compounding the visibility impact

Management efforts to meet air quality standards and direction, and not exceed the TSP baseline value of 7,300 tons annually, will compound resource management complexities and raise the overall management costs in the affected alternatives. Day-to-day burning restrictions could limit the actual accomplishments, extending the amount of time and increasing the effort necessary to accomplish the necessary prescribed burning Reforestation efforts, for example, in harvested units could be slowed or delayed because of inadequately treated or unburned logging slash due to the limited availability of suitable burning days from a smoke management standpoint Planting costs could be higher due to additional requirements and slower production rates associated with untreated or marginally treated units. Accumulations of marginally-treated slash could jeopardize the Forest's ability to attain visual management objectives along travel routes while increasing the risk of wildfire.

FISH

None of the alternatives would degrade salmonid (salmon, trout, and steelhead) habitat capability below current condition described in Chapter III, **FISH**. However, some alternatives would place individual planning basins at risk of minor adverse impact (moderate for one basin in one alternative); water quality standards could be exceeded on a short-duration, localized basis. A summary of potential risk for environmental effects on fish habitat is shown by alternative in Table II-43. Discussion of the projected risk and environmental effects by planning basin for each alternative, along with the definitions of the terms can be found in Chapter IV, **FISH**. Major factors affecting Forest fish habitat, under the current condition, have been identified as water temperature, stream flow, pool depth, instream cover (large woody material), and overhead vegetative shade cover. These interrelated environmental factors combine to have prime influence over salmonid rearing capability.

Table II-43. Comparison of Alternatives and Potential Risk for Effects on Fish (Smolt) Habitat Capability 1/

Alternative	Range by Basin	Forest-wide Effect
NC, A, and A-Departure	Minor adverse to negligible	Negligible
B, D, and D1	Moderate adverse to minor improvement	Minor adverse to negligible
C	Moderate adverse to negligible	Minor adverse to negligible
E and G	Negligible to moderate improvement	Minor improvement
K and S	Minor adverse to minor improvement	Negligible to minor improve
M	Minor to moderate improvement	Minor to moderate improve

1/ This assessment is based on the land allocation, excluding the benefits of capital investment

Forest salmonid output is influence by land treatments and their effect on aquatic habitat, both on and off the Forest. Forest habitat capability is an indicator for adult production since the Forest habitat primarily involves capability to rear juvenile fish to the smolt stage Off-Forest influence, such as sedimentation, water availability, water temperature, ocean survival, and fish-passage obstructions also influence Forest salmonid output.

Supplemental Resource Management Area allocations contribute to maintenance and improvement of production capability. Juvenile salmonids produced off-site find a refuge from warm summer water and nongame fish competition by moving into superior habitat provided by many of these inner-gorge Management Areas. Although credit is given to the basins from which juvenile salmonids originated, their survival must be attributed to the condition of the entire watershed of which the Supplemental Resource management Areas are a key component. Tables II-2 and II-3 display the number and location of acres allocated to the Supplemental Resource Management Area.

The management direction for riparian areas is of particular importance to salmonid habitat. Table II-44 summarizes the Riparian Prescriptions included in each alternative, and the anticipated gains for the fishery. Application of Riparian Prescription B, C, or Minimum Level (M) involves the total riparian system within each planning basin rather than individual streams By application of the Prescription C or M, maximum benefit for the added protection is the improvement in salmonid capability anticipated by the end of the third decade.

Table II-44. Potential Annual First Decade Gain on Fisheries from Riparian Prescription, by Alternative (First Decade), Relative to the Current Condition

Alternative	Riparian Prescription	Expected Annual Gain 1/ Relative to Current Condition Commercial Lbs	WFUD's
NC, A, and A-Departure	18 Basins-B 1 Basin-M	0 0	0 0
B, D, and D1	12 Basins-B 6 Basins-C 1 Basin-M	0 18,000 0	0 1,100 0
C	18 Basins-B 1 Basin-M	0 0	0 0
E	19 Basins-M	19,000	1,500
G	18 Basins-C 1 Basin-M	19,000 0	1,500 0
K	17 Basins-B 1 Basin-C 1 Basin-M	0 1,000 0	0 100 0
M	19 Basins-M	19,000	1,500
S	11 Basins-B 7 Basins-C 1 Basin-M	0 14,000 0	0 1,000 0

1/ Yields in subsequent decades (through the third decade) are higher.

Fish production may also be influenced by instream enhancement projects. Anticipated first decade fisheries outputs attributable to capital investments included in the alternatives is displayed in Table II-45

Table II-45. Potential Annual First Decade Gain in Fisheries from Capital Investment, by Alternative 1/

		Potential Fisheries Gain	
Alternative	Annual Investment ($)	Commercial Lbs	WFUD's
NC, A, and A-Departure	227,000	98,000	8,100
B	350,000	150,000	12,500
C	260,000	112,000	9,300
D and D1	250,000	107,000	8,900
E	250,000	112,000	9,200
G and M	260,000	115,000	9,500
K	350,000	147,000	12,300
S	350,000	150,000	12,500

1/ Gains from project work are adjusted for the influence of land and vegetation treatment

WILDLIFE

Management of wildlife resources is directly related to Planning Problem #7 and touches on two others (#1 and #2) Planning Problem #7, "How should wildlife habitats on the Forest be managed?" is addressed in terms of programs and environmental effects through the following discussion Planning Problems #1 "How much timber should the Forest produce?," and #2 "How much old-growth forest should be preserved?" are not answered directly here, but can be inferred from the land allocations within the various alternatives.

WILDLIFE-RELATED RECREATION

The portion of Wildlife and Fish User Days (WFUD's) attributable to wildlife are derived from two sources, game (hunting) and nongame (viewing) The Forest assumes game WFUD's are tied to deer habitat capability; when habitat capability goes up or down in response to timber harvest levels (acres harvested), so do the "attached" game WFUD's. This assumption is based on the contention that people will continue to hunt only if their opportunity for success does not diminish. This modeling assumption would not be quite correct if hunters are willing to accept lower success rates, but it provides a fair method for comparing the alternatives at a constant quality level (success rate). It is also assumed that nongame WFUD's are not tied to timber harvest and will increase by one-half percent per year similar to the predicted increase in demand for other recreation opportunities for southwestern Oregon (Gibbs and others 1979)

In relation to present day use (80,900 WFUD's), use increases more than 10 percent during the first five decades in all alternatives except E, G, and M (Table II-46). Significant decreases in WFUD's would result from implementation of Alternative M.

Improvement projects can be used to increase the quality of habitat for a variety of species, both game and nongame. Increased availability of wildlife results in increased WFUD's. Capital investments are included in all alternatives except NC Capital investments would be scheduled at 56 thousand dollars per year in all alternatives except D, B, and S Alternative D would schedule 28 thousand dollars per year Capital investments in B would be 110 thousand dollars to meet RPA habitat goals In Alternative S, capital investments would be programmed at 123 thousand dollars per year The WFUD's displayed in Table II-46 include those attributable to capital investments

Table II-46. Average Annual (by Decade) Wildlife User Days, in M Visitor Days 1/, by Alternative (Includes Capital Investment 2/)

	Decade (Average Annual Percent)							
Alternative	1	2	3	4	5	Average 1-5	10	15
NC	77 3	81.7	85 1	89 3	92 6	85 2	82.0	87 9
A	83 6	87 9	91.9	95 8	99 1	91.7	88 2	94.5
A-Departure	84 2	88 7	92.9	95.7	99 2	92 1	88 3	94.7
B	94 3	96.2	100 3	96 9	104 7	99 9	100 0	100 7
C	93 3	92 9	94.1	95 9	99 1	95 1	93.6	94 8
D	87 1	88 9	88 4	90 7	92.6	89.5	91 8	90 2
D1	85 8	90.1	94 0	97 3	99.3	93.3	96 3	96 9
E	75 5	77 3	79 5	82.0	84 6	79 8	84 5	84.6
G	78 6	80.6	83 3	86 2	89 1	83.6	87 2	88 1
K	83 1	85 5	88 2	90.9	93.8	88 3	91 5	92 6
M	60 0	69.7	73.5	76 0	78 1	71 5	75 6	77 8
S	97.1	99 6	102.6	104 9	107 4	102 3	106 3	106 7

1/ The "Present Situation" is 80.9 M WFUD's per year and contains no WFUD's attributable to capital investments.
2/ Capital investments are programmed for all alternatives except NC This table includes M WFUD's attributable to capital investments added per decade for each alternative D (3.7), B (14 5); S (21 4), all other alternatives, (7 4)

The capital investment program is based on the Forest's Comprehensive Fish and Wildlife Plan (Sikes Act, Public Law 93-452). Historically, planned habitat improvement projects have not received full funding. This same situation could prevail in the future regardless of which alternative is used as the basis for management of the Forest. It may be possible to utilize K-V funding (Knutson-Vandenberg) to accomplish a portion of the capital investment program; but K-V funds are limited to use for projects within timber sale areas

BALD EAGLE AND OSPREY

Prime habitat for bald eagle and osprey identified on the Siskiyou totals 58,260 acres. At least 48,620 acres are protected in all alternatives:

Alternatives	Protected Acres
E, G, and M	58,260
NC	54,815
A and A-Departure	54,719
S	53,995
K	52,062
B, C, D, and D1	48,620

This habitat is located along the Rogue, Illinois, and Chetco Rivers. Additional secondary habitat is available, although much of it could be altered by timber management in the long term, except in Alternative M. In all alternatives, the osprey population is maintained at average level (18) recorded during the 1980's. Standards and Guidelines (Chapter IV of the Forest Plan) will govern management of bald eagle and osprey habitat, whether primary, secondary, or otherwise. Bald eagle habitat and populations will be managed in accordance with the Pacific Bald Eagle Recovery Plan (USDI Fish and Wildlife Service 1986). Informal consultation with the U.S. Fish and Wildlife Service is taking place concurrently with development of this FEIS and the Forest Plan; formal consultation will occur any time an activity may adversely affect a bald eagle or its habitat (this is also true for the endangered peregrine falcon).

SPOTTED OWL, PILEATED WOODPECKER, PINE MARTEN

The spotted owl is dependent on old-growth forest, the viability of this species is tied to the amount and dispersion of this habitat type on the Siskiyou and adjacent National Forests, and Bureau of Land Management areas The habitat needed to support a viable population would be spread among a variety of National Forests and BLM Districts. To meet minimum dispersion needs, the Siskiyou must provide designated SOHA's for 28 owl pairs in areas tentatively suitable for timber production Habitat for another 33 pairs is available in Wildernesses and land unsuitable for timber management The Siskiyou presently supports an estimated 153 pairs of spotted owls. Pileated woodpeckers and pine marten require mature forest habitat Together with the spotted owl, all three animals are used as indicators to represent the myriad of wildlife species using mature or old-growth forest

A Forest-wide habitat network was established to meet Management Requirements (MR's) for all three species. Because a given alternative influences each species similarly, and because very little mature forest exists on the Siskiyou, old-growth habitat was designated to fulfill the MR needs for pileated woodpeckers and pine marten The habitat networks for all three species were designed to minimize the opportunity costs to timber production by locating habitat areas to the extent possible on lands unavailable or unsuitable for timber management, or on lands with less than full timber yield (such as Retention Visual areas), refer to Table II-47 for the effects.

Table II-47 Spotted Owl Habitat, by Land Allocation Category, by Alternative (Acres)

	Acres by Category 1/			
			Designated SOHA's	
Alternative	Reserved	No Yield	Reduced Yield	Full Yield
NC	98,900	50,500	2,500	1,100
A and A-Departure	98,900	61,100	11,100	2,700
B, D, and D1	98,900	58,400	9,500	4,200
C	98,900	53,400	6,900	6,900
E	98,900	165,700	7,000	1,500
G	98,900	144,900	7,700	2,500
K	98,900	74,000	7,500	4,300
M	98,900	182,300	7,000	1,400
S	98,900	82,900	8,400	7,900

1/ Acreage figures are estimates made by comparing maps of land unsuitable for timber management, Designated Habitat, and Alternatives (see Appendix I, Planning Problem 2, for list of mature and old-growth acreage by Management Area, by Alternative) RESERVED = existing land allocations by Chief of Forest Service or higher, includes Management Areas 1 through 4 NO YIELD = includes Management Areas 2 through 4, if allocated in this Forest Plan, plus land in Management Areas 5 through 7, plus 9, plus land unsuitable for timber harvest in Management Areas 10 through 14 REDUCED YIELD = land in Management Area 8 which is also allocated to Management Areas 10 through 13 FULL YIELD = land in Management Area 8 which would otherwise be allocated to Management Area 14 (General Forest)

Mature and old-growth components of the commercial forest land base will diminish as more timber stands are harvested and brought under intensive timber management Alternatives E, G, and M would provide additional habitat enclaves for spotted owls, pileated woodpeckers, and pine marten (see Table II-3). Under Alternative M, numbers of all three indicator species would be maintained at near current levels. Although mature and old-growth habitat would diminish under Alternatives E and G, relatively high populations of the three indicator species would be maintained indefinitely Except for Alternative NC, wildlife species dependent on mature or old-growth forest would eventually decline significantly from present levels, but would never be less than MR's Under Alternative NC, by the tenth decade populations of the three species would drop below the levels needed to meet MR's Figure II-10 shows the location of habitat areas in the MR networks for all three species

Table II-48 displays estimated capability of the Forest to support spotted owls, by alternative and by decade, in terms of acres and numbers of owl pairs These data correspond to generalized capability estimates provided in the Spotted Owl Guidelines (USDA 1988b). Table II-49 displays the number of habitat areas available to pileated woodpeckers and pine marten by decade and by alternative In this table, the number of pileated and marten home ranges is strictly a function of available habitat Fragmentation of habitat will become increasingly important as more timber areas are harvested for the first time; this concept was a factor in the calculations Numbers of habitat areas were calculated by dividing the amount of available habitat by 600 and 160 for pileated woodpecker and pine marten respectively, total habitat areas actually occupied by pairs (reproductive units) are probably fewer than indicated.

Table II-48. Spotted Owl Habitat and Capability to Support Pairs, by Alternative, by Decade (M Acres/Owl Pairs)

	Average Annual Per Decade--M Acres/Owl Pairs

WOODPECKERS

In unmanaged timber stands, the total woodpecker population is limited by territorial needs, not by the availability of wildlife trees (dead or defective trees, i.e., snags). For managed timber stands, two sets of timber yield tables were used as part of the FORPLAN data base; snags were prescribed at levels capable of providing either 20 or 60 percent of the potential capability in the various alternatives. Under Alternatives NC, A, A-Departure, E, G, K, M, and S, snag habitat would be provided in managed harvested stands to sustain woodpecker populations at 60 percent of the potential capability. Under Alternatives B, C, D, and D1, less snag habitat would be maintained; only enough to provide for 20 percent of the potential woodpecker capability The 20 percent level is a Management Requirement; a woodpecker population at this level would be considered minimally viable, and not capable of playing an active role in its ecosystem. Woodpecker populations at 60 percent or higher are considered highly viable.

Currently, woodpecker population levels range from 100 percent in areas not under a managed rotation, to 20 percent or less in areas harvested before the late 1970's. In 1976, Wildlife Tree Guidelines were implemented on the Siskiyou, since then, enough snags have been left in managed stands to support woodpecker population levels in the 50-60 percent range. Because only 13 percent of the Siskiyou is presently under a managed rotation, existing snag habitat (on a Forest-wide "average") supports woodpecker populations at approximately 92 percent of potential.

At the fifth decade, under Alternatives NC, A, A-Departure, E, G, K, M, and S, the Forest-wide average would still be above 80 percent. However, significant reductions in habitat capability would take place in those alternatives (B, C, D, and D1) which only provide for 20 percent population levels in managed stands. Even though the Forest-wide average for these alternatives would be approximately 70 percent, woodpecker populations would be below effective levels in areas managed for timber. Table II-50 depicts the trends in Forest-wide habitat capability for woodpeckers by alternative, by decade

Dead and down woody material is important to many wildlife species. Under current direction (Alternative A), at least two cull logs (40 cubic feet minimum volume) per acre are left after timber harvesting.

Table II-50 Average Forest-wide Habitat Capability for Woodpeckers, by Alternative, by Decade (Percent at Beginning of Decade)

		Forest-wide Percent by Decade						
Alternative	Managed Stand Snag %	1	2	3	4	5	10	15
NC	60	92	89	87	84	81	75	75
A	60	92	90	87	85	82	76	76
A-Departure	60	92	90	87	85	82	76	76
B	20	92	86	81	75	69	46	46
C	20	92	86	80	74	68	46	46

S	60	92	90	88	85	83	79	79

BLACK-TAIL DEER AND ROOSEVELT ELK

Present habitat capability for black-tail deer and elk would be maintained over the long term under all alternatives except Alternatives E, G, and M As shown in Table II-51, average habitat capability of Alternatives NC, A, A-Departure, B, C, D, and D1 would increase during the first five decades Alternatives K and S would average close to the present situation. Reductions would occur in Alternatives E, G, and M, ranging from an average drop of 24 percent in Alternative E to 41 percent in Alternative M.

Tables II-52 (deer) and II-53 (elk) depict the same relative differences among alternatives, but in terms of predicted herd size rather than habitat capability. By the tenth decade, habitat capability would decrease in most of the alternatives, primarily because commercial thinnings will make up an increasingly larger proportion of the timber harvest (thinnings produce less forage than final harvests). Calculations in Tables II-51, II-52, and II-53 do not include increases in habitat capability due to habitat improvement projects.

Table II-51. Average Habitat Capability for Black-tail Deer and Roosevelt Elk, by Alternative, by Decade (Percent Change from Present Situation) 1/

1/ "Present Situation" Habitat Capability is set at 1,300 elk

SPECIAL WILDLIFE HABITATS

Hardwoods

Hardwood stands occupy approximately 95,000 acres of the Siskiyou National Forest Approximately 48,000 acres occur on land tentatively suitable for the production of timber. No management indicator species were chosen to represent this habitat type because not enough is known about use by wildlife. Hardwood stands are thought to be important for game mammals and birds that live in the forest canopy. Hardwoods do provide habitat diversity Alternatives B, C, D, and D1 would allow significant acres of hardwoods to be converted to conifer plantations in the first decade. However, actual acres converted would depend on market conditions. First decade harvests in other alternatives range from moderate to no conversion at all Few options for the management of this habitat would be precluded by activities during the next decade.

Riparian Habitat

From a wildlife perspective, there are two basic options for management of riparian areas: Minimum Level (M) with no programmed timber harvest, or Riparian Prescription B or C which program partial timber harvest with stands managed to attain uneven-aged or multi-aged structure. Riparian areas not managed for timber harvest retain the most value as wildlife habitat (e.g., travel corridors, security cover). In alternatives where timber would be harvested from riparian areas, the total acres converted to uneven-aged management would be related to the size of the land base devoted to timber management. Lands assigned to Prescription C would retain more value to wildlife than under Prescription B due to fewer trees being harvested. Although lands assigned to Riparian Prescription B would sustain the highest level of timber harvest, "B" areas are still very productive habitat, especially when compared to other suggested options (see Table II-54).

Alternatives with higher amounts of land managed for timber (Alternatives NC through D1 and K) would result in approximately 76,000 to 86,000 acres converted to uneven-aged management over an entire rotation. A large proportion of managed riparian habitat would be allocated to Prescription C in Alternatives B, D, D1, G, and S. A significant amount of land would be managed for timber in Alternative S, but only 66,000 acres of riparian zone would be entered (40 percent being Prescription C) Relatively few acres (46,000) would be impacted in Alternative G No timber harvest would take place in riparian habitat in Alternatives E and M. Table II-54 displays the various management levels for the Riparian Management Area, by alternative

Table II-54 Management Prescriptions for Riparian Habitat (Acres) 1/

	Prescription				
	Managed for Partial Timber Harvest		Not Managed for Timber Harvest		
Alternative	B 1/	C 2/	Minimum Level 3/	Other 4/	Total 5/
NC	81,313	-	29,147	65,035	175,500
A and A-Departure	84,598	-	29,407	61,492	175,500
B	49,872	34,419	29,953	61,256	175,500
C	86,028	-	32,215	57,257	175,500
D	49,895	34,434	29,920	61,251	175,500
D1	45,769	31,651	36,809	61,271	175,500
E	-	-	62,337	113,163	175,500
G	-	46,382	27,271	101,847	175,500
K	69,895	6,161	26,888	72,556	175,500
M	-	-	42,920	132,580	175,500
S	39,497	26,899	22,810	86,294	175,500

1/ Prescription B = retention of at least 85% canopy closure on Class I and II streams (average 150' either side of stream); 70% along Class III (100' either side of stream)
2/ Prescription C = retention of at least 90% canopy closure on Class I and II streams, 80% along Class III
3/ Minimum Level = adjacent land managed for timber, but no harvest from riparian habitat
4/ Other = Riparian areas within land allocations with no programmed timber harvest (e g , Wilderness, RNA)
5/ Total = Total riparian area on Forest

Meadows

Meadows are the most important Special Wildlife Sites Meadow habitat was mapped from aerial photographs in 1979; 4,711 acres were catalogued. Since that time, an additional 1,805 acres were located in areas otherwise classified as tentatively suitable forest land, for a total of 6,677 acres Fifty years ago meadow habitat on the Siskiyou totaled at least 9,050 acres; control of forest fires has allowed adjacent forest stands to encroach on many of the meadows Meadows are very productive wildlife habitat; they contribute to maintenance of overall habitat diversity. In all alternatives, 6,677 acres of meadow habitat would be allocated to wildlife. Except for Alternatives NC, A, and A-Departure, all alternatives include protection of meadow buffers (edge). Some timber may be harvested (unprogrammed) from buffer areas, but only as a management tool in reaching wildlife objectives.

Special Wildlife Sites

Special Wildlife Sites were identified during the planning process. These special habitats are important wildlife resources and furnish considerable habitat diversity. Thirteen types of Special Wildlife Sites would be allocated with Alternative S (Table II-55, see footnote for explanation). Eleven types of sites would be allocated with Alternatives E, G, K, and M. In all other alternatives, only five types of sites would be allocated. In addition, four Supplemental Resource Management Areas have high values for wildlife; these are allocated by alternative as follows: Morris Rodgers (Alternatives E through S); Fishhook Peak (E through S); Pebble Hill (E, G, M, and S); and Windy Valley (NC, A, A-Departure, and E through S).

Table II-55. Special Wildlife Areas, by Alternative (Acres)

Type of Habitat Site	Total Acres by Alternative			
	NC, A, and A-Dep	B, C, D, and D1	E, G, K, and M	S 1/
Meadows	6,677	6,677	6,677	6,516
Meadow buffers	-	4,431	4,431	4,346
Swamps/Springs	15	15	15	15
Lakes/Ponds/Bogs	-	272	272	270
Tanoak areas	-	-	298	300
Elk areas	-	-	309	307
Pigeon areas	-	-	528	526
Osprey nest sites	5	5	5	5
Wildlife areas	539	-	539	4,809
Rock bluffs	-	-	11,706	11,109
Botanical sites	224	-	224	194
Dispersed Old Growth	-	-	-	14,705
Hardwoods	-	-	-	2,040
Total	7,460	11,400	25,004	45,142
Connecting Habitat-MA 8	-	-	18,086	-
Supplemental Resource-MA 7	-	-	1,516 2/	-

1/ The array of wildlife sites in Alternative S varies from all other alternatives Alternative S includes two types of sites (Dispersed Old Growth and Hardwoods) which in other alternatives are listed as "Connecting Habitat" under Management Area 8 (see Special Area Assignments, Table II-3); Alternative S also includes Wildlife Areas (such as Horse Creek) which were allocated to Connecting Habitat in other alternatives, and three Wildlife Areas which were listed as Supplemental Resource Management Areas in other alternatives (Pebble Hill, Morris Rodgers, and Fish Hook Peak). Shifting habitat types between Management Areas in Alternative S causes acre totals to vary (due to overlaps and rounding) for some types of sites, such as meadows, even though the allocations are the same
2/ For Alternative K, acres are 739 (less Pebble Hill)

VISUAL RESOURCES

Land allocations to visual resource management vary by alternative. The alternatives are ranked in the following list according to their beneficial value to the visual resource:

1. M
2. E
3 G
4. S
5. NC, A, and A-Departure
6. K
7. D, D1, and B
8. C

Table II-56 displays the acres expected to meet Preservation, Retention, and Partial Retention VQO's for each alternative. Note that in some alternatives a decrease in Retention or Partial Retention acres may not mean a reduction in visual quality, these areas are being overlapped by more restrictive allocations and are shown under Preservation.

Table II-56. Visual Quality Objectives by Alternative (M Acres)1/

	Alternative (M Acres)										
Visual Quality Objective	NC	A and A-Dep	B	C	D	D1	E	G	K	M	S
Preservation	356	356	349	342	349	349	704	585	402	726	487
Retention	65	65	18	9	18	18	26	31	15	23	21
Partial Retention	246	246	106	97	106	106	116	164	145	109	148
Modification 2/	423	423	618	643	618	618	245	311	529	233	435

1/ Acres shown are approximate.
2/ "Modification" includes both VQO's of Modification and Maximum Modification

Alternative M would be most beneficial to the visual resource because of the extended harvest rotation (250 years), the restriction of harvest to areas that have been previously entered, and the allocation of all the unroaded areas to Backcountry Recreation Management Area. The net effect would be the return of visual conditions to a more natural appearance throughout the entire Forest.

Alternative E is similar to Alternative M in land allocations; however, harvest rotations are shorter in areas allocated to Partial Retention (130 years) and General Forest (100 years) so that some reductions in the character of the Forest landscape would be expected. The most substantial benefits to the visual resource under this alternative would be the allocation of all of the unroaded areas to the Backcountry Recreation. These areas would be managed to achieve a Preservation visual objective and remain essentially unaffected by management activities. Inventoried Retention and Partial Retention areas outside of unroaded areas would be allocated to meet full inventoried objectives in all viewsheds A modified appearance would be expected in all areas of the Forest allocated to General Forest.

Alternative G is similar to E, though the allocations to Backcountry Recreation are fewer. Inventoried visual objectives would be achieved in all viewsheds. Backcountry Recreation allocations would have the most benefit to the upper and lower sections of the Illinois Wild and Scenic River.

Alternative S would allocate inventoried Retention and Partial Retention in six of the Forest's most sensitive viewsheds. The maintenance of a natural or near-natural character in the landscape could be expected. Fourteen more of the Forest's more sensitive viewsheds would be allocated to reduced schemes of visual management designed to achieve Partial Retention objectives. The reduction in character of the landscape would result in maintenance of near natural and modified appearances. Allocations to Backcountry Recreation would be expected to retain the undisturbed character of the landscape on 108,000 acres consisting of portions of eight roadless areas.

Alternatives NC, A and A-Departure would allocate the existing visual inventory Forest-wide, resulting in the maintenance of natural and near-natural appearances in the landscape character in heavily used recreation areas and major travel routes. There would be no allocations to Backcountry Recreation; modifications to the landscape character in most of the unroaded areas would be expected. The viewshed adjacent to the last six miles of the Wild section of the Illinois River would be protected through allocation to Supplemental Resource; while this would allow road construction subject to the Retention visual objective, the potential to compromise the natural character of the existing landscape is low.

Alternative K would allocate inventoried Retention and Partial Retention in four of the Forest's most sensitive viewsheds. The maintenance of a natural and near-natural character in the landscape can be expected. Ten more of the Forest's more sensitive viewsheds would be allocated to reduced schemes of visual

management designed to achieve Partial Retention objectives Reduction in the character of the landscape resulting in the maintenance of near natural and modified appearances would be expected in these viewsheds Allocations to Backcountry Recreation under these alternative would maintain the viewshed adjacent to the last six miles of the Wild section of the Illinois River in an undisturbed (unroaded) condition.

Alternatives B, D, and D1, would have a similar effect on the visual resource All of these alternatives would allocate inventoried visual objectives in only three of the Forest's sensitive viewsheds Four more of the Forest's sensitive viewsheds (including the Rogue-Illinois) would be allocated to reduced levels of visual management designed to achieve the Partial Retention visual objective Reductions in the character of the landscape resulting in near natural and modified appearances would be expected in these viewsheds All of the remaining viewsheds would be allocated to General Forest management so that modifications to the character of the landscape would be expected

Alternative C would have the most detrimental effect on the visual resource Under this alternative, four of the Forest's most sensitive viewsheds would be allocated to reduced levels designed to achieve the Partial Retention objective. Near natural and modified appearances would be expected in these viewsheds There would be no allocations to the Retention visual objective other than those required by law under this alternative All of the remaining viewsheds would be allocated to General Forest management

RECREATION SETTINGS

The effects of management activities on the recreation resource will vary through the range of alternatives Alternatives are ranked according to the range of opportunities provided in all elements of the recreational spectrum. Alternatives have the following order when ranked from most to least beneficial.

1. S
2 K
3 NC, A and A-Departure
4. G
5 B, C, D, and D1
6. E and M

The effects of the alternatives on the recreation resource are best illustrated through the fluctuations in the Recreation Opportunity Spectrum (ROS) inventory (See Table II-57).

Table II-57. ROS Acreages by Alternative (M Acres) 1/

	Alternative (M Acres)										
ROS Class	A	A-Dep	B	C	D	D1	E	G	K	M	S
Primitive	0	0	0	0	0	0	14	12	4	14	9
Semi-Primitive Non-Motorized	29	29	29	29	29	29	97	98	33	101	52
Semi-Primitive Motorized	111	111	109	109	109	109	99	101	108	97	95
Roaded Natural	720	720	722	722	722	722	650	649	715	648	704
WRS Class 2/											
Pristine	93	93	90	93	90	90	93	88	85	93	85
Primitive	21	21	24	21	24	24	21	25	29	20	29
Semi-Primitive	119	119	119	119	119	119	119	119	119	119	119

1/ Acres shown are approximate, but show valid trends for comparisons
2/ Wilderness Recreation Spectrum (WRS)

The existing developed sites have a capacity for approximately 1,900 RVD's each day. Any of the alternatives could sustain the demand for developed recreation until approximately the seventh decade of the planning horizon. The Forest has 18 potential developed sites that could be constructed as demand approaches or reaches capacity, therefore, the Forest could sustain projected levels of demand for developed recreation regardless of the alternative.

Alternative S would enhance or improve both motorized and non-motorized recreation opportunities outside of Wilderness through allocations to Backcountry Recreation. Opportunities for Primitive and Semi-primitive Wilderness recreation would increase The recreation settings in 26 of the Forest's viewsheds would be maintained in a natural or near natural condition through allocations to varying levels of visual management. Viewsheds adjacent to all of the Wild and Scenic Rivers corridors would be allocated to their inventoried level of visual management. Recreation settings would be further enhanced by land allocations to the Supplemental Resource Management Areas The inventoried foreground Retention areas within the Recreation and Scenic sections of the Rogue River (9,943 acres) would not have programmed timber harvest in order to protect the vegetative character. The viewshed adjacent to the last six miles of the Wild section is included in the 42,000 acres of Backcountry Recreation allocated within the inventoried North Kalmiopsis roadless area and would remain in an undisturbed condition. Trail construction would be programmed in the Kalmiopsis, Wild Rogue, and Grassy Knob Wildernesses

Alternative K would enhance or improve motorized opportunities, reduce non-motorized opportunities in the areas with programmed development (Management Areas 10-14), and increase slightly the opportunity for Primitive and Semi-primitive Wilderness recreation opportunities The recreation settings would be maintained in a natural or near natural condition through the allocation of 16 of the Forest's sensitive viewsheds to varying levels of visual management Both the Rogue and the Illinois River corridors would be allocated to their inventoried level of visual management Recreation settings would be further enhanced by land allocations to the Supplemental Resource Management Area designation in two areas The inventoried foreground Retention areas within the Recreation and Scenic sections of the Rogue River (9,943 acres) would not have programmed timber harvest in order to protect the vegetative character. The viewshed adjacent to the last six miles of the Wild section of the Illinois River (5,400 acres) would be maintained in an unroaded condition (Backcountry Recreation) that would protect the natural appearance of the area, and provide some additional capacity for Primitive recreation opportunities outside of Wilderness. Viewsheds adjacent to the Chetco, North Fork Smith, and Elk Rivers would be allocated to reduced levels of Visual Management Trail construction would be programmed in the Kalmiopsis and Wild Rogue Wildernesses. No trails are proposed for the Grassy Knob Wilderness so that the Wilderness is capable of providing trailless recreation opportunities.

Alternatives A and A-Departure would maintain the current management direction for recreation. Motorized opportunities would be increased, while Primitive and Semi-primitive Non-motorized opportunities in the areas with programmed development (Management Areas 10-14) would be lost or reduced. Wilderness recreation opportunities would be increased slightly. Recreation settings would be affected by management activities and would, in turn, affect the quality of the recreation experiences. The full inventory of visual objectives would be allocated as guidelines in all viewsheds Natural and near natural Forest settings would be expected in the designated and potential Wild and Scenic River corridors and a range of near natural to modified settings in the remainder of the Forest. There would be no allocations to Backcountry Recreation so that all unroaded areas would be managed for timber harvest. Capacities for Primitive recreation opportunities would be lost in the areas programmed for development, and capacities for Semi-primitive Non-motorized opportunities reduced to a point that would not sustain projected levels of use. Trail construction would be programmed in the Kalmiopsis Wilderness while all other trails would be maintained in their current condition

Alternative G would increase opportunities for motorized recreation and maintain the opportunities for Primitive and Semi-primitive Non-motorized recreation opportunities outside of Wilderness Approximately 150,000 acres from eight roadless areas would be allocated to Backcountry Recreation in Alternative G and maintained in a roadless condition that would provide Primitive and Semi-primitive Non-motorized recreation opportunities The portion of the North Kalmiopsis Roadless Area allocated to Backcountry Recreation would include the viewshed adjacent to the last six miles of the Wild section of the Illinois River. Other roadless allocations occur in the Upper Illinois viewshed would be beneficial to the maintenance of the recreation settings in the river corridor. The opportunity for Wilderness recreation opportunities would be increased through trail construction in the Kalmiopsis and Wild Rogue Wilderness. The Grassy Knob Wilderness would be maintained in a trailless condition Recreation settings throughout the Forest would be maintained in a natural or near natural condition due to the allocation of the full inventory of visual objectives in all viewsheds.

Alternatives B, C, D, and D1 would have a significant effect on the quality of the recreation setting throughout the Forest Motorized recreation opportunities would be increased while Primitive and Semi-primitive Non-motorized opportunities would be lost or reduced to a point below the demand for this type of recreation Due to reduced visual allocations, a reduction in the character of the landscape would be expected and would affect the quality of the recreation setting All roadless areas would be allocated to areas with some level of programmed harvest and other activity. Aggressive programs of trail construction would be implemented in the Kalmiopsis and Wild Rogue Wildernesses that would affect the trailless character that currently exists.

Alternatives E and M would maintain the Forest in its existing condition and maintain recreation opportunities With Alternative M, access would be limited to existing road systems and significant portions of the Forest would be accessible only by foot. Alternative E would construct new roads only in those areas outside of the former inventoried roadless areas The full inventory of visual objectives would be allocated in all viewsheds Significant reductions in the character of the landscape would not be expected in either alternative; recreation settings would be expected to remain in a natural or near natural condition

ECONOMIC EFFICIENCY ANALYSIS OF ALTERNATIVES

The purpose of this section is to display and compare the differences in economic costs and benefits of the alternatives, and to discuss the general reasons for these differences More complete discussions of the relationship between economic values and net public benefits appear in the following section, **MAJOR TRADEOFFS AMONG ALTERNATIVES**, and the **SUMMARY OF EFFECTS** section in Appendix B.

COMPARISON OF COSTS AND BENEFITS

Table II-58 displays Present Net Value (PNV) and total discounted costs and benefits for the alternatives and the Maximum PNV Benchmark PNV is the primary measure of economic efficiency used by the Forest Service. It is the sum of priced benefits minus the sum of costs for the 150-year planning horizon, discounted to the present at the rate of four percent per year. An additional sensitivity analysis has been completed using a discount rate of 7 1/8 percent per year. Results of the analysis are documented in Appendix B.

Table II-58. PNV, Discounted Costs, and Discounted Benefits, with Incremental Changes for Alternatives ranked in order of decreasing PNV (MM $ discounted at four percent for 15 periods)

	MM $					
Alternative	PNV	Change	Costs	Change	Benefits	Change
Maximum PNV Benchmark	1,278		785		2,062	
		-37		+15		-21
B	1,241		800		2,041	
		-27		-8		-35
D1	1,214		792		2,006	
		0		-61		-61

Generally, both discounted costs and discounted benefits decrease as PNV decreases. All three variables are directly related to the level of timber harvest. As the amount of timber harvested increases, PNV, discounted benefits, and discounted costs all increase (and conversely decrease as timber harvest declines). *Benefits generally decline faster than costs. PNV and level of timber harvest range from the* highest in Alternative B to the lowest in Alternative M.

Exceptions to the relationship described above occur in Alternatives NC, B, C, and D1 Alternatives B and C were modeled to maximize timber production They would achieve higher timber outputs by including lands and management regimes that are less economically desirable than those selected for alternatives designed to maximize PNV. Alternative NC would operate on the largest suitable land base, but would not maximize timber production as would Alternatives B and C Alternative D1 has a shorter rotation length

which increases harvest levels of existing old-growth, but would provide less benefits in the future due to the smaller diameter of timber harvested.

Benefits associated with nonmarket goods, such as recreation, do not vary as much between the alternatives as do timber benefits. Recreational benefits are very similar between alternatives due to existing excess capacity compared to present and near-future use. Fisheries benefits increase with increased capital improvements and increased protection due to riparian prescriptions. With increased vegetative diversity, wildlife benefits also increase. Benefits associated with minerals production are presently not quantified except for recreational mining and mineral use fees. The mineral benefits could become greater in the future if the demand for minerals increases.

Table II-59 displays PNV and discounted benefits for the major resources, and Table II-60 displays discounted costs. Timber is the main component of PNV, discounted costs and discounted benefits. Wilderness accounts for less than four percent of each variable in all alternatives.

Direct comparisons of benefits and costs displayed for individual resource outputs provide general indications of relationships However, many activities of multiple-use forestry have common costs and benefits, and cannot be exclusively separated and attributed to individual resources For example, harvest clearcuts produce additional forage while decreasing cover which changes the population of big-game animals with subsequent effects on wildlife benefits.

Table II-59 PNV and Discounted Benefits by Major Resource, by Alternative (MM $ discounted at four percent for 15 periods)

	MM $	Discounted Benefits (MM $)					
Alternative	PNV	Timber	Recreation	Fish	Wildlife	Wilderness	Misc

M	90	16	13	8	2	1	199

1/ Direct comparisons of benefits and costs displayed for individual resource outputs provide general indications of relationships However, many activities of multiple use forestry have common costs and benefits, and cannot be exclusively separated and attributed to individual resources

2/ Costs for roads includes Forest Service and purchaser costs for road construction and reconstruction but not maintenance

COSTS

Two types of costs are included in Forest management. (1) operation and maintenance, and (2) capital investment.

Operation and maintenance costs are the costs of activities required to plan and manage outputs, and maintain existing capital assets at standard levels. These include fixed costs such as general administration, and variable costs which vary with different levels of outputs. Fixed costs are constant across all alternatives, whereas variable costs differ among alternatives. The major determinant affecting variable costs is the quantity of timber produced, timber production generates the analyses and project support needed to assure quality management of the fisheries, wildlife, and watershed resources

Capital investment costs are the costs of creating or enhancing capital assets, such as roads, trails, or fish habitat improvement structures Road construction costs are the main component of capital investments; they are also a direct function of timber harvest activity. Other capital investment costs such as fish and wildlife vary independently of the timber program. Total costs for alternatives vary both above and below the current direction (Alternative A) budget level of 21 million dollars per year.

NET CASH FLOWS, ECONOMIC BENEFITS, AND COSTS

Table II-61 displays average annual net cash flows, total receipts, total costs, and noncash economic benefits, by alternative, for the first and fifth decades. The fifth decade is shown because it represents the RPA planning horizon and captures most of the changes within the alternatives that occur in later decades.

In Table II-61, annual net cash receipts are total Forest receipts minus total Forest costs. This economic indicator, like others discussed earlier, varies directly with the level of timber outputs. Net cash flow would be positive for all of the alternatives with the exception of Alternative M. In Alternative M, costs of operating and maintaining the Forest would be greater than the receipts from selling timber and other outputs.

Table II-61 Average Annual Net Cash Receipts, Total Costs, Total Cash Receipts, and Noncash Benefits for Decades 1 and 5 (MM $)

	MM $/Decade							
	Net Cash Receipts		Total Cost		Total Receipts		Noncash Benefits	
Alternative	1	5	1	5	1	5	1	5
B	43 0	25 0	24 9	26 0	67 9	51 0	8 8	10 8
D1	38 2	29 8	23 1	27 0	61 3	56 8	8 6	10 4
NC	36 0	41 1	21 0	27 1	57 0	68 2	8 6	10 2
A-Departure	35 8	35 4	21 6	27 3	57 4	62 7	8.6	10 2
A	34 1	37 8	21 1	27 1	55 3	64 9	8 6	10 2
C	32 1	45 3	26 3	27 9	58 4	73 2	8 6	9 9
S	31 9	34 3	21 7	25 0	53 6	59 2	9 1	11 0
D	31.6	42 0	24 2	26 2	55 8	68 2	8 5	10 3
K	29 0	35 8	21 6	24 5	50 6	60 3	8 7	10 5
G	20 1	20 5	17 8	20 7	37 9	41 2	8 6	10 5
E	13 2	12 6	16 7	18 4	29 9	31 0	8 7	10 4
M	-1 4	-0 9	12 2	13 0	10 8	12 1	8 7	10 5

The alternatives are listed in order of decreasing first decade net cash flows. The ranking of the alternatives is somewhat different than under the decreasing PNV ranking. The primary difference is that the departure Alternatives A-Departure and B would have higher first decade net cash flows because they would harvest more timber in the first decade. Alternatives C and D (which have higher PNV for 15 decades than Alternative A-Departure) are modeled somewhat differently than the other alternatives. They would have higher costs because they include less economically desirable lands and practices in order to increase overall timber outputs Alternative S is different due to the more intensive timber management of lands currently roaded; fertilization of plantations and the exclusion of expensive road construction in areas allocated to Backcountry Recreation allow cash flows to be higher. Net cash flows for the other alternatives follow the same pattern as that for PNV.

Economic benefits are reported in two columns: as total receipts, and as noncash benefits Total receipts are money that the Forest receives from the sale of products and uses They include timber, fuelwood, developed recreation, river permit fees, range fees, special use permits, and power and minerals use fees. Commercial timber sales represent approximately 99 percent of total receipts across the alternatives, with the exception of Alternative M where they comprise approximately 50 percent because of reduced harvests due to longer rotations and no additional roading. Changes in the amount of timber sold also account for virtually all of the differences in total receipts among the alternatives The other components of total receipts remain relatively constant through all alternatives

Noncash benefits are economic values that have been assigned to uses of Forest resources that have value, but have not been generally traded in a marketplace where money is exchanged They are based on research of individuals' willingness to pay for certain types of experiences. The noncash benefits included in the Siskiyou's planning model are Recreation Visitor Day (RVD) use values for various types of wildlife, fishing, and general recreation experiences General recreation use does not vary much between the alternatives due to excess capacity over existing use The increase shown in future decades is the result of projections of increased demand for outdoor recreation on the Forest. The RVD values for fishing experiences depend on the fisheries outputs As more fish are produced as a result of capital investments or more restrictive riparian prescriptions, more use is predicted Wildlife use is modeled by projecting increasing use with increased habitat capability for big game and game birds, and with increased recreational use over time for nongame wildlife use

PAYMENTS TO COUNTIES

National Forest Funds (NFF), which comprise 25 percent of all Forest receipts to the U.S. Treasury, are distributed to counties based on the amount of Forest land in each county. O&C funds, which are 50 percent of funds generated from O&C lands, are distributed on the basis of a percentage established by Federal law The returns projected for each alternative (Figure II-26) vary due to the level of Allowable Sale Quantity and land allocations

RELATED EMPLOYMENT AND INCOME CHANGES

Projected changes in timber harvest, recreational use, and fish harvest would result in changes in employment and income for the four-county area of influence. The total employment and income for the four-county area in 1983 were 76,000 jobs and 1.163 billion dollars. The estimated changes in employment are calculated using Alternative A (Current Direction) as the basis, with two base conditions for timber outputs: the 10-year average annual historic harvest of 128 1 MMBF, and the Allowable Sale Quantity for Alternative A of 167.9 MMBF. The variation among alternatives in projected employment and income changes (Figures II-27 and II-28) is primarily due to timber harvest related activities The figures represent direct, indirect, and induced effects of producing outputs

Alternative B has the highest projected gain in jobs and income, while Alternatives NC, A, A-Departure, C, D, D1, and S project sizable increases (greater than 500 jobs and greater than 13 million dollars income). Moderate increases in jobs and income are projected for Alternative K Alternative G projects moderate decreases in jobs and incomes (less than 350 jobs and greater than 7 million dollars) Alternatives E and M have sizable decreases in projected jobs and incomes

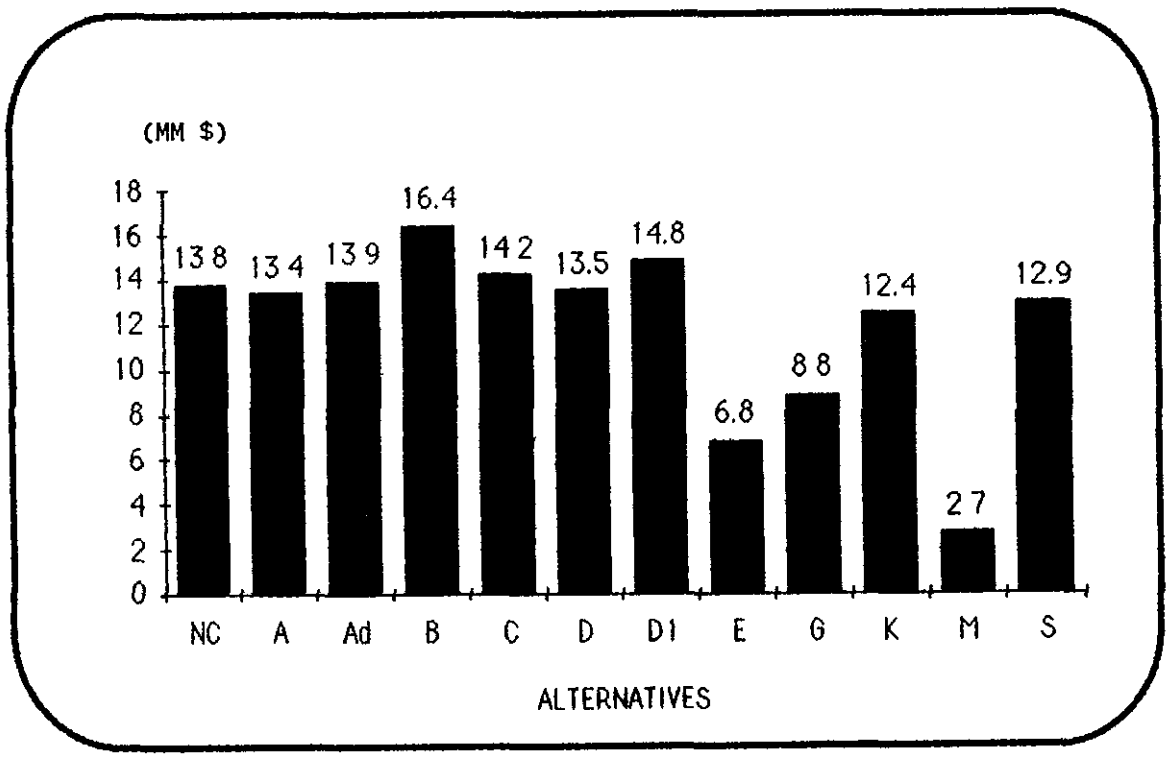

Figure II-26 Predicted Payments to Counties

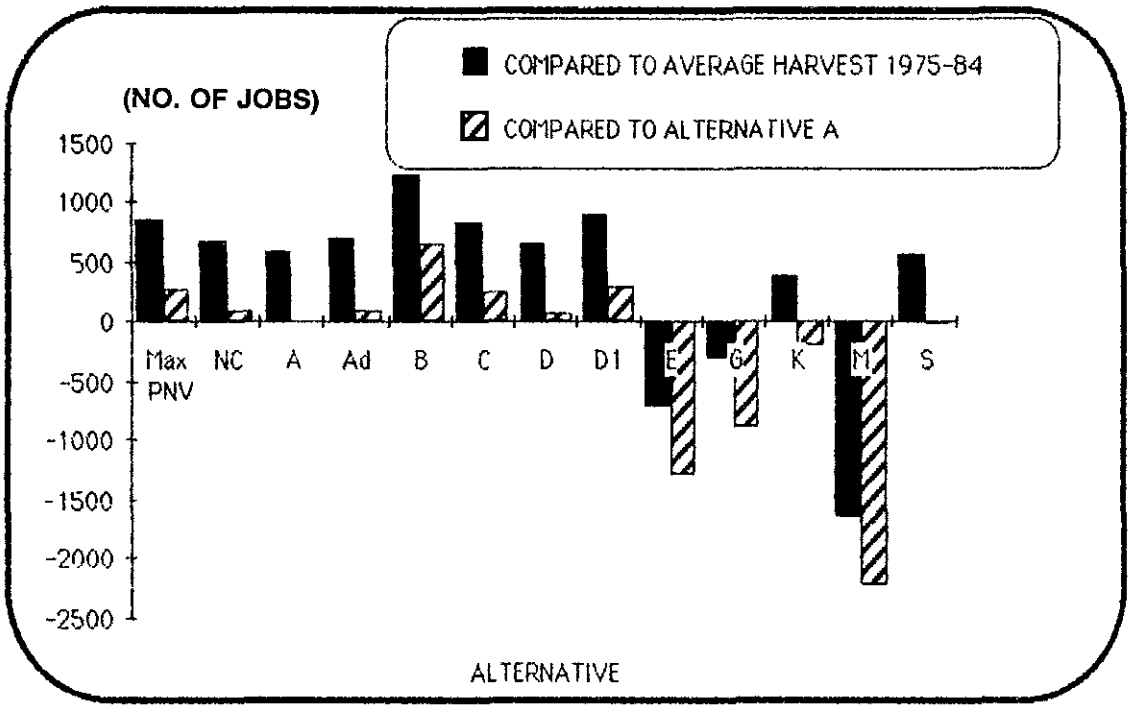

Figure II-27. Predicted Effects on Jobs

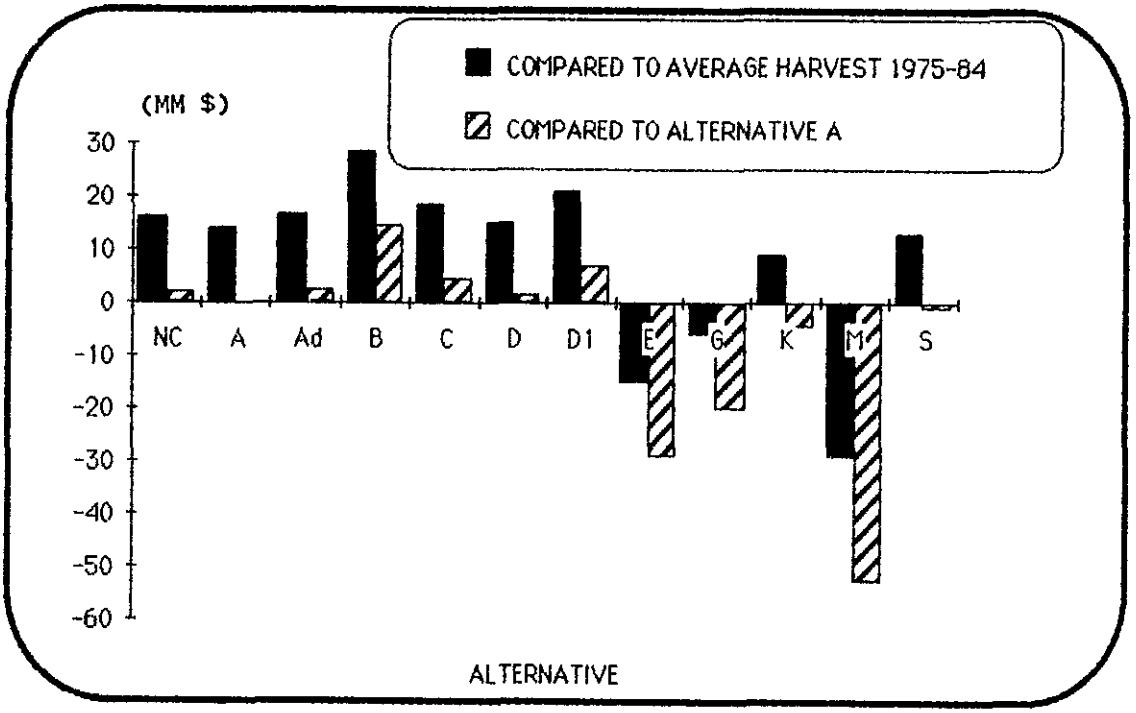

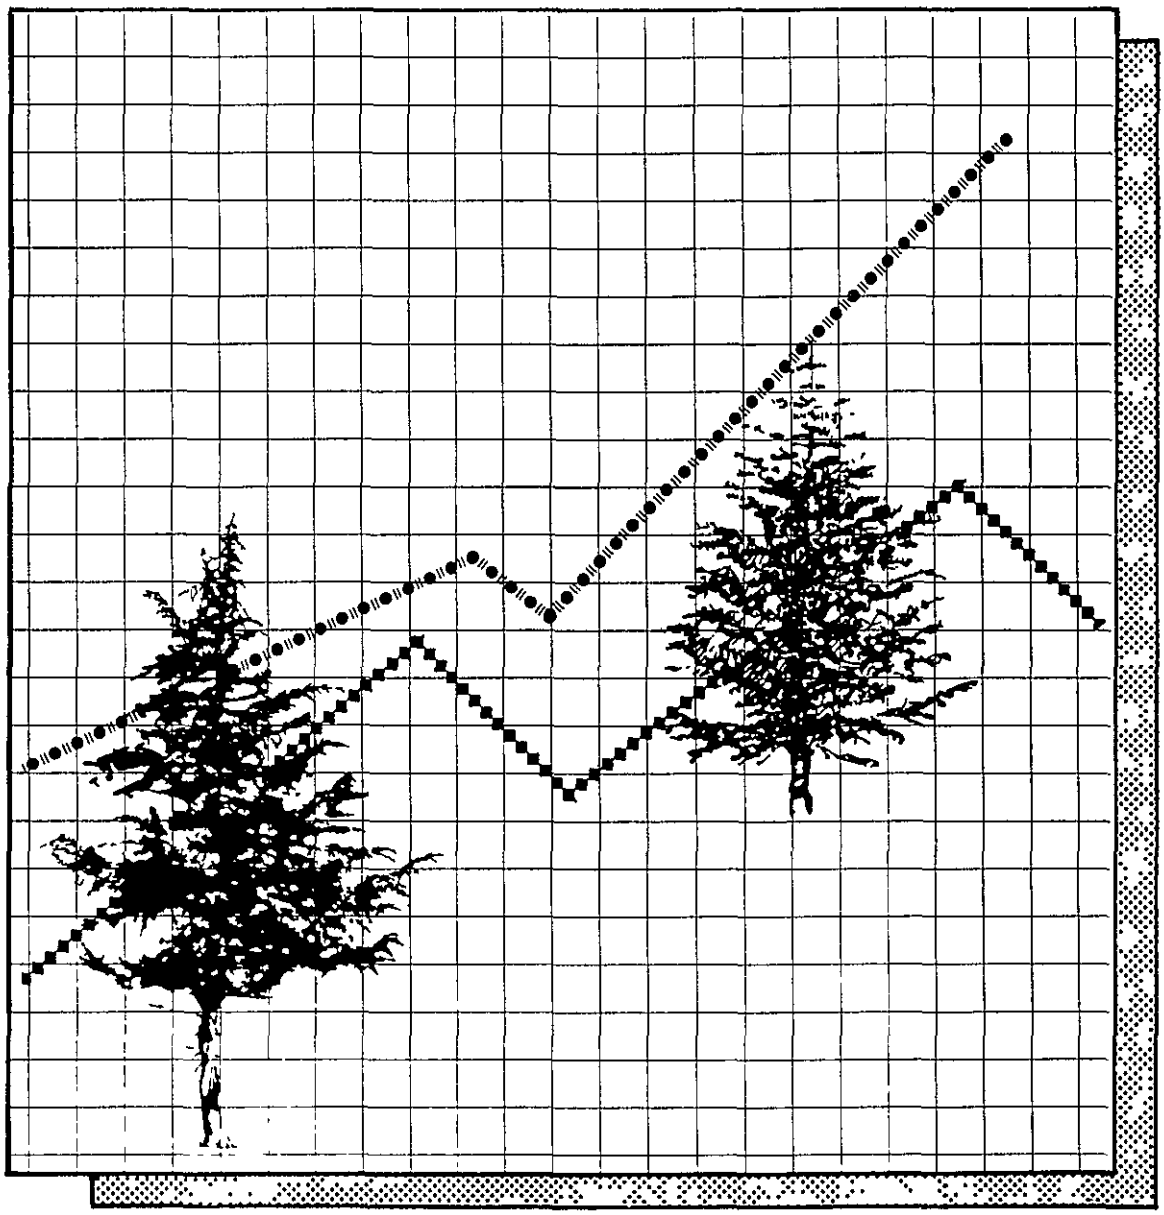

Figure II-28. Predicted Effects on Income

COMMUNITY EFFECTS

The previous discussion has considered only the economic programs of the Forest The social effects of the alternatives including the effects on community stability, lifestyles, and community cohesion are also important considerations

"Community stability" is defined as a community's capacity to handle change without major hardships or disruptions to component groups or institutions. Slow, steady growth is the desired condition for economic and social stability It allows for limited economic displacement of jobs due to sudden change with steadily increasing opportunities Sudden economic booms are also avoided An acceptable range for change will be defined as a predicted increase of less than two percent in jobs or income in the area of influence due to changes in Forest outputs Any decrease in present jobs or future outputs is deemed less desirable. Within this range, the communities would be able to readily adjust to the changes brought on by an increase in jobs and income If economic stagnation is prevalent, a loss of jobs, now as in the future may require significant community adjustment

Of course, these communities do not operate in a vacuum and forces other than Forest outputs influence the economic climate. However, for this analysis, these other forces are assumed to be constant. In general, Alternatives NC, A, C, D, D1, K, and S are classified as being more desirable for community stability. Alternatives A-Departure, B, E, G, and M are labeled as being less desirable for community stability due to decreases in either present jobs or future outputs and associated jobs.

Lifestyles are a result of the economic climate and local environment. The freedom, individualism, and security associated with the existing local lifestyles are affected little by any alternative, except perhaps Alternative M which greatly reduces Forest-related employment. Increases in Forest outputs could increase personal incomes which might provide added security to an individuals chosen lifestyle, provided the economic climate is not favoring development to the point of encroaching on individual freedom.

Alternatives NC, C, D, and D1 have the potential to increase incomes significantly (greater than one percent of total income in the area). Alternatives A-Departure and B would also boost income significantly in the first decade, but would have decreased outputs in the future. Alternatives A, K, and S would not tend to affect incomes very significantly (less than one percent total change in income). Alternatives E, G, and M have potential to decrease incomes significantly (greater than three percent decline in total income in the area of influence).

"Community cohesion" is defined as the degree of unity and cooperation evident in a community as it defines problems and attempts to resolve them. As with lifestyles, community cohesion is not significantly affected by different alternatives due to the degree of existing conflict. The many differing opinions about Forest management can only be resolved by participation and communication of the parties with conflicting opinions Alternatives that emphasize timber production at the expense of preservation of old growth and unroaded areas, or favor the preservation of old growth and unroaded areas at the expense of timber production, may tend to accentuate the conflict over Forest management. Alternatives NC, A-Departure, B, C, D, D1, G, E, and M may then aggravate conflict in those communities where conflict already exists Alternatives A, K, and S, because they tend to continue present direction or seek a better balance, will not solve conflict, but should not encourage conflict beyond its present evolution.

OPPORTUNITY COSTS

Opportunity cost is the value of the opportunity lost or foregone when implementing an alternative instead of the Maximum PNV Benchmark It is calculated as the difference in total PNV between the PNV benchmark and the alternative Most of the opportunity costs (Figure II-29) for each alternative are related to foregoing timber harvest due to unroaded designation, riparian prescriptions, suitable wildlife habitat, quality visuals management, or old growth preservation

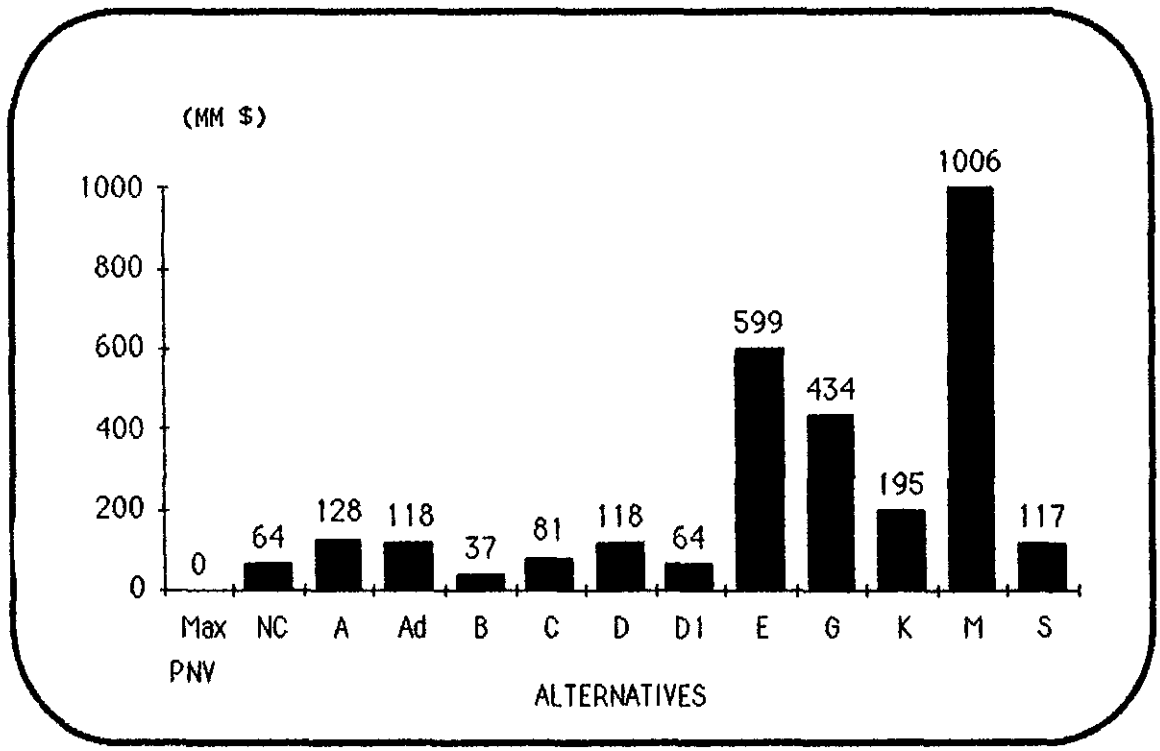

Figure II-29 Change in Opportunity Costs Compared to Maximum PNV Benchmark (MM $)

MAJOR TRADEOFFS AMONG ALTERNATIVES

This section summarizes the relationships among the economic values and community effects discussed in the previous section, **ECONOMIC EFFICIENCY ANALYSIS OF ALTERNATIVES**, and the differing responses among alternatives to the selected Planning Problems discussed in Appendix A. The purpose is to highlight major economic and non-economic tradeoffs or combinations of differences that can be quantified as indicators of response to the Planning Problems However, a complete understanding of the differences among alternatives requires reading all of Chapters II and IV, and Appendix B

To provide a partial framework for assessing these tradeoffs, the long-term resource demands or needs of the Nation, region, and local communities are briefly summarized; then selected economic values and quantified indicators of responsiveness to the Planning Problems are tabulated Finally, differences and similarities among individual alternatives are summarized in terms of major tradeoffs among competing objectives or responses to expressed public issues, management concerns, or resource use and development opportunities.

NATIONAL, REGIONAL, AND LOCAL OVERVIEW

National (RPA) planning estimates that total National demands will rise for outputs from all National Forests. At the same time, there is a strong demand to protect and enhance the quality of the environment. Demands and prices for production are generally determined in National markets and the Nation benefits most when supplies are provided using the most efficient sources of production

The demands for outdoor recreation uses and wildlife uses are mainly local and regional, although the Rogue River does attract National attention. Recreationists that visit the Siskiyou National Forest generally come from southwestern Oregon and northern California Total recreation growth is predicted to increase by one-half percent per year

The 1980 population in the four-county area was 271,500 This was an increase of approximately 35 percent from 1970, at least moderate growth is predicted for the next 10 years In 1980, total employment was about 76,000 for the area of influence with approximately 3,500 of those jobs coming from direct, indirect, and induced effects of Forest outputs Approximately 70 percent of the Forest-dependent jobs are due to consumption of timber outputs. Recreation, wildlife, and fisheries activities generate the rest of the Forest-derived employment. (For more information, refer to Appendix B and Chapter III.)

ECONOMIC VALUES AND RESPONSES TO MAJOR ISSUES, CONCERNS, AND OPPORTUNITIES

Alternatives differ so that each responds to the Planning Problems identified for this Forest in a different way. This section summarizes many of these differences in response by defining quantitative indicators for gauging the resolution of the Planning Problems It also discusses indicators of central concern to the Nation as a whole Appendix A and Chapter I discuss the development of the Planning Problems from the issues, concerns, and opportunities identified during scoping, and provides the linkages between the Planning Problems and key indicators The indicators for the Planning Problems which incorporate the major issues, concerns, and opportunities, and the local and National indicators used in this comparison are:

1. Indicators for TIMBER PRODUCTION
   - Selected suitable area (M Acres)
   - First decade Allowable Sale Quantity (ASQ) (MMCF)
   - Long-term sustained yield (LTSY) (MMCF)

2. Indicators for OLD-GROWTH FOREST preservation
   - Reserved area (M Acres)
   - Old-growth habitat available at end of fifth decade (M Acres)

3. Indicators for maintaining or improving the Forest's SOIL PRODUCTIVITY, WATER QUALITY, and FISH HABITAT
   - Anadromous sport Fish User Days (M WFUD's)
   - Average annual sediment (M Tons per decade)

4. Indicator for management of lands in and adjacent to river corridors to protect, preserve, and enhance WILD AND SCENIC RIVER attributes
   - Adjacent area meeting Visual Quality Objectives (M Acres)

5. Indicators for SENSITIVE PLANT resource management
   - Area allocated to Botanical Areas (M Acres)
   - Area allocated to Research Natural Areas (M Acres)

6. Indicators for management of the VISUAL RESOURCES
   - Area allocated to meet Preservation, Retention, and Partial Retention Visual Quality Objectives (VQO's) (M Acres)
   - Area that meets or exceeds Partial Retention (M Acres)

7. Indicators of WILDLIFE HABITAT management
   - Wildlife User Days (M WFUD's)
   - Old-growth habitat in fifth decade (Percent of Forest acreage)

8 Indicator of recreation opportunities in the WILDERNESS and UNROADED areas
   - Areas allocated to remain unroaded (M Acres)

9 Indicator of MINERAL resources development
   - Area accessible with limited restrictions (M Acres)

Indicators of LOCAL ECONOMIC and SOCIAL STABILITY.
   - First decade payments to counties (MM $)
   - First decade changes in employment (Jobs)
   - First decade changes in income (MM $)

Indicators of NATIONAL INTEREST.
   - PNV (MM $, discounted at four percent over 150-year period)
   - Net cash flow (MM $)
   - Noncash economic benefits (MM $)

In Table II-62, the indicators identified above are used to suggest the degree of response of each alternative to these Planning Problems. Other displays in Chapter II and discussions in Chapter IV and Appendix B provide more detailed information about specific effects and tradeoffs. The alternatives are arranged in order of decreasing PNV.

Table II 62 Indicators of Responsiveness to Planning Problems Alternatives are Ranked in Order of Decreasing PNV

| ALTERNATIVE | National Indicators | | | | | | | | | | Local Indicators | | | | | | | | | | | Planning Problems | | | | | | | | | | |

Maximum PNV Benchmark

PNV $1,278 MM
Opportunity Cost. None

The Maximum PNV Benchmark identifies the mix of goods and services with market and assigned values that results in the largest excess of discounted benefits over discounted costs It meets MR's for resource protection and produces a high level of timber harvest on a nondeclining yield schedule It is summarized here for comparison purposes

The Maximum PNV Benchmark provides 32.4 MMCF of timber the first decade with an LTSY of 51.9 MMCF Protection of old-growth vegetation amounts to 164,000 acres, while 74,000 WFUD's for fisheries, 69,000 WFUD's for wildlife uses, and 735,000 RVD's per year are projected for the first decade.

All unroaded areas outside designated Wildernesses would be developed. Allocations to Botanical and Research Natural Areas are 1,000 acres and 2,000 acres, respectively. A total of 820,000 acres would be available for mineral development

Average net receipts are $37.8 MM with noncash benefits of $8 8 MM for the first decade In the fifth decade, the net receipts increase to $48.1 MM with noncash benefits of $10 7 MM.

Alternative B

PNV: $1,241 MM
Opportunity Cost· $37 MM

INCREMENTAL CHANGE COMPARED TO MAXIMUM PNV BENCHMARK

Alternative B has the highest PNV of any alternative, primarily because first decade timber outputs are high The departure from nondeclining flow allowing more timber harvest in the first decade increases the PNV by $75 MM. A reduced land base results in approximately a $13 MM reduction in PNV. The production of the maximum amount of timber given the land base reduces the PNV by approximately $35 MM. Other opportunity costs are reflected in reduced harvest levels in riparian areas and General Forest areas in six basins (which reduces PNV by $21 MM) The additional allocation of visual management areas reduces the PNV by $26 MM. The remainder of the changes compared to the PNV Benchmark are due to wildlife, recreation, fisheries, and other miscellaneous programs (net $17 MM reduction)

Returns to the U.S. Treasury are increased by $5 2 MM in the first decade. The returns decline in the third decade due to reduced timber harvests. By the fifth decade, the federal receipts drop by $23 1 MM. Noncash economic benefits, for which no fees would be collected, would stay relatively constant, averaging about $8.8 MM per year in the first decade and increasing to $10.8 MM in the fifth decade

High timber harvests and a large road construction program would result in the largest contributions to community employment (more than 1,220 jobs), income (more than $28 7 MM), and the largest payments to counties ($16 4 MM annually) for the first decade. These would lead to increased economic growth assuming demand for wood products is high enough to result in consumption of all timber offered.

Acreages of old-growth trees, Botanical areas, and Research Natural Areas would be increased. The amount of scenic vistas would increase while the area allocated to Backcountry Recreation would remain constant The projected demand for Primitive and Semi-primitive recreation opportunities exceeds capacity in later decades and Primitive recreation opportunities would be limited to designated Wilderness and Wild River areas by the second decade

Fisheries values are increased due to an intensive capital investment program Though timber harvest from Riparian Management Areas would be implemented in all planning basins, six basins have more restricted timber harvest constraints in riparian areas and more restrictive scheduling constraints in General Forest areas This alternative would place the least restrictions on mineral accessibility

INCREASED INDICATORS COMPARED TO MAXIMUM PNV BENCHMARK

1. First decade ASQ (+3 6 MMCF)
2 LTSY (+2.9 MMCF)
3. Botanical areas (+5 M Acres)
4. Research Natural Areas (+1 M Acres)
5 Wildlife (+14 6 M WFUD's)
6 Visual areas (+132 M Acres)
7 Amount of reserved old growth (+6 M Acres)
8 First decade annual net receipts (+$5.2 MM)

DECREASED INDICATORS COMPARED TO MAXIMUM PNV BENCHMARK

1. Selected suitable area for timber production (-9 M Acres)
2. Fisheries (-2 M WFUD's)
3. Fifth decade annual net receipts (-$23 1 MM)
4 PNV (-$37 MM)

Alternative D1

PNV. $1,214 MM
Opportunity Cost: $27 MM Compared to Alternative B

INCREMENTAL CHANGES COMPARED TO ALTERNATIVE B

This alternative is second to Alternative B in PNV, net receipts, payments to counties, jobs, and income for the first decade

The major difference between Alternative D1 and Alternative B is the shorter timber rotation and the nondeclining yield timber harvest constraint The nondeclining yield constraint results in lower first decade timber outputs. This accounts for most of the opportunity costs ($75 MM reduction in PNV). The shorter rotation increases PNV by $54 MM. The fisheries capital investment program is also reduced with a reduced PNV ($5 MM) for the fisheries program Other benefits and costs do not substantially change.

The old-growth trees, unroaded areas, Botanical areas, and area managed for visual resources for this alternative are very similar to Alternative B. Six basins would still be managed with the more restrictive timber harvest within Riparian Management Areas and in General Forest, but fisheries would be managed with a lower capital investment program compared to Alternative B, resulting in slightly lower fisheries benefits. Predicted sedimentation, on the average, would be lower than for Alternative B. However, projected sediment would increase in the third, fourth, and fifth decades due to a larger number of acres harvested per year No substantial change would occur in mineral access

INCREASED INDICATORS COMPARED TO ALTERNATIVE B

1 Increased harvest in the third through fifth decades.
2. Amount of reserved old growth (+1 M Acres)
3 Fifth decade annual receipts (+$4 8 MM)

DECREASED INDICATORS COMPARED TO ALTERNATIVE B

1. First decade ASQ (-3 6 MMCF)
2. Selected suitable area for timber production (-8 M Acres)
3. LTSY (-5.8 MMCF)
4. Wildlife (-2.8 M WFUD's)
5. Old-growth habitat fifth decade (-0 2 percent of Forest)
6 Sedimentation (-46 M tons per decade)
7. Fisheries (-3 M WFUD's)
8. First decade payments to counties (-$1.6 MM)
9. First decade jobs (-350) and income (-$8.0 MM)
10. First decade annual net receipts (-$4.8 MM)
11. PNV (-$27 MM)

Alternative NC

PNV: $1,214 MM
Opportunity Cost. None Compared to Alternative D1

INCREMENTAL CHANGES COMPARED TO ALTERNATIVE D1

Although the No Change Alternative (Alternative NC) has the same PNV as Alternative D1, there are significant differences in the timber, recreation, fisheries, and wildlife programs.

Alternative NC has a larger land base for timber production, which increases the PNV by approximately $33.8 MM It also has a longer rotation which decreases PNV by $54 MM. Because this alternative does not maximize timber production where costs exceed benefits, its PNV is increased by $35.7 MM compared to Alternative D1. The increased land base allocated to visual management reduces the PNV by $29.3 MM Streamside management with Prescription B in all basins increases PNV by approximately $20.8 MM. The total change in the timber program is a $7 MM increase in net benefits.

Other programs are significantly different. A decreased budget for capital investments for recreation improvements results in a $1 MM increase in net benefits due to surplus recreational capacity. Lower amounts of fisheries capital investments produce lower net benefits for the fisheries program. Last of all, the lower amount of seral vegetation in the Alternative NC leads to decreased wildlife benefits compared to Alternative D1.

Annual net receipts, payments to counties, and jobs are lower than Alternative D1 in the first decade However, due to the large land base, the fifth decade annual net receipts are larger.

Areas reserved for botanical objectives are reduced by approximately 4,000 acres and old-growth habitat reserves are reduced by 39,000 acres. Old-growth habitat existing in the fifth decade would be about 16.9 percent of the Forest, which is an increase compared to Alternative D1. This increase is due to longer rotation on the land base for timber management.

Other changes for key indicators are noted. This alternative has the largest land allocation for retention and partial retention visual management. Sediment yields are projected to increase compared to Alternative D1, partially due to less restrictive basin constraints on six sensitive basins.

INCREASED INDICATORS COMPARED TO ALTERNATIVE D1

1 Selected suitable area for timber production (+26 M Acres)
2. LTSY (+5 2 MMCF)
3. Old growth habitat - fifth decade (+1.1 percent of Forest)
4 Visual Management (+207 M Acres Retention and Partial Retention)
5 Annual Net Receipts - fifth decade (+$11 3 MM)

DECREASED INDICATORS COMPARED TO ALTERNATIVE D1

1. Payments to counties (-$1 MM)
2 Jobs (-220) and Income (-$5 MM)
3. First Decade ASQ (-2 2 MMCF)
4. Old-growth Reserves (-39 M Acres)
5. Botanical Areas (-4,600 acres)
6 First Decade Annual Net Receipts (-$2.2 MM)

Alternative C

PNV. $1,197 MM
Opportunity Cost: $17 MM Compared to Alternative NC

INCREMENTAL CHANGES COMPARED TO ALTERNATIVE NC

Alternative C has a lower PNV than Alternative NC due to a reduction in the timber base and due to production of the maximum amount of timber on the land base The maximum timber objective function has timber produced where the additional costs exceed the marginal benefits. The change in the land base and the timber objective function decrease PNV by $58 5 MM Decreased allocations to visual management offset the decreased land base by $35.5 MM

First decade net annual receipts are decreased due to the additional cost of timber management. Payments to counties and local jobs are increased due to additional first decade ASQ Fifth decade annual net receipts are increased due to the payoff from additional investment in the timber program with increased harvest levels

The amount of reserved old-growth habitat, the area allocated to Botanical Areas, and the amount of WFUD's would be increased compared to Alternative NC. The change in the old-growth habitat would be mainly due to increased land allocation for Management Requirements (MR's) for old-growth dependent species

Projected sediment yields are significantly increased compared to Alternative NC due to increased hardwood conversion activity. Area managed for visuals would also be decreased significantly

INCREASED INDICATORS COMPARED TO ALTERNATIVE NC

1 Increased payments to counties (+$0 4 MM)
2 Jobs (+170) and income (+$2 5 MM)
3 First decade ASQ (+0 8 MMCF)
4 LTSY (+2 8 MMCF)
5. Reserved old-growth habitat (+36 M Acres)
6 Botanical areas (+5 M Acres)
7 Annual net receipts - Fifth Decade (+$2 2 MM)

DECREASED INDICATORS COMPARED TO ALTERNATIVE NC

1. Selected suitable area for timber production (-10 M Acres)
2. Sedimentation (+110 M tons per decade)
3. Visual management (-223 M Acres of Retention and Partial Retention)
4. Average annual net receipts - First Decade (-$3 9 MM)
5. PNV (-$17 MM)

Alternative D

PNV: $1,160 MM
Opportunity Cost. $37 MM Compared to Alternative C

INCREMENTAL CHANGES COMPARED TO ALTERNATIVE C

This alternative has the next lowest PNV (-$37 MM) primarily due to a mixed emphasis on all commodity production. Unlike Alternative C, less intensive timber harvest in Riparian Management Areas and more restrictive watershed harvest constraints are planned for six basins, thus reducing timber outputs while increasing fisheries outputs. The cumulative effect on reduced timber outputs then reduces the net receipts, payments to counties, and other indicators for the first decade. LTSY is less by 2.2 MMCF due to operating on a smaller land base

The major reason for reduction of PNV compared to Alternative C is due to reduction in selected suitable acres (-$12 MM), an increase in visual management areas (-$5 MM), and more restricted harvest in Riparian Management Areas with stricter harvest constraints in six basins (-$20 MM). Less intensive timber management of the riparian areas and more restrictive harvest constraints are planned in six basins, so fisheries benefits are relatively high (+$5 MM) compared to Alternative C.

The amount of old growth that is in a preserved status is 171,000 acres. Backcountry Recreation, Research Natural Areas, Botanical, Wild River, and Scenic and Recreation River Management Areas are identical to previous alternatives. There is an increase of 24,000 acres for visual management. Sediment production would be lower than Alternative C due to less road construction in the first decade, though still at a relatively high level. Access to lands for mineral production changes little Wildlife use is expected to decrease due to reduced seral vegetation in the first decade

INCREASED INDICATORS COMPARED TO ALTERNATIVE C

1. Amount of reserved old growth (+2 M Acres)
2. Sedimentation (-108 M tons per decade)
3. Fisheries (+1 M WFUD's)
4. Visual areas (+24 M Acres)
5. Old-growth habitat fifth decade (+0.6 percent of Forest)
6. Area available for mineral development (+1 M Acres)

DECREASED INDICATORS COMPARED TO ALTERNATIVE C

1. First decade ASQ (-1.4 MMCF)
2. LTSY (-2 2 MMCF)
3. First decade payments to counties (-$0 7 MM)
4. First decade jobs (-190) and income (-$3.2 MM)
5. Wildlife (-9 0 M WFUD's)
6. PNV (-$37 MM)
7. First decade annual net receipts (-$0.5 MM)

Alternative A-Departure

PNV· $1,160 MM
Opportunity Cost: None compared to Alternative D

INCREMENTAL CHANGE COMPARED TO ALTERNATIVE D

Though the opportunity costs of Alternatives A-Departure and D are equal, each program is different. The increase in Supplemental Resource area reduces the acres for timber production This reduces the PNV by $8 MM. The removal of the timber objective function increases PNV (+$35 MM). The increase in areas managed for visuals lowers the lands available for intensive timber management and PNV (-$48 MM). Managing all basins with the least restrictive riparian harvest prescriptions increases PNV by $19 MM. Using Prescription B and lowering capital investments for fisheries result in decreased fisheries benefits Lower investment in recreation does not significantly affect benefits, due to surplus capacity.

The first decade outputs for net receipts, payments to counties, jobs, and income are greater due to the departure of timber outputs However, by the third decade, the timber outputs are reduced.

The amount of old-growth habitat, reserved old growth, and Backcountry Recreation areas are slightly increased The land dedicated to Botanical areas and RNA's would be the least of any alternative. The land allocated to visual management would be the highest of any alternative. The fisheries outputs are expected to decrease due to the implementation of Prescription B in the Riparian areas while projected sedimentation is somewhat lower than Alternative D

INCREASED INDICATORS COMPARED TO ALTERNATIVE D

1 First decade ASQ (+0 8 MMCF)
2 Amount of reserved old growth (+2 M Acres)
3 Visual areas (+193 M Acres)
4. Unroaded areas (+5 M Acres)
5. Area available for mineral development (+4 M Acres)
6. County payments (+$0 4 MM), jobs (+40), and income (+$1 1 MM)
7. Sedimentation (-6 M tons per decade)
8. First decade annual net receipts (+$4.2 MM)

DECREASED INDICATORS COMPARED TO ALTERNATIVE D

1. LTSY (-2.1 MMCF)
2. Fisheries (-2 M WFUD's)
3 Botanical (-5 M Acres) and Research Natural Areas (-1 M Acres)
4. Wildlife (-0.8 M WFUD's)
5. Reduced ASQ, annual net receipts, and payments to counties in future due to departure scheduling

Alternative A

PNV $1,150 MM
Opportunity Cost· $10 MM Compared to Alternative A-Departure

INCREMENTAL CHANGE COMPARED TO ALTERNATIVE A-DEPARTURE

The only significant difference between Alternatives A and A-Departure, which explain the $10 MM opportunity cost, is the decrease in first decade timber outputs in Alternative A Since A has the nondeclining yield timber harvest constraint, the first and second decade outputs are significantly less than the departure alternative. Wildlife values are reduced by $1 MM due to the decreased production of seral stages Other factors are equal including land allocation, program costs, and other benefits.

The change compared to Alternative A-Departure in payments to counties, net receipts, and social indicators of jobs and income changes follows the same trend as the amount of timber harvest for the first decade. Third decade outputs are higher due to the use of the nondeclining yield constraint.

Most other indicators including mineral accessibility, do not change significantly. However, the first decade sediment outputs are less by 6,000 tons due to less harvest and road construction in the first decade

INCREASED INDICATORS COMPARED TO ALTERNATIVE A-DEPARTURE

1. Amount of reserved old growth (+2 M Acres)
2. Sedimentation (-20 M tons per decade)
3 Higher ASQ, annual net receipts, and payments to counties in third, fourth, and fifth decades

DECREASED INDICATORS COMPARED TO ALTERNATIVE A-DEPARTURE

1. First decade ASQ (-1 1 MMCF)
2. Wildlife (-1 1 M WFUD's)
3 First decade payments to counties (-$0.5 MM)
4. First decade jobs (-100) and income (-$2.3 MM)
5 First decade annual net receipts (-$1 7 MM)
6. PNV (-$10 MM)

Alternative S

PNV: $1,131 MM
Opportunity Cost $19 MM Compared to Alternative A

INCREMENTAL CHANGES COMPARED TO ALTERNATIVE A

All program costs are different for Alternatives A and S. An increase in the land allocated to Research Natural Areas, Botanical, Backcountry Recreation, Supplemental Resource, and Special Wildlife Sites Management Areas reduces the land available for timber harvest However, the land available for timber production is managed more intensively with fertilizer applications. The land available for timber production drops by 52,000 acres with a corresponding drop in PNV (-$18 MM). Use of the timber objective function in Alternative S reduces the PNV by approximately $31 MM compared to Alternative A. A reduction in the area allocated to visual management increases the land available for intensive timber management Relative to Alternative A, the percent increase in General Forest acres corresponds with a $40 MM increase in PNV. The change of seven basins to Riparian Prescription C reduces PNV by $2 MM

The capital investment programs for recreation are increased over those of Alternative A. However, all benefits remain the same due to excess capacity for recreation and wilderness experiences in the first decade. The capital investment program for fisheries is increased and results in increased net benefits of $6 MM.

Because of timber outputs, changes in wildlife habitat, and increased fish production, a slight increase of jobs, payments to counties, net receipts, and incomes are predicted

The fish outputs are increased due to implementation of a more restrictive riparian harvest in several basins and due to an increased capital investment program. Sediment projected in the first decade is lower (-114 tons) due to less acres harvested Mineral access would be highly restricted on an additional 32,000 acres Wildlife use would increase due to an increased wildlife capital investment schedule. The amount of reserved old growth is also increased

INCREASED INDICATORS COMPARED TO ALTERNATIVE A

1. Wildlife (+21 M WFUD's)
2. Amount of reserved old growth (+23 M Acres)
3. Sedimentation (-114 M tons per decade)
4. Fisheries (+11 M WFUD's)
5. Old-growth habitat (+1.4 percent of Forest in fifth decade)
6 Unroaded areas (+78 M Acres)
7. Botanical areas (+15 M Acres)
8. Research Natural Areas (+1 M Acres)
9 Average annual Noncash Benefits (+ $0 5 MM)

DECREASED INDICATORS COMPARED TO ALTERNATIVE A

1. First decade ASQ (-1 1 MMCF)
2. LTSY (-4.7 MMCF)
9. Acres available for mineral development (-32 M Acres)
4. Visual areas (12 M Acres)
6 First decade payments to counties (-0 5 MM $/Yr)
7 First decade jobs (-20) and income (-$0 9 MM)
5 PNV (-$19 MM)
11 First decade annual net receipts (- $2 2 MM)

Alternative K

PNV: $1,083 MM
Opportunity Cost· $48 MM Compared to Alternative S

INCREMENTAL CHANGES COMPARED TO ALTERNATIVE S

Alternative K has some differences in land allocations and constraints compared to Alternative S. A decrease in land allocations for Backcountry Recreation, Special Wildlife Sites, and Scenic/Recreation Rivers provides a larger land base (+13,000 acres) for timber management which results in a plus $28 MM for PNV A small reduction in visual management results in a slight increase in PNV (+$0 7 MM).

Taking away fertilization as a treatment option and the tighter constraint for watershed management result in a significant decrease in PNV (-$63 MM) The capital investment program for fisheries is the highest for all alternatives, resulting in high fisheries benefits The recreation and wildlife programs are lower than

Alternative S The recreation program has an increased PNV of $2.8 MM due to existing surplus capacity. The wildlife program has a decreased PNV compared to Alternative S of $13 MM due to a reduced capital investment program

Decreases in the annual net receipts, payments to counties, change in jobs, and change in income would occur in the first decade.

Alternative K would have slightly less old-growth habitat suitable for wildlife use in the fifth decade. Sediment production projected for the first decade is slightly less than Alternative S due to the lower level of harvest and roading Fish production decreases some due to more intensive timber management in six basins. The accessibility of minerals is slightly increased to that in Alternative S.

INCREASED INDICATORS COMPARED TO ALTERNATIVE S

1. Average Annual Net Receipts - 5th Decade (+$1.5 MM)
2 Suitable Land for Timber Production (+24 M Acres)
3 Sedimentation (-28 M Tons/Decade)
4 Minerals (+15 M Acres)

DECREASED INDICATORS COMPARED TO ALTERNATIVE S

1 First decade ASQ (-1.2 MMCF)
2. Payments to counties first decade (-$0.5 MM)
3. Number of jobs (-180) and income (-$3.9 MM) first decade
4. Wildlife (-22 M WFUD's)
5. Old Growth Preserved (-9 M Acres)
6. Botanical and RNA Areas (-9 M Acres)
7. Fisheries (-7 M WFUD's)
8. PNV (-$48 MM)
9. Annual net receipts first decade (-$2.9 MM)
10. Average annual noncash benefits (-$0 4 MM)

All other indicators remain relatively constant

Alternative G

PNV: $844 MM
Opportunity Cost. $107 MM Compared to Alternative K

INCREMENTAL CHANGE COMPARED TO ALTERNATIVE K

This alternative has significantly lower PNV compared to the previous Alternative (K) with spin-off decreases in payments to counties, net revenues, jobs, and incomes.

Alternative G's increasing opportunity costs are mainly due to the reduction of investment in the timber program. The opportunity costs for timber riparian management are $11 MM. Additional areas in Backcountry Recreation, Supplemental Resource, Botanical, and Designated Wildlife Habitat Management Areas reduce the investment opportunities for timber production and PNV by $84 MM. An increase in the visual management areas reduces the land available for intensive timber production The resulting decrease in General Forest acres equals $10 MM reduction in PNV. Due to high capital investments and the lack of harvest in riparian areas, the fisheries benefits are high with an increased PNV (+$3 MM)

The amount of reserved old growth (+27,000 acres) increases in connection with the unroaded areas Projected sediment decreases significantly in the first decade due to a decrease in road construction and harvest.

INCREASED INDICATORS COMPARED TO ALTERNATIVE K

1 Amount of reserved old growth (+74 M Acres)
2 Sedimentation (-182 M tons per decade)
3 Fisheries (+1 M WFUD's)
4. Botanical areas (+28 M Acres outside of Wilderness)
5 Visual areas (+219 M Acres)
6. Old-growth habitat fifth decade (+4 5 percent of Forest)
7. Unroaded area (+70 M Acres)

DECREASED INDICATORS COMPARED TO ALTERNATIVE K

1 First decade ASQ (-7.3 MMCF)
2 LTSY (-10.1 MMCF)
3 Selected suitable area for timber management (-123 M Acres)
4 Wildlife (-8.9 M WFUD's)
5. Acres available for mineral development (-37 M Acres)
6. Payments to counties (-$3.6 MM)
7. Number of jobs (-680) and income (-$15 4 MM)
8. PNV (-$239 MM)
9. Annual net receipts (-$8.9 MM)

All other indicators are relatively constant

Alternative E

PNV· $679 MM
Opportunity Cost. $165 MM Compared to Alternative G

INCREMENTAL CHANGES COMPARED TO ALTERNATIVE G

The PNV for Alternative E is $165 MM less than Alternative G The decreases in net receipts, county receipts, jobs, and incomes occur mainly due to a decrease of 4 3 MMCF in timber outputs The decrease is due to fewer acres managed for timber with a corresponding decrease in the LTSY (-6.5 MMCF)

Alternative E's emphasis on preserving unroaded areas foregoes timber management opportunities on 302,000 acres The increase in unroaded areas and subsequent decrease in land managed for timber production reduce PNV by $149 MM. Alternative E also foregoes timber management opportunities in all riparian areas This management reduces PNV by $22 MM Other economic programs are not significantly different. The capital investment program for fisheries is reduced. The lack of timber harvest in unroaded areas, Riparian areas, and Supplemental Resource areas provide fisheries benefits (though slightly reduced from Alternative G).

The unroaded area allocation and area of preserved old growth are increased The old-growth habitat suitable for wildlife would be increased as would visual management areas The area allocated to Botanical and RNA's would be decreased by 11,000 acres Projected sediment is less due to lower harvest levels and less road construction The areas open to mineral development would be decreased by 148,000 acres

INCREASED INDICATORS COMPARED TO ALTERNATIVE G

1 Amount of reserved old growth (+63 M Acres)
2. Sedimentation (-108 M tons per decade)
3 Visual areas (+66 M Acres)
4 Old-growth habitat fifth decade (+4.3 percent of Forest)
5 Unroaded areas (+10 M Acres)

DECREASED INDICATORS COMPARED TO ALTERNATIVE G

1. First decade ASQ (-4 3 MMCF)
2. LTSY (-6.5 MMCF)
3. Selected suitable area for timber management (-119 M Acres)
4 Wildlife (-6.1 M WFUD's)
5 Acres available for mineral development (-148 M Acres)
6 Botanical areas (-11 M Acres outside of Wilderness)
7 Payments to counties (-$2 0 MM)
8. Number of jobs (-400) and income (-$8.9 MM)
9 PNV (-$165 MM)
10 Annual net receipts (-$6 9 MM)

All other indicators remain relatively constant.

Alternative M

PNV. $272 MM
Opportunity Cost: $407 MM Compared to Alternative E

INCREMENTAL CHANGES COMPARED TO ALTERNATIVE E

Alternative M has the highest opportunity costs due to the long rotation length for timber management on a much reduced land base. Compared to Alternative E, the longer rotation of Alternative M reduces PNV by $239 MM. The maximum area is allocated to an unroaded status, Supplemental Resource, Botanical, RNA's, and Designated Wildlife Habitat areas. The opportunity costs of the reduced area allocated to timber production equals $161 MM compared to Alternative E. These costs are offset somewhat because some of these acres allocated to management not allowing programmed harvest were visual management acres. This reduces the opportunity costs by approximately $10 MM No harvest is programmed from riparian areas and the maximum amount of land is allocated to scenic vistas including preservation status. The increased fisheries budget combined with the lack of timber harvest in riparian areas results in high fisheries benefits, though slightly less than Alternative G. Other economic programs such as recreation and wilderness benefits do not increase due to projected surplus supply of unroaded areas compared to projected use in the near future.

The incremental decrease in county receipts, net cash flow, jobs, and income is the greatest of any alternative. As with the other alternatives, the amount of planned timber harvest accounts for most of this change. The amount of area managed for timber is the lowest for all alternatives and the planned rotation for the Forest is the longest, resulting in a lower LTSY.

The most old growth of any alternative would be preserved with corresponding habitat for old-growth-dependent species The maximum amount of land of all alternatives would be allocated to Preservation, Retention, and Partial Retention visual management. Fish production would also be high, with sediment production the lowest of all alternatives. Due to lack of activities that would create forage areas and habitat diversity, big game, small game, and nonconsumptive wildlife use would decline

INCREASED INDICATORS COMPARED TO ALTERNATIVE E

1. Amount of reserved old growth (+63 M Acres)
2. Sedimentation (-334 M tons per decade)
3. Botanical areas (+11 M Acres outside of Wilderness)
4. Visual areas (+11 M Acres)
5. Old-growth habitat (+5.5 percent of Forest in fifth decade)
6. Unroaded areas (+94 M Acres)

Decreased Indicators Compared to Alternative E

1. First decade ASQ (-10.1 MMCF)
2. LTSY (-10.0 MMCF)
3. Wildlife (-14.9 M WFUD's)
4. Payments to counties (-$4.1 MM)
5. Number of jobs (-950) and income (-$23.5 MM)
6. Fisheries (-1 M WFUD's)
7. PNV (-$407 MM)
8. First decade annual net receipts (-$14.6 MM)

IMPLICATIONS OF THE 1987 FIRES

The Siskiyou National Forest was impacted by several large fires in 1987. The effects of those fires and subsequent timber salvage projects, and the changes in the environmental components relevant to this Forest Plan analysis are described in the section **1987 FIRES** in Chapter III. Numerous changes have occurred which have little implication for the Forest Plan analysis. While they affect the Forest potential to produce a particular output or condition, the changes are small fractions of the Forest totals and will be the same regardless of the alternative selected in this analysis None of the alternatives or environmental components are significantly affected when viewed on a Forest-wide scale. Only those elements which have implications for changed outputs or conditions that may be of some interest in the design or evaluation of the alternatives will be discussed here. Based on the discussion in Chapter III, the more important resource changes to consider are changes in: (1) the timber inventory, (2) fish habitat and water quality, (3) wildlife habitat for mature and old growth dependent species, and (4) the recreational setting

TIMBER

The loss of timber volume from the inventory has some implications for the alternatives, particularly those that project high levels of timber harvest. The volumes salvaged in place of sales that would normally have been scheduled offset part of the potential loss Since most of the available volume in the Galice and Longwood Fire areas will be salvaged, the only losses of any importance occur in the Silver Fire area. Alternatives that would allocate part or all of the burned areas to uses with programmed timber outputs would be affected; others would not. The Silver Fire Recovery Project analysis also identified some additional lands that are unsuitable due to reforestation difficulty or potential for irreversible soil damage. The Record of Decision for the project indicated that the final Forest Plan would account for these inventory changes along with the changes from the fires themselves

Table II-63 displays the ASQ projected for each alternative and the ASQ that would be projected with the changes from the 1987 fires and revised suitability in the Silver Fire area Any alternative selected would be modified to be consistent with these resource potentials prior to development of the Forest Plan for implementation Departure Alternatives (A-Departure and B) could remain the same for the first decade, but would have slightly more reduction in future decades than projected.

Table II-63 ASQ Adjustments for 1987 Fires and Silver Fire Suitability (Chargeable Sawtimber)

	Alternative											
	NC	A	A-Dep	B	C	D	D1	E	G	K	M	S
Original ASQ												
MMCF	31 0	30 1	31 2	36 8	31 8	30 4	31 2	16 2	20 5	27 8	6 1	29 0
MMBF	167 5	168 0	174 1	205 3	177 4	169 6	174 1	90 4	114 4	155,1	34 0	161 8
Adjusted ASQ												
MMCF	31 0	29 4	31 2	36 8	31 1	29 7	30 5	16 2	20 5	27 1	6 1	28 4
MMBF	167 5	164 1	174 1	205 3	173 5	165 7	170 2	90 4	114 4	151 2	34 0	158 5

FISH HABITAT AND WATER QUALITY

The discussion in Chapter III explains the scope of the impacts to the fisheries resource (the primary beneficial use of water for the areas impacted). The total impact to fish production is projected to be less than one percent when viewed in the Forest-wide context. This impact has already been incurred and will not be affected by the alternatives considered in this analysis. The only consideration here is the need to

allow the burned areas to recover before additional timber harvest is scheduled within the perimeter of the Silver Fire area. Harvest scheduling for any alternative selected for implementation could be modified to provide additional mitigation in these areas until recovery has progressed to a stage allowing further harvest activities without significant adverse cumulative impacts.

MATURE AND OLD-GROWTH WILDLIFE HABITAT

Impacts to the habitat networks for species dependent on mature and old-growth habitat are described in Chapter III Although the acres of mature and old-growth forest are now approximately 25,000 acres less than displayed from the planning inventory (443,000 acres), Forest-wide there is no serious impact as a result of the fires on the habitat network proposed to maintain minimum viable populations of wildlife species dependent on mature and old-growth forest

RECREATIONAL SETTING

The character of the recreational setting is changed in the burned areas as a result of changes in the vegetation caused by the fires. The more important change relative to this analysis is the modification of the unroaded character and the ROS inventory resulting from the roading associated with the Silver Fire Recovery Project These changes are described in Appendix C. Alternatives which would allocate areas with new roads to the Backcountry Recreation Management Area would need restoration for these areas to return them to a more natural, undeveloped condition over time. Alternatives that would be affected are E, G, and M

Chapter III
AFFECTED ENVIRONMENT
INTRODUCTION

The purpose of Chapter III is to describe the physical, biological, social, and economic components of the environment that would be affected by the array of alternatives. This chapter sets the stage for the discussion of significant interactions and environmental effects in Chapter IV.

For ease of discussion, the affected environment was divided into 21 separate environmental components as listed at the bottom of this page Most components are discussed from three standpoints. The first deals with the **EXISTING CONDITION** and provides an inventory of the raw material, explains why the component is important, and relates the local existing condition to the situation in southwestern Oregon and northwestern California The second describes the **CURRENT DEMANDS, WANTS, AND DESIRES** placed on the environmental component as expressed by the general public. The third focuses on the Forest's **ABILITY TO SATISFY DEMAND** (i.e., the wants, needs, and desires expressed about the component).

Discussion of Location, Climate, and Geology and Topography is provided as a basis for understanding the remaining components As such, the discussion of these components is limited primarily to the existing condition.

The interdependence of the various environmental components makes it difficult to present them in a logical sequence. In general, the more basic or fundamental components are listed before the more consumptive or output-related components.

The *Environmental Components* are.

1. Location
2. Climate
3. Geology and Topography
4 Land Allocations
5. Cultural Resources
6. Energy
7. Mineral Deposits
8. Improvements
9. Wilderness and Roadless Areas
10 Wild and Scenic Rivers
11. Soil and Water
12 Fire
13. Vegetation
14 Sensitive Plants
15. Air Quality
16 Fish
17. Wildlife
18. Biological Diversity
19 Visual Resource
20. Recréation Settings
21. Economic and Social

CHANGES BETWEEN DRAFT AND FINAL

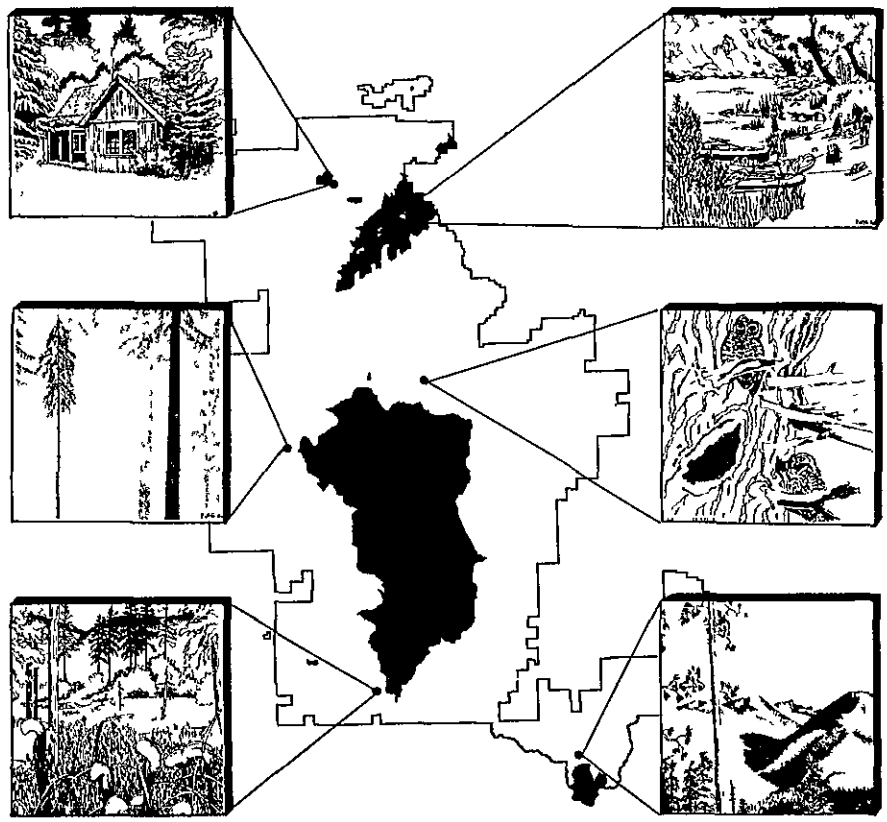
As a result of public comments, on-going Forest management activity, the 1987 fires, and Congressional designation of three Wild and Scenic Rivers in late 1988, Chapter III of the DEIS has been updated to accurately reflect the significant environmental changes.

The **1987 FIRES** received Nationwide notoriety. The changes in the physical and biological environment brought about by three major fires are summarized at the end of this chapter.

In late 1988, the Chetco, Elk, and North Fork Smith Rivers were designated as Wild and Scenic Rivers under the Omnibus Oregon Wild and Scenic Rivers Act Both the Chetco and North Fork Smith Rivers had been carried as inventoried rivers for possible recommendation to the National System Following an administrative study this year, the Elk was also determined eligible for possible inclusion See **WILD AND SCENIC RIVERS** for further discussion.

Both the public and members of the Forest Management Team felt that **BIOLOGICAL DIVERSITY** should receive added emphasis. The discussion provided under the same heading will add value to the analysis and the reader's understanding of this important concept. This highlighted component, while still addressed under several environmental components, has been given a separate section to collectively describe the existing condition

The inventoried roadless areas have not remained fixed since the 1984 update. Along with some timber sale activity and pre-existing conditions, the salvage activity following the 1987 Silver Fire has reduced the inventoried amount from 314,000 to 284,000 acres The decision for the projects covered under the Silver Fire Recovery Project FEIS (USDA 1988d) accounts for approximately 19,000 acres of the reduction For a summary of the changes, refer to the section titled **WILDERNESS AND ROADLESS AREAS.** For a detailed summary of changes by inventoried roadless area, see Appendix C



Public and other agency comments also resulted in other changes in the text throughout the chapter. More substantive rewrites are in the sections **SOIL AND WATER** and **FISH.**

LOCATION

The Siskiyou National Forest is located in the Klamath Mountains and Coast Range of southwestern Oregon (See Figure I-2). Oregon counties include Josephine, Curry, and Coos. A small segment of the Forest extends into northern California (Del Norte County). The Forest is positioned between the Cascades and the Pacific Ocean. The ocean can be viewed from the western edge of the Forest. The southern part borders the Six Rivers, Klamath, and Rogue River National Forests.

The Siskiyou contains 1,162,030 acres within its boundaries, 69,728 acres of which are privately owned or managed by other government agencies (refer to **LAND ALLOCATIONS**). The FEIS and Forest Plan apply only to the 1,092,302 acres of National Forest System lands

CLIMATE

The overall climate on the Forest can be characterized as a maritime climate with fairly hot, dry summers and warm, wet winters. Most of the annual precipitation falls between October and April. Precipitation amounts across the Forest range from 40 to 150 inches (see Figure III-1) Average monthly summertime maximum temperatures range from 72 to 89 degrees Fahrenheit Maximum high temperatures have exceeded 105 degrees at several locations

Several distinct climatic zones have been identified on the Forest, based primarily on available summer moisture (Atzet and Wheeler 1982) Two coastal zones are identified to the west of the coastal crest These zones are influenced strongly by the Pacific Ocean and are characterized by summer precipitation and fog. The northern zone, in the vicinity of the drainages of the Elk and Sixes Rivers, receives considerably more fog and is cooler than the coastal zone to the south The average annual precipitation in these zones ranges from 80 to 90 inches along the coast to 150 inches along the coastal crest. Most of the precipitation falls between November and March Mean winter temperatures in the coastal zones are in the mid-40's Mean summer temperatures reach the mid-60's

Fog is most prevalent in these zones during the summer months and extends inland via the river drainages to an elevation of 1,500 to 2,500 feet. This inland penetration is dependent on the height of marine inversion layers Hence, while the lower elevations along the coast may be cool and humid, higher elevations in the Coast Range above the inversion layer will be warm and dry

A drier zone, often characterized as a rainshadow, lies to the east of the coastal crest and extends to the vicinity of Grants Pass and Illinois Valley It has a mean winter temperature of 40 degrees Fahrenheit and a mean summer temperature in the 80's. During the summer and early fall, maximum daily temperatures often exceed 100 degrees. Precipitation averages 30 to 45 inches per year in the valley areas and 45 to 60 inches in the mountains.

A fourth climatic zone is located in the Siskiyou Mountains southeast of the Cave Junction area. The temperature regime there is similar to that of the rainshadow zone but receives up to 90 inches of annual precipitation

Because of the topographic irregularity and its influence on precipitation, the actual amounts of precipitation are quite variable within the narrow east-west range of the Forest. Many local areas receive precipitation amounts significantly above or below the yearly averages indicated for the broad climatic zones Rainfall intensities during winter storms tend to be highest on the west side of the Coast Range due to the orographic effect Potential evapotranspiration exceeds precipitation during the summer months. This is particularly so east of the coastal crest and on southerly aspects

East wind episodes are a common occurrence across the Forest and are a real concern to fire managers during the months of May through October These episodes are characterized by strong easterly winds, low humidities, and relatively high day and night temperatures. Maximum high temperatures of 80 to 85 degrees Fahrenheit have been recorded along the Pacific Coast at Brookings, Oregon during such periods. Temperatures in excess of 100 degrees have been recorded at mountain sites west of the coastal crest during east wind episodes. The most severe periods occur primarily in the late summer and fall months and are responsible for the local "Indian Summer" Many of the major wildfires on the Siskiyou National Forest have occurred under east wind conditions

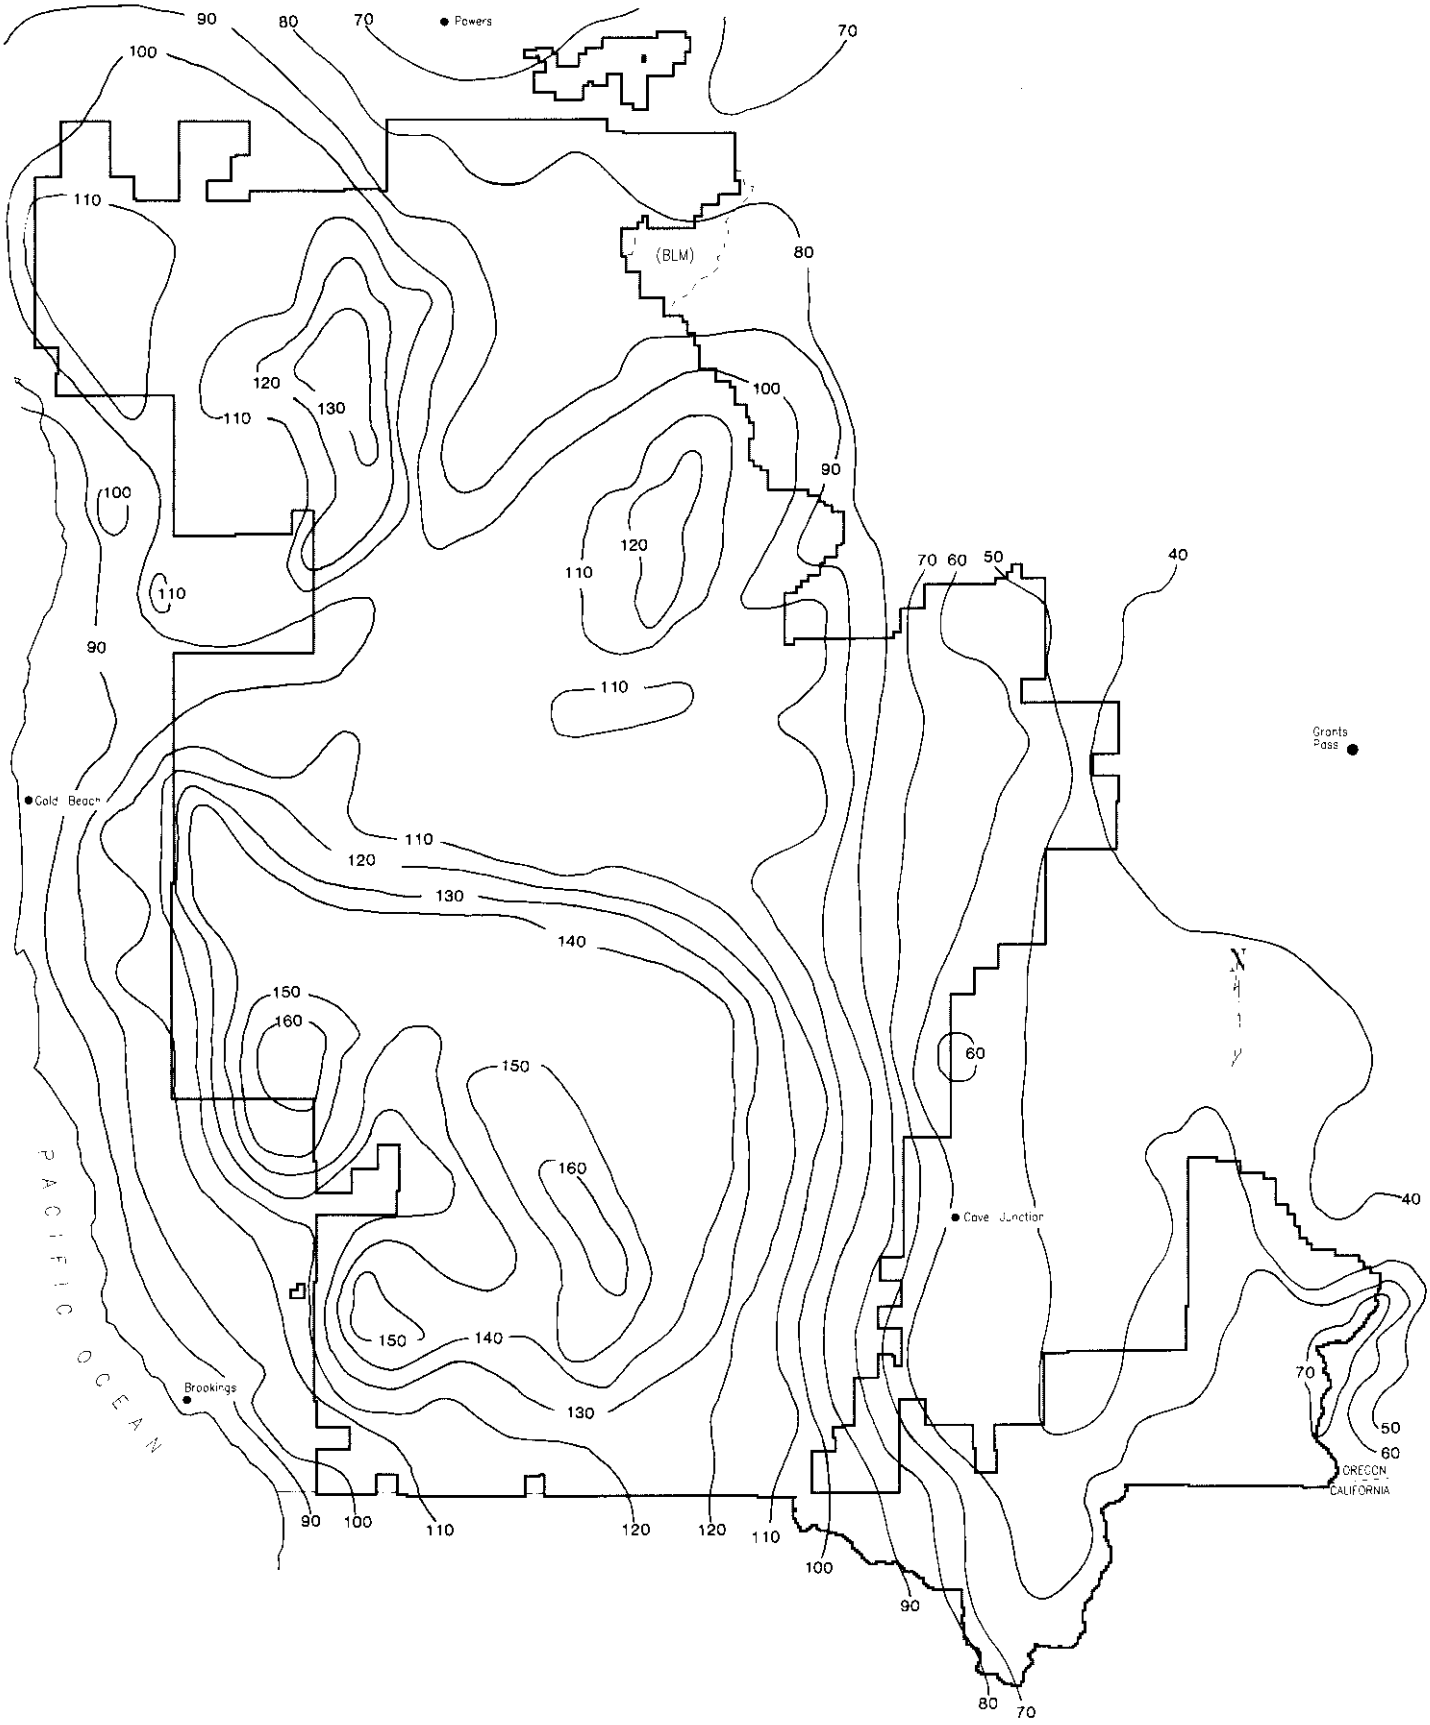


Figure III-1. Precipitation Map (Inches per Year)

GEOLOGY AND TOPOGRAPHY

The Siskiyou National Forest is included within portions of the Klamath Mountains and Oregon Coast Range Provinces Much of the Forest lies within the Siskiyou Mountains, which are loosely defined as the part of the Klamath along the Oregon-California border Northern portions of the Forest lie within the Oregon Coast Range Province, and differ in geology and topography (Baldwin 1986; Bailey 1966).

The Forest is characterized by deeply incised streams in narrow canyons, rocky ridges, steep slopes, rock cliffs, and numerous landslides Elevations range from 7,055 feet above sea level at Grayback Mountain to less than 100 feet along several of the coastal streams Many major ridges are at or near 4,000 feet The steep slopes, rocky canyons, and high-gradient streams are the products of bedrock geology and climate interacting over millions of years. The products of those ancient times, such as numerous soil types and oversteepened slopes, are parts of the environment currently managed by the Forest. Understanding the processes that formed the mountains and the limits of the natural systems provides a basis for resource management without degradation of environmental quality or long-term productivity.

Klamath Mountains Province

Most of the Forest is underlain by metamorphosed marine sedimentary and volcanic rocks. Near-surface rock is typically weathered or decomposed The common varieties are shaley slate, sandstone, schist, and greenstone (mostly andesitic lavas). Minor varieties include tuffs, chert, and conglomerate Intruded into the metamorphics are granitic rocks (mostly diorites and gabbros) and ultramafics (peridotite and serpentine) A geologic map is included in the Forest Soils Resource Inventory (USDA 1979c).

The rocks were formed during the Triassic and Jurassic Periods (200 million to 140 million years ago). The Triassic rocks are known as the Applegate Group. The Jurassic rocks are known as the Galice, Rogue, Dothan, and Otter Point Formations. Since Jurassic time, the area encompassed by the Forest has alternately been above and below sea level. Marine sediments were deposited over much of the area during the latter part of the Jurassic and during the Cretaceous Period (100 million years ago). Subsequent uplift and erosion have removed most of this cover. These strata make up the Humbug Mountain, Rocky Point, and Days Creek Formations

Coast Range Province

In the north central part of the Forest, the Klamath rocks are locally overlain by even younger sedimentary rocks (about 50 million years old) which are part of the Oregon Coast Range geologic province These are the Lookingglass, Flournoy, and Tyee Formations. In this area the ridges are broader and more rounded, although the inner gorges through which many streams flow are very steep and unstable. There are also plateaus, such as Eden Valley, which contrast with the steep terrain of the rest of the Forest.

Origin Of Canyon Landscape

The present canyons were eroded into the older, flatter landscape during the last two million years (known as the Pleistocene Epoch, or Ice Ages) As water was alternately stored in or released from glaciers, the land surface was intermittently high relative to sea level Precipitation was sometimes much greater than that of present times. Rock masses more resistant to weathering and erosion, such as greenstone, hard sandstone, and peridotite, became rocky ridges and buttes Easily eroded rocks, such as slates, some sedimentary rocks, schists, and some granitic rocks, became canyons and valleys A few glacially carved cirque basins and moraine deposits occur at elevations above 4,000 feet

The canyon landscape was sculpted by giant landslides that were many times larger than those of recent times The eroded landforms of these ancient slides occur throughout the Forest Intermittent strong earthquakes may have activated landslides during times of high groundwater. Many temporary lakes formed behind landslide debris dams; only a few small ones now exist.

LAND ALLOCATIONS

EXISTING CONDITION

Land allocations establish the permissible activities and restrictions on use. Use restrictions and management direction regarding activities are reflected in the Standards and Guidelines for each Management Area Table III-1 describes the primary objective for each Management Area

The relationship between land allocations and associated activities is an important concept introduced in this chapter. Many of the following resource component sections in Chapter III discuss various aspects of the existing land allocations However, in Chapter IV, a far more extensive discussion and analysis of the effects of alternative land allocations is presented Interactions exist among almost all of the land allocations, activities and uses, and the environmental components Given physical suitability, the number of acres allocated to each Management Area determines the types of activities and public uses that the Forest will provide Agency activities and public consumption of the opportunities afforded are the basis (causative agent) for most of the significant environmental effects evaluated in Chapter IV.

Existing allocations (classifications) of Management Areas are provided through the Land Management Plans and Multiple Use Plans prepared in the 1960's and 1970's. Many of the Management Area descriptions used in this document are similar in many respects to the older descriptions. The reader is referred to the following documents to gain a better understanding of the current land allocations and prescriptions:

Land Management Plans	**FEIS Filed**
Land Use Plan for Rogue Planning Unit (essentially the Wild Rogue Wilderness)	2/12/75
Land Use Plan for Mt Butler-Dry Creek Planning Unit (essentially the Grassy Knob Wilderness)	5/20/76
Rogue-Illinois Land Management Plan	10/12/79
Chetco-Grayback Land Management Plan	12/05/79
Multiple Use Plans	**Date Approved**
Powers Ranger District Multiple Use Plan	5/27/69
Illinois Valley Ranger District Multiple Use Plan (Revised)	6/08/70 6/08/82

Figure III-2 displays the location of lands whose status is unaffected by alternatives considered in the FEIS While physical changes in these lands are quite limited, the Forest does take credit for the special values that may occur, such as wildlife habitat, plant diversity, mineral potential, and wilderness character

The Siskiyou National Forest encompasses 1,162,030 acres, of which 69,728 are in Other Ownerships (Figure III-3). Approximately 55,000 acres are considered Non-forested Another 250,000 acres have been designated by the Chief of the Forest Service or higher authority to special uses (a combination of Wilderness and Other). For planning purposes, the remaining 787,000 acres of land are initially characterized as Forested Land (Figure III-3)

Table III-1 Management Areas of the Siskiyou National Forest

Management Area	
No - Name	Objective
1 - Wilderness	Maintain wilderness character in its natural condition and provide opportunities for solitude and recreation.
2 - Wild River	Maintain the natural, free-flowing, and primitive character of Wild segments of the river corridor
3 - Research Natural Area	Provide opportunities for research, observation and study of ecosystems influenced only by natural processes
4 - Botanical	Provide exhibits of plants, plant groups and communities with exceptional botanical and ecological value.
5 - Unique Interest	Provide opportunities for understanding the earth's unique geologic, historical, and archaeological features.
6 - Backcountry Recreation	Provide both motorized and non-motorized recreation opportunities in a largely undeveloped setting with the minimum management necessary for resource protection
7 - Supplemental Resource	Provide quality fisheries, water, wildlife habitat and recreation opportunities in a largely undeveloped setting.
8 - Designated Wildlife Habitat	Provide mature and old-growth habitat for dependent wildlife species
9 - Special Wildlife Site	Provide an array of unique plant and animal conditions that contribute to overall wildlife habitat diversity
10 - Scenic/Recreation River	Provide river-oriented recreation in an area of high quality scenery and largely undeveloped shoreline of of Scenic and Recreation segments of the river corridor.
11 - Riparian	Protect intrinsic values of ecosystems bordering bodies of water and wetlands while providing limited multiple-use development opportunities
12 - Retention Visual	Protect scenic values while providing multiple-use development opportunities that are not visually evident to the casual Forest visitor.
13 - Partial Retention Visual	Protect scenic values while providing multiple-use development opportunities that are visually subordinate to the characteristic landscape
14 - General Forest	Provide multiple-use development opportunities and a high yield of timber, subject to multiple use constraints.

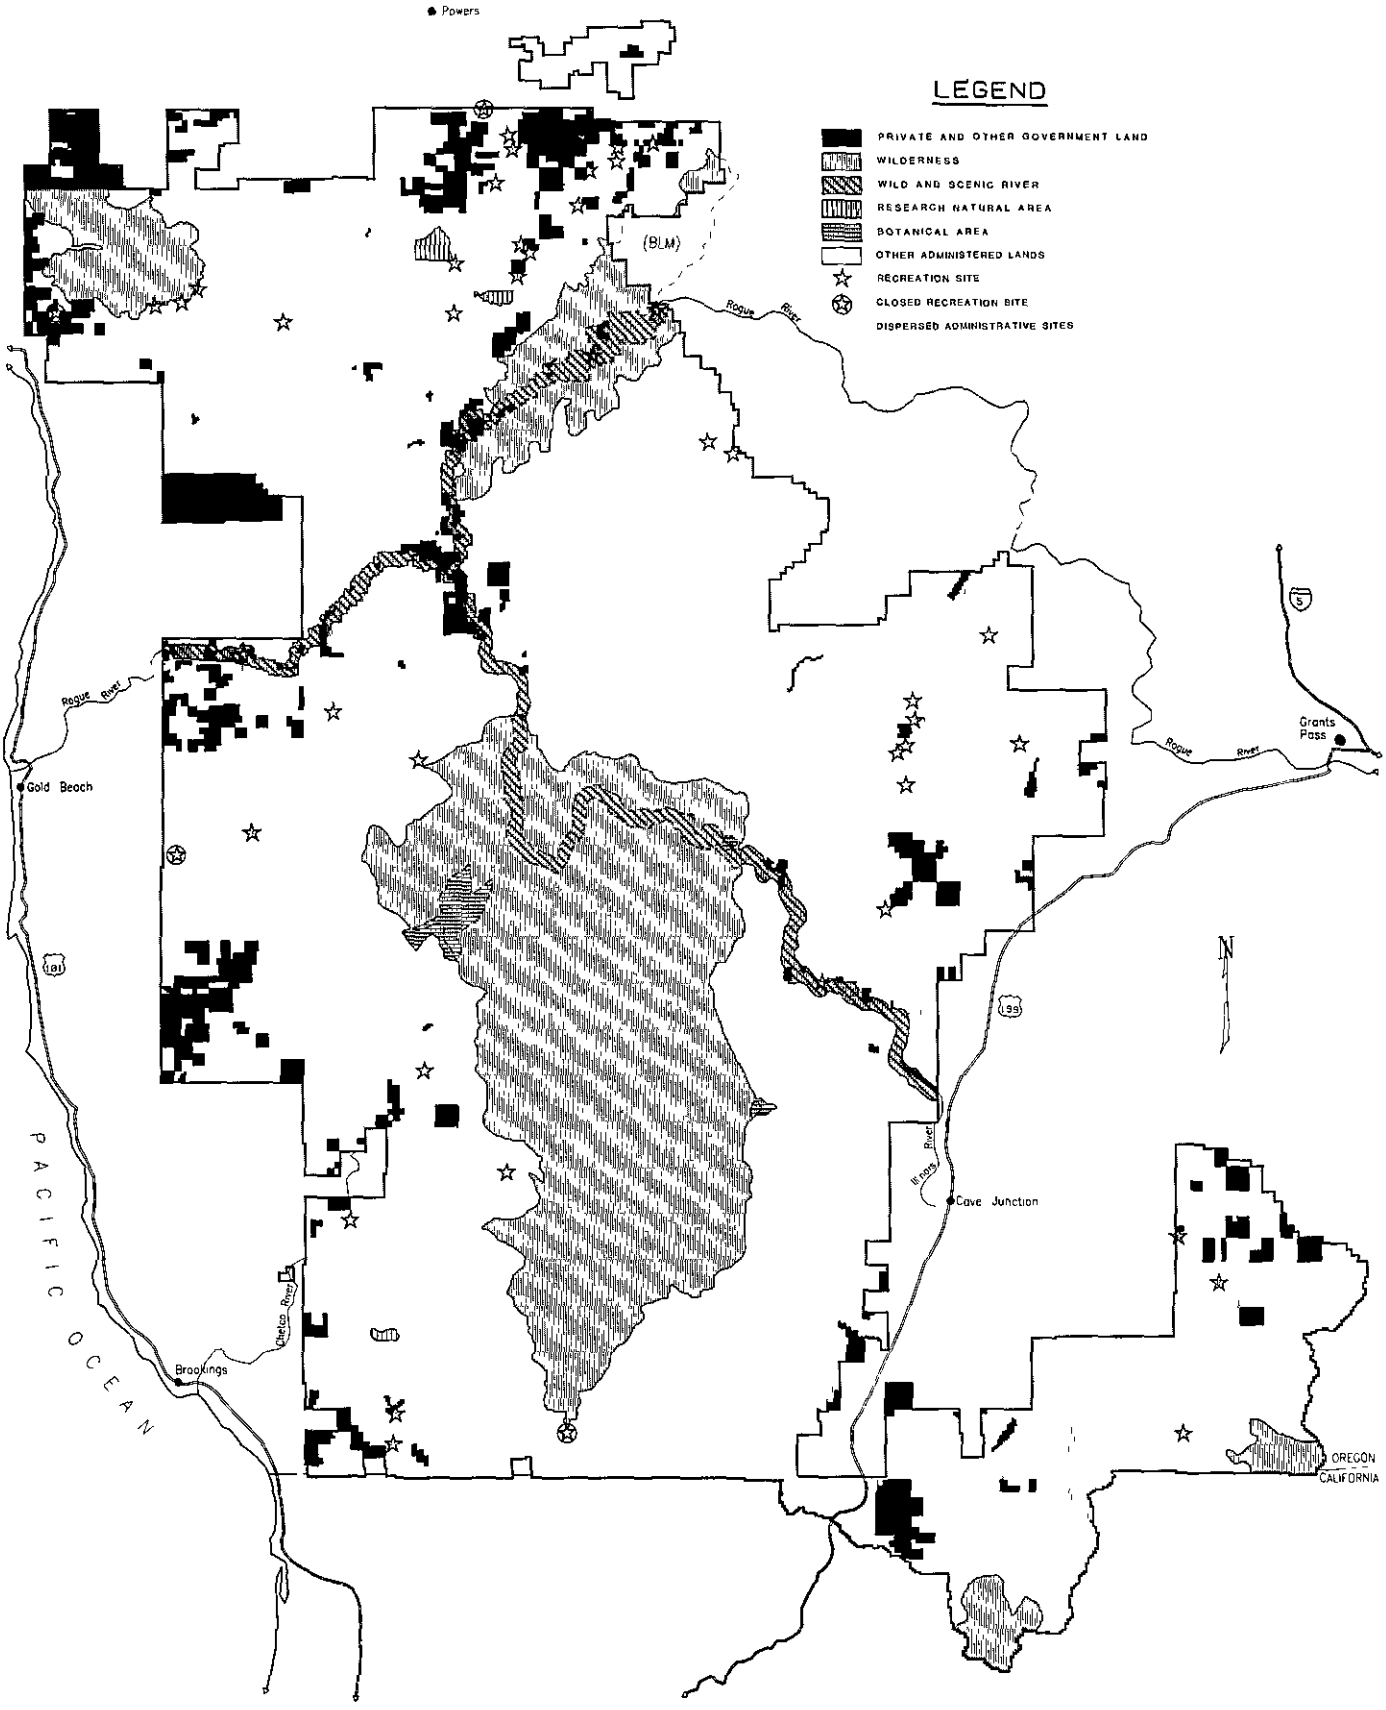

Figure III-2 Land Status Map

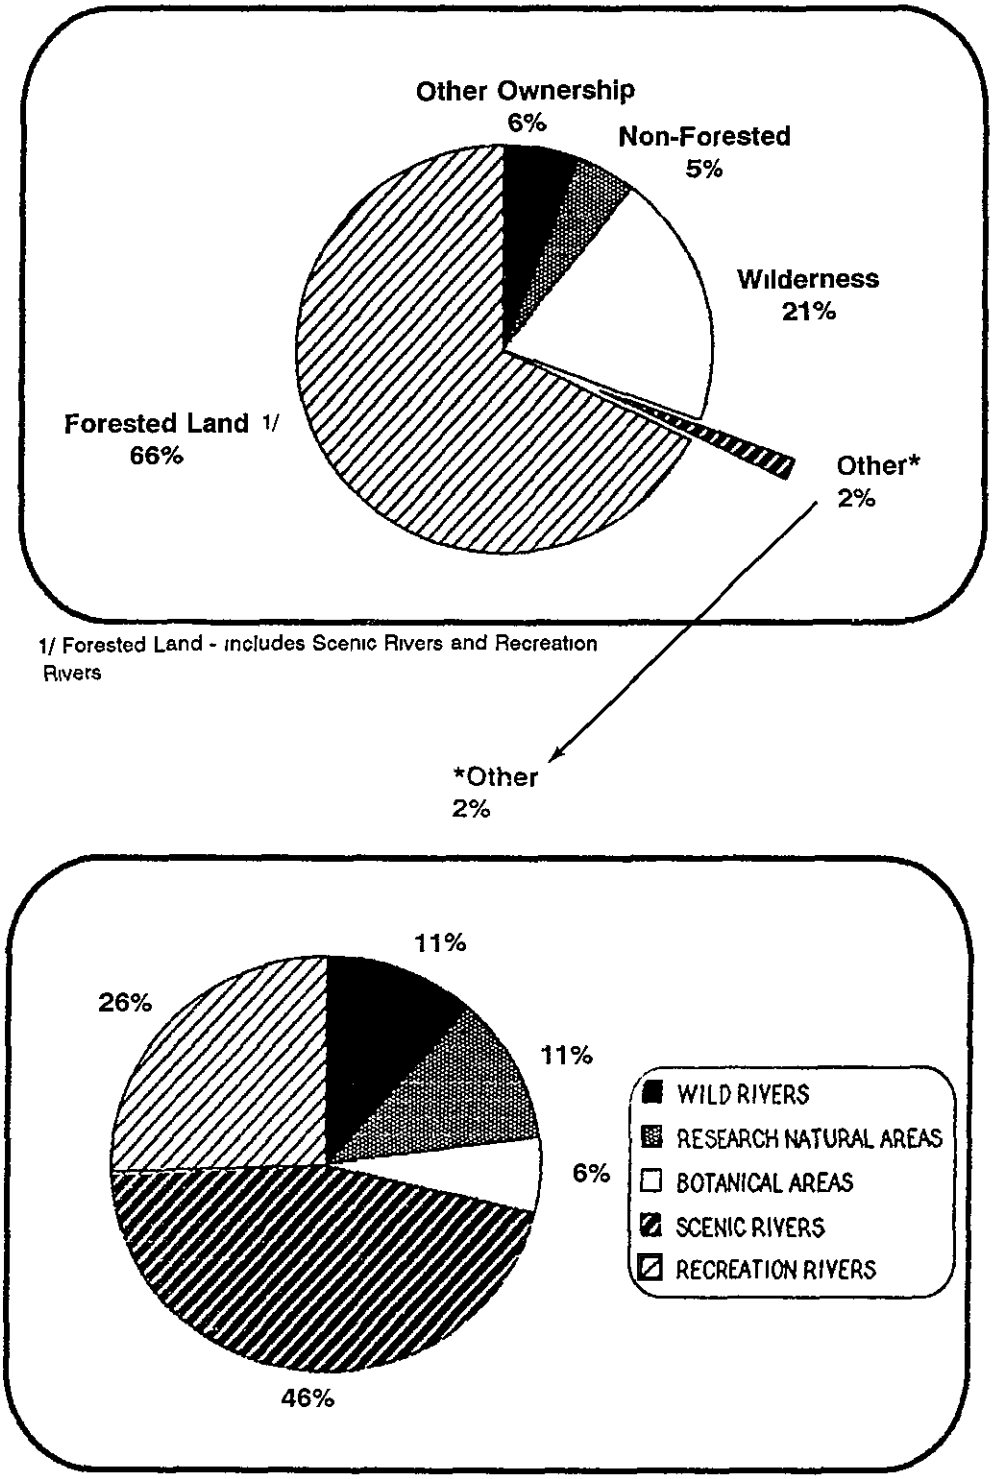

Figure III-3. Land Status Acreage

Some limitations on activities and uses of land within the Forest boundary are permanently established Unsuitable physical conditions are responsible for a few limitations, however, most are due to decisions made by the Chief of the Forest Service or higher authority The Regional Forester (the responsible official for the Forest Plan decision) does not have the authority to affect the land status in these cases without the Chief's approval Figure III-3 displays the inventory of acres on the Forest including those that presently have restrictions on use (again, Wilderness and Other) Table III-2 displays additional encumbrances existing on portions of the Forest

Table III-2. Special Use Permits and Withdrawal Orders

Permit/Order Category	Number of Cases	Acres Affected
Special Use Permits		
Recreation Use	15	27
Industrial Use	10	6
Research, Study, Training	8	362
Transportation	36	112
Utilities/Communications	44	242
Water Use	38	11
Other (Community, Public Information)	4	2
Withdrawal Orders		
Power	7	43,037
Mineral	28	50,101
TOTALS	190	93,900

CURRENT DEMANDS, WANTS, AND DESIRES

Maximizing the number of acres with a certain status, as reflected in the land allocations (Management Area assignments), best illustrates the level of demand associated with the resolution of the Planning Problems. This section describes the types of land allocations and changes in land status that would be necessary to move toward resolving a single Planning Problem. The physical capability of the Forest to satisfy the desired future condition through just land allocations is presented in the following:

1. "How Much Timber Should the Forest Produce?"

Timber production, measured by long-term sustained yield, is directly related to the number of acres selected as suitable for timber operations. Timber harvest can be programmed on lands selected as suitable in five Management Areas: Scenic/Recreation River, Riparian, Retention Visual, Partial Retention Visual, and General Forest Of the five Management Areas with timber potential, General Forest is the primary timber-producing allocation (having relatively few use or activity restrictions, other than those necessary to comply with laws and regulations). The greater the number of acres selected for timber production in General Forest, the greater the long-term sustained yield level. Lands selected as suitable for timber production in the other four Management Areas yield less volume per acre because of other multiple-use resource objectives, principally the visual resource Under current direction (Alternative A), 746,846 acres are allocated to the five Management Areas with programmed timber harvest. The General Forest acreage amounts to nearly half (376,144) of the total.

2. "How Much Old-Growth Forest Should Be Preserved?"

Old-growth forest characteristics are preserved when lands meeting the definition of old growth (see GLOSSARY) are allocated to Management Areas that do not allow physical manipulation of vegetation. Except for lands where timber harvest has occurred over the last 30 to 40 years, a considerable area of

the Forest meets the definition Land allocations to all Management Areas except Scenic/Recreation River, Riparian, Retention and Partial Retention Visuals, and General Forest should maintain existing old-growth characteristics In some situations, Scenic/Recreation River and Riparian are managed to maintain existing vegetation. A large part of the Riparian Management Area adjacent to larger streams and rivers could be considered "managed" old growth Under current direction (Alternative A), 173,754 acres of mature and old-growth forest are protected.

3 "How Can the Forest's Fish Habitat, Water Quality, and Soil Productivity Be Maintained or Improved?"

Minimizing adverse site-disturbing activities and rehabilitating areas degraded as a result of past activities would maintain and improve fish habitat, water quality, and soil productivity As with the previous Planning Problem, land allocations to Management Areas that either do not allow or limit manipulation of vegetation and/or where site disturbance are most advantageous to the resolution of this Planning Problem Application of watershed constraints that disperse management activities over time and space can also reduce potential risks of cumulative impacts Many of the Standards and Guidelines, and associated Best Management Practices, which accompany the specific land allocations also provide for the protection of these resources Under current direction (Alternative A), 327,456 acres are allocated to Management Areas with little or no disturbance Substantive constraints on site disturbance are applied to another 170,157 acres (Scenic/Recreation River, Riparian, and Retention Visual Management Areas).

4 "How, and to What Extent, Should Lands In and Adjacent to River Corridors Be Managed to Protect, Preserve, and Enhance Wild and Scenic River Attributes?"

For planning purposes, areas of peripheral protection take into account all lands within view of the Wild and Scenic River segments Water quality aspects, too, enter into the evaluation While quality of tributary streams to the Wild and Scenic Rivers are maintained by the Standards and Guidelines governing all Management Areas, land allocations to those Management Areas that limit site disturbance and vegetative manipulation on high risk landtypes can provide an added degree of protection This aspect of the Planning Problem is presented and evaluated through the prior Planning Problem 3.

A similar situation exists for visuals Lands adjacent to the Wild and Scenic River corridors that are allocated to Retention or Partial Retention generally satisfy the Visual Quality Objectives (VQO's) for the area However, allocations that do not allow site disturbance may be preferred in specific instances. Under Alternative A, the existing direction for visual management within the river corridor viewsheds is complemented by the full assignment of inventoried VQO's. Additionally, an array of Management Areas other than General Forest either overlay or are immediately adjacent to the river corridors

5. "How Should Sensitive Plant Resources Be Managed?"

Standards and Guidelines for all Management Areas are designed to maintain or enhance the viability of sensitive plants to ensure that none become threatened or endangered. Allocations to Management Areas 1 through 9 that minimize site disturbance are generally advantageous to most plants (some plants require disturbance), while acres allocated to Botanical Management Areas are specifically oriented to management and protection of the more unique or important botanical features. Under existing management, 30 percent (327,456 acres) of the Forest is allocated to Management Areas 1 through 9, while 4,475 acres are specifically assigned to Botanical Management Area 4

6. "How, and to What Degree, Should Forest Scenic Values Be Protected Through Visual Resource Management?"

Resolution of this Planning Problem would require allocations to Management Areas that allow managers to reduce, meet, or exceed inventoried VQO's. The Forest is stratified into 44 viewsheds, each with VQO's ranging from Preservation to Modification Presently, all Management Areas meet their inventoried VQO.

7. "How Should Wildlife Habitats on the Forest Be Managed?"

Management Requirements (MR's) for the maintenance of wildlife habitat are incorporated in the allocation to Designated Wildlife Habitat Management Areas, and Forest-wide Standards and Guidelines Complete resolution of this Planning Problem would provide a diverse array of successional stages proportionately distributed over the entire Forest in space and time Genetic viability of wildlife populations would be maintained. Natural site productivity would regulate the number of individuals. Current direction (Alternative A) meets the MR's for species dependent on old growth through allocation to Designated Wildlife Habitat and other areas of no programmed timber harvest In addition, numerous Special Wildlife Sites exist from past and present set-asides

8 "How Will Management Direction Affect Recreation Opportunities in the Wilderness and Unroaded Areas?"

Wilderness and unroaded areas supply the majority of Primitive and Semi-primitive Non-motorized recreation opportunities on the Forest Management activities in and around existing Wilderness could change the character of the recreation experience Allocation of land to Management Areas (in general, Management Areas 1 through 9) that preserve the character of unroaded areas provides additional Primitive and Semi-primitive recreation opportunities. This is particularly so if the combination of the first nine Management Areas provides for a larger block of land area. Many of the unroaded areas also tend to geographically buffer existing Wilderness, minimizing the influence of development activities on Wilderness users and characteristics

Future demands for a variety of non-motorized opportunities may require management decisions that maintain options in and around existing Wilderness to continue providing the experience of solitude and primitive experience desired of such areas Under current direction (Alternative A), roadless areas remaining unroaded within Management Areas 1 through 9 is 47,214 acres. This does not include the existing 232,495 acres of Wilderness, large blocks of land that will not likely be roaded due to being unsuitable for timber production (such as in parts of the South Kalmiopsis), nor smaller parcels included primarily in allocations to Research Natural Areas and Supplemental Resource Management Areas

9. "How Should Mineral Resources of the Forest Be Developed in Coordination With Management of Other Resources?"

Mineral exploration and development are facilitated by land allocations that provide economically attractive opportunities with the least restrictions and good access while still maintaining environmental integrity of the land. Management with reasonable (low to moderate) restraints to operations, options as to access, and a multiple-value approach of mining proposals that coordinate, rather than conflict, with other sensitive resources is generally provided through land allocations to General Forest, Retention and Partial Retention Visuals, Riparian, and Backcountry Recreation These Management Areas with low to moderate restrictions to mineral exploration and development presently amount to 786,705 acres (Alternative A)

ABILITY TO SATISFY DEMAND

A change in land allocations may be required to resolve Planning Problems where the activities and uses characteristic of General Forest are not compatible Allocations to any of the first nine Management Areas will generally satisfy those Planning Problems where site disturbance is contrary to the condition necessary to resolve the "demands" described above The ability of the Forest to satisfy Planning Problems 2 through 8 is only limited by the amount of land under Forest Service jurisdiction (1,092,302 acres). Resolution of the first Planning Problem is limited by the amount of land tentatively suitable for timber harvest. Of the 787,000 acres existing in General Forest, 624,000 is considered tentatively suitable

CULTURAL RESOURCES

EXISTING CONDITION

The Siskiyou National Forest Cultural Resource Overview (Beckham 1978) describes the cultural heritage of southwestern Oregon The document lists known cultural resource values and presents the historical characteristics of the Forest as presently understood The inventory is updated periodically as additional land parcels are examined and previously unknown cultural resources are discovered and evaluated

The area within and adjacent to the Siskiyou National Forest has likely been inhabited by human beings for at least the past 8-9,000 years. Over the centuries, the small bands of nomadic hunters and gatherers were gradually succeeded by more permanently based groups who depended heavily upon major food resources such as salmon, acorns, camas bulbs, deer, and elk. These later people lived in semipermanent winter villages along low elevation rivers and streams, traveling into surrounding uplands during the warm seasons to hunt game and gather edible plants. Archaeological evidence of the prehistoric inhabitants is relatively sparse to date, although new information is continually collected.

Artifacts collected in recent studies are representative of a hunting and gathering subsistence. Projectile points, scrapers, drills, and knives of chert, jasper, and some obsidian dominate the flaked-stone tool kit. Ground stone bowls, pestles, and mortars characterize the plant processing implements. Due to the climate of southwestern Oregon, preservation of organic artifacts, made from such materials as plant fiber, shell, wood, and bone, is very poor Therefore, the Indian artifact collections on the Forest are notably dominated by tools made from stone

During the prehistoric period (pre-1840's) the native population living within lands now administered by the Siskiyou National Forest included the Takilma and Athabascan Indians The Takilma resided along the Upper Rogue and Illinois Rivers The Athabascan people lived along the southern Oregon coast and along the lower Rogue River Pockets of Athabascan villages, within the general Takilma territory, were located at Galice Creek and along the Applegate River

The historic period began approximately 150 years ago with the arrival of the first Euro-American trappers and explorers in the Rogue and Illinois River drainages and along the southern Oregon coastline The Indian villages and traditional use areas were eventually overtaken by the newcomers in a series of battles culminating in the Rogue River Indian Wars of 1855 to 1856. This was the demise of the native culture in southwestern Oregon. Survivors of the battles were forcibly relocated to reservations at Siletz and Grande Ronde in the northwestern part of the State Due to their removal, the native population had little or no effect on those who have resided in this area since.

Today, two Federally recognized Indian Tribes occupy lands adjacent to the Siskiyou National Forest. They have been consulted regarding their interests and concerns in management of the Forest lands The Tolowa are located near Smith River, California; the Coos, Siuslaw, and Lower Umpqua are centered in Coos Bay, Oregon The Siskiyou National Forest recognizes their treaty rights and respects their interests in this land and resource management planning. Contacts have been established between representatives of these Indian tribes and the Forest to provide communication and understanding among all interested parties. To the best of our knowledge, National Forest lands do not overlap lands within the territorial boundaries of the Tolowa or Coos/Siuslaw/Lower Umpqua Indians The service area of the Coos tribe, however, does include all lands within Coos and Curry Counties; this does overlap National Forest lands

A third Indian tribe, the Coquilles, is scheduled to receive Federal recognition in 1989 They, too, have been contacted A portion of their aboriginal territory was located on what in now the Powers Ranger District. Active dialogue with the Coquilles is underway on several issues, including mitigation measures taken on specific sites and public interpretation of prehistoric sites

The contemporary Indian population within the Forest accounts for 1 5 percent of the total population. Most of these individuals are not descendants of either the Takilma or Athabascan Indians, but of people of northern California or elsewhere No Indian groups within the Forest have Federal recognition as tribes

With the "gold rush" period of the early 1850's came permanent settlement of the area by miners, farmers, and ranchers. By 1900, mining, grazing, hunting, trapping, homesteading, logging, and recreation activities were gaining prominence in the area Evidence of the historic period is therefore relatively plentiful.

Probability for sites on the Forest is based upon determining environmental factors that are conducive to site presence, such as river terraces, meadows, ridgetops, saddles, and springs. Known site locations also help predict discovery of new finds in areas with comparable environmental characteristics.

The Sample Survey Design (1983) for the Forest classifies the land into three probability zones for cultural resource presence:

1. High probability for sites - 18,766 acres (1.6 percent),
2. Moderate probability for sites - 149,623 acres (12 9 percent), and
3 Low probability for sites - 993,636 acres (85.5 percent).

The majority of high and moderate probability zones occur on relatively flat land, as steep slopes are less habitable and desirable for human use Only 10 percent of the land on the Forest has slopes less than 30 percent This factor, in part, explains why moderate and high probability zones are so limited.

The cultural resource base of the Siskiyou National Forest includes a range of historic and prehistoric artifacts and sites representing perhaps 9,000 years of human use and settlement. They include:

1. Prehistoric campsites, villages, graves, quarries, trails, vision quest sites, house pits, lithic scatters, and petroglyphs;
2. Historic cabins, trails, mines, ditches, railroad grades, mills, logging camps, and homesteads; and
3 Historic Forest Service structures, including guard stations, lookout towers, camps, administrative centers, and Depression-Era CCC improvements

Many of these sites are unique in southwestern Oregon. They may provide the sole record of former inhabitants, ways of life, and past human activities. An understanding of human adaptation to the forest and coastal mountains, and nature of probable contact with neighboring areas may be gained.

All cultural resources are evaluated to determine eligibility for the National Register of Historic Places National Register eligibility identifies those cultural resources which are worthy of protection, preservation, enhancement, or other management. When determined eligible, a property is managed as if it were already listed on the Register. All sites will be evaluated for National Register eligibility within five years after completion of the Forest-wide cultural resource inventory. Sites that may be in conflict with proposed actions are evaluated immediately.

The significance of a cultural resource site is measured by the eligibility criteria used in nominating properties to the National Register of Historic Places. These criteria are listed in 36 CFR 60.4 and Section 101 (a)(1)(a) of the National Historic Preservation Act of 1966 Cultural resources are divided into three basic classes according to their potential eligibility to the National Register. Forest-wide there are 60 sites (totaling approximately 35 acres) identified as Class I cultural resources, 108 sites (approximately 60 acres) identified as Class II; and 58 sites (approximately 30 acres) identified as Class III. Table III-3 lists the number of known cultural resource sites on the Siskiyou National Forest.

Table III-3. Recorded Cultural Resource Sites by Ranger District (as of May 1986)

Site Types	Chetco	Galice	Gold Beach	Illinois Valley	Powers
Historic -					
Class I 1/	6	1	13	3	3
Class II 2/	6	21	25	20	13
Class III 3/	12	7	13	7	16
SUBTOTAL	24	29	51	30	32
Prehistoric -					
Class I	10	3	21	0	0
Class II	1	2	13	3	4
Class III	0	0	0	2	1
SUBTOTAL	11	5	34	5	5
TOTAL	35	34	85	35	37

1/ Class I - Properties evaluated as being eligible to the National Register of Historic Places
2/ Class II - Properties identified, but not evaluated
3/ Class III - Properties evaluated as being ineligible to the National Register.

CURRENT DEMANDS, WANTS, AND DESIRES

Various segments of the public interested in the heritage of southwestern Oregon request access to information and artifacts and request that proper care and security be given to the Forest cultural resource collections. In particular, current demands are summarized below:

1 Discovery of Sites
   a. Access to site information
   b Participation in authorized data recovery projects

2 Protection of Sites
   a Proper curation of cultural archives and artifacts
   b Protection of Class I sites in their natural setting

3. Interpretation of Sites
   a. Access to new information acquired via analysis of cultural data.
   b. Cultural resource presentations to public groups.
   c. Access to view artifacts recovered from authorized excavations for educational and interpretive purposes.

ABILITY TO SATISFY DEMAND

The ability of the Forest to satisfy the public demand for cultural resource information is limited to the size and nature of the site data base in southwestern Oregon and to the opportunity to conduct interpretive studies of appropriate sites presently managed. Numerous methods are employed in an attempt to satisfy current public desires for the resource

There are two general types of protection. (1) preservation in place and (2) data recovery and analysis using current professional archaeological methods Cultural resources eligible for the National Register will be preserved in place whenever practical.

In addition to potential disturbances to sites as a result of ground-disturbing activities, site vandalism and natural deterioration also warrant attention Vandalism is a recurring problem at certain sites on the National Forest. Unauthorized excavation and surface collection of artifacts is affecting the quantity and accuracy of the information these items contain To address this problem, the Forest Service periodically patrols and monitors known archaeological sites and historic structures for damages Educational and interpretive programs are given by the Forest Archaeologist to foster an appreciation for preserving our local heritage

Because of recent vandalism to Class I sites in the Rogue River corridor, this portion of the Forest is given close surveillance. Once identified, the ability of the Forest Service to preserve, interpret, and otherwise manage significant sites will improve. The probability of further site vandalism depends upon the degree of trail construction, recreation developments, and subsequent use of such improvements by Forest visitors

Although all areas proposed for timber harvest and road construction are surveyed, sites may be overlooked and inadvertently damaged Often, contemporary mineral development occurs in areas mined historically. Remains of cabins, trails, tunnels, ditches, and equipment frequently occur at such cultural sites. Conflicts may arise when possession of surface artifacts and/or features having historic significance are desired or damaged by a claimant Often in areas where such conflicts are anticipated, known sites can be protected by means of adjusting a miner's operating plan

Road alignments are surveyed for cultural resources. As with timber sales, sites may exist but remain undiscovered prior to actual construction. Frequently, roads are aligned on top of historic trails. It is no coincidence that a given path chosen by the Indians or early settlers is judged today as the most economical and/or efficient for a road location.

Natural deterioration results from precipitation, high winds, landslides, and flooding Efforts are made to minimize the adverse effects these forces have on the Forest's significant sites by means of stabilizing river banks, maintaining the exteriors of historically significant structures, and other measures, as needed.

Enhancement opportunities include· interpretation of sites (using exhibits, articles, brochures, signs, public talks and slide programs); restoration and rehabilitation of buildings; offering research opportunities to professional archeologists and historians; and collection and curation of artifacts, documents, and photographs. Many of these means of interpreting the cultural history of southwestern Oregon are currently in use

The American Indian Religious Freedom Act of 1978 (AIRFA), states that the United States shall protect and preserve for American Indians "the inherent right of freedom to believe, express, and exercise their traditional religions " This includes, but is not limited to, access to sites, use and possession of sacred objects, and the freedom to worship through ceremonial and traditional rites. AIRFA does not grant free use of Forest products, ownership of antiquities or other cultural resources, exclusive use of areas, or access without consideration for other existing or potential uses or activities It does protect religious freedom for American Indians without apparent regard for Federal tribal recognition.

Approximately 225,000 acres (20 percent) of the Siskiyou National Forest have been inventoried for cultural resources. Currently, 246 prehistoric and historic sites are recorded Table III-4 provides a summary of the cultural resource site inventory by current and projected types of sites.

Table III-4 Cultural Resource Site Inventory

Site Type	Current 1986	Projected 1996	Projected 2006
Historic	186	400	600
Prehistoric	60	200	400
TOTAL	246	600	1,000

With respect to the Forest Plan, land allocations and their associated Standards and Guidelines will contribute to the resolution of current public demands and serve to integrate these demands into the management of cultural resources The land allocations which protect high probability parcels (such as Wild and Scenic/Recreation Rivers, Special Wildlife Sites, and Riparian areas) concurrently best meet the demand for preservation-in-place of cultural sites Land allocations which permit site development and ground-disturbing activities (such as General Forest and Partial Retention Visual Management Areas) best meet the public demand for discovery of new sites and new information, as every proposed ground-disturbing activity must comply with Federal mandates requiring survey and evaluation of cultural resources in these areas

ENERGY

EXISTING CONDITION

The Siskiyou National Forest has potential for energy production from oil, coal, and natural gas sources. See **MINERAL DEPOSITS** for information on energy minerals. In addition, the Forest has potential for windpower and hydroelectric power. The Forest does have a large firewood resource (fuelwood).

Due to upslope and across-ridge winds, there is a source of energy for wind turbines However, there are presently no windpower projects or proposed sites on the Forest As a result of the Cape Blanco Windfarm Project north of Port Orford, Oregon, there has been some consideration given to wind turbines on National Forest lands

Although many potential Forest sites have been identified by various agencies, no major hydropower sites are either in the planning stages or generating power. The largest recent proposal was the Eden Ridge Pump Storage Hydroelectric Project in the South Fork Coquille River headwaters. Within or directly affecting the Forest, there have been approximately 20 small hydropower applications made through the Federal Energy Regulatory Commission (FERC) process since 1980, few have actually been constructed. The others have been rescinded.

Fuelwood is currently the dominant energy source derived from the Forest. With both hardwoods and softwoods available for fuelwood, wood is an attractive, renewable energy source. Hardwoods are abundant and comprise approximately 17 percent of the total standing board-foot volume. Potential fuelwood from hardwood species, principally tanoak, Pacific madrone, red alder, and golden chinquapin, is available from standing trees, as residue from type conversion projects, and as by-products from timber sales.

CURRENT DEMANDS, WANTS, AND DESIRES

The U.S. Geological Survey is responsible for classification of public lands as to their mineral content, water conservation potential, and potential for water power. Utility companies and other government agencies (U.S Army Corps of Engineers, U.S. Bureau of Reclamation, State of Oregon, and counties) have completed inventories of potential sites

Hydroelectric Power

Currently, there are approximately 60 water rights for power within, or downstream from, the Forest. Total appropriation of water is about 10,000 cubic feet per second on numerous streams and rivers. Not all of these rights are currently being exercised as many individuals, corporations, or agencies file for water rights in anticipation of future development

Pumped-storage waterpower denotes a hydroelectric system in which off-peak power of limited value is converted into valuable power during peak use periods Many sites were previously identified as potential pumped-storage hydropower projects

Fuelwood

The primary use of wood from the Forest as a source of energy is in heating residential dwellings. The wood products industry also uses wood residue as an energy source for its facilities. When compared to fossil fuel, wood suffers from bulk (in proportion to energy content) and lacks homogeneity.

Actual consumption depends upon distance from population centers, proximity to roads, and species of wood. From 1974 through 1982, Siskiyou National Forest fuelwood permits increased from 1,000 to more than 8,500 per year. The woodchip market competes directly with other firewood users for these residues

Fuelwood cutting permits are sold to many local residents for their personal home use Professional fuelwood cutters also obtain wood through commercial wood-cutting permits for standing hardwoods and logging residues There are many individuals who occasionally supplement their primary sources of income by cutting and selling a truckload of fuelwood In addition, several large-scale fuelwood business ventures ship fuelwood by rail or truck to California cities Despite the increase in permits, the present rate of fuelwood consumption for residential use is likely to remain constant, at least in the short term. According to the Coos-Curry Electric Cooperative, most homes that can be retrofitted with wood stoves, and most people who have the inclination to do so, are probably burning wood now.

The value and convenience of using wood for heating residential dwellings are major factors affecting use levels. Due to recent laws regarding wood-heating stove construction and Forest Service regulations that require pay-permits for collection of fuelwood, the cost of wood heat could actually reduce the present consumer value. As the quantity of fuelwood close to local population centers and roads becomes depleted, consumer value will decrease unless substantial changes in the methods of collecting fuelwood occur. As state laws and local ordinances are developed to deal with numerous concerns related to residential wood heating, and as the Forest Service develops policies dealing with wood gathering, the convenience of wood heat could drop.

Some optimism surrounds the future of wood for many industrial applications. Use of wood residues for industrial purposes is promising, but is currently limited to wood products facilities A preliminary biomass energy study (Perry 1983) encompassed the southern Oregon coastal area and indicated 100 megawatts of electrical energy could be generated for 20 years from several biomass energy fuel sources. These sources include standing hardwoods, unused mill residues, logging residues, and municipal solid wastes. Two locations outside the Forest boundary were evaluated as power generating sites It was expected that about 20 percent of the logging residue and 30 percent of the hardwood biomass materials would come from four Ranger Districts on the Forest At present there are no known plans to utilize the material at those locations. In the long term, large increases in fuelwood demand would probably come from industry.

ABILITY TO SATISFY DEMAND

Reservoir sites large enough to store winter and spring flows for use during the long, dry summers are quite limited. In most cases power can be generated with only seasonal assurances Another obstacle to hydropower development has been the long distance from load centers. Other major factors limiting hydropower development include designations of five rivers as National Wild and Scenic Rivers and the importance of anadromous fisheries

Substantial development of the Forest's hydropower potential could be tapped in the future to meet regional demands Currently, demand for added hydroelectric power is low in the Pacific Northwest. Likewise, the impetus to develop the better proposed sites on the Forest has waned.

Of all the potential sites identified, only Eden Ridge has survived preliminary feasibility studies The Eden Ridge facility could be designed with a generating capacity of 90 megawatts The applicants, Pacific Power & Light Company and the City of Bandon, have set the proposal aside for future consideration

The total volume of hardwoods on suitable land is about 1,150,000 cords. Activity-generated fuelwood volume is dependent on regular timber harvest The Forest presently generates about 49,000 cords of fuelwood per year as a result of timber harvest activities

MINERAL DEPOSITS

EXISTING CONDITION

The Siskiyou National Forest is a geologically diverse area which contains occurrences of gold, silver, nickel, chrome, cobalt, copper, manganese, molybdenum, mercury, coal, and limestone Of these, nickel, cobalt, chrome, manganese, and mercury are classified as strategic minerals With these significant deposits, Planning Problem #9, "How should mineral resources of the Forest be developed in coordination with management of other resources?," becomes extremely important to the mineral industry relative to exploration and development opportunities. The discussions in this section are pertinent to the resolution of this Planning Problem

Metallic Minerals

More than any other metallic mineral, gold has been the most sought-after mineral on the Forest, with a prospecting and production history (from both placer and lode deposits) dating back to 1850 Gold placer activity is concentrated heavily along the Illinois River and Josephine, Sucker, Althouse, Galice, and Silver Creeks Prospecting and production are likely to continue into the distant future Recreational gold panning and dredging have also been increasing Mining will most probably be from placer deposits located along and near various stream courses long known to contain gold-bearing gravels. A few open pit and underground lode operations of small to medium size may become active within the next 10 years

Between 1850 and 1965, Oregon produced 5 8 million fine ounces of gold and 5 4 million fine ounces of silver. Most of this production was in southwestern and northeastern Oregon, the Siskiyou National Forest playing a significant role in this production. Recently production has been down, however, it is believed future potential exists at a somewhat reduced rate

Beginning in the 1970's and continuing to date, exploration of low-grade laterite deposits for nickel and cobalt has increased in the serpentinite-peridotite areas in the southern half of the Forest. Actual production from these deposits may begin 10 to 15 years into the future, with an expected life of 20 years. A 1976 estimate of 13 lateritic prospects indicated a total net tonnage of 28 million metric tons, with an average content of 0 82 percent nickel, 1 3 percent chromium, 0.08 percent cobalt, and 26 percent iron. These deposits may become very important nationally. The known significant deposits in the United States are in Alaska, Montana, northern California (Gasquet area), and southwestern Oregon. The deposits in Montana are the largest but are very low grade. Known deposits would not supply the United States for more than 15-20 years if we were suddenly denied foreign sources

Chromite was extracted, particularly from Forest podiform deposits, during both World Wars and as part of a Federally supported chromite stockpiling program in the mid-1950's. Present work by the U S. Bureau of Mines indicates that both massive and disseminated deposits of chromite could well be workable when chrome prices increase. Little production is expected unless incentive prices are paid, as in the past

Although there has been production of copper ore in the past (1860's to 1920's), no production has occurred recently. Future copper production from volcanogenic sulfide deposits would be affected by a significant increase in the price of copper. However, copper deposits in the area appear to be limited

The remaining metallic minerals appear to be located in small, insignificant deposits. These notably include manganese, molybdenum, and mercury.

Other Minerals

Limestone is present in the southeastern portion of the Forest. The known locations (all south of Oregon Caves National Monument) are small and scattered Development of these areas is not expected

Past coal production on the Forest was in the Eden Ridge area during the late 1800's Some of these coal beds may be developed in the future. More than 50 million tons of coal are estimated to occur in this area Underground mining methods will most likely be used because of the depth of the beds. Depending upon the method of use, the coal could be extracted over a 20-year period at a rate of 2.5 million tons per year Deposits are very significant statewide, but not nationally In addition, this coal is high in sulphur, low in BTU's, and not in demand

While there are no known oil or gas deposits on the Forest, a few known geologic sites could be favorable for oil and gas development

Mineral materials suitable for road construction needs are generally available, but may become scarce for some localized areas of the Forest In 1980, the Siskiyou National Forest used over 600,000 tons of rock, almost all from bedrock quarries, for road-related purposes. In 1984, the usage was 372,000 tons. Currently, this is the largest mineral usage on the Forest. The need for suitable rock for road-related purposes (e.g , surfacing aggregates and riprap) will continue.

A small quantity of mineral material has been used for building stone. In 1984 this use amounted to about 25,000 tons The use is expected to continue and may even increase in the future.

The Forest has a limited variety of lapidary materials. Some items found include agate, jasper, rhodonite, grossularite, and chert. The extensive areas of serpentinite and peridotite may have some cutting-grade serpentinite and minor nephrite Two rare minerals, Oregonite and Josephinite (both metallic nickel-iron alloys) occur near Cave Junction. Petrified wood and fossils of clams and crabs are also found.

Mineral Potential

Figure III-4 shows the general location of the mineral potential on the Forest. A preliminary estimate of potential for locatable and leasable minerals on the Forest has been made Broad areas of Forest land have been apportioned to one of the following mineral potential categories:

Rating	Characteristics of Mineral Potential
High (145,300 acres)	Lands where geologic, geochemical, and/or geophysical characteristics favorable for resource accumulations are known to be present Evidence shows that mineral concentration/mineralization in a broad sense has taken place.
Moderate (298,700 acres)	Lands where geologic, geochemical, and/or geophysical characteristics favorable for resource accumulations are known or can reasonably be interpreted to be present Evidence of mineralization is less clear or has not yet been found.
Low (648,300 acres)	Lands where geologic, geochemical, and/or geophysical characteristics are unfavorable for resource accumulation. Evidence indicates the mineral concentrations are unlikely. This rating embraces areas with obvious, but dispersed and apparently uneconomical mineral occurrences
Unknown	Lands where the level of knowledge is so low that to classify otherwise would be unjustified (No lands are inventoried in this category)

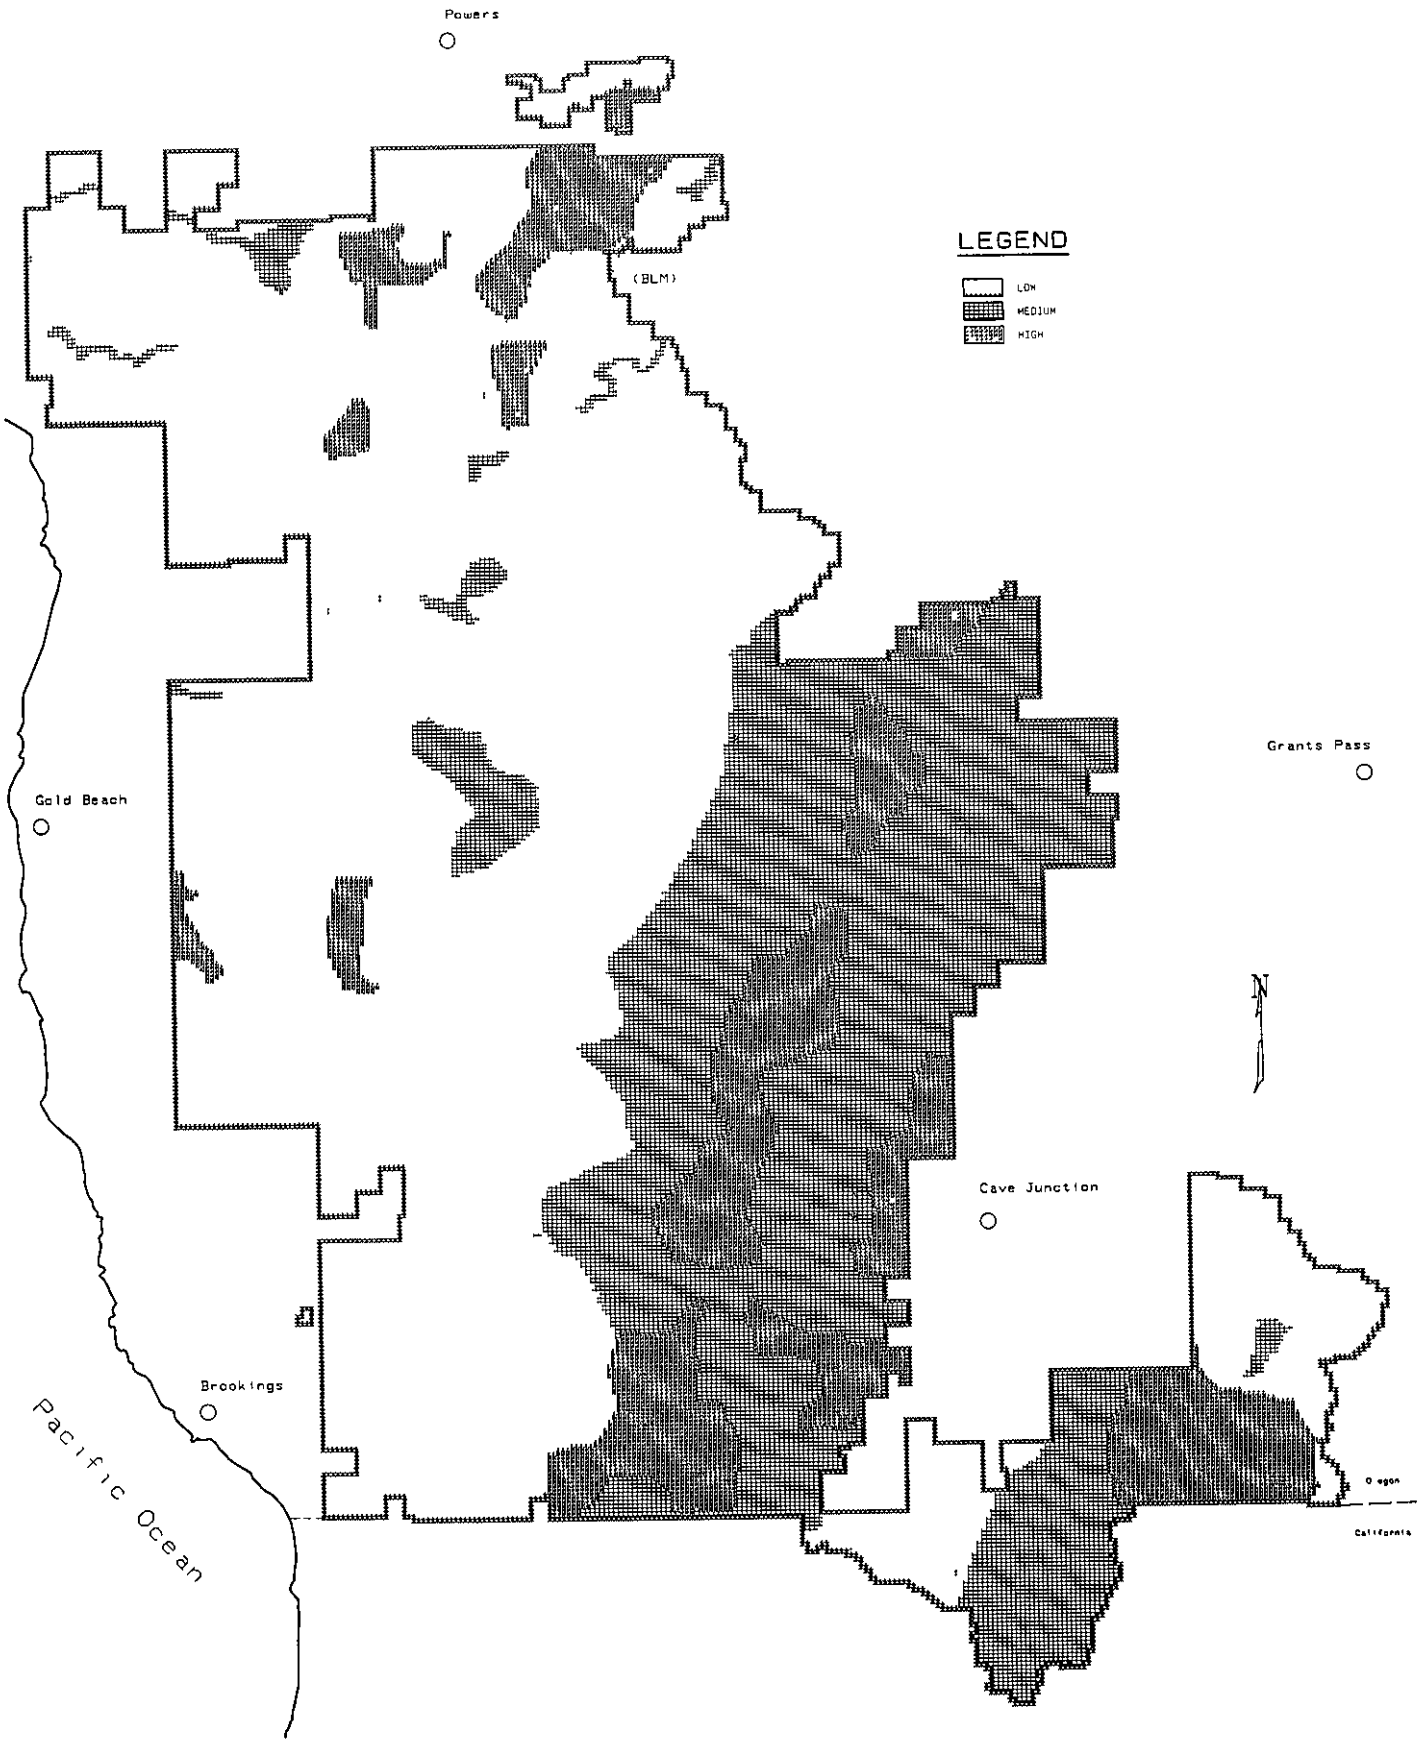

Figure III-4. Mineral Potential - 1985 Map

Mineral Access

The accessibility constraints under current direction (Alternative A) for Siskiyou National Forest lands have also been reviewed For analysis in this document, these lands were placed in one of the following access restriction categories:

Restrictions	General Characteristics of the Restriction
Withdrawn (267,000 acres)	Lands withdrawn from mineral entry Includes statutory and administrative withdrawals In comparing land management alternatives, this category will also include areas where preservation of other resource values require subsequent withdrawal from mineral entry
High (39,000 acres)	Lands where mineral activities are permitted, but administrative designations preclude or highly restrict access and/or ground-disturbing activities. This category includes statutory or regulatory designations where mineral development is permitted, but access is highly restricted due to resource constraints Also included are lands where through changes in landownership status, some portion, or all, of the mineral rights were retained by a prior landowner. Leases usually would contain no surface occupancy stipulations
Moderate (203,000 acres)	Lands where management designations or other resource considerations require special mitigative measures. Special lease stipulations or plan of operation considerations are needed to accomplish resource coordination
Low (584,000 acres)	Lands where management designations would not require special mitigative measures over extended areas Restrictive lease stipulations or operating conditions may be required to mitigate site-specific resource coordination needs For the most part, however, standard field practices for mining and mineral lease activities can be utilized

When considered together, these two factors (mineral potential and access restrictions) tend to indicate the potential for development of the mineral resource Areas more likely to be developed would have a High potential of minerals being present and a limited (Low to Moderate) restraint on access.

Protection of Surface Resources

Some areas on the Forest are required by law to receive special considerations in mineral operations, such as Wilderness, Wild and Scenic Rivers, and cultural resource areas Nearly 267,000 acres of land have been withdrawn from mineral entry Approximately 232,500 of the withdrawn acres are located in existing Wilderness. In the case of Wildernesses, operations are to be conducted in a manner that is compatible with the preservation of wilderness character.

The existence of threatened or endangered plant species in some of the mineralized areas may present special problems. These problems will have to be resolved on a case-by-case basis according to Forest Standards and Guidelines

CURRENT DEMANDS, WANTS, AND DESIRES

On the Forest in 1984, there were approximately 8,100 mining claims recorded with the Bureau of Land Management, up from about 2,560 recorded in 1980 Currently, a vast majority of claims are being located for placer gold. There are also surface and underground operations for gold and other minerals.

There were 125 approved operating plans, up from 38 in 1980 Two coal leases were in effect in 1984, along with 27 active mineral material permits. The coal leases have since been abandoned.

In most cases less than five acres per site are impacted. Although exploration of broad areas may encompass more acres, the total impact per operation is normally less than five acres.

Aggregate production for road-related purposes represents the highest continuing mineral use. Alluvial sand and gravel are not utilized. The approximately 200 existing sources are bedrock or talus quarries located throughout the Forest.

Mining activities on the Forest, from prospecting through production, are expected to continue. Demand for minerals is variable Those mineral commodities in high demand are gold and quarry rock; in moderate demand are coal and lapidary materials. The remaining mineral commodities are in low demand.

The current gold market, coupled with recent employment trends, could contribute to more gold mining in the future Recreational gold panning and dredging is increasing, as is prospecting for semiprecious gem stones. The increase in mining claims and approved operating plans, described previously, indicate the amount of increase in use levels

Although not as important as it was 50 to 100 years ago, mining does support a segment of the labor force. These jobs in turn help support other jobs at the local, regional, and National levels With the nickel-laterite and coal potentials on this Forest, there could be a significant effect on the local labor market, and on local and regional economies.

ABILITY TO SATISFY DEMAND

The Bureau of Land Management (U S Department of Interior) is primarily responsible for the management of minerals on Federal lands Through various laws, regulations, and inter-departmental agreements and rules, the Forest Service has various levels of responsibilities with regard to surface management on mining claims on National Forest System lands.

Forest Service minerals program objectives are to manage National Forest System lands to accommodate and facilitate the exploration, development, and production of mineral resources, while integrating these activities with the use and conservation of other resources to the fullest extent possible

Many parts of the Forest have essentially unlimited supplies of bedrock suitable for production of crushed aggregate for road surfacing and riprap In some areas, quality rock has to be hauled for less-than-desirable distances. This problem may increase in the future, particularly on the west side of the Forest. Visual Quality Objectives or other reasons may restrict or prevent access to potential rock sources in some places.

Citizens have a statutory right to prospect, locate, and develop locatable minerals on lands open to such entry. The basic law predates the establishment of National Forests. On lands open to location of minerals, the Forest Service has established surface-use regulations on prospecting, exploration, and mining activities These and other Federal mineral regulations integrate mineral development and use with the management of the surface resources

With regard to the leasable minerals, the Forest Service provides advice on how to protect surface resource values and gives recommendations or consent to leasing Where the Forest Service is permitted to sell certain mineral materials, the permit includes requirements for adequate protection of other resource values

The Forest Service has a responsibility to identify areas which have competing resource values that could be affected by mining activities. Where the Forest Service believes the value of the competing resource exceeds those of the known (or potential) mineral values, the Forest Service will recommend that the Bureau of Land Management remove the area from mineral entry.

As a surface resource manager, the Forest Service protects the interest of the United States by requiring operator compliance with the mining laws and regulations, and preventing unauthorized uses on mining claims. The mining laws and regulations governing Forest Service administration of this resource are:

1 Placer Mining Act of 1870, 16 Stat. 217;
2. General Mining Law of 1872, 17 Stat 91;
3. Public Law 167, Multiple Surface Use Act of July 23, 1955, 69 Stat. 367, (also known as the Surface Resources Act);
4. Section 314, Federal Land Policy and Management Act of 1976, 90 Stat. 2743;
5. 43 CFR 2860 - Mineral Patent Applications;
6. 36 CFR 228, Subpart A - National Forest Surface Use Under U.S. Mining Laws; and
7. 36 CFR 228 4 Subpart C - Mineral Material Regulations

On some lands that are acquired for National Forest purposes, and where a prior landowner has not retained the mineral rights, what would have been locatable hard rock minerals are included in the leasable minerals category.

Forest Service policy for managing minerals is to·

1. Provide professional assessment of mineral resources;
2. Keep lands available for exploration and evaluation of mineral potential,
3. Respond to proposed mineral activities in a timely and reasonable manner;
4 Ensure prompt reclamation of lands to productive uses;
5 Cooperate actively with appropriate agencies, and
6 Manage the minerals program consistent with applicable laws and multiple use principles.

IMPROVEMENTS

The existing constructed improvements used by the Forest Service and the public include:

1. Roads - the roadway and structures, e.g , bridges, culverts, retaining walls, cattle guards, and gates;
2. Trails - the trailway and structures;
3. Developed Recreation Sites - roads, structures, and utilities;
4. Administrative Sites - roads, structures, and utilities,
5. Utility and Transportation Corridors - strips of land for electrical power transmission (greater than 69kV), and State and Federal highways used for interstate commerce,
6. *Water Storage Developments - dams and pond developments; and*
7. Miscellaneous Improvements - Forest Service, public and private improvements within the National Forest boundary, e g., lodges and campgrounds.

EXISTING CONDITION

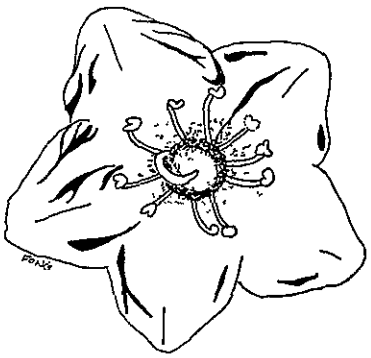
Roads

In 1984, the Siskiyou National Forest transportation system had 2,645 miles of road, including 2,538 miles in Oregon and 107 miles in California. Current maintenance emphases on these roads are displayed in Table III-5. Each of the maintenance levels is discussed in the Transportation System Maintenance Handbook (FSH 7709.15).

The majority of the Forest road system is single laned; several major roads are double laned. Almost all have gravel surfacing, while a few have some portion of their length asphalt paved. The arterial/collector road system for the Forest is provided in Figure III-5.

Sections of US Highway 199 (Redwood Highway) cross through the Siskiyou National Forest. The portion in California is listed as eligible for designation as a California Scenic Highway by the State of California. The eastern 11.5 miles of Oregon State Highway 46 (Oregon Caves Highway) is part of the Oregon Historic and Scenic Highway Program; a significant portion is on the Forest.

There are five through-Forest routes that are used by the public and by commercial concerns·



1. Agness Road (56 miles) between Gold Beach and Powers;
2. Bear Camp Road (25 miles) between Galice and Agness;
3. Happy Camp Road (1 mile) between Cave Junction and Happy Camp;
4. Wimer Road (7 miles) between O'Brien and US Highway 199 in California at Patrick Creek; and
5. Grayback Road (11 miles) between Oregon State Highway 46 and Williams.

There are 108 road bridges on the Forest Over 135 gates are located to limit access for a variety of reasons.

Table III-5 Road Mileage by Current Condition Classification and Maintenance Level (Miles) 1/

	Current Condition			
Identified Management Maintenance Level 2/	Total Miles	Closed	Available for Public Use	Suitable for Passenger Cars
Arterial Roads 3/				
1	0	0	-	-
2	0	-	0	-
3	0	-	0	0
4	114	-	114	114
5	0	-	0	0
Collector Roads 4/				
1	0	0	-	-
2	58	-	58	9 6/
3	615	-	615	615
4	50	-	50	50
5	0	-	0	0
Local Roads 5/				
1	258	258	0	-
2	1,301	-	1,301	195 6/
3	243	-	243	243
4	6	-	6	6
5	0	-	0	0
Total Miles	2,645	258	2,387	1,232

1/ 1984 data
2/ Maintenance levels Level 1 - Long-term storage between use, Level 2 - Limited passage of traffic, primarily for high ground clearance vehicles, Level 3 - For public passenger car passage at prudent driving speeds averaging 20 mph, Level 4 - Similar to Level 3 but with higher speeds and more user comfort given consideration, and Level 5 - Same as Level 4 with safe travel speeds in excess of 35 mph
3/ Primary roads that provide main access into the Forest and connect with other Forest arterial or public roads
4/ Secondary roads accessing smaller land areas than arterial roads and generally provide the linkage between Forest arterial, public, other Forest collector roads, and local roads
5/ Terminal roads in the transportation system or provides linkages with other roads
6/ Represents a portion of the road system adequate for passenger cars for a period following timber sale maintenance activities

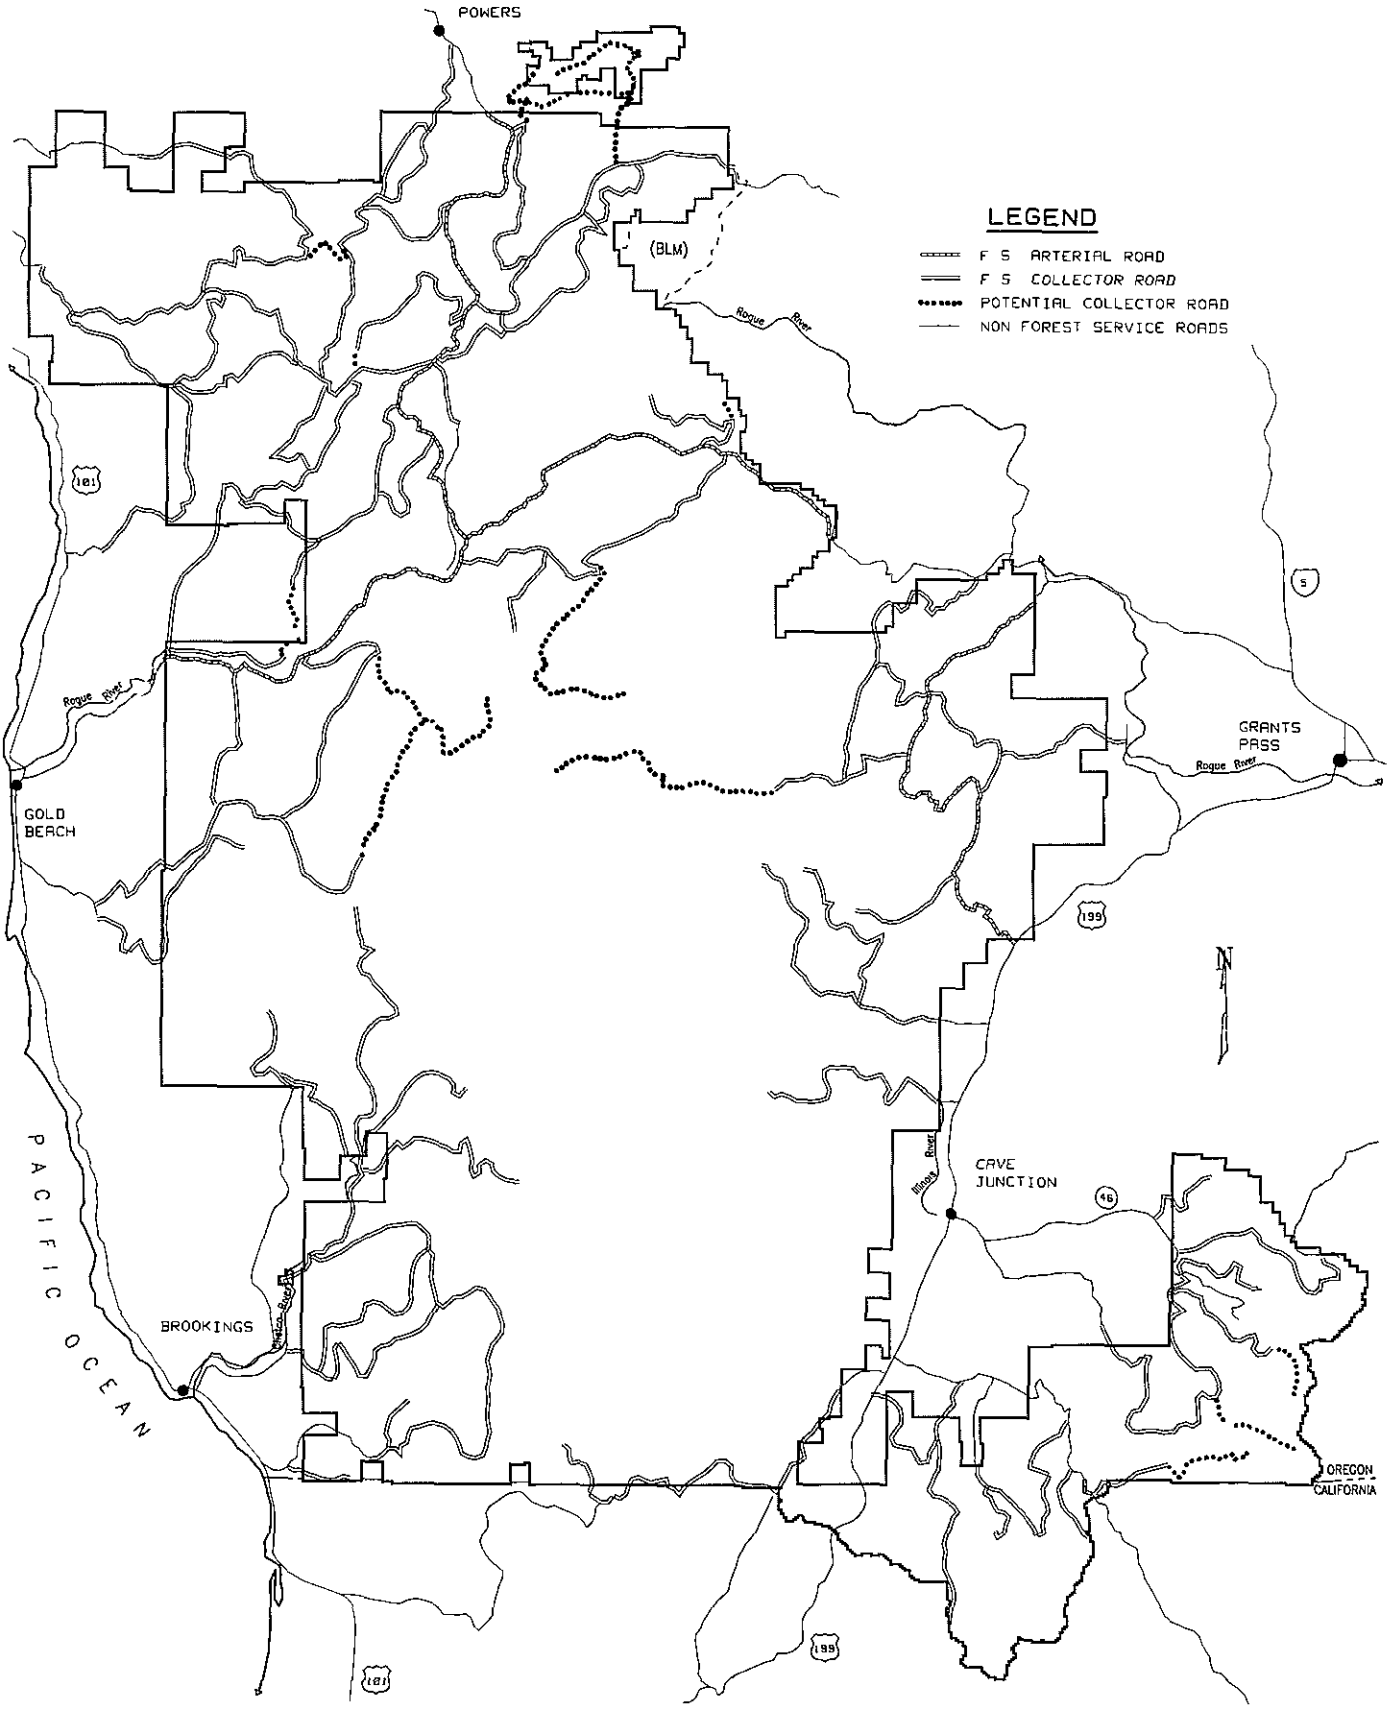


Figure III-5. Arterial and Collector Road System Map

Trails

There are 450 miles of maintained trail on the Siskiyou (Figure III-6) In addition, there are uncounted miles of abandoned trails scattered about the Forest See **RECREATION SETTING** for limitations on trail use. Table III-6 displays the availability and suitability of trails for various users.

Three National Recreation Trails on the Forest total 36 miles in length. The three trails are the Boundary Trail, a portion of the Illinois River Trail, and the Rogue River Trail. Due to past road construction, the Forest no longer has any through-Forest trails.

Table III-6. Summary of Trail Mileages by Trail Type 1/

Trail Type	Total Miles	Wilderness	Non-Wilderness
Hiker	450	217	233
Pack and Saddle	417	204 2/	200
Motorized vehicle 3/	171	- 4/	171
Cross-country ski	0	0	0
Snowmobile	0	- 4/	0
Barrier Free	0	-	0
Interpretative	2	-	2

1/ 1986 data
2/ 13 miles of Rogue River Trail within Wild Rogue Wilderness closed, as well as remainder of trail, to pack and saddle stock use
3/ Vehicles less than 40 inches wide Also includes mountain bicycles
4/ All vehicle use prohibited without a special permit

Developed Recreation Sites

There are 46 established recreation sites on the Forest currently open An additional 4 sites are closed Table III-7 summarizes developed recreation sites on the Siskiyou National Forest.

Table III-7 Number of Recreation Sites and Total Number of Units by Site Type 1/

Site Type	Total Sites	Camp Units	Picnic Units	Boat Ramps
Minimum Developed 2/	25 3/	41	23	0
Developed 4/	21 5/	223	51	4
TOTALS	46	264	74	4

1/ 1986 data
2/ Formalized dispersed recreation sites, does not include three closed sites
3/ Includes five sites with trailer units
4/ Does not include one closed site
5/ Includes 12 sites with trailer units, eight sites with drinking water, and five sites with handicap access

Administrative Sites

In all, there are 245 buildings of all sizes, including 31 for housing, 56 for storage, and 7 offices. Several buildings built before 1937 have National historic significance

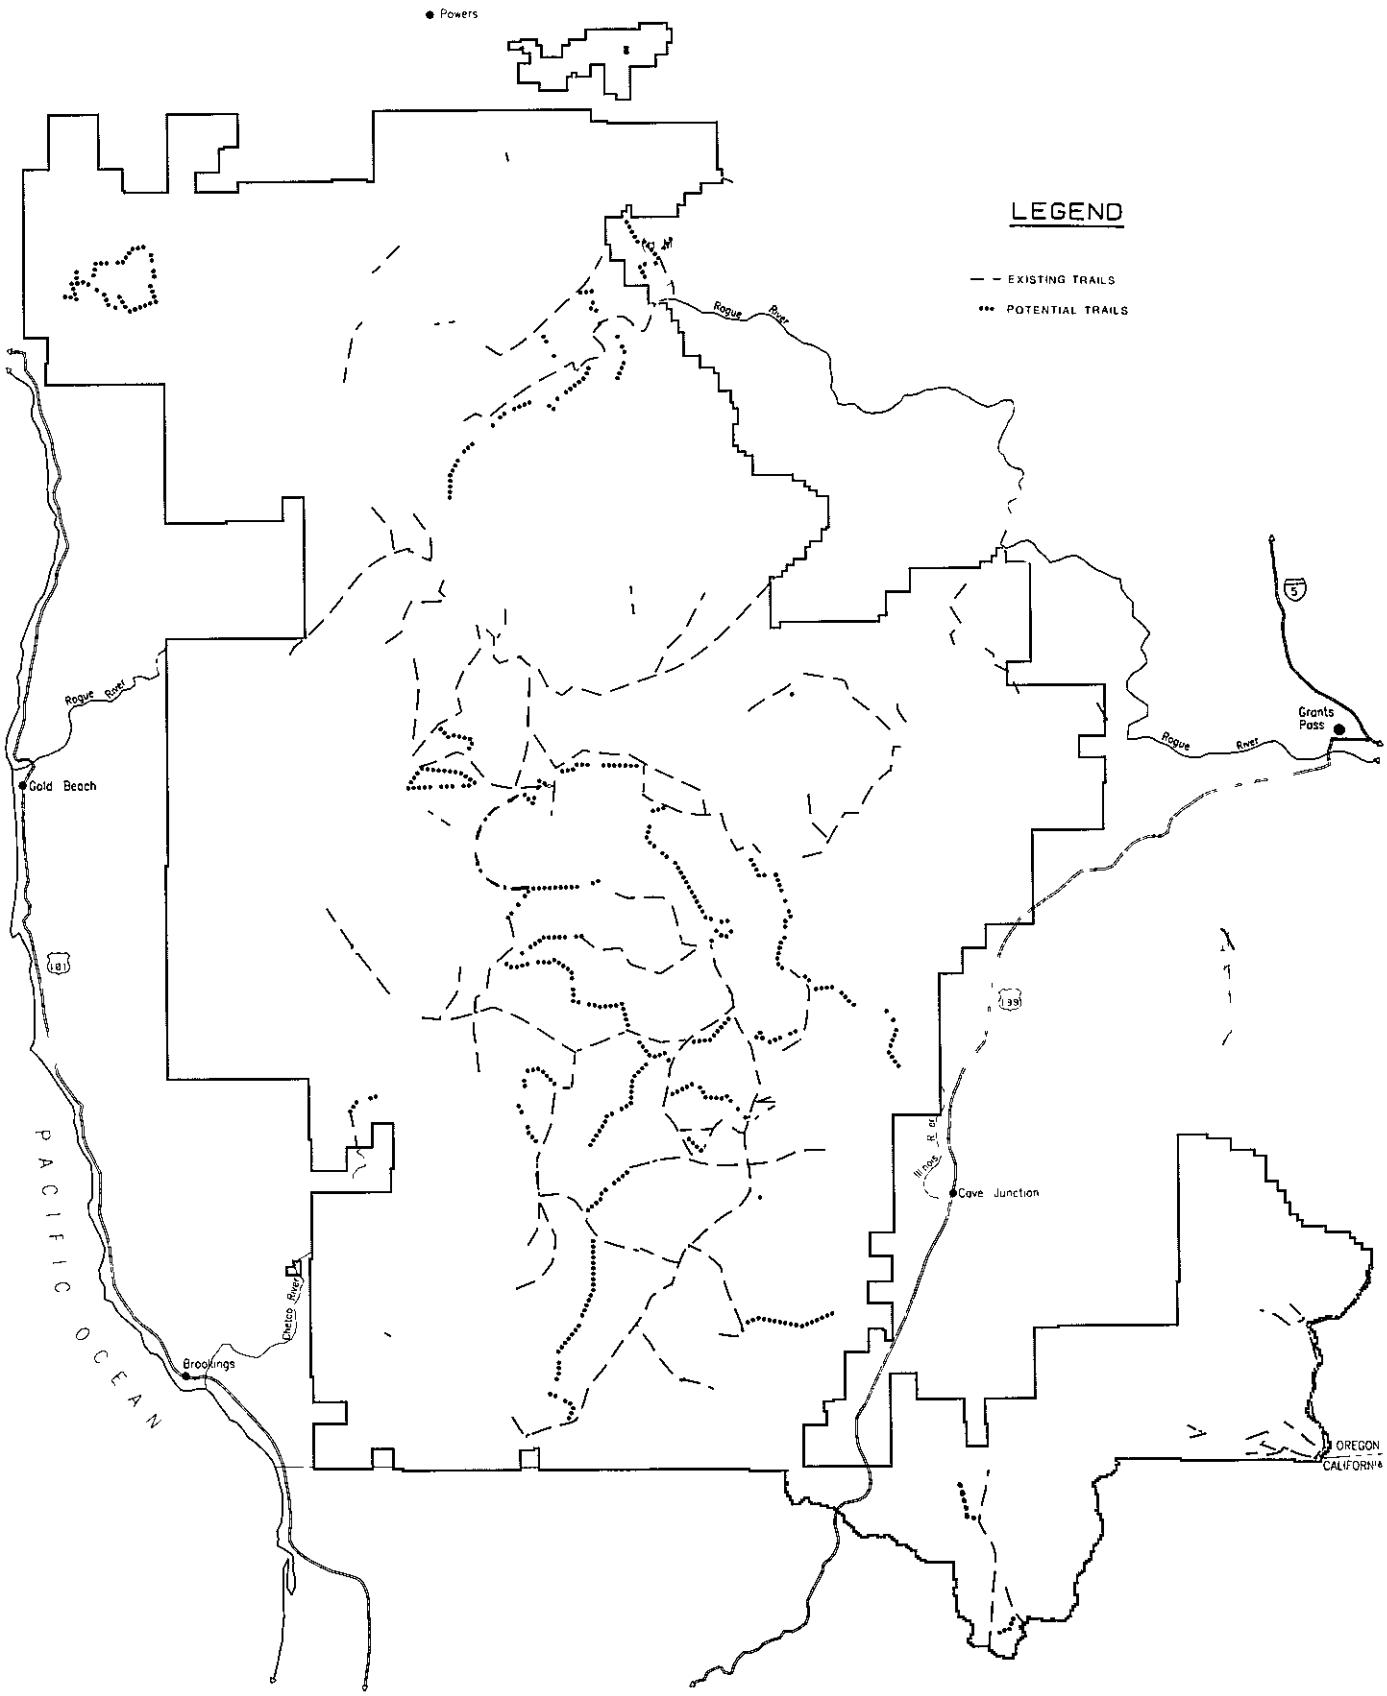

Figure III-6 Trail System Map

Utility and Transportation Corridors

Portions of the Happy Camp and O'Brien electrical power transmission corridors are within the Forest These corridors are shown on the Land Status Map, Figure III-2 These lines are not considered Utility Corridors by the Klamath or Six Rivers National Forests The O'Brien corridor contains the O'Brien and Whiskey Creek transmission systems A brief description of the corridors is displayed in Table III-8

Table III-8 Electrical Power Transmission Corridors

Corridor	Length	Existing Width	Kilovolt Limitation
Happy Camp	5 1 miles	100 feet	100
O'Brien	7 7 miles	200 feet	200

Another powerline just crosses a corner of the Forest next to U S Highway 199 Although meeting criteria for a utility corridor, this line is simply considered part of the highway corridor.

Within the Forest boundary, U S Highway 199 is a two-lane highway This highway continues into the Six Rivers National Forest through the Collier Tunnel in California

Water Storage Development

The only dam on the Forest is at Bolan Lake It is 14 feet in height and impounds 165 acre-feet of water. There are 109 constructed water sources used for fire suppression, of which 23 have been designed for use by helicopters. There are several mine development settling ponds

Miscellaneous Improvements

There are miscellaneous Forest Service, other government, and private improvements throughout the Forest Many of these require a permit or agreement to utilize National Forest System land In 1986, there were 155 Special Use Permits covering private use of National Forest lands, a summary of these is displayed in Table III-2 in the **LAND ALLOCATIONS** section Included within the Forest boundary are the Oregon Caves National Monument and the Agness townsite. Both include numerous improvements including roads, trails, lodges, stores, residences, a private landing strip, and other structures

CURRENT DEMANDS, WANTS, AND DESIRES

The existence of present and future improvements is in response to needs for use, protection, and management of Forest resources.

Roads

Various publics and Forest Service personnel utilize the road system for a variety of activities Wood production requires transportation of the raw materials (logs or chips) to a processing plant (plywood, lumber, or pulpwood mill) Much of this transportation is provided by the existing road system Where the timber resource is beyond the economic reach of logging systems (e g , helicopter, skyline, and highlead), additional roads may be required The amount of road needed per acre harvested varies in response to many factors, e g , logging system used, topographic relief, and environmental factors Needs are identified in the Ten-year Timber Sale Action Plan (Appendix C of the Forest Plan)

Trails

During the public involvement process, displacement of trails by roads was a topic of concern. The Forest-wide Standards and Guidelines have provisions which deal with this In recent years, there have been some efforts towards a "Coastal Trail" system in Oregon and most recently a "New Oregon Trail"; both would utilize some portion of the Forest

Developed Recreation Sites

With increased tourism, the expected concentration of use along the rivers will require facilities which protect recreationists' health and safety needs and meet their demands for this form of recreation.

Administrative Sites

Efficient management of the Forest will continue to require administrative sites based on resource program needs, and budget and personnel limitations

Utility and Transportation Corridors

The 1986 Western Regional Corridor Study, an update to a 1980 study, shows a long-range plan for a utility corridor from the Murphy-Wilderville area to the vicinity of Buzzards Roost, near Agness. A potential future corridor, on or near this same location and extending to Agness and Gold Beach, has been suggested by Bonneville Power Administration and Pacific Power and Light as an option for a crossing of the coastal mountains in southwestern Oregon

A 1984 environmental report by Coos-Curry Electric Cooperative displays two alternative corridors between Gold Beach and Brookings which traverse a western portion of the Forest This corridor study suggests a 230 kilovolt electrical power transmission system may be needed by the year 2030, or sooner, to serve their customers in the Brookings area The corridor has potential for an intertie with the electrical power transmission system in the Crescent City, California area.

The Happy Camp Road crosses through the Forest and connects the Cave Junction, Oregon area with the Happy Camp, California area. This route does not meet the Regional Guide definition for a Transportation Corridor In the long term, the road has potential to become a state highway. Within the Siskiyou National Forest boundary, all but one mile is under Josephine County, Oregon jurisdiction, the remaining mile is under Forest Service jurisdiction

Water Storage Developments

There is not much demand for water storage development on the Forest. There are several minor diversions for domestic purposes. There are several proposals on file for hydroelectric projects which would require impoundment of water. There has been no recent activity on these proposals There is work being done to develop a small dam and pond at the Spalding Mill recreation site.

Miscellaneous Improvements

As more commercial firms expand their area of activities, there will be additional needs for electronic sites. Improvement and extension of existing power and telephone lines can be expected. These types of miscellaneous improvements were not identified as a concern during the public involvement process Future special-use emphasis areas may include permits associated with coal mining and hydroelectric power generation

ABILITY TO SATISFY DEMAND

Roads

Roads are built to satisfy a demand Over time, the initial reason for a road may fade or road usage may change. Historically, mining and timber harvest activities have initiated construction of the major portion of the road system Many of these roads have acquired other purposes since construction

Within the limits of environmental and financial constraints, roads could be built almost anywhere The objective, however, is to ensure that the total transportation system best serves the identified resources at the lowest cost with the least impact to the environment

For planning purposes, potential new constructed road density varies by Planning Basin The new construction road ratio ranged from 1 5 to 2 5 miles per square mile in areas with existing roads, and from 2 9 to 5 1 miles per square mile in areas that are presently unroaded. Future roading density in areas currently having no roads will be lower than those areas where road development has been ongoing The existing road density does not represent the total needs for a developed system. Included in these factors are the minor mileages projected to satisfy the access needs for recreation, mining, and other activities.

In the benchmark analysis, 1,596 miles of new construction was the highest mileage indicated as being needed to complete the road system. New construction would be mostly local roads There is a potential for the construction of 44 miles of collector roads, 43 miles of existing local roads may be reclassified to collector status. Some collector and local roads may be upgraded to arterial status to meet future management objectives

The user or benefiting resource program (e.g , recreation, timber, and fire) pays for the construction and maintenance of the road. Funding sources include purchaser road credits, capital investment program, Oregon and California Railroad, Forest Highway, and other miscellaneous sources

Public and commercial use of roads is controlled through road management plans which are flexible to accommodate changes in use, to assure safety of users, and to meet legal obligations

Access to motorized, developed, and dispersed recreation areas is provided over the Forest road system. Roads constructed for other purposes are generally available for recreation access. However, the current trend is to close many newly constructed roads to reduce maintenance costs and complement other resource values

Trails

Trails can be constructed almost anyplace in response to demands Trail system capital investments are based on the Forest Trail Plan New trails (130 miles of new trails, 95 miles being within Wilderness) have the potential to satisfy some of the user demands Use of volunteers or groups to accomplish trail work has and will continue to be fostered Proposals for through-Forest trails would require some construction to make a continuous trail system

Developed Recreation Sites

Potential recreational development projects have been identified and can be variously incorporated in land management alternatives to support increased recreational demand (see Table II-4) These projects include an information center, picnic sites, campgrounds, boat launch sites, and vista points Some of the projects would upgrade existing facilities

Administrative Sites

A Facilities Master Plan for administrative sites will be prepared as part of the implementation of the Forest Plan. It will guide overall management of each administrative site used in management of the Forest. The plan will coordinate individual sites and facilities to provide support for management objectives in a cost-effective manner. The completed Facilities Master Plan may identify additional projects for the Capital Investment Program.

Utility and Transportation Corridors

Uses in these corridors are approved through issuance of special use permits or through grants of right-of-way. It should be recognized that few additional uses might occur in these corridors Corridors are considered a part of the Management Areas they traverse

The existing Happy Camp and O'Brien electrical power transmission corridors will be designated as Utility Corridors in the Forest Plan Provisions for adding new electrical power transmission corridors are covered in the Standards and Guidelines.

The Buzzards Roost power site proposal was dropped when the State of Oregon included the Illinois River as a part of the Oregon Wild and Scenic River System The dam site and reservoir would have been located within the Wild section of both the State and National Wild and Scenic River systems Section 7 of the National Wild and Scenic Rivers Act prohibits the Federal Power Commission from licensing water-related projects on Wild and Scenic Rivers. Therefore, this utility corridor is no longer a viable option

The possible extension of this Buzzards Roost utility route to Agness and Gold Beach needs to be delineated before any judgment beyond "it looks possible" can be made For the Forest Service to identify a specific corridor between Grants Pass and Gold Beach is purely speculative as to need and adequacy of location It is the intent of Forest Plans to eliminate or lessen the need to consider routing alternatives by proponents However, the selection of a corridor is based on the assumption that "...the project proponent agrees to locate within a designated corridor." Future actual locations of potential transmission systems may be different due to changes in technologies and the level of service envisioned Therefore, this undefined corridor has not been evaluated or given more indepth consideration in this planning period

The alternative corridors proposed by Coos-Curry Electric Cooperative in the western section of the Forest will need additional environmental review

Those sections of US Highway 199 within the National Forest boundaries will be designated as Transportation Corridors in the Forest Plan The Hays Hill section of this route (which also carries a power transmission line) will be a joint-use corridor The Happy Camp Road will be identified as a potential transportation corridor within the National Forest boundary.

Miscellaneous Improvements

Structural improvements for fish and wildlife have varying lengths of useful life. They will need replacement more often than other types of improvements. The average life of wildlife structures is 10 years; for fish structures, 20 years.

In general, existing right-of-ways for roads and special use permits for utility lines on the Forest pose few problems Utility lines to private property within the Forest have the potential of creating problems if the private land is highly developed. The problem can be solved by combining the lines and controlling location with the special use permit.

WILDERNESS AND ROADLESS AREAS

EXISTING CONDITION

Discussions in this section are pertinent to the resolution of two Planning Problems While not directly related to the old-growth issue, Wilderness and the resolution of roadless areas through allocations arrayed in the alternatives will have an effect on the amount of remaining old growth Planning Problem #2, "How much old-growth forest should be preserved?," bears on this subject. Background information for Planning Problem #8, "How will management direction affect recreation opportunities in the Wilderness and unroaded areas?," is also provided

DESIGNATED WILDERNESS

Kalmiopsis Wilderness

The Kalmiopsis Wilderness is located in the Siskiyou Mountains of southwestern Oregon Established under Secretary of Agriculture Regulation U-2 in 1946, it was originally known as the Kalmiopsis Wild Area (then containing 76,000 acres). The Wilderness Act of 1964 converted the Wild Area to Wilderness The Endangered American Wilderness Act of 1978 then added 102,950 acres to the Wilderness, making its present size 179,850 acres

The area is characterized by deep, rough canyons; sharp, rock ridges, and clear, rushing, mountain streams. Elevations range from 500 to 5,100 feet. The area is geologically unusual and contains plants that are found principally in the Kalmiopsis Wilderness. An endemic shrub, *Kalmiopsis leachiana*, first located near Gold Basin in 1930, gives the Wilderness its name In fact, the initial set-aside was for this plant and other unique botanical features.

The wilderness character of the area is nearly intact, but is compromised in a few isolated locations by the presence of mines and roads accessing them. Topographic and vegetative diversity are abundant. The interior of the Wilderness is completely screened from the influence of management so that opportunities for solitude and self-reliance are readily available. The area is capable of providing a high quality, rugged wilderness experience.

There are 13 trailheads that provide access to 153 miles of trail in the Wilderness Most of the recreation use is concentrated on that system since cross-country travel is extremely difficult, if not impossible, to the average Wilderness user The Illinois River receives a light to moderate amount of use (approximately 1,700 RVD's), and Babyfoot and Vulcan Lakes receive relatively heavy use due to easy access.

Wild Rogue Wilderness

This Wilderness was established by Congress under the Endangered American Wilderness Act of 1978. The Wilderness consists of approximately 26,708 acres that is bisected by the Rogue Wild and Scenic River corridor. Through a cooperative agreement with the Bureau of Land Management, the Forest Service manages the remaining 9,000 acres of this Wilderness that is outside, but contiguous to, the Forest boundary. There are approximately 400 acres of private land ownership within the Wild Rogue Wilderness.

The area is characterized by deep, rough canyons, with rocky ridges and forested slopes Elevations vary from approximately 300 feet above sea level along the Rogue River to more than 4,300 feet at Mt. Bolivar. The landform is characteristically steep (almost half the slopes exceed 70 percent) and provides a tangled geologic puzzle of chaotically-arranged rocks

The character of the Wilderness is compromised somewhat by the degree of human influence (lodges, airstrip, and motor boats) With the exception of the Wild section of the Rogue River, the encompassing Wilderness is one of the least-visited and least-known in the Wilderness system

Grassy Knob Wilderness

Established by the Oregon Wilderness Act of 1984, this area is characterized by deep, steep canyons and heavily forested slopes Elevations range from 200 feet along Dry Creek and Elk River to almost 2,400 feet at Anvil Mountain

Recreational access and passage through the area presents a challenge for even the most avid hiker The Grassy Knob Road, off Highway 101 on the west, provides access onto the ridge separating the Elk River and Dry Creek drainages. From here, visitors can see the Pacific Ocean, but the steep terrain, dense vegetation, lack of water, and lack of suitable campsites or trail access into the Wilderness greatly limit recreation use.

The wilderness character is nearly intact, but is compromised by past private-land logging activities in Section 36 (now in public ownership) and the access road Section 36 is in advancing stages of natural revegetation The access road has not been maintained for years It does, though, provide access for hikers to the interior. Otherwise, cross-country travel is the only means of moving through the area; there are no developed trails.

Red Buttes Wilderness

Located in the Siskiyou Mountains, the Red Buttes Wilderness was established by Congress under the Oregon Wilderness Act of 1984. The 3,414 acre Siskiyou National Forest portion of the Wilderness is contiguous to and part of the much larger Wilderness located on the Rogue River National Forest Management of the area is coordinated through the designated lead Forest, the Rogue River National Forest

The Wilderness is quite scenic, consisting of sharp and steep, glaciated ridge systems. It is considered one of the more scenic areas on the Forest. Elevations vary from approximately 3,600 feet to 6,300 feet. The area is in a natural condition, with only minor alterations resulting from past grazing and mining activities. Red Buttes receives relatively heavy recreation use due primarily to the National Recreation Trail that passes through the area Opportunities for Primitive recreation experiences in the Siskiyou National Forest portion of the Wilderness are precluded by the close proximity of management activities.

Siskiyou Wilderness

Also located in the Siskiyou Mountains, this Wilderness was established under the California Wilderness Act of 1984. The area is part of the much larger Wilderness located on the adjacent Six Rivers and Klamath National Forests. The Klamath is designated as the lead Forest for management of this area

The Siskiyou Wilderness is also considered part of the more scenic portions of the Forest. The area presents a setting in which a high quality, Semi-primitive recreation experience can be obtained Primitive recreation opportunities are not available due to the close proximity of management activities. Recreation use in the area is low There are several old trails that receive only limited maintenance because of low visitor use.

ROADLESS AREAS

The Forest has 18 inventoried roadless areas that total 284,000 acres. Each of these areas has been analyzed for their Wilderness potential Complete disclosure of the area-specific analysis is found in Appendix C - Roadless Areas

In 1984, the inventoried area totalled 314,000 acres. The inventoried portion has been reduced by 30,000 acres due to continuing management activities, older activities, and the decision covering the Silver Fire. The decision covering the salvage timber sales and associated roading of the Silver Fire accounted for

19,000 acres. This reduction was all within the inventoried North Kalmiopsis Roadless Area The project received National coverage and extreme notoriety. For specifics, please refer to the Silver Fire Recovery Project FEIS (1988d).

Some reduction is attributable to two inventoried areas that were partially roaded years earlier but not updated in 1984. The balance of the change comes from timber sale activity between May of 1984 and the end of 1988. This includes sales completed, operating, or under contract. For specifics of inventory updates for each inventoried roadless area, refer to Appendix C.

Five of the roadless areas have demonstrable Wilderness potential. These are Grassy Knob (5,492 acres), North Kalmiopsis (88,812 acres), Siskiyou (3,284 acres), Kangaroo (6,656 acres), and South Kalmiopsis (104,823 acres). These acreages are also the updated 1988 figures. A complete description of each area and an area location map are provided in Appendix C.

Grassy Knob Unroaded Area

This roadless area is divided by the Grassy Knob Wilderness; the western portion is approximately 1,200 acres and the eastern portion 4,300 acres. The two portions are not easily manageable as separate roadless areas, but being contiguous to the Grassy Knob Wilderness provides options that would not otherwise be available. The terrain is extremely steep and rugged, with deeply incised canyons Elevation varies from near sea level to 2,900 feet at Mt. Butler.

The area is capable of providing a Semi-primitive Non-motorized recreation experience. Existing use is very low due to dense vegetation and steep topography; use primarily stems from local communities. There are no trails providing access to the interior of either portion. Being adjacent to the existing Wilderness is this area's strongest Wilderness attribute.

North Kalmiopsis Roadless Area

This large inventoried roadless area is contiguous to the existing Kalmiopsis Wilderness The roadless portion nearly encircles the northern half of the Kalmiopsis Wilderness. Numerous tributaries to the Illinois and Chetco Rivers are heavily wooded with steep slopes and very deep inner gorges. A large percentage of the area is extremely rugged, precipitous, and rocky, particularly in the Silver Creek Falls vicinity. The Wild section of the Illinois River flows through the lower six miles.

The primary attribute of the North Kalmiopsis is its relationship to the Kalmiopsis Wilderness and Wild and Scenic Illinois River. With topography being highly broken and most of the area densely vegetated, the natural screening provides ample opportunity for localized solitude and primitive experience. The overall opportunity is judged as moderate on the fringes not bordered by Wilderness, and high in the interior Silver Creek's lower reach is totally screened from external sights and sounds, and offers ample opportunities for solitude and remoteness.

Both Primitive and Semi-primitive opportunities are available. The area inventoried as Primitive is located within the Silver Creek drainage north of the Kalmiopsis Wilderness It is the only area on the Forest outside of the Kalmiopsis that offers this type of limited opportunity. Recreation of approximately 700 RVD's per year is very low for the area's size.

The majority of the North Kalmiopsis is capable of offering Semi-primitive Non-motorized opportunities. The area identified as Semi-primitive Motorized falls in this category because of current management which allows for the use of motorized bikes on trail systems within the area. If motorized use was restricted, this area would shift to the Non-motorized category.

Of the 96,540 acres involved in the 1987 Silver Fire, over 42,000 acres of the North Kalmiopsis were burned. The intensity of burn varied greatly and has temporarily altered the setting Inventory changes for this area and the other two major wildfires in 1987 are covered under **1987 FIRES** at the end of this Chapter Refer to the Silver Fire Recovery Project FEIS for a detailed discussion of the affected environment

Siskiyou Roadless Area

This roadless area is contiguous to the Siskiyou Wilderness. It offers essentially the same features and opportunities as does the Siskiyou Wilderness described above The roadless area offers the opportunity for localized solitude and Semi-primitive recreation experiences. Recreation use levels are low (estimated at 50 RVD's per year).

The entire area is classified as Roaded Natural due to proximity of management activities. The area can be effectively managed to provide recreation opportunities in an area exhibiting a landscape character that is limited on the rest of the Forest

Kangaroo Roadless Area

The Kangaroo is contiguous to the Red Buttes Wilderness Elevations vary from about 4,000 feet to 7,055 feet at Grayback Mountain The upper elevations offer considerable variety in both vegetation and topography.

Recreation use in the area is light to moderate (estimated at 1,200 RVD's per year). The Boundary National Recreation Trail enters the area from Oregon Caves National Monument and holds the ridgecrest position into the Red Buttes Wilderness. The area is capable of providing Roaded Natural and Semi-primitive Motorized experiences. This area can also be managed to provide recreation opportunities not available elsewhere on the Forest.

South Kalmiopsis Roadless Area

This area consists of four separate segments The area is adjacent to and contiguous with the southern half of the Kalmiopsis Wilderness. Elevations vary between 500 and 5,098 feet at Pearsoll Peak. The widest bodies of the unroaded area adjacent to the Wilderness provide the highest degree of solitude and primitive experience, and consequently exhibit the greatest Wilderness potential. Recreation use in the area is approximately 5,000 RVD's

The eastern portion is strongly influenced by serpentine soils which provide diversity to an otherwise steep, heavily forested, country. The greatest attractions are provided by the adjacent Wilderness and Scenic section of the Wild and Scenic Illinois River. A large number of unique or sensitive plants occur in association with the serpentine rock type. The soils on the northeastern segment are notably different. Developed mostly from metavolcanic rock, they provide a mixed-conifer forest setting

The western segments have broken and steep topography with deep canyons. Vegetation is usually dense. Douglas-fir is the dominant species as a result of moderate to highly productive sedimentary soils. The area is capable of providing Roaded Natural and Semi-primitive Non-motorized recreation opportunities

CURRENT DEMANDS, WANTS, AND DESIRES

Strong interests and vocal concerns have been expressed for keeping the North Kalmiopsis and portions of the South Kalmiopsis roadless areas in a natural state. Particular concern has been focused on that portion of the North Kalmiopsis within the viewshed adjacent to the last six miles of the Wild section of the Illinois River. The focus is on maintenance of the potential wilderness character in these areas rather than the Primitive recreation opportunities currently available.

Likewise, very strong input has been expressed by development- oriented interests. Many parts of these two areas contain highly productive forests. Removing the North and South Kalmiopsis areas from the lands suitable for timber production has been a long, hotly contested issue A more thorough discussion is provided for these two areas in the Status and Public Involvement portions of Appendix C Secondly, mining interests and activities are more prominent in these two large blocks of land than on many other parts of the Forest Potential for significant mineral deposits is moderate to high County governments have relied on this land base as a sustainable resource to aid community socioeconomic stability and income from timber sale receipts. The areas have been in the political forum and legal halls several times.

ABILITY TO SATISFY DEMAND

Of the 284,000 acres of inventoried roadless areas, all or portions of any of the 18 areas could be left in their existing condition in order to preserve their Wilderness potential From the above, five of the Forest's roadless areas have greater potential for Wilderness than the other areas described and evaluated in Appendix C.

Based on projected levels of use and estimated carrying capacities, the Forest has the ability to satisfy the demand for wilderness experiences Demand for Primitive opportunities in the existing Wildernesses will be met until the fifth decade when projected demand would exceed capacity. Semi-primitive opportunities would be met over the course of the planning period

WILD AND SCENIC RIVERS

EXISTING CONDITION

The discussions in this section are pertinent to the resolution of Planning Problem #4, "How, and to what extent, should lands in and adjacent to river corridors be managed to protect, preserve, and enhance Wild and Scenic River attributes?"

Figure III-7 shows the locations of the Wild, Scenic, and Recreation rivers on the Siskiyou National Forest. The Forest is best known for its Wild and Scenic River system, particularly the Rogue River. The Rogue was one of the original rivers designated in the 1968 Wild and Scenic Rivers Act (PL 90-452) With its designation as "Wild and Scenic," the Rogue River gained widespread recognition as a major western white water river, attracting additional users seeking this particular recreation opportunity

The Illinois River was designated as "Wild and Scenic" by Congress in 1984 (PL 98-454). It is not as well known as the Rogue River, but does provide a high quality, technically difficult white water experience in an extremely rugged pristine river canyon, accessible primarily by watercraft The only limitation to an otherwise exceptional condition is flow Good white water rafting and kayaking conditions occur only during a rather narrow window of flows in the spring period, summer low flows make the river essentially non-raftable Forest river managers recognize that the Illinois offers one of the most primitive river experiences remaining in the western United States primarily because of its untouched character and lack of human influences throughout the entire length of the Wild section (Illinois Wild and Scenic River Management Plan, 1985).

The Chetco, North Fork Smith, and Elk Rivers were designated for inclusion in the National System under the Omnibus Oregon Wild and Scenic River Act of 1988 (passed in October) These previously inventoried and eligible rivers are treated differently by each alternative The very recent action by Congress has changed the emphasis on Planning Problem #4 (see Chapter I). In the DEIS, the three rivers were given a range of management options in order to analyze environmental impacts and tradeoffs associated with the alternatives. Any alternative would be brought into conformance with the Act prior to implementation.

Management plans for the three newly designated rivers will be prepared. Any management activity in the interim would be planned to meet the objectives for maintenance of the Wild and Scenic River characteristics and values for which they were established.

The five designated National Wild and Scenic Rivers provide users with opportunities ranging from an extremely primitive experience offering few interactions with other people, to recreation experiences in a relatively natural Forest setting where the frequency of human contact is common.

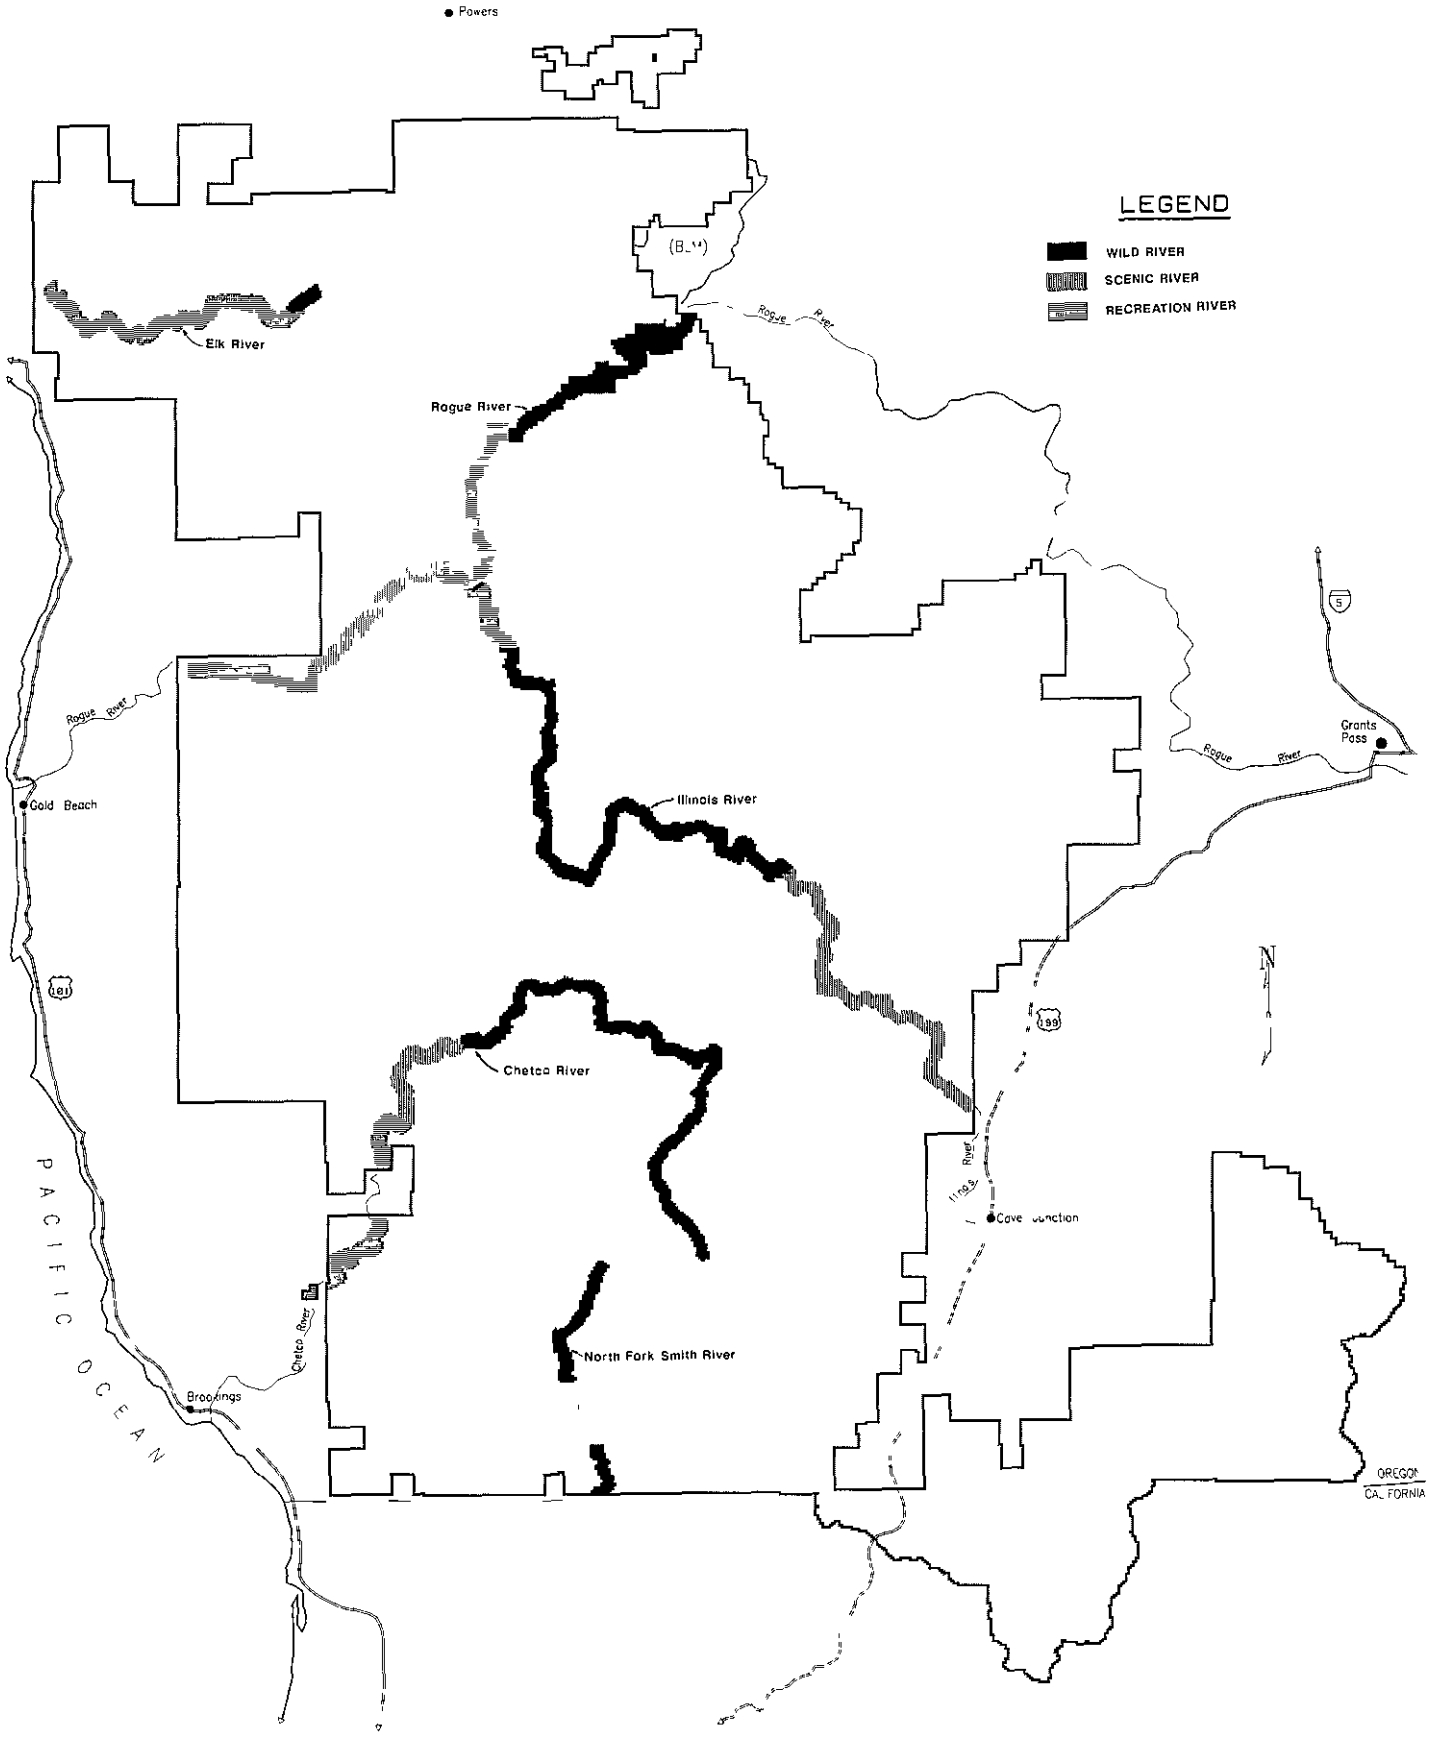

Figure III-7. Wild/Scenic/Recreation Rivers Map

Rogue River

The Forest Service has the responsibility for administering 37 miles (11,731 acres) of the Rogue River which are located within the Forest boundary, including sections designated as Wild, Scenic, and Recreation The highest values associated with the Rogue River are its potential for high-quality white water recreation opportunities, excellent fisheries, free-flowing condition, and the natural or near-natural character of the landscape throughout much of the river corridor

The Wild section of the River is encompassed by the Wild Rogue Wilderness; as such, the river corridor will remain in a natural condition over the course of the planning period. The landscape character varies from steep, nearly vertical canyon walls offering vivid focal points to a more open and extended river canyon with a variety of vegetative patterns. There are human influences within the lower section such as lodges, an air strip, and jet boats up to Blossom Bar These types of influences tend to detract from a truly wild river experience and affect the type of recreation opportunities available. This section will provide recreation users with a Semi-primitive experience influenced by motorized use on the river.

The Recreation and Scenic sections of the River extend from Watson Creek to near the bridge at Lobster Creek These river sections pass through a viewshed that encompasses approximately 70,000 acres of National Forest land There are obvious human intrusions which include roads, bridges at three locations, various lodges and recreation residences, campgrounds, boat launch facilities, the townsite of Agness, and timber-related road construction and harvest units both on public and private land Harvest activities have been tempered in order to maintain a near-natural condition in the landscape character More recent activities are noticeable on private land, but are mostly visible in the background

The river corridor offers open extended views to adjacent lands on both sides of the river between Watson Creek and Agness From there, the River runs through Copper Canyon where the character changes into a steep, rather narrow, scenic river canyon where human influences are least noticeable. Near Skookumhouse Butte, the character of the river changes again (within the Recreation section) to an open river corridor with extended views to either side. The viewshed is, with the exception of a few sites, in a natural or near-natural condition that provides a recreation setting that is compatible with the wide range of Roaded Natural and Semi-primitive Motorized recreation opportunities

Illinois River

The Forest Service has the responsibility to manage the entire 50.4 mile designated portion of the river (15,200 acres). The highest values associated with the Illinois River are its scenic, recreational, botanical, water quality, fisheries, and wilderness characteristics in the Wild section.

The Wild section of the River extends from Briggs Creek just outside of the Kalmiopsis Wilderness to Nancy Creek near the river's confluence with the Rogue River The last six miles of this section are located outside the Kalmiopsis Wilderness. Virtually the entire section is free of human influence Minimal impacts from historic uses exist in the vicinity of Pine Flat, but from there until Nancy Creek the river corridor and adjacent viewshed are free of human intrusions to the natural landscape

The River provides unity to the scenic experience, yet it is composed of an unlimited variety of elements. The variety stems from the water itself and is enhanced by the diverse geology and rugged mountain backdrops. The landform of the surrounding area approaches vertical, which conveys both a feeling of excitement and demands a sense of awe. The vegetative cover along the River is extremely diverse. The textural pattern, spring or fall color, plant form, and the wide variety of stem and leaf details add to the visual qualities The makeup and combination of the unlimited elements create the outstanding scenic values.

This value is further enhanced by the fact that nearly 28 miles of the River are virtually untouched by civilization (USDA 1978) Because of this, the River corridor provides a recreation setting that is compatible with some of the wildest and most primitive recreation opportunities available in the western United States

The Scenic section of the River extends from the Forest boundary to Briggs Creek The corridor and adjacent viewshed are in a natural or near-natural condition throughout this section. Some human influences in the form of roads, bridges, campgrounds, private residences, and harvest activities are apparent, but tend not to detract from the character of the landscape This section of the river corridor provides a recreation setting that is compatible with the Roaded Natural, and Semi-primitive (Motorized and Non-Motorized) recreation opportunities.

The Recreation section of the River extends from Nancy Creek to the confluence with the Rogue River Roads, a few residences, campgrounds, and timber harvest are apparent to river users, but are at a level that does not detract from the near-natural character of this portion of the river corridor This section will provide a recreation setting that is compatible with the Roaded Natural recreation opportunities available.

North Fork Smith River

The entire 4,325 acres in the Wild and Scenic corridor of the North Fork Smith River are National Forest System land The Oregon portion of this Wild and Scenic River extends from the border of California approximately 13 miles to the headwaters in the Kalmiopsis Wilderness. The entire California portion of the North Fork is currently designated as Wild and Scenic

The classification of the North Fork divides the river into three segments. The upper 6.5-mile section from the headwaters of the North Fork to Horse Creek and the two-mile section from Baldface Creek to the California border is classified as "Wild." Between the Wild sections is a four-mile section classified as "Scenic "

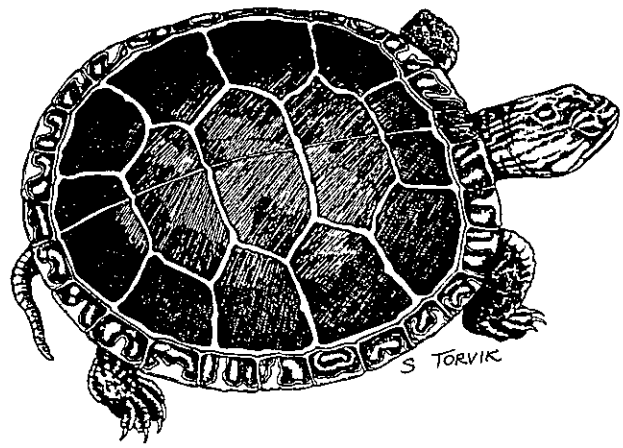
In response to public comment on the DEIS, the Interdisciplinary Team reassessed the classification from Horse Creek to a point approximately two miles downstream and concluded that it does meet the criteria for "Wild" classification. This two-mile adjustment was not made in the Omnibus Oregon Wild and Scenic Rivers Act of 1988, but is carried by the Forest as an inventoried Wild segment.

The first 4.5 miles of the Wild section from the headwaters downstream is encompassed by the Kalmiopsis Wilderness. This segment and the four-mile segment outside of the Wilderness are essentially free of human influences within the river corridor. Human intrusions to the adjacent viewsheds are virtually non-existent so that the area's recreation setting provides Primitive and Semi-primitive recreation opportunities

The four-mile Scenic section from Horse Creek to Baldface Creek is bordered on the westside by land suitable for timber harvest Some roads and limited harvest activities exist, however the area is in a natural/near-natural condition and provides a recreation setting compatible with Roaded Natural recreation opportunities The North Fork provides the boundary of the Kalmiopsis Wilderness, on the eastside, the corridor and viewshed are within Wilderness.

The two-mile section between Baldface Creek and the stateline is largely within lands unsuitable for the production of timber. Some mineral exploration activity has occurred upslope, but activities within the corridor and adjacent viewshed are quite limited This section exhibits a natural landscape compatible with the Semi-primitive recreation opportunities

Chetco River



Approximately 44 miles of the Chetco River was designated in the Omnibus Oregon Wild and Scenic River Act of 1988. The corridor includes 14,357 acres of National Forest land, and additional parcels of private land at the mouth of Mislatnah Creek (Tolman Ranch) and approximately three miles in the lower reach of the River River sections have been classified as Recreation between the Forest boundary and Steel Bridge (11 miles), Scenic from the Steel Bridge to Boulder Creek (8 miles), and Wild from Boulder Creek to its source in the Kalmiopsis Wilderness (25.5 miles)

In response to public comments on the DEIS, an Interdisciplinary Team reassessed a two-mile section of the Chetco between Boulder Creek and Mislatnah Creek and found that it meets criteria for "Wild" classification. This two-mile adjustment was not made in the Omnibus Oregon Wild and Scenic River Act of 1988, but has been carried by the Forest as an inventoried Wild segment.

Virtually the entire length of the Wild section except for the lower two miles is encompassed by the Kalmiopsis Wilderness. The river corridor and the adjacent viewshed is in a natural condition along its entire length. Both the primitive character of the River and the recreation opportunities available are compromised somewhat by the presence of a mining road in the vicinity of Taggarts Bar and Slide Creek. The road is the only noticeable intrusion to the natural character of the River and the adjacent Wilderness viewshed. Topographic and vegetative diversity is abundant, providing a scenic backdrop enhanced by the presence of the river The recreation setting is compatible with the Primitive and Semi-primitive recreation opportunities available

The Scenic section of the corridor is in a natural or near-natural condition in both the river corridor and adjacent viewshed. There are intrusions to the natural character of the landscape in the form of roads, a residence, and some harvest and hardwood conversion activities The recreation setting is compatible with the Semi-primitive and Roaded Natural recreation opportunities

The inventoried Recreation section of the River is in a near-natural/modified condition along its entire length The River does exhibit a natural character in the immediate foreground, however, intrusions to the landscape by roads, campgrounds, bridges, and harvest activities, are obvious to river users The heavily modified character of much of the adjacent viewshed can be attributed, in part, to the extent of harvest activities on private land Within these visually impacted areas, it is doubtful that recreationists would have a meaningful experience Overall, the corridor and adjacent viewsheds provide a recreation setting compatible with Roaded Natural/Modified opportunities.

DETERMINATION OF ELIGIBILITY

A number of other rivers were analyzed in July 1988 for possible eligibility to the National Wild and Scenic River System. These included the Winchuck, Pistol, South Fork Chetco, Elk, South Fork Coquille, and the South Fork Sixes Rivers. Only the Elk River was found to qualify as eligible for possible inclusion

The eligibility of a river for inclusion in the National System is determined by applying the criteria cited in Section 1(b) and 2(b) of the Wild and Scenic Rivers Act as interpreted by the USDA-USDI Guidelines. To be eligible for inclusion, a river must be free-flowing or restored to a free-flowing condition and possess one or more "outstandingly remarkable" values For a river to be eligible for designation to the National System, one or more of the following values within the river area must be outstandingly remarkable.

1 Scenic,
2 Recreational,
3. Geological,
4. Fish and Wildlife,
5 Historical,
6 Cultural, and
7 Other values, including ecological values.

Studies of rivers other than those mandated by Congress may be discontinued upon a finding of ineligibility in the Forest Planning Process or a subsequent Wild and Scenic River study. It was determined by the 1988 evaluation that these rivers, except for the Elk River, do not have any outstandingly remarkable characteristics and are not eligible for inclusion in the National System Documentation is on file in the Planning Record.

Elk River

The eligibility assessment conducted in July 1988 found 19 miles of the Elk River meets the criteria due primarily to its high quality anadromous fisheries Within months of this assessment, the Elk was included in the Congressional designation of Oregon rivers under the Omnibus Oregon Wild and Scenic Rivers Act. Designation affects 5,405 acres of National Forest land Some private land occurs in the lower reach of the Elk River.

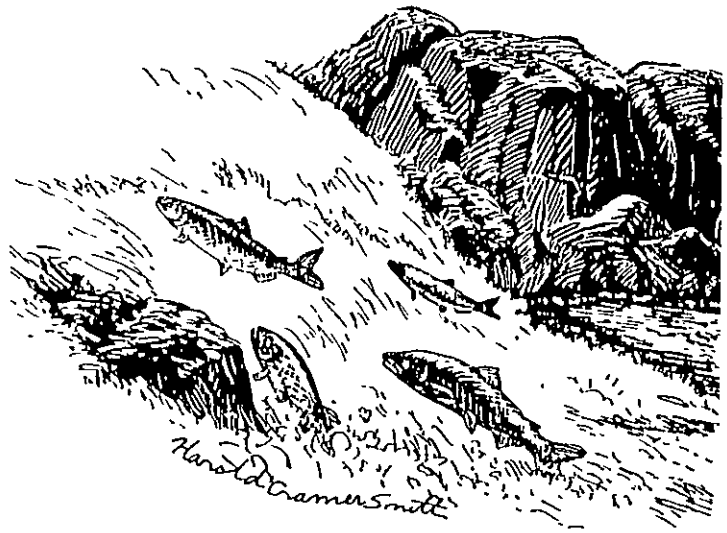
Two sections of the River have been classified The main stem of Elk River is classed as Recreation from Anvil Creek near the Forest boundary to the confluence of the North and South Forks (17 miles). The Wilderness borders the river for 9 5 miles Approximately 1,550 acres on the north side of the Elk River corridor are within the Grassy Knob Wilderness The North Fork is classified as Wild for approximately 2 miles (to a fish blockage).

The river corridor and adjacent viewshed are in a natural or near-natural condition along their entire lengths. The Elk River road and tributary roads in the corridor provide the most noticeable human intrusion to the natural character of the river and adjacent viewshed. Topographic and vegetative diversity abundant throughout the entire corridor provides a dramatic scenic backdrop that is enhanced by the presence of the river. The steep narrow canyon and the fast-flowing crystal clear water combine to provide a natural or near-natural Forest setting compatible with Roaded Natural and Semi-primitive recreation opportunities available in the area

CURRENT DEMANDS, WANTS, AND DESIRES

Due to the consistent and growing interest in river-related recreation activities, particularly white water rafting, it is reasonable to assume that there will always be a demand for the recreation opportunities associated with Wild and Scenic Rivers.

Demand, too, exists for mineral and timber resources occupying the river corridors and viewsheds Much of the area is tentatively suitable for the production of timber, many feel that harvesting within the visual guidelines is quite compatible with recreational uses, and that opportunities for multiple use should not be foregone. A similar concern was expressed about changes in State water quality standards as they apply to the antidegradation policy, the change occurs upon Wild and Scenic River designation. Timber management in tributary drainages some distance from the rivers can be indirectly affected by the potential for constraints being applied to this resource.



There has been concern expressed for the degree of protection provided for the visual resources within the viewsheds adjacent to the Rogue and the Illinois Rivers, and to a limited extent on the Chetco, North Fork Smith, and Elk Rivers. Particular concern has been expressed for the maintenance of the viewshed adjacent to the last six miles of the Wild section of the Illinois River (between Silver Creek and Nancy Creek) in an undisturbed condition

ABILITY TO SATISFY DEMAND

The Forest has the ability to satisfy the demand for recreation opportunities associated with Wild and Scenic Rivers Recreation use on these rivers is within the estimated capacities so that demand can be satisfied over the course of the planning period.

The current inventory of Visual Quality Objectives reflects the amount of recreation use that is occurring within river corridors, and is designed to maintain the corridors and the adjacent viewsheds in a natural or near-natural condition. The ability to reduce or increase the degree of visual resource protection in all of the river corridors exists.

The visual resource management for these river viewsheds is an important aspect in the maintenance of a quality experience associated with the five Wild and Scenic Rivers. While the degree of visual protection in the viewsheds outside the river corridor is not directly tied to Wild and Scenic River status, it certainly has a bearing on retaining complementary visual objectives.

SOIL AND WATER

The discussions in this section, when combined with those in the **FISH** section, are pertinent to resolution of Planning Problem #3, "How can the Forest's fish habitat, water quality, and soil productivity be maintained or improved?"

EXISTING CONDITION

Water that originates on the Forest is of high quality A general description of the soil and water resource on the Forest and of each Planning Basin is provided Additionally, features of each basin are described in the accompanying tables and figures.

An excellent description of the water resources conditions within the entire Rogue River basin is contained in the Oregon Water Resources Department study (OWRD 1985). The report describes the geology, soil, water, reservoirs and potential sites, and beneficial uses of water in the Rogue River basin. The present and future demand for water in the basin is also provided. The South Coast Basin Report (SWRB 1963) presents a similar, but briefer description of the water and related resources of the South Coast Drainage Basin.

SOIL

Soil is a fundamental, largely nonrenewable, resource which must be conserved to assure high-level sustained yields of water, recreational opportunities, and wildlife and fisheries habitat All renewable resources of the Forest are dependent on a viable and healthy soil resource. Soil conditions and plant growth of the Forest are exceptionally complex and diverse, due in large part to the variability of parent material. Rock weathering and soil formation rates are largely influenced by the combination of mild and moist winters, hot and dry summers, steep mountainous topography, and range of plant associations.

The Forest Soil Resource Inventory (SRI), in which soils of the Forest are mapped and analyzed, was completed in 1979 (USDA 1979c). The SRI provides descriptions and interpretations for 85 landtypes of which soil is the primary component Landtype interpretations are designed for planning and managing the transportation system, as well as the timber, recreation and wildlife programs The SRI is most complementary to broad planning levels; it was not designed for site specific project level use

The Forest has 22,206 acres classified as unsuitable for timber management due to the potential for irreversible soil damage by mass wasting and erosion Another 153,362 acres have been classified unsuitable for timber management due to low potential for regeneration following timber harvest. These lands are usually associated with thin soils over rock, a chemical imbalance in the soil, rock outcrops, or rock talus slopes Lands of varying soil productivity comprise the remaining 624,240 acres of forest land tentatively suitable for timber production

The variable nature of Forest soils can be linked to geologic history and to topography, as well as to local soil properties. Some soils lack the cohesion provided by clays or plastic silts and are prone to surface erosion and ravelling. Cohesive soils high in silt and clay are prone to mass wasting. Other soils throughout the Forest are very thin, with high rock content Surface litter and duff layers, important for soil protection, water storage, and nutrient cycling, are often thin or absent

WATER

Water originating on the Forest's watersheds is the life source for many beneficial uses, such as fish habitat and other aquatic life, wildlife habitat, and riparian vegetation. Water is also the focus of on- and off-Forest recreation and domestic uses, such as boating, camping, fishing, and irrigation.

Precipitation and Streamflow

As a result of heavy precipitation in the winter and spring, the Forest annually yields about 8.2 million acre-feet of water that is unevenly distributed throughout the year As much as 70 to 80 percent of the total annual water yield runs off during the winter period (December - March). The summer months often experience seasonal drought.

Streamflow on the Forest responds rapidly to changes in precipitation due to high runoff efficiencies in most watersheds Intense winter storms saturate the soil and produce high streamflow, causing both surface and channel erosion. These periods of high soil moisture also increase soil instability on the mountain slopes and within the inner gorges of many streams.

Nearly 50 percent of the Rogue River's streamflow reaching the Pacific Ocean originates from the Siskiyou National Forest. The Illinois River, a major tributary of the Rogue River, receives 90 percent of its flow from the Forest. While the greatest percentage of the Forest drains into the Rogue River basin, the remainder feeds directly into the Pacific Ocean via smaller coastal streams and rivers

Summer flows on the west side of the Forest are adequate for the maintenance of fish and wildlife resources. Summer flows on the east side are seriously depleted on many streams by irrigation and domestic use withdrawals. To highlight this problem, summer withdrawals, combined with naturally low summer flows, result in a severe rating for water temperatures in the Illinois River and segments of the East and West Forks (ODEQ In Press). The severe rating indicates that there is a substantial or near complete interference with the beneficial use Summer anadromous fish habitat in the Wild and Scenic Illinois River is seriously impacted by the elevated temperatures. A substantial adverse effect on the survival of juvenile and adult salmonids exists. Most of the diversions and consumptive uses for the irrigated lands occur outside the National Forest boundary.

Minimum stream flows have been established for selected streams and rivers in both the South Coast and Rogue River basins to support aquatic life and minimize pollution (OWRD 1984a and 1984b) However, in these basins where summer flows are already critically low, water quality and associated beneficial uses on specific reaches of Forest streams are expected to further degrade due to increasing upstream demand for domestic water.

Groundwater

Except for large alluvial valleys like the Illinois, groundwater resources in the Rogue River basin are generally limited (OWRD 1985) Groundwater quality in the Forest portion of both the Rogue and South Coast basins is good. Aside from providing drinking water at developed recreation sites, there are no significant uses of Forest groundwater resources

Stream Classification and Beneficial Uses

Forest streams are classified according to their beneficial uses. Class I and II streams are either domestic water supplies or important fisheries Class III streams are generally smaller, perennial non-fish-bearing streams Class IV streams flow intermittently. Both Class III and IV streams are managed to protect downstream values in the Class I and II streams and rivers. For more information about this classification system and management of the riparian ecosystem, refer to the Siskiyou National Forest policy contained in FSM 2526 (Supplement No. 1), and Best Management Practices (Appendix G, Forest Plan) as applied to the riparian area through the Standards and Guidelines.

There are approximately 175,500 acres of riparian areas on the Forest Of these, about 99,000 are tentatively suitable for timber production

Water Quality

Protection of water quality is required by the Organic Administration Act which created the National Forests, the Clean Water Act, and the National Forest Management Act (NFMA) The Clean Water Act gives States authority to enforce water quality standards on Federal land. NFMA states that National Forest lands will be managed "to prevent detrimental changes in water flow and water quality "

Implementation of the State of Oregon and State of California Water Quality Management Plans on lands administered by the Forest Service is described in the following memoranda of understanding:

> **Memorandum of Understanding.** The Oregon Department of Environmental Quality and U S. Department of Agriculture, Forest Service (2/79), including Attachment A - Implementation Plan for Water Quality Planning on National Forest lands in the Pacific Northwest (12/78)
>
> **Memorandum of Understanding:** The State Water Resources Control Board, State of California, and U S Department of Agriculture Forest Service, Pacific Southwest Region, 1981

The agreements provide for annual meetings between the Regional Forester and the respective state agencies (Oregon Department of Environmental Quality and the California Water Resources Control Board) to evaluate the program and progress being made.

The quality of water flowing into the Forest from the middle Rogue River (above river mile 65) is good, and the quality of the lower Rogue River (below river mile 65) is very good The quality of water in the Illinois River basin is generally good (OWRD 1985) Despite the fact that good water quality exists within the Forest, above-optimum stream water temperatures in the summer (due to low summer flows, water withdrawals, and lack of streamside vegetation) and high turbidity (natural and human induced) during the major winter storms are primary water quality concerns

In 1978 the DEQ completed the first statewide assessment of nonpoint source pollution The report and accompanying maps provide an overview of existing water quality conditions both on- and off-Forest Generally, the worst conditions for elevated water temperatures and sedimentation on the Forest do not exceed "moderate" severity (ODEQ 1978) In response to requirements in Section 319 of the Clean Water Act (1987 Amendments), the DEQ updated the assessment. A final report is due in 1989

Current sediment production for the Forest is estimated to be about 623,000 tons per year. This value is an index of current sediment production; it includes natural erosion and human-induced erosion from existing road systems On the average, this background value is equal to about one-half ton per year (or one-half cubic yard) for each acre of the Forest.

Stream power, i.e., the ability of water to move material, is a function of channel gradient and streamflow Stream power is great enough over most of the Forest to transport sediment through the river systems Only in cases of extreme amounts of material delivered into smaller streams over a short period will stream power be insufficient to recut and transport sediment out of the system The principles of sedimentation, e g , aggradation or degradation, in forest and mountain aquatic systems apply similarly to the Siskiyou National Forest The balance of inputs with outputs is key to maintaining a healthy and properly functioning ecosystem There are, however, significant differences in natural and altered conditions, and in the responses and outputs of each. One of the more notable variables is the change in channel morphology and resource values associated with low and higher stream gradients Likewise, major differences in channel characteristics are associated with various parent rock and landforms

Existing soil and geology monitoring on the Forest includes landslide inventories, landslide movement, soil compaction, soil erodibility, soil productivity, effective ground cover, and mycorrhiza Water quality-related monitoring includes water temperature and streamside canopy shade, turbidity, chemical (e g , herbicide

and fertilizer), drinking water, stream flow, and Best Management Practices (BMP) implementation and effectiveness monitoring Considerable surveillance has also occurred through formal and informal field reviews of project activities. Soil, geology, and water monitoring for the Silver Fire Recovery Project is described in the Project FEIS (USDA 1988d).

Watershed Improvement

The Forest maintains a Watershed Improvement Needs (WIN) inventory Examples of restoration projects to improve watershed condition on the Forest are road and landing sidecast pullback, surface erosion control, and channel stabilization. Potential projects are annually prioritized.

BASIN DESCRIPTIONS

The Forest is divided into 19 Planning Basins (Figure III-8) to provide greater site specificity in the analysis of effects for various resources. Planning basin size ranges from 34,566 to 93,802 acres Appendix B includes a description of the basins and rationale for their use in the model. Soil, water, and fisheries resource discussions in this chapter use inventories within Planning Basins to describe the affected environment.

For reader clarification, references to Planning Basins indicate a total of 19, but are numbered to 20 Basin 18 was deleted; the basin area was distributed between adjoining Basins 15 and 19.

Another clarification relates to **Basin 14 - Upper Chetco.** This basin is treated separately in the inventory and analysis from other Planning Basins in that the entire area is within the Kalmiopsis Wilderness.

Tables and figures that describe some soil and water features of each Planning Basin are briefly described below.

Municipal Supply Watersheds. Table III-9 lists the municipal supply watersheds on the Forest.

Descriptive Indices by Planning Basin. Table III-10 contains descriptive indices for each basin, ranging from total basin acreage to the percentage of National Forest System land in each Planning Basin harvested from 1950 to 1970, and from 1970 to 1980.

Beneficial Uses of Water by Planning Basin. Table III-11 lists the beneficial uses of water in each Planning Basin, and categorizes them as either major, moderate, or minor.

Beneficial Uses and Water Quality Condition Relationship With Existing Beneficial Uses. Table III-12 summarizes the baseline water quality condition relationship with the existing beneficial uses. Table III-21 in the **FISH** section presents a summary of baseline habitat conditions for the fish production.

Soil Erosion Hazard Figures III-9 and III-10 show the percentage of tentatively suitable land in each Planning Basin with high potential soil erosion hazard (surface and mass movement) for timber management (including harvest and regeneration activities) and roads. The bar graphs provide a means of comparing the sensitivity of each Planning Basin with respect to timber management and road construction The graph indicates where special care must be taken when planning for such activities.

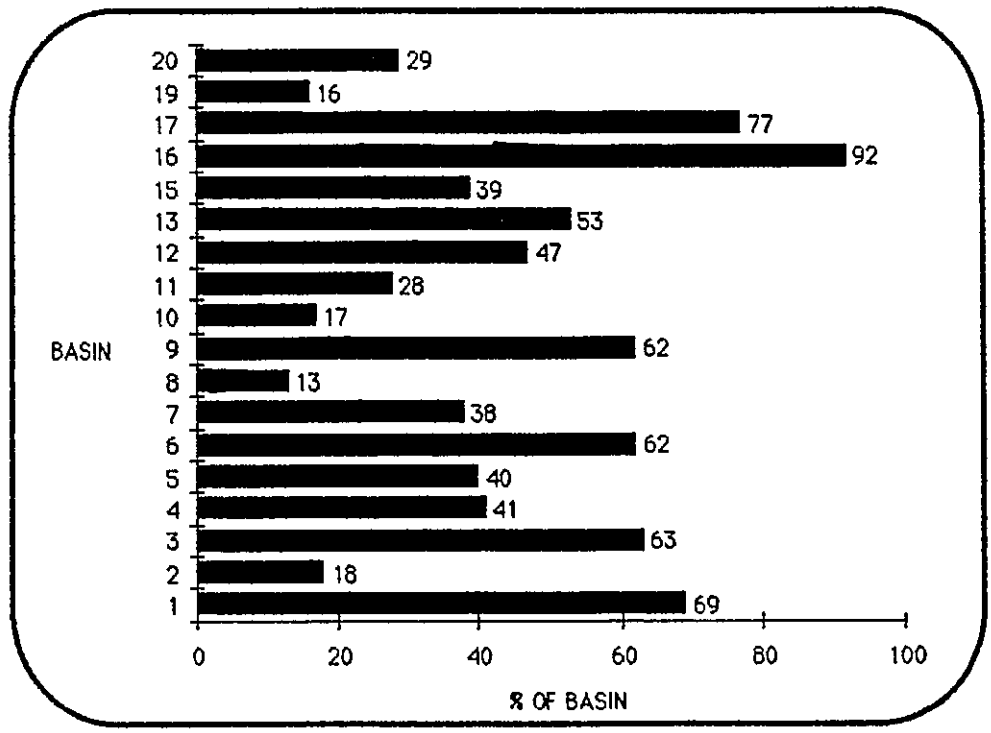

Figure III-10 Percentage of Tentatively Suitable Lands Within Each Basin With a High Potential Erosion Hazard for Road Construction

CURRENT DEMANDS, WANTS, AND DESIRES

SOIL

To meet the sustained demand for renewable resources and clean water from the Forest, adequate soil cover, stability, porosity, and soil productivity must be maintained Severity of impacts on soil resources depends upon the properties of individual soil types, and the type and intensity of management actions. Owing to their importance in maintenance of long-term productivity, protection of litter and duff layers cannot be overemphasized in planning and implementation of all activities

In areas where site conditions indicate a potential for mass wasting, proper selection and skillful applications of management activities must occur. Activities which compact soils and reduce porosity must be avoided Similarly, activities that degrade site quality and long-term productivity must also be avoided.

The intensity of management activity, rather than the type of activity, often determines the degree of adverse soil impact. Thus, activities that drastically alter soil properties and processes should be avoided By dispersing watershed disturbances over time and space, off-site watershed impacts are reduced Forest-wide Standards and Guidelines limit specific soil disturbances and impacts so that many resource demands can be met

WATER

In order to maintain beneficial water uses and comply with Oregon and California requirements for water protection in accordance with the Clean Water Act, the Forest requires that Best Management Practices (BMP's) be implemented for management activities. For more information on the relationship between State requirements, beneficial uses, and BMP's, see Chapter IV, **SOIL AND WATER** Beneficial uses by Planning Basin are shown in Table III-11

The quality of water leaving the Forest is important to the welfare of downstream individuals and communities. Several municipalities withdraw water downstream from the Forest boundary. Although there are no formally designated municipal watersheds, individual landowners and communities (Table III-9) depend on the water that originates on the Forest. Also, there are over 1,075 water rights filed on or downstream from the Forest.

The time of greatest water yield is generally mismatched with demands, especially those of irrigation and fisheries The naturally low summer stream flows are directly affected by dewatering for agricultural and domestic purposes, seriously depleting flows critical to instream fish habitat needs

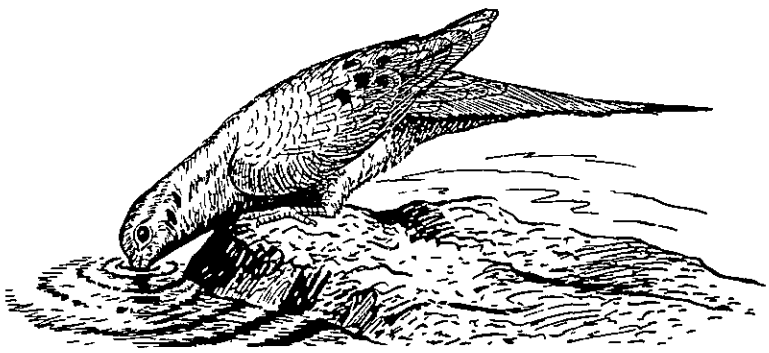
Timing and rate of runoff are other considerations. The rate of runoff, in terms of high flows, can be extreme Floods areas are a frequent and costly problem on the Forest. The cost of road damage prevention work and flood repairs is exceptionally high Greater maintenance work and road reconstruction to effectively handle areas where water drainage is concentrated would be beneficial to both the transportation system and the resources

The goal for water management is to meet or exceed State and Federal water quality standards, and to maintain the existing water yield while preventing unacceptable environmental impacts to both on- and off-site values and uses

ABILITY TO SATISFY DEMAND

SOIL

The ability of each soil type to respond to future demands depends on the inherent characteristics of the soil and the way it is managed. Practices which minimize soil erosion, nutrient loss, duff reduction, and compaction will help maintain soil productivity.



WATER

The Forest will continue to maintain present levels of water yield regardless of Forest management actions Low summer flows will continue to be fully utilized for fish, recreation, irrigation, and domestic use. The demand for water rights of others on the west and east sides of the Forest is expected to increase. Off-Forest water withdrawal can seriously reduce water quantity and increase water temperatures on selected streams.

Because of natural low flows during the summer growing season and the consumptive uses, water produced on the east side of the Forest is severely limited Both Sucker and Althouse Creeks, as well as their tributaries, have been closed by the State to further appropriation since 1934. New water rights in the rest of the East and West Forks of the Illinois River drainage can only be granted for irrigating less than one half acre of land for domestic and stock watering use, provided that the minimum stream flows established in the State's Rogue River Basin program are maintained.

The total supply of water yielded from the Forest, however, greatly exceeds the demand Purchase of water rights, supplementation of water during low-flow periods by reservoir storage, restrictions on water uses and rights, and changes in consumptive use practices are means to satisfy the demand. Such efforts, though, have to be coordinated Secondly, the effort has to be oriented to improved timing of yield and conservation of the water resource

The ability of the Forest to absorb and respond to increased future demand depends largely on the way watersheds are managed. Resource management activities will not be implemented where there is sufficient reason to believe the soil and water resource or beneficial uses of water will be significantly degraded, and State requirements for protection of waters are not met

FIRE

EXISTING CONDITION

Fire is a complex phenomenon with a natural role in the energy budget of many ecosystems. As human interactions with those ecosystems increase, the dichotomy of fire as a useful tool (prescribed fire) and a natural hazard (wildfire) becomes more intense. At one extreme is the seemingly unavoidable catastrophic wildfire. At the other extreme is the need for fire to play its natural role and for human beings to use it as an effective, economic management tool (Arnold 1972)

The fires that occurred in southwestern Oregon in the summer of 1987 are most noteworthy in context of the following However, for additional discussion and a specific update of the affected environment and changes in Forest conditions, see **1987 FIRES** section at the end of this chapter.

Fire Environment

The fire environment is defined by Countryman (1972) as the conditions, influences, and modifying forces that control fire behavior these include vegetation, weather, and topography The components of the fire regime, i e fire type, intensity, size, and frequency (Heinselman 1981), are dependent upon the fire environment In the Pacific Northwest, a broad range of fire environments and resulting fire regimes are present They range from ecosystems where fires are frequent but of low intensity (surface fires), to those where the frequency is low but intensity is high (crown or stand replacement fires), and some where fire occurrence is not significant (Agee 1981).

Only one factor of the fire environment, vegetation, is within the direct control of land managers It is the key factor in providing fuel for fire, determining conditions of fire hazard, and most immediately and directly affected by fire (Kozlowski and Ahlgren 1974). The other components of the fire environment, weather (climate) and topography, are beyond direct control. Climate and air mass characteristics are highly variable, and little can be done to modify them. Micro-climate, however, is strongly influenced by management activities which alter the vegetative cover. Topography is usually considered static

A key concept related directly to fire environment is that of "risk" and "hazard " These two factors serve as the link between the fire environment and fire regimes, and the fire management program on the Siskiyou National Forest In fire management terminology (USDA 1979b), "risk" and "hazard" are defined as follows: Risk is "the chance of fire starting as determined by the presence and activity of causative agents." The two causative agents present are human activity and lightning. Hazard is "a fuels complex defined by kind, arrangement, volume, condition, and location that forms a special threat of ignition or of suppression difficulty." The hazard presented by fuels on the Forest is the result of resource management activities, previous fire suppression, fire exclusion policies, and natural disturbance events (e g , wind, insect, disease, and wildfire).

The natural fuels on National Forests in Oregon and Washington have been classified by Dell (1980) using Kuchler's Potential Vegetation Types He identified five vegetation types on the Forest, two of which are found only on the Siskiyou National Forest The vegetation on the Forest has been identified in greater detail by Atzet and Wheeler (1984) Eleven plant series with over 90 plant associations have been identified

Three broad fire environments can be used to characterize the Forest Fire Environment A is influenced by coastal fog and tends to be cool and damp relative to the other two fire environments Also, it tends to have more rugged terrain without significant topographic relief when compared to the others. The fuels complex is dominated by the Western Hemlock Series (Atzet and Wheeler 1984) and is characterized by heavy fuel loadings, particularly in the larger diameter classes The fuels are best represented by National Fire Danger Rating System fuel model G (Bradshaw and others 1983, Deeming and others 1977)

Fire Environment B can be characterized as warm and damp. The fog influence in this zone is much less than in A, and the topography is less rugged The fuels complex is dominated by the Tanoak Series This complex is characterized as having a live fuel ladder with only light to moderate amounts of fuels accumulations because of rapid decomposition Some large fuels are associated with the conifer component of this series Fuel models F and G provide the best broad-scale representation of the fuels complex in this zone.

Fire Environment C is warm and dry as it is located in the rain shadow, east of the crest of the coastal mountains. The topography is similar to that of B but with greater topographic relief The fuels complex is dominated by the White Fir and Douglas-fir Series. Large fuels, a good fuel ladder, and an accumulation of fine fuels and surface litter characterize the Douglas-fir Series. The White Fir Series has only limited large fuels, but does have an excellent fuel ladder and some accumulation of fine fuels and surface litter. Fuel models F and G also provide a good representation of the fuels in this particular fire environment.

Relative to fire environments throughout the remainder of the Pacific Northwest Region, the Siskiyou National Forest can be classified from warm and dry, to hot and dry.

Natural Role of Fire

Fire has always been an integral part of the forest environment of North America (Wilson and Dell 1971) It has been recognized as an agent of change in forest ecosystems (Omi and Laven 1982) The degree of change generated by fire is highly dependent on the intensity and duration of the fire, the return frequency, and the extent of the area burned

Fire has interacted with Pacific Northwest forests for thousands of years (Agee 1981) While we are aware of the influence of fire on local forest structure, species composition, species diversity, and nutrient cycling, little is known of the local pre-1800 fire regime and, therefore, of the natural role of fire on the Siskiyou National Forest Atzet and Wheeler (1982) report that detailed fire history studies have been completed in many areas of the Pacific Northwest, but that southwestern Oregon has been virtually ignored. Moreover, the uniqueness of the environment and vegetation in the area precludes extrapolation of results from other areas.

From the mid-1800's through the early 1930's, white settlers had a tremendous influence on the frequency of wildfires During that period, many areas on the Forest under-burned, on the average, every 20 years. This is most noticeable in the white fir and Douglas-fir plant associations. These frequent, low-intensity surface fires eliminated much of the natural fuel accumulations and understory vegetation. The fire prevention and suppression efforts, beginning in the early 1900's, reversed this trend. As a result of fire exclusion, the natural species composition in the local forest ecosystems is changing and the fuels complexes are becoming more flammable. White Fir, for example, is currently replacing Douglas-fir over large areas of the Forest Similarly, fire-dependent species, such as kalmiopsis (*Kalmiopsis leachiana*), are slowly being relegated to subordinate positions in their respective ecosystems And, the area of meadow habitat has decreased by at least one-third in the last four to five decades.

More long-term fire patterns have been tentatively recognized. Catastrophic or stand replacement wildfires seem to occur, on the average, at 200-year intervals in Fire Environment A and parts of B. These extensive, high intensity burns are associated with the natural fuels buildup in old-growth Douglas-fir stands, drought conditions, and "east wind periods" which are characterized by very low humidities and strong winds The conditions leading to the 1987 fires exemplify this Historically, the ignition source was lightning and prehistoric inhabitants, since the early 1800's the influx of settlers has altered the ignition sources.

Fire frequency of 70 to 100 years seems to occur in the southern part of Fire Environment B. Even shorter intervals, 50 years in white fir and 20 years in Douglas-fir, seem apparent in Fire Environment C.

Forest Wildfire History

Southwestern Oregon and the Siskiyou National Forest have a long history of major wildfires (Pyne 1983, Haefner 1975; Cooper 1939, Morris 1934) Long summers, high to extreme fire weather conditions, east wind periods, lightning, steep terrain, heavy fuel loading, and limited ground access were all factors involved in the catastrophic wildfires of the past, and they are all relevant today. Some significant fire seasons on the Forest since its establishment in 1907 include 1917, 1918, and 1987 when 179,000, 152,000, and 112,000 acres, respectively, were consumed by wildfire Other major years include 1910, 1915, 1924, 1929, 1931, and 1932, when 20,000 to 40,000 acres were lost annually to wildfire. In 1938, 50,777 acres burned.

During the 1970's, the Forest experienced 495 fires which burned 2,884 acres. This represented a sharp increase in fire activity over the previous 30 years The trend in burned acres, however, has been downward over the last 50 years. A summary of the fire activity for the 1930 through 1970 decades is presented in Table III-13 A detailed analysis of fire activity from 1970-1979, by fire management analysis zone (see Figure III-11), is presented in Table III-14

Table III-13. Summary of Fire Activity by Decade for the Period 1930 through 1979

Decade	Lightning Fires	Human-Caused Fires	Total Acres Burned
1930	114	623	153,822
1940	179	96	4,893
1950	165	114	5,805
1960	124	153	4,601
1970	140	355	2,884

NOTE: The acres protected by the Forest Service have decreased from 1,539,461 (1936) to 1,105,178 (1979).

Table III-14 Summary of Fire Activity and Acres Burned by Wildfire For the Years 1970 through 1979 by Fire Management Analysis Zone

	Lightning		Human-Caused		Total	
Fire Management Analysis Zone	Fires	Acres	Fires	Acres	Fires	Acres

Total	140	44	355	2,840	495	2,884

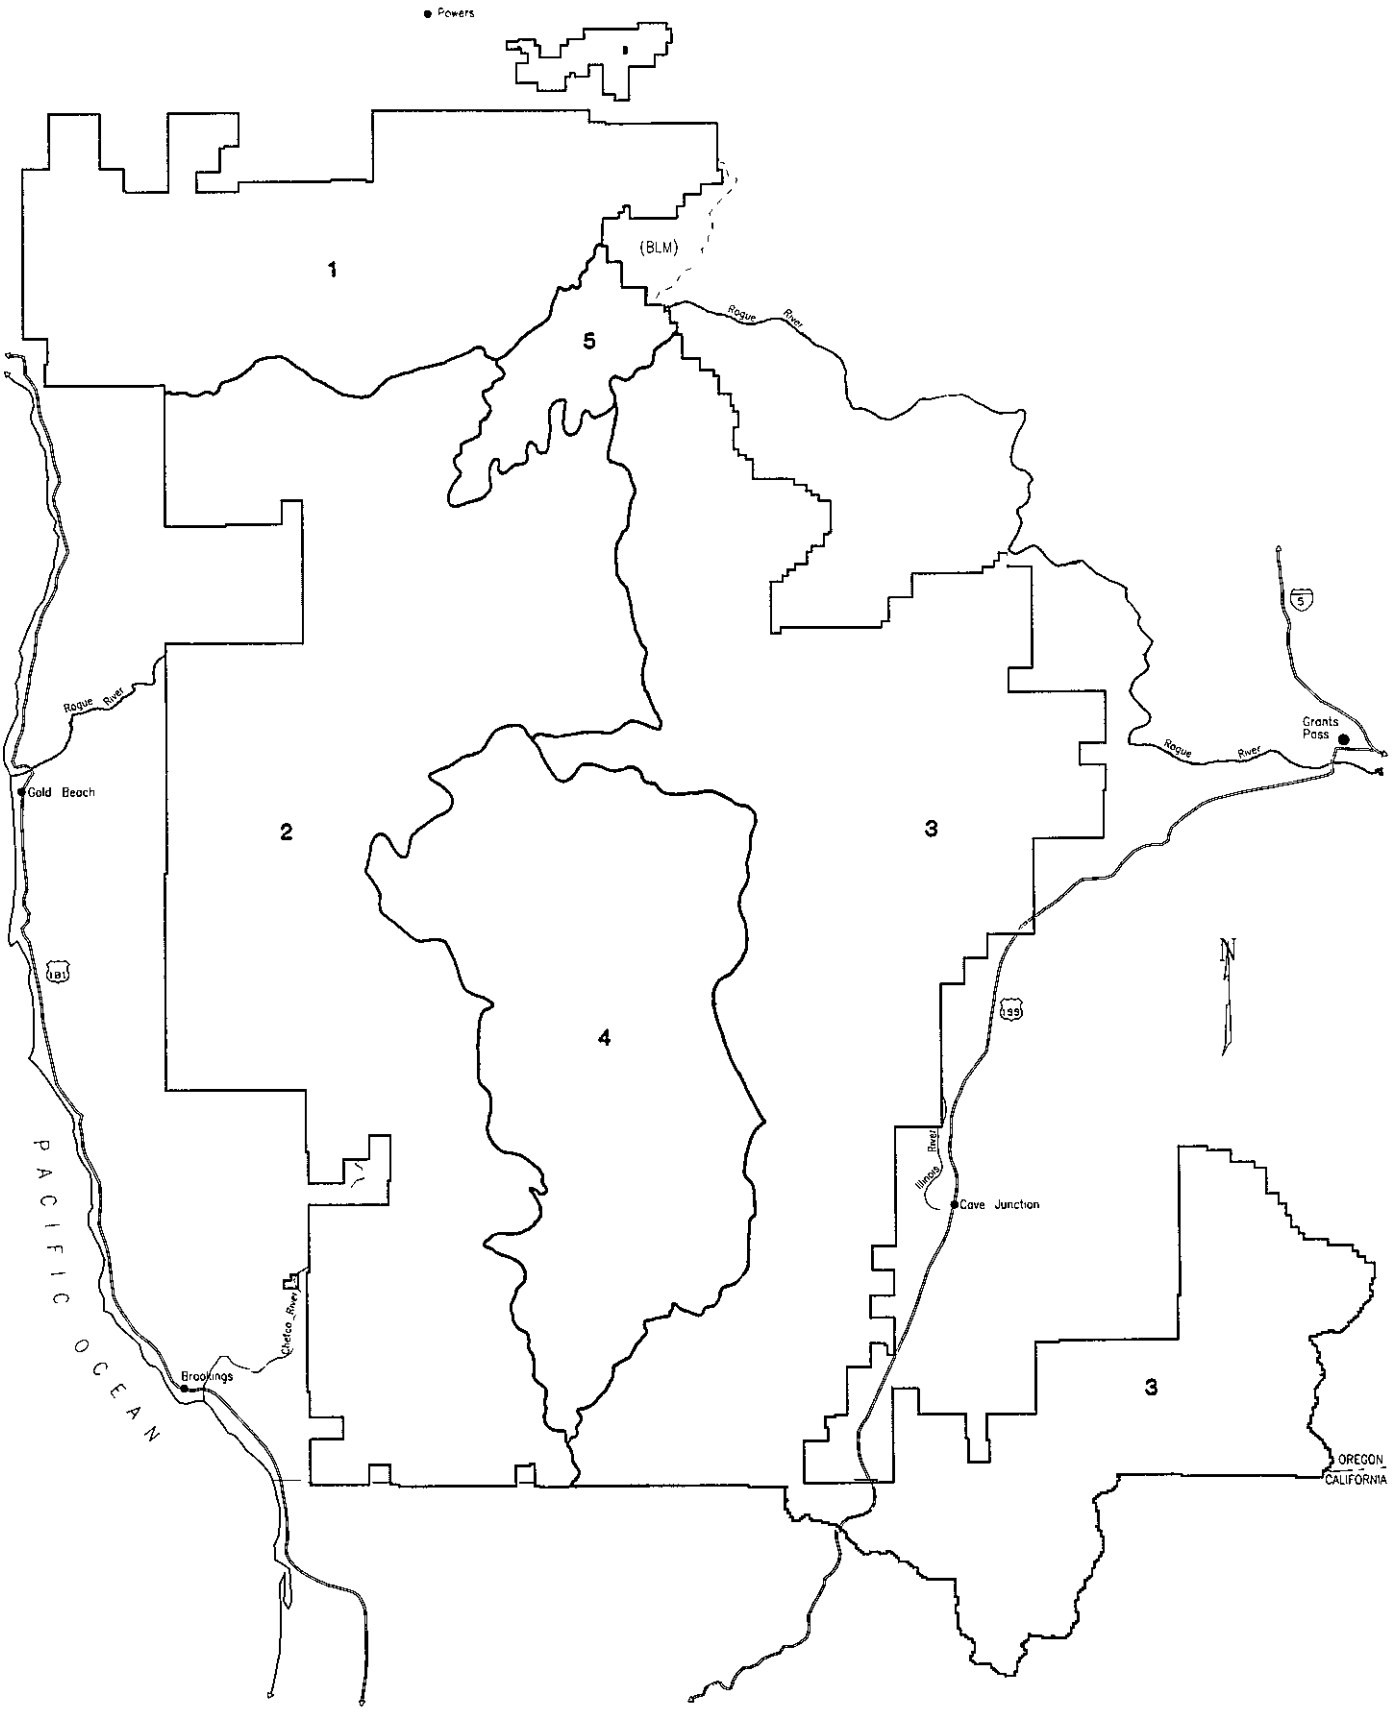

Figure III-11. Fire Management Analysis Zones Map

Wildfire Suppression

Historically, the Forest's fire management policy has been to aggressively attack and extinguish all fires as quickly as possible, regardless of vegetative type, fuel loading, burning conditions, resource values, or management objectives This policy is currently evolving to one which stresses a cost-efficient fire suppression action based on resource values and management objectives

In many locations, other Federal or State-protected lands lie within or adjacent to National Forest System land The Forest has entered into fire protection agreements with the Oregon Caves National Monument, Oregon State Department of Forestry, Coos Forest Protective Association, and the California Department of Forestry (with their respective cooperators) for fire protection. These cooperative and mutual-aid agreements are within the same context as National Forest System policy These agreements provide for the sharing of trained personnel and equipment for initial attack and support purposes for up to 24 hours at no cost to the benefiting agency. An average of 20 mutual-aid responses per year have been initiated by the Siskiyou National Forest in the past five years, with the number increasing yearly.

Prescribed Fire

Because of the importance of fire in the major ecosystems on the Forest, prescribed fire has traditionally been used for the removal of logging residues and the preparation of sites for reforestation after timber harvest In the past five years, it has come to play an important role in the hardwood site conversion program Annually, the Forest utilizes prescribed fire to treat an average of 3,800 acres. Hardwood site conversion adds an average of 200 acres yearly. Right-of-way burning and the burning of handpiles and decks adds another 1,000 acres annually Detailed accomplishments are presented in Table III-15

Table III-15 Prescribed Burning Accomplishments, 1970-1979

	Acres Burned		
Year	Logging Slash	Hardwood Conversion	Estimated Tons Consumed 1/
1970	1,369	--	--
1971	3,936	--	--
1972	4,798	--	--
1973	2,840	--	--
1974	1,345	--	--
1975	4,157	--	230,119

1977	5,987	255	293,447
1978	5,623	439	363,973
1979	3,487	62	164,616

1/ Data extracted from the Oregon Smoke Management Plan Annual Report and does not include fuel consumed by prescribed fire on the California portion of the Forest

Prescribed fire has also been used to a limited extent in meadow and wildlife habitat management programs. It has yet to be used in the management of the array of natural fuel complexes on the Forest. The objective of this use would be to reduce the consequences of moderate and high intensity wildfires while meeting other resource needs

All prescribed burning operations are conducted under the Oregon Smoke Management Plan (OAR 629-43-043) which is promulgated by the Oregon Department of Forestry

CURRENT DEMANDS, WANTS, AND DESIRES

Early scoping identified several concerns among the public and local forest resource managers related to fire An expressed concern was for the potential of catastrophic fire being greatly increased if the Forest could not treat activity fuels and stay within economic and environmental guidelines

Management also expressed a desire that fire be used to both improve and protect Forest resources. Others have indicated the same desire, that fire be allowed to play out its natural role in various Forest ecosystems

ABILITY TO SATISFY DEMAND

The Forest has an array of skills and technology available to deal with the wants and concerns expressed about fire and the potential buildup of activity fuels. The timing and spatial distribution of activity units (e.g , timber harvest and thinning units), utilization standards, and prescribed fire are all tools and techniques that can be employed to meet the demands, wants, and desires expressed by the public and management relative to fire.

Cost of maintaining effective fire suppression forces increases as fuel hazards increase. Any wildland area protected from fire will have a set of probabilities on the occurrence of wildfires of various sizes and intensities (Zivnuska 1972). As fuel hazards increase on a yearly basis and fuel conditions become uniformly high, the probabilities of large intense wildfires increase If fire suppression is to be effective, an appropriate adjustment in the fire suppression forces must be made. Greater crew numbers, added air support, and more sophisticated equipment result in much higher costs which may not provide equivalent benefits

The careful timing, spatial distribution, and management of agency activities such as timber harvest, manual and chemical release, precommercial thinning, and wildlife habitat improvement projects can do much to improve the ability of the Forest to provide cost effective fire protection and reduce the risk of a catastrophic fire The timing, spacing, and treatment of fuels associated with these activities will create a mosaic of acceptable fuel profiles and greatly reduce the risk of a wildfire spreading quickly through vast acreages of highly flammable and continuous fuels The timing and spatial distribution of the agency activities must, however, be coupled with cost-effective fuels treatment before fire management efficiency is truly recognized

Increased utilization standards and opportunities would remove additional activity fuels or residues from the forest environment and greatly reduce the fire hazard Better utilization of forest residues depends largely on market conditions and the needs for raw materials (Wilson and Dell 1971) Costs of collecting, transporting, and processing forest residues in most situations would exceed the market value of the existing products (Henley and Clarke 1976). The only exception is in cases where residues can be removed from landings and transported 30 miles or less to markets (Marcus 1983).

Prescribed burning is an invaluable forest management tool (Resler 1976). It is an effective tool for insect and disease control, wildlife habitat improvement, and silvicultural treatments It has also been used successfully in southwestern Oregon for several years in site preparation and in reducing the fire hazard created by management activities which, if not treated, would remain a wildfire hazard for many years (Dell and Green 1968).

Presently there is no practice substantially equivalent to burning that achieves the major objectives of forest management and regeneration Options that could minimize the need for burning or mitigate its adverse effects include different methods of site preparation, planting, harvesting, and marketing (Marcus 1983)

Long-term studies in Oregon Douglas-fir stands have shown that the use of prescribed fire reduced the resistance to control for 12 years and reduced the estimated rate of spread for 16 years (Morris 1970). Estimates of this benefit are probably greater today, considering the effects of current utilization philosophies and fuel treatment standards

The use of prescribed fire is also an appropriate tool when restoring fire to its natural role in Wilderness ecosystems (Heinselman 1981). In Wilderness ecosystems modified by prolonged exclusion of fire, prescribed burning may be used to reduce fuel loading to natural levels, thereby reducing risks and effects of wildfire to acceptable levels. Risks and consequences of wildfire crossing into or out of the Wilderness would also be reduced. Actual ignitions may be on either a planned basis or from lightning, in either case they must conform to a detailed burning prescription which prepared prior to the ignition, identifies the conditions under which the prescribed fire will burn.

VEGETATION

EXISTING CONDITION

Vegetation on the Siskiyou National Forest occurs along complex environmental gradients that are related to geology, climate, and topography. Localized disturbances caused by storms, fires, and past grazing blur these "natural" patterns Consequently, it is often difficult to determine site potential or limitations.

The Siskiyou Mountains are rugged, steep, and very diverse geologically Parent rock varies from acid-igneous rocks, such as the granites common in the Grants Pass area, to infertile ultrabasic rocks, like the serpentines in the hills west of Cave Junction The area has been severely folded and faulted, creating new combinations of rocks that are scrambled into a jigsaw mosaic These highly variable rocks, and the soils developed from them, produce an extremely diverse substrata for vegetation.

The climate is recognizably different from the rest of Oregon. It is not consistently dry, like the east side of the Cascades, nor is it consistently wet as expected west of the Cascade crest. There is a mixture of both climates, including wide variation in temperature and precipitation. The major difference between the Siskiyous and the rest of western Oregon is the number of days without cloud cover and the accompanying high rates of evapotranspiration. High evapotranspirational demand is one of the most important factors limiting plant growth in the area.

This combination of climate, geology, and topography has produced such a mix of habitats that the Siskiyou National Forest supports both a large and complex set of ecosystems. This highly productive forest contains a set of biologically diverse plant communities not exceeded in vegetative complexity anywhere in the States.

SUITABILITY

Of the 1,092,302 acres of Siskiyou National Forest land, 624,240 acres are classified as tentatively suitable for timber production, as defined in 36 CFR 219 12 (b). The location of the various classifications of tentatively suitable land is displayed on Figure III-12. Table III-16 summarizes the suitable acreage for the Forest, and Figure III-13 provides a more detailed breakdown of the Forest acres by land types Many of the terms used in these tables are defined in the GLOSSARY. Refer to Appendix B for further discussion of suitability.

Table III-16 does not display the changes resulting from the Omnibus Oregon Wild and Scenic Rivers Act of 1988, nor adjustments in suitability resulting from the Silver Fire Recovery Project field inventory of 1987-88. The newly designated rivers cause withdrawal of 1,684 acres from the available land base due to "Wild Rivers" outside Wilderness. Most of these acres are either unsuitable for the production of timber or are overlapped by Management Areas 3-9. About 6,000 acres were found unsuitable following intensive field investigations of the Silver Fire. For this FEIS, land suitability is fixed as of 1984 for purposes of alternative comparisons. These adjustments would be applied to the alternative selected in the Record of Decision

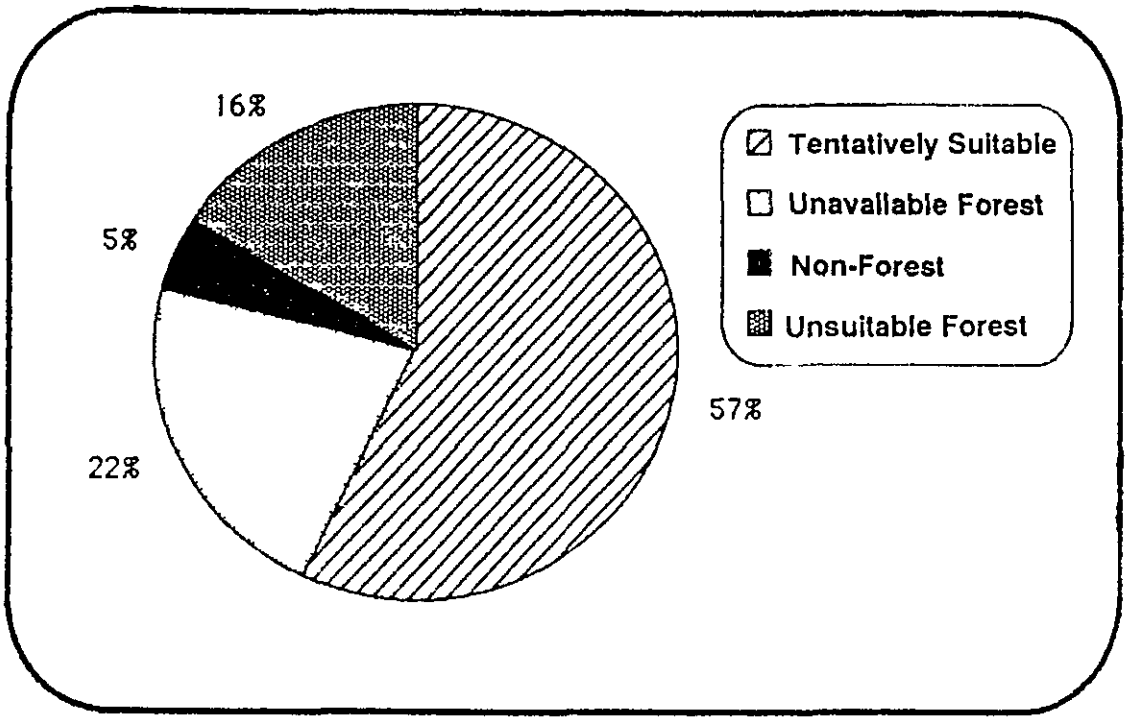

Figure III-13. Land Types

ROLE OF FIRE

Before the Indians, settlers, miners, and ranchers learned to use fire for clearing the forest, lightning-caused fires commonly performed that task. Natural fires were frequent enough to consume accumulated fuels before they built to a level that would sustain a major forest fire Most burned young trees and understory vegetation. This "natural" fire regime was prevalent during the evolution of many plant species and consequently some became "fire dependent." For example, Douglas-fir relies on fire or other disturbance to eliminate its more shade-tolerant competitors such as white fir Similarly, redwood tolerates fire, but tanoak succumbs Redwood depends on the help of fire to dominate and reproduce on sites where tanoak is the climax species.

The natural fire regime varies greatly in the Siskiyous. The coastal side is characterized by infrequent but relatively intense fires that have produced hardwood-dominated stands. The inland side is similar to the east side of the Cascades where fire is frequent, but of low intensity Low intensity fires generally change species composition and eliminate, temporarily and/or locally, some soil pathogens Fire suppression efforts in the last half century have played a major role in reducing many populations of fire-dependent plants, causing overstocking of some sites, and allowing fuel levels to build and stand health to decline

Local fire history is the key to understanding present age-class structure and successional stages on the Forest. Most of the Douglas-fir dominated stands were established as a direct or indirect result of burning. Many of the 70- to 170-year-old age classes are on sites burned by settlers and miners. Because the intent was to burn off as much of the vegetation as possible, these burns were often more intense than natural fires; many were ignited during the driest, hottest weather. The older age classes in these fire-generated stands are now declining in vigor and being replaced by more tolerant species, such as tanoak on the coastal side and white fir inland.

As succession toward climax occurs (climax is the end point of stand development where productivity equals decomposition and stand structure and composition are relatively static), much of the forest will be dominated by white fir and tanoak. This will occur providing the effects of fire are minimized and there is no interruption of natural succession by man. Whether species are successional such as redwood, Douglas-fir (on some sites Douglas-fir may be climax), and ponderosa pine, or climax such as tanoak, white fir, and western hemlock, some form of management will be necessary for their maintenance. Otherwise, wildfire will be the determinant of the composition and structure of the forest.

When fire is the major disturbance, it directly affects the health of a stand by eliminating or setting back susceptible species and leaving more resources for the survivors. Their general vigor improves and they become less susceptible to insect attack. Fire also often reduces the populations of soil pathogens, usually favoring the pioneer species For example, fire eliminates damping-off disease that attacks redwood seedlings

Ecosystem health seems to be the result of two opposing forces. One force tends to stabilize the site by keeping species composition and stand structure the same over long periods of time. Climax species tend to dominate where disturbances are infrequent In such cases, pioneer species (those that tend to invade after a disturbance) would be reduced or eliminated. On the other hand, nature consistently introduces disturbances that assure the continued existence of the pioneers. Thus, the forces of nature maintain a diversity of both pioneer and climax species to assure the health and potential of the system regardless of the severity of the disturbance.

SPECIES DIVERSITY

There are a number of issues related to the diversity of species, or species composition of the forest or site. For example, the viability of sensitive plants, the availability of commercial conifers, and the management of redwood are issues related to the variability of species rather than the variability in seral

stages or age class Some issues are related to both species composition and age class distribution. The issue of hardwood conversion is an example The Forest is concerned with the diversity of both rare and common species Rare species, endemics or species at the limits of their range (Brewer spruce and redwood, respectively), are often managed through land allocations such as Research Natural Areas and Botanical areas Maintaining the diversity of the more common species is accomplished by Standards and Guidelines. Both rare and common species are monitored

Meadows

Most meadows on the Forest are climax to tree species. Many were burned by the Indians to provide hunting grounds and later by ranchers to maintain forage for game and stock The meadows provide edge (the transition from forest to meadow) for wildlife species, and a concentration of grass species They are now gradually returning to forest

Sensitive Plants

A plant classified as sensitive generally (1) needs special habitat; (2) is at the limit of its range and is only locally rare, or (3) can survive on a variety of habitats, but has a limited range The Siskiyou National Forest has all three types. The Forest Service is particularly concerned about endemics and species requiring special habitat (Webb 1988). The objective is to maintain the genetic diversity and viability of all species, but endemics may require special consideration

To maintain diversity and viability, some species (such as *Kalmiopsis leachiana*) require disturbance; others require protection (like *Darlingtonia Californica*). Requirements for many sensitive species are still unknown, more information is needed to understand their population dynamics. Many sensitive plants are in areas where no activities will take place, as such, options for maintaining population viability remain open Some sensitive species which occur in General Forest may actually benefit from timber harvest activities; reproduction is stimulated. However, if management activities are detrimental, sensitive plants are protected from significant reduction by Standards and Guidelines A more detailed discussion of sensitive plants can be found in the **SENSITIVE PLANTS** section of this chapter

Botanical Areas and Research Natural Areas

Both Botanical and Research Natural Areas help maintain species diversity on the Forest. For a detailed discussion of these important areas, refer to the **SENSITIVE PLANTS** section

Riparian Areas

From a vegetative standpoint, riparian sites are unique They are moist habitats surrounded by moisture-limited systems. The complement of species near the water's edge is usually quite different than the adjacent area. There is often more structural diversity, and the age-class distribution is usually more complete They have some of the oldest trees because fire is often less influential than erosional processes as the cause of vegetational changes. Younger trees are in the newly flooded or recently eroded areas; the older trees are scattered throughout

Hardwoods

Hardwood species include tanoak, Pacific madrone, red alder, manzanitas, canyon live oak, Pacific rhododendron, golden chinquapin, and various others. There has been little commercial market for these species, although some tanoak and red alder have been harvested for pulp Most of the hardwoods are cut by local residents for firewood

Some hardwood sites are climax to tanoak, others are climax to western hemlock, white fir, or Douglas-fir Those on the southern coast of Oregon are generally climax to tanoak and will, therefore, remain as such

unless converted to an early seral stage and regenerated with coniferous species. These sites are productive sites. Their potential to produce timber is usually high, and they are prime areas for many species of wildlife Sites climax to western hemlock are also productive, but they will gradually and naturally return to western hemlock They are most common on the north end of the Forest

Inland hardwoods are quite different. They are usually dominated by seral hardwoods such as Pacific madrone, golden chinquapin, and tanoak. They are climax to white fir on the better sites, and to Douglas-fir on the less productive sites Most stands are in the mid-seral stages (70 to 120 years) and are only beginning to seed in with conifers.

Conifers

SPECIES COMPOSITION Coniferous timber is the most important commercial product on the Forest. The 1979 timber inventory indicates that 85 percent of the coniferous timber on the Forest is Douglas-fir. The remaining 15 percent is sugar pine, Port-Orford-cedar, redwood, western and mountain hemlock, Jeffrey and ponderosa pine, Shasta red and white fir, and minor amounts of other species. Brewer spruce, a species with a very limited range, is found at mid to high elevations on some parts of the Forest

SPECIAL MANAGEMENT CONSIDERATIONS. Three conifer species are currently given special management considerations. These include Port-Orford-cedar, redwood, and Brewer spruce.

1. Port-Orford-cedar (*Chamaecyparis lawsoniana*) occurs only in northwestern California and southwestern Oregon. This is somewhat surprising given the wide range of conditions under which the species occurs. Its habitat includes sand dunes along the the coast to elevations over 4,000 feet in the Siskiyou Mountains and interior valleys, and from swampy sites to dry rocky ridges, including serpentine soils. Some of the largest concentrations, and the largest tree of this species, occur on the Forest.

   Special efforts are made to plant Port-Orford-cedar on sites where they were harvested and sites where there is potential to grow them. The species is being monitored to insure it remains a viable species on commercial sites; seed is also being collected for reforestation.

   Two Research Natural Areas (RNA's) were established to provide examples of virgin old-growth Port-Orford-cedar. These are the Port Orford Cedar RNA (1,122 acres) established in 1937, and the Coquille River Falls RNA (500 acres) established in 1945

   Port-Orford-cedar root disease (*Phytophthora lateralis*) has been killing Port-Orford-cedar for more than 60 years The fungus was discovered in the Puget Sound area as early as 1922 and has since worked its way south, probably through movement of infected seedlings in the horticultural market. The disease was found in the Coos Bay area in 1952 and has since spread into the Forest through movement of the spores in mud on vehicles and hoofs of grazing animals. Primary areas of concern are roads and streams since resting spores are moved in mud and swimming spores are transported in water Specific management strategies for Port-Orford-cedar are displayed in the Forest Plan Standards and Guidelines These standards and guidelines are based on the Region Five-Region Six Port-Orford-Cedar Root Disease Action Plan of June 1988 which was developed through a concensus process (group) whose membership included industry, agency, environmental, and university personnel and citizens. Figure III-14 displays the areas of Port-Orford-cedar occurrence Also shown are known areas of root disease infection.

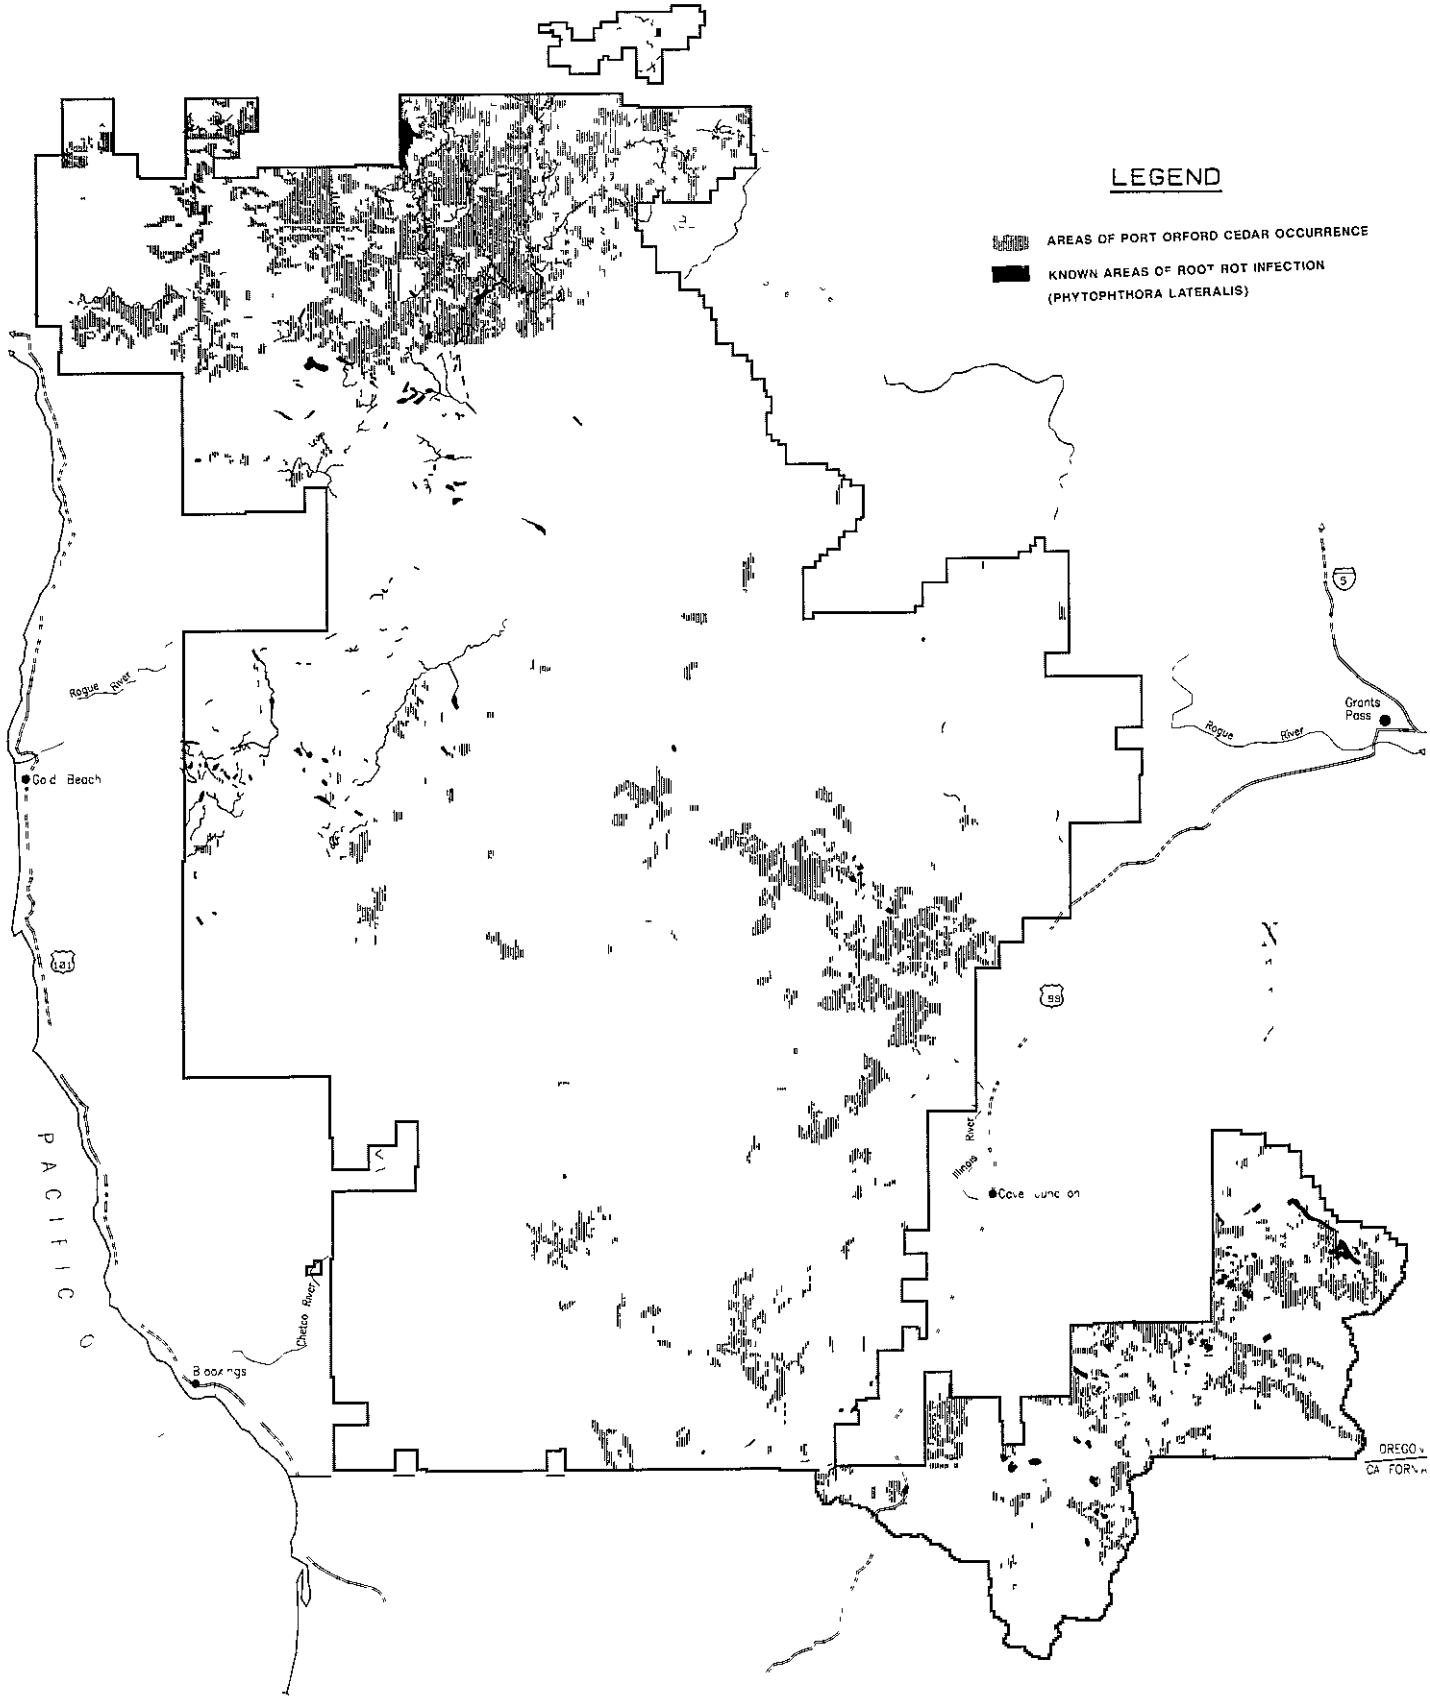

Figure III-14 Port-Orford-Cedar Occurrence and Known Areas of Root-Rot Infection Map

2 The range of redwood (*Sequoia sempervirons*) extends south along the coast from two stands near the Chetco River in southwestern Oregon to Monterey County, California. There are about 18,540 acres of the redwood type, or land capable of growing redwood, on the Forest Redwood is a major species on approximately 4,000 acres, approximately 1350 acres contain old-growth redwood. Though redwood has a much larger range than Brewer spruce or Port-Orford-cedar, it reaches its northern limits on the Forest

The Wheeler Creek RNA (334 acres) was established in 1972 specifically to preserve an example of redwood forest near the northern limits of its range. The 120-acre Chetco-Redwood Recreation Area also contains a stand of redwoods This property is an isolated parcel of National Forest land located adjacent to the Alfred A. Loeb State Park.

Special efforts are made to plant redwood on sites where they were removed and onto sites where there is potential to grow them The species is being monitored to insure it remains a viable species on commercial sites, seed is also being collected for use in reforestation. A Redwood Management Plan is available (Planning Records).

3 Brewer spruce (*Picea breweriana*) is found only in a few remote locations of southwestern Oregon and northwestern California The majority of Brewer spruce stands occur within National Forest boundaries, including the Siskiyou. The tremendous vegetational diversity and complexity associated with the occurrence of Brewer spruce magnifies the importance of this uncommon species (Amaranthus 1982)

Prospects for expanding the range of Brewer spruce are low. However, special efforts are made to plant Brewer spruce on sites where they were removed and where there is potential to grow them. The species is being monitored to insure its viability on commercial sites; seed is also being collected for use in reforestation

The Babyfoot Unusual Interest Area (Botanical) (352 acres) was established in 1963 to protect Brewer spruce and other rare plant species The Big Craggies Botanical Area (3,800 acres) was established in 1964, primarily to protect Brewer spruce and *Kalmiopsis leachiana*.

REFORESTATION. Since timber harvesting began on the Forest, approximately 100,000 acres have had a regeneration harvest. Of the total, about 99,300 acres meet minimum stocking levels. Stocking levels are 150 trees per acre for Site Class III and better, and 125 trees per acre for all other productivity levels. For additional details, a reforestation report (October 1988) is available in the Planning Records.

To determine whether the Forest is meeting its five-year reforestation objective, all harvested acres during the 10-year period 1974 through 1983 were tracked through reforestation. Each year's total acreage was tracked until all of that acreage was satisfactorily stocked. This analysis showed that essentially all acres regeneration harvested were successfully reforested within five years (27,322 acres were harvested; 163 acres were not satisfactorily stocked within five years).

Additional analysis of the reforestation program was done in regard to whether plantations contain unsatisfactorily stocked holes. For this purpose, a hole is defined as an area of one acre or larger that contained less than the minimum stocking level. An 18 percent sample of all plantations on the Forest was randomly selected and evaluated These plantations totaled 15,748 acres; of this total, 581 acres did not meet minimum stocking levels. These holes contain about 60 crop trees per acre and are 3.7 percent of the total sample. This is within the 10 percent adjustment for yield projections for holes created by unsatisfactory stocking, landings, and temporary roads.

AGE-CLASS DISTRIBUTION

The amount and distribution of seral stages, including early grass/forb stages, mature stages that provide timber products, and old growth that provides special habitat for a number of management indicator species, are issues related to the age class of the forest and its structure. The general forest will be in various stages that reflect the Forest's ability to provide for the wants and desires of Forest users.

Successional Stages

Vegetation on the Forest can be divided into a series of age classes, or successional stages, each with a specific vegetative character Seven stages have been categorized, from grass/forb to old growth Each age class is an important component of habitat diversity Young stages (0-10 years, low-growing vegetation) presently account for five percent of the Forest land base Mid-age stages (large shrubs to small trees, 11-100 years) account for 31 percent And, mature/old growth (101+ years) account for 41 percent

Other habitats are also important for maintenance of habitat diversity on the Siskiyou. Hardwood stands and brushfields account for 9 percent, serpentine sites for 14 percent, and cliffs/rock balds/talus for 1 percent of the Forest. Riparian habitat occupies 17 percent. A very small portion of the Forest is meadow habitat (316 separate sites comprising 6,677 acres). These successional stages and habitat types constitute existing habitat diversity on the Forest (Table III-17).

Old Growth

Old growth refers more to structural character than age. For example, many of the Jeffrey pine stands on ultrabasic parent rock are over 300 years old, yet they are not considered old growth The number of species, canopy structure, and the distribution and amount of woody material on the forest floor are the most important characteristics (see GLOSSARY definition) Old-growth and mature timber are well distributed throughout the Forest (Figure III-15) The coastal side and the northern half of the Forest has slightly more than the southern and eastern half

Table III-17. Successional Stages and Other Habitats (Private Land not Included) 1/

	Age (Years)	Acres	Percent
Successional Stages			
Grass/Forb 2/	0-3	20,000	2
Low Shrub	4-10	36,000	3
Tall Shrub	11-20	51,000	5
Pole/Sapling	21-40	101,000	9
Young	41-100	186,000	17
Mature	101-200	50,000	5
Old Growth	200+	393,000	36
Habitat Types			
Hardwood Stands		94,000	9
Cliffs, Rock Balds, Talus		11,000	1
Serpentine (scattered trees)		150,000	14
Totals		1,092,000	100

1/ Data primarily from ecoclass mapping project, 1978-79, some data from TRI data base and LIM System 175,500 acres (16 percent of the Forest) of riparian habitat is included as part of all types listed in the table Riparian habitat, as used here, is that land within 150 feet of the edge of Class I and II streams, and within 100 feet of Class III streams

2/ Grass/Forb stage includes 6,677 acres of meadows, otherwise, successional stages describe coniferous Forest land

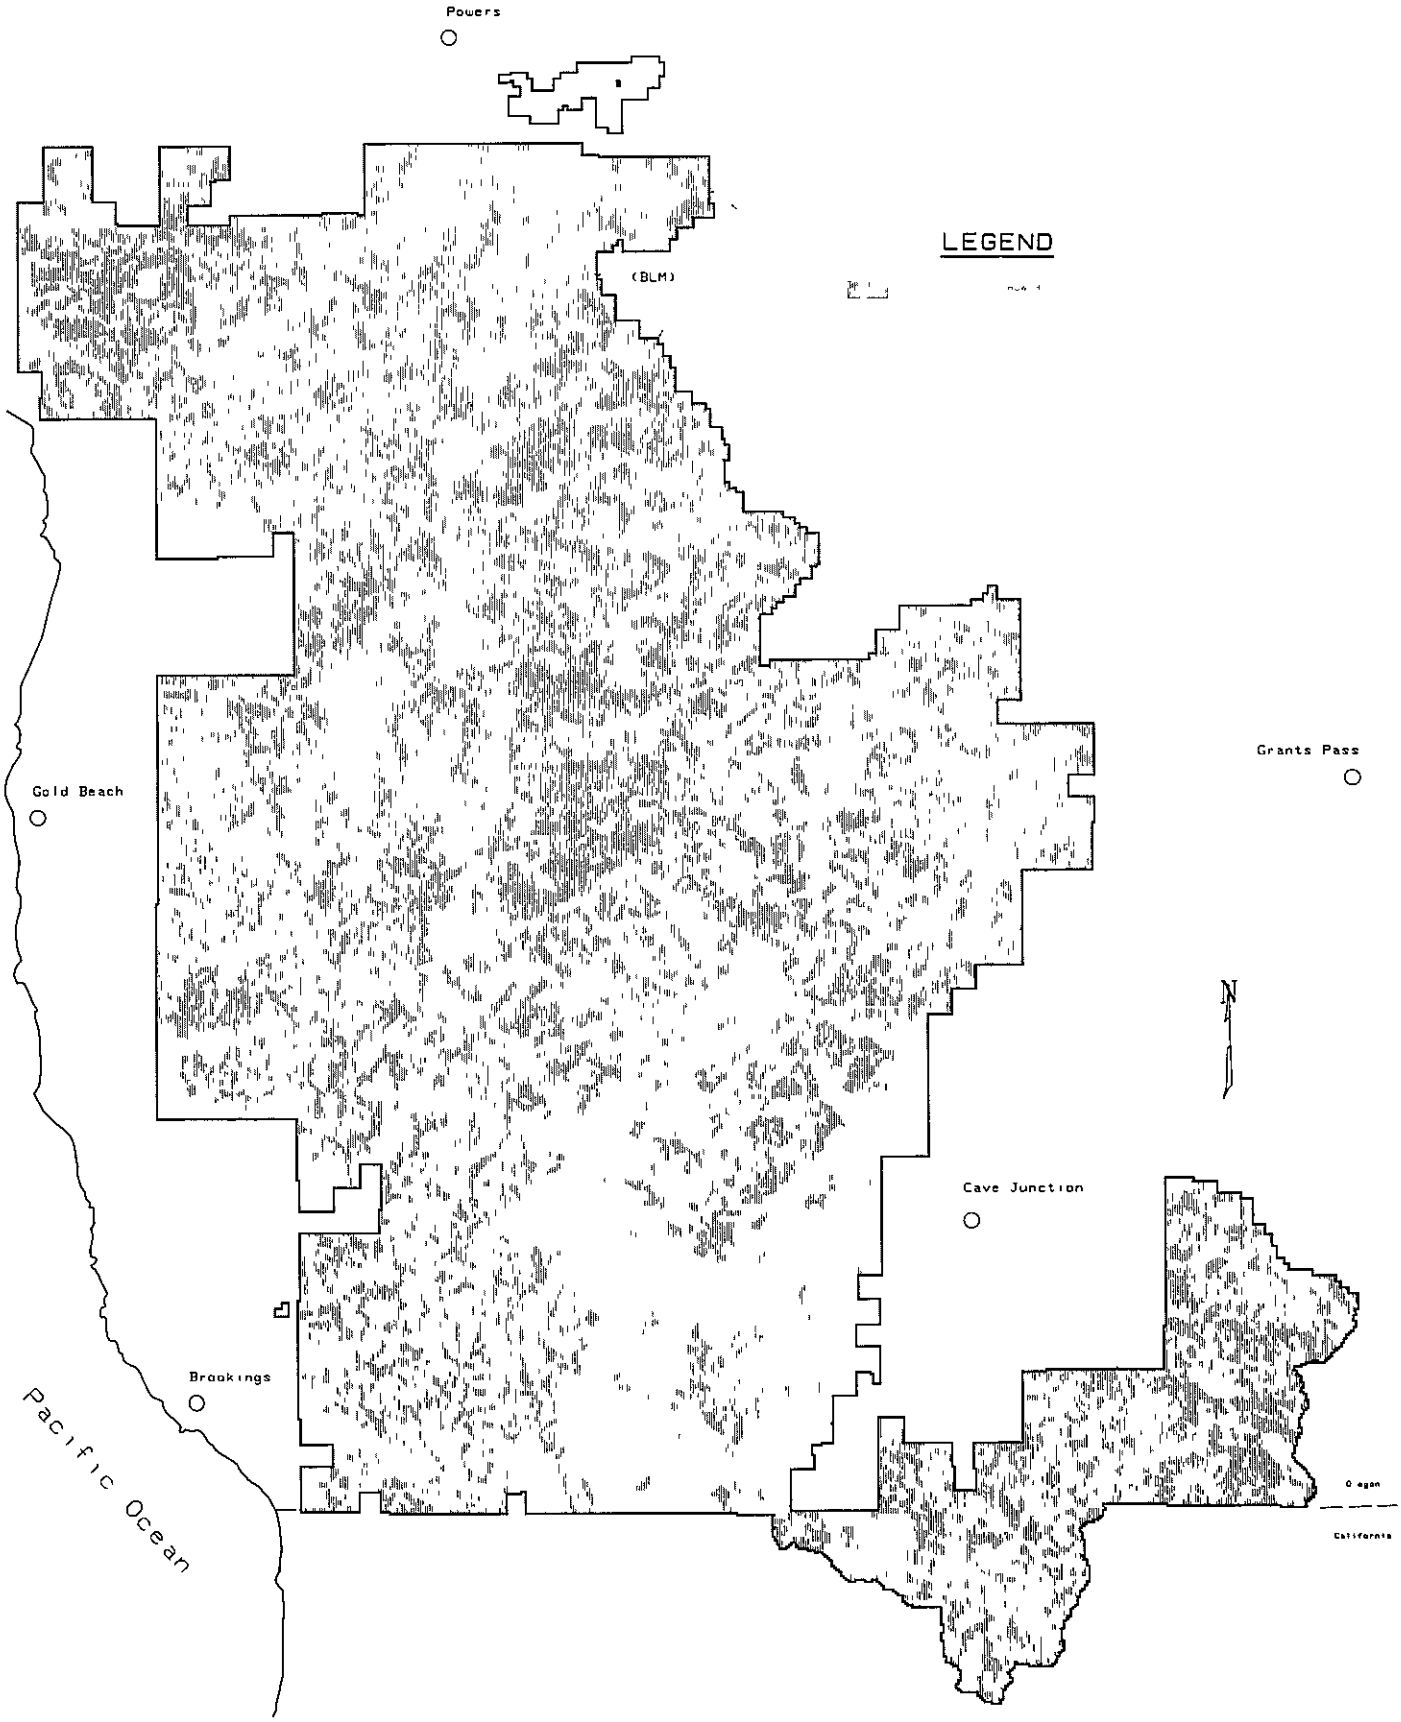

Figure III-15. Mature/Old-growth Forest Map

Although generally younger than old growth found in the Cascades, it is usually in better health. Most of the sites are in mid-seral stages and are not at high risk due to insects or fire Risk, though, increases with time. As these stands age, their character and health will change significantly. Management will be required to maintain old-growth character, or natural processes will prevail, i.e., fire, insects, or disease.

Existing inventory data indicate the Forest contains 443,000 acres of mature and old-growth trees. Wilderness areas contain approximately 95,000 acres (21 percent) of the mature and old-growth trees. Another four percent has been withdrawn from the Forest's suitable land base and placed in RNA's, Wild River corridors, and other land allocations with no programmed timber harvest Area currently unroaded is 28 percent (124,900 acres), most of these acres are tentatively suitable for timber production The remaining 208,000 acres, or approximately 47 percent of the total mature and old-growth acreage, is scattered throughout the Forest, and is mostly on lands tentatively suitable for timber production A new resource inventory scheduled to begin in 1990 will provide updated acreages

General Forest Allocation

General Forest is expected to provide the potential for timber products Age-class distribution is an important consideration, the ideal being a balance between young managed stands and mature stands. This distribution would provide a continuous flow of mature timber over the rotation. A diversity of age classes would also serve to reduce the risk of catastrophic losses from pests, disease, or other causative agents

General Forest also provides a great deal of species diversity and habitat in addition to timber products Over 500 species were found on 700 ecological plots. 35 species of trees, 86 shrubs, 362 herb, and over 50 grass or grass-like plants Most of these species remain even after harvest operations Dyrness (1973) reported that only 6 of 48 species were eliminated on the immediate site after timber harvest and site preparation activities. In fact, there was a net increase of 24 early seral species within the first six years after harvest. General Forest will continue to contribute to overall diversity regardless of age class or seral stage

The 624,240 acres of land tentatively suitable for timber production on the Forest contain a total standing inventory volume of 10,695 MMBF (2,090 MMCF) of conifer timber, and 1,279 MMBF (272 MMCF) of hardwood timber. This compares with a total standing inventory volume for all acres on the Forest of 15,486 MMBF (2,899 MMCF) of conifer timber, and 1,982 MMBF (427 MMCF) of hardwood timber (Table III-18). Percent Forest acreage by Timber Condition Class is represented in Figure III-16. Timber Condition Classes are mapped for tentatively suitable lands in Figure III-12.

Table III-18 Acreage and Volume by Timber Condition Class on Tentatively Suitable Forest Land

Timber Condition	Acres	Softwood Volume MMBF	Softwood Volume MMCF	Hardwood Volume MMBF	Hardwood Volume MMCF
Mature	305,743	8,696	1,549	613	111
Immature-Small Timber	20,422	584	127	37	8
Immature-Poles	93,994	1,118	253	210	47
Seedlings and Saplings	137,604	1/		1/	
Hardwoods (Nonstocked)	47,764	180	45	419	105

2/ Separate Suitability Component

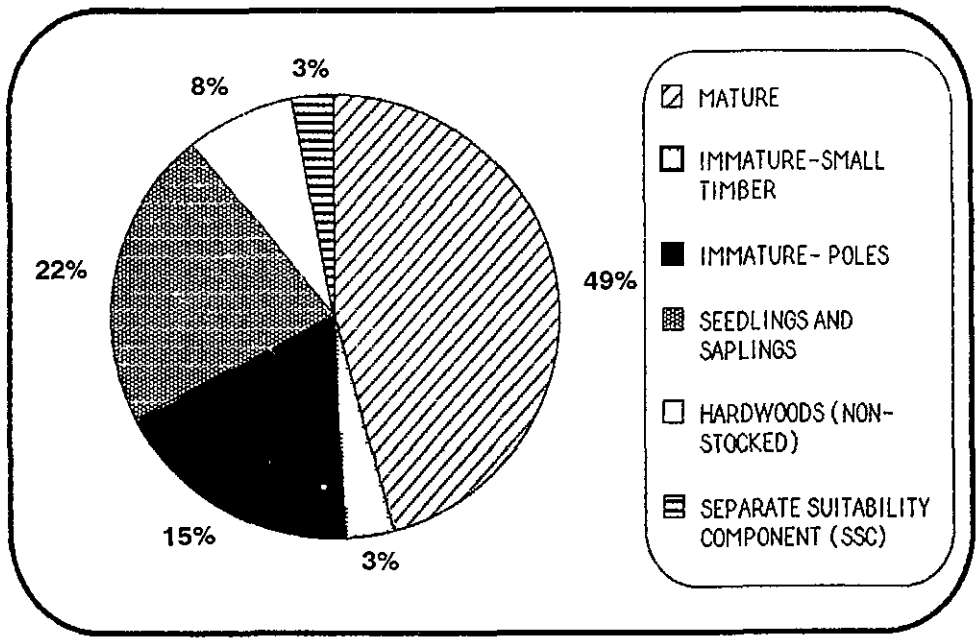

Figure III-16 Timber Condition Classes (Percent of Tentatively Suitable Forest Land)

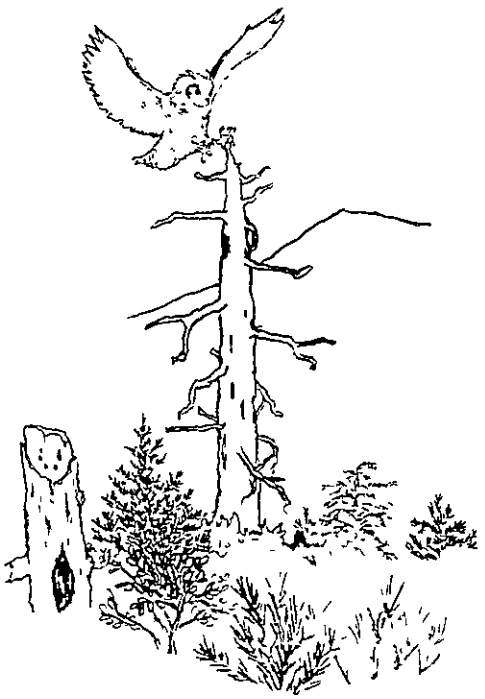
CURRENT DEMANDS, WANTS, AND DESIRES

Public demands that relate to species diversity include the establishment of Research Natural Area, Botanical, and Riparian Management Areas. Maintaining the viability of sensitive plants, meadow maintenance, and conversion of hardwood areas are also part of diversity management. It is evident that most people want to maintain the Forest's species diversity Some want diversity perpetuated for research, others simply feel diversity is strongly tied to ecosystem health and its ability to respond to various needs, disturbances, or even changes in climate.

Demands associated with age-class distribution are the perpetuation of old growth and the provision for a sustained flow of managed age classes for timber harvest The separation of demands into those associated with diversity and age helps to categorize the problems, but the two concepts should not be considered as separate. Many species only do well in the environmental conditions accompanying certain seral stages, the diversity of species is linked to age diversity

ABILITY TO SATISFY DEMAND

DIVERSITY



Biologically, the Forest is capable of maintaining the present complement of species, barring an extensive catastrophe. Land allocations may be key to maintaining viable populations of some plants, but the greatest need is for information on life cycles and environmental requirements of sensitive species and even some timber species. The use of "minor" species (less common trees in a forest stand) in forestry practices is becoming commonplace, but information on their performance is lacking. Harvested units are being planted with a species mix similar to preharvest conditions, but predicting yields in such mixtures is in its infancy

Allocations to Botanical, Research Natural Area, Special Wildlife Site, Designated Wildlife Habitat, and selected Supplemental Resource Management Areas all basically maintain plant or animal diversity. Wilderness, Wild Rivers, Unique Interest, Backcountry Recreation, Scenic and Recreation Rivers, Riparian, and Retention Visual Resource Management Areas are primarily allocated for other purposes, but, in essence, acres placed in these categories receive medium to low consumptive use Plants that thrive on infrequent disturbance will do well in these areas. Partial Retention Visual and General Forest, on the other hand, will be intensively managed Plants requiring disturbance will do well in both these areas If plants requiring infrequent disturbance are found here, they will be protected If plants requiring frequent disturbance are found in areas other than General Forest and Partial Retention Visual, a method of introducing disturbance in the proper frequency and intensity would be needed to assure total species diversity

AGE CLASS

Mature timber and old growth are well distributed throughout the Forest Both age classes are renewable. Mature sawtimber is being harvested and regrown, but there is a gap in age classes that must be considered if sustained yield is a goal and other resources are not sacrificed. Intensive silvicultural practices and allocation of resources to the better sites show promise for increasing future productivity and yield

While old growth will always be present on the Forest, individual stands cannot be sustained forever. Management can prolong their existence, but they will eventually have to be replaced Since structural characteristics, not age, are the primary value, it may be possible to develop stands with old-growth characteristics in less than the assumed 200 years It is becoming more common to leave shelterwood or seed trees for the next rotation rather than removing them after the new stand is established. These larger, older trees provide snags and large woody material needed for bird and small mammal habitat They also provide genetic and structural continuity between rotations.

SENSITIVE PLANTS

EXISTING CONDITION

The unique geologic and climatic history of the Siskiyou Mountains of southwestern Oregon and northwestern California is responsible for the evolution of a number of rare plants not found elsewhere The ranges of some of these plants are almost entirely within the Forest.

Two categories of rare plants receive special consideration from Siskiyou National Forest land managers:

1. Federally listed or proposed endangered or threatened species must be protected from adverse impact (presently, none known on the Forest).

2 Regional Forester identified Sensitive species are those plant species for which viability is a concern, as evidenced by (a) significant current or predicted downward trends in population numbers or density, or (b) significant current or predicted downward trends in habitat capability that could reduce a species' existing distribution The Forest harbors 64 sensitive species, and an additional 30 may occur here

Ten other species are potential candidates for the Regional Forester's list of sensitive plants (nine are known to occur on the Forest) Management of sensitive species is closely coordinated with the Oregon Natural Heritage Data Base (ONHDB 1985) and the California Native Plant Society (Smith and York 1984).

The Forest also manages endangered, threatened, or sensitive plants in accordance with Oregon's Endangered Species Act of 1987 (ORS 496 004, 498.026, and 564.040), and California's Endangered Species Act (1984 amendments) and Plant Protection Act (1977)

Common and scientific names of all rare plants are listed in the current *Status List of Endangered, Threatened, Sensitive and Rare Plants on the Siskiyou National Forest* (USDA 1988a) Various plant lists are described in Appendix F. *A Guide to Sensitive Plants of the Siskiyou National Forest* (Webb 1988a) and the *Guide to Common Forest Plants Rogue River, Siskiyou, and Umpqua National Forests* (Wheeler and Atzet 1985) are used by Forest Service employees and volunteers to identify sensitive plants in the field.

Four indicator habitats for sensitive plants are designated in the Forest Plan: (a) open slopes, fields, meadows, (b) dry rocky places, serpentine/nonserpentine, (c) moist rocky places; and (d) bog and wet/moist places, with serpentine and non-serpentine subgroups. Indicator habitats will be monitored during the life of the Plan to document any changes in sensitive plant populations. See Appendix F and the **MONITORING AND EVALUATION PLAN** in Chapter V (LRMP) for more detail.

BOTANICAL AREAS

Concentration areas of rare plants occur frequently on the Forest Botanical areas are allocated to provide protected habitat for a species or a combination of species, including rare and sensitive plants. An area's ability to support a diversity of species is directly dependent on the variability of their environment. The likelihood of variation is somewhat dependent on size. Generally, the larger the area, the greater the diversity until a point of diminishing returns occurs, where more area does not "mean" more diversity.

One strategy to maximize diversity and capture the integrity of specific sites is through land allocations. Generally, many small scattered areas are more efficient than a few large areas To include the widest variation in environments, sites should be selected from both sides of the coastal crest, from low and high elevations, and include a variety of parent rock Existing and potential Botanical areas represent a variety of environments, but many are restricted to serpentine soils Figure II-6 shows the location of these areas on the Forest. Each of the existing and proposed Botanical Areas is detailed in Appendix F.

Existing Botanical Areas

The Forest contains three existing Botanical areas totalling 4,475 acres Of these acres, 3,401 acres (or 76 percent) are within the Kalmiopsis Wilderness. Sensitive plant species are present in all three areas The 352-acre Babyfoot Unusual Interest Area (Botanical) was established in 1966 to protect Brewer spruce and other rare plant species The 3,803-acre Big Craggies Botanical Area was established in 1964, primarily to protect Brewer spruce and *Kalmiopsis leachiana*. The 320-acre York Creek Unusual Interest Area (Botanical) was established in 1966 primarily to protect an extensive patch of *K leachiana*

Potential Botanical Areas

Two types of potential Botanical areas have been identified· (1) those designed to protect sensitive plants, and (2) those designed to preserve outstanding examples of old-growth stands (very large, old trees)

1. **Sensitive Plant Botanical Areas**. There are 19 potential Sensitive Plant Botanical areas (35,596 acres) identified throughout the Forest. Eight Dollar Mountain is probably the best known site. Over 20 sensitive plants are present (almost one-third of those known to be on the Forest); this same assemblage is not known to be present elsewhere (as a group). Sensitive species are located on both bog and dry sites at a variety of locations, the largest Darlingtonia bogs on the Forest are within the Eight Dollar Mountain site. This site has been continually botanized since the 1880's, and is of much historical interest in regard to early-day botanists. A number of species were first collected in this area. Another outstanding example is the Bigelow Lakes site. A large variety of sensitive species are present Some plant species are at their most northern or western limits This concentration of plants is not known elsewhere on the Siskiyou or adjacent National Forests

2 **Old-growth Botanical Areas** There are five potential Old-growth Botanical Areas (1,321 acres) on the Forest The best example is the Lobster Grove site which is dominated by very large Douglas-fir *(Picea breweriana)* and Port-Orford-cedar, some approaching 8 feet in diameter There are also outstanding examples of large tanoak, Pacific madrone, and Oregon myrtle (the world's largest myrtle tree is located within the Grove).

RESEARCH NATURAL AREAS

Research Natural Areas (RNA's) are allocated for research and education These ecosystems are unaffected by man and are intended to be baseline representatives for the study of natural processes and the maintenance of gene pools Representatives of both rare and common ecosystems are included. A system of RNA's has been set up throughout the Pacific states to preserve representatives of plant communities Many plant communities are not yet represented by RNA's. The present representation of cells (ecosystems, species, or special areas earmarked for inclusion by the RNA Committee) falls short of the Committee's recommendations for this Forest The Siskiyou presently has three RNA's Four additional RNA's have been proposed by Forest Service researchers and others for inclusion into the RNA system (Dyrness and others 1975) See Appendix F for more detail on individual areas

Existing Research Natural Areas

Three RNA's (1,957 acres) exist on the Forest The Port Orford Cedar RNA (1,120 acres) was established in 1937, it contains six plant communities (cells) not represented in other RNA's. Most of the RNA is covered with old-growth Port-Orford-cedar and Douglas-fir. Although ages are not accurately known, many of the dominant specimens are undoubtedly 400 to 500 years old. The Coquille River Falls RNA (501 acres), established in 1945, contains two plant communities It was established primarily to provide examples of virgin old-growth Port-Orford-cedar. Both RNA's with Port-Orford-cedar have been infected since about 1967 with Port-Orford-cedar root disease, an introduced pathogen The ability of the RNA's to retain Port-Orford-cedar is receiving much attention The Wheeler Creek RNA (336 acres) was established in

1972 to preserve an example of redwood forest near the northern limits of its range This RNA contains three plant communities

Potential Research Natural Areas

Ecologists have identified four sites on the Forest suitable for establishment of new RNA's Hoover Gulch, Lemmingsworth Gulch, Cedar Log Flat, and Craggy Peak (Figure II-5) See Appendix F for detailed descriptions. Hoover Gulch (1,292 acres) contains three plant communities (cells) not represented in other RNA's. Lemmingsworth Gulch contains eight plant communities on 965 acres. It is marked by a sharp contrast between geologic substratum which results in a dramatic contrast in vegetation types, including seven sensitive plant species. Cedar Log Flat (441 acres) contains 10 sensitive plants and one plant community type (Jeffrey Pine-Grass at low elevations) The Craggy Peak site contains six plant communities. Two plant communities on 100 acres occur in the Siskiyou portion Another 1,100 acres, containing the remaining four plant communities, are located on the adjoining Rogue River National Forest.

CURRENT DEMANDS, WANTS, AND DESIRES

Three Planning Problems, which reflect current demands, pertain to management of sensitive or unique plant resources.

2. "How Much Old-Growth Forest Should Be Preserved?"

Some people have expressed a desire to preserve unique stands of old growth in various locations in the general forest. They feel these areas should be set aside for purposes of study, and aesthetic and biological diversity values.

5 "How Should Sensitive Plant Resources Be Managed?"

Approximately 40 percent of the Forest is habitat for sensitive and rare plants. The large variety of plants present has generated considerable local, state, and national notoriety Citizens interested in the botanical resources of the Siskiyou National Forest (including RNA's) feel that unique concentrations of rare plants should be protected from detrimental change There is concern that some sensitive plant areas could be overused. A decision can be made to either ignore sensitive plants and their habitats, or manage these resources to protect their inherent values.

9. "How Should Mineral Resources of the Forest Be Developed in Coordination With Management of Other Resources?"

Some citizens are concerned that protection of botanical resources may have a detrimental effect on mining operations (and to a lesser extent, timber).

ABILITY TO SATISFY DEMAND

2 "How Much Old-Growth Forest Should Be Preserved?"

Five sites (total acreage 1,321) have been identified which contain outstanding examples of old-growth stands (very large, old trees). Some or all of these sites can be excluded from timber harvest through land allocations such as Botanical Management Areas, or they can remain as areas which will eventually be harvested.

5 "How Should Sensitive Plant Resources Be Managed?"

Nineteen potential Sensitive Plant Botanical areas have been identified along with four potential RNA's (all containing sensitive or rare species). Potential Botanical areas total 36,917 acres, proposed RNA's total 2,799. These sites can be individually allocated as Botanical areas or RNA's, or the sites can retain their present land allocation status If, in the future, new data on plant habitat requirements show a need for increased allocations of certain types of habitat, the Forest will have the ability to make those allocations for at least the next two decades, and possibly longer.

Standards and Guidelines can be developed to manage (protect, enhance, and rehabilitate) sensitive plant resources Forest wide. Special precautions can be taken in layout of timber sales and location of roads to make sure the needs of sensitive species are met Vegetation management activities can be altered or avoided in areas where sensitive species are known to exist In some cases, individual management plans can be devised for specific species, such as *Bensoniella oregana*, a plant which could be heavily impacted by timber management activities More intensive inventories can be conducted in sensitive plant concentration areas; intensive surveys can be made for specific sensitive species Capital investments can be made to improve habitat for sensitive species.

9 "How Should Mineral Resources of the Forest Be Developed in Coordination With Management of Other Resources?"

The Forest Service has the opportunity to work with mining interests to design, prescribe, and recommend ways to prevent resource damage to sensitive plant habitats Areas with significant sensitive plant values may be withdrawn from mineral entry. Restrictions (high, moderate, or low) on mineral extraction activities can be developed to protect sensitive plant resources. Standards and Guidelines can be developed to provide basic management direction for conservation of sensitive plants

AIR QUALITY

EXISTING CONDITION

Air quality degradation from forest fires has been an output of natural ecosystems for thousands of years, cycling carbon and other materials into the atmosphere (Komarek 1970). Forest fires, along with natural hydrocarbon emissions from plants and emissions from volcanic eruptions, are major sources of natural air pollution (Pecora 1970, Went 1960). During 1984, wildfires accounted for about 13 percent of the state-wide fine particulate emissions in Oregon which impair visibility (ODEQ 1985).

The combination of good air circulation along the Pacific coast and relatively limited industrial development have resulted in only minor air quality problems west of the coastal crest. East of the crest, however, inversion layers combine with topography, trapping pollutants and causing serious air quality problems in the Rogue River valley. This condition occurs most commonly in the fall and winter months and to a limited degree in the early spring. For Medford, the afternoon ventilation index is classed as "poor" over half the time from October through February. The Medford/Ashland air quality maintenance area, 30 miles east of the Forest, frequently exceeds Federal and State standards for particulates, carbon monoxide, and photochemical oxidants (smog). The particulates, in the form of soot, dust, and fumes, are mostly the result of industrial emissions, and residential and industrial woodburning. Smog and carbon monoxide are produced by automobiles and, to a lesser extent, industries. Grants Pass also has a particulate problem, but it has not reached noncompliance levels.

Of all the current management practices on the Forest, prescribed burning has the greatest impact on local air quality. This impact is only temporary in nature and, unlike major emitting facilities such as factories, is difficult to quantify.

Total suspended particulate (TSP) emissions from National Forest lands in southwestern Oregon have been analyzed (U S Forest Service 1984) and individual Forest baselines developed as a result of that analysis The baseline level for the Siskiyou is 7,300 tons annually This baseline value represents the arithmetic average of the annual TSP production for the Forest for the years 1975 through 1979 (see Table III-19). The average annual production of TSP from forest lands in Oregon during the same period was 92,835 tons. In 1982, TSP output from the Forest was less than 3,000 tons while the State-wide production was approximately 45,600 tons Estimated TSP emissions for broadcast burning on the Siskiyou range from 1,000 to 2,600 pounds per acre burned, with an average of 1,750 pounds of TSP per acre burned

Table III-19. Estimated Production of Total Suspended Particulate (TSP) Emissions for 1975-1979

Year	Estimated Fuel Consumed (Tons) 1/	Estimated TSP (Tons) 2/
1975	230,119	5,753
1976	353,707	8,843
1977	293,447	7,336
1978	363,973	9,099
1979	164,616	4,115

1/ Data extracted from the Oregon Smoke Management Plan, Annual Report, and does not include fuel consumed by prescribed fire on the California portion of the Forest
2/ An emission factor of 50 pounds of TSP per ton of fuel consumed was used in the estimates (Ward and others 1976)

Class I areas are special areas protected for their air quality related values The Federal Class I area located on the Forest is the original portion of the Kalmiopsis Wilderness as defined by the Clean Air Act (PL 88-206, as amended) Preliminary results of visibility monitoring within the Kalmiopsis (ODEQ 1985) indicate that the visual range is quite good The median summertime standard visual range is 95 miles. Ten percent of the time the standard visual range exceeds 178 miles Visibility is temporarily impaired by smoke from prescribed burning operations or pollutants from unknown sources. Sources of natural impairment include fog, high humidity, rain, wildfire smoke and aerosols associated with vegetative emissions of terpenes.

Other nearby Class I areas that could be impacted by Forest activities include Marble Mountains, Diamond Peak, and Mountain Lakes Wildernesses, administered by the Forest Service; and Crater Lake and Redwood National Parks, administered by the National Park Service. Redwood National Park, located approximately 15 air miles south of the Forest, is a Class I area with the most potential for impact

Four Designated Areas (i.e , smoke sensitive areas) are located within 35 miles of the Forest boundary. These are Coos Bay, Medford/Ashland, Grants Pass, and Roseburg All of the Designated Areas have a ceiling (maximum vertical boundary) of 2,500 feet except Coos Bay, which has a ceiling of 2,000 feet. Over the past 10 years, smoke from prescribed fire operations on the Forest has intruded into these Designated Areas on five occasions

CURRENT DEMANDS, WANTS, AND DESIRES

Air quality was not raised as a separate issue during the initial scoping of the Forest Plan It is closely tied to issues relating to residue management, visuals, and management concerns about using fire to protect and enhance Forest resources Air quality and smoke management were raised, however, as a public issue in the scoping process for the Regional Guide

National Ambient Air Quality Standards have been developed by the Environmental Protection Agency under authority of the Clean Air Act Amendments (PL 91-604). The standards establish acceptable levels for certain criteria pollutants. One is TSP, the visible component of smoke; the maximum annual geometric mean for TSP shall not exceed 75 micrograms per cubic meter of air. A 24-hour concentration limit of 260 micrograms per cubic meter was also established, and it shall not be exceeded more than once per year. The 1977 Clean Air Act Amendments (PL 95-95) contained specific provisions for dealing with visibility and visibility impairment in Class I Areas.

ABILITY TO SATISFY DEMAND

The potential exists for serious air quality problems in the Rogue Valley. The specific problems, however, are likely to be most heavily influenced by industrial development, residential woodstove use, and population growth rather than by management practices on the Siskiyou National Forest.

If ways are found to create less smoke from each acre burned, the use of fire can be maintained at near-present levels while improving air quality (Sandberg 1983). The Forest utilizes a number of methods, techniques, and strategies to reduce the amount of smoke from prescribed burning operations. These have been incorporated into the Standards and Guidelines (Chapter IV, Forest Plan).

The average slash burn in western Oregon likely emits 1,800 to 2,800 pounds of TSP per acre burned if no special actions are taken to reduce emissions (Sandberg 1983). Harvesting of firewood is estimated to further reduce TSP production, i e , removing 3 cords per acre could reduce emissions by 6 to 10 percent. A YUM provision in the timber sale contract to yard material to a 6-inch by 6-foot specification would reduce TSP emissions by an estimated 17 to 30 percent A 4-inch by 4-foot YUM provision would reduce emissions by 30 percent or more Also, for each 1 percent fuel moisture increase in the large-fuels (3" to 9" in diameter), a 3 percent reduction in emissions should be experienced Burning in the spring or wetter periods should reduce emissions by 50 percent or more (Sandberg 1985)

Smoke management is not without costs. Management efforts to meet air quality standards and direction, while not exceeding the TSP baseline, will compound resource management complexities and raise the overall costs An analysis of the direct and indirect costs of smoke management programs by Sandberg and Schmidt (1982) indicated that complying with the programs on the west side of the Cascades increased costs $26 per acre burned.

Wildfires are a random occurrence in a complex environment No efforts other than suppressing the fire will be made to manage the smoke from these situations.

A permanent visibility monitoring station is located at Quail Prairie Mountain adjacent to the western edge of the Kalmiopsis Wilderness. This site monitors visibility across the northern portion of the Wilderness and provides information as to actual visibility changes.

FISH

Discussions in this section, when combined with those in the **SOIL AND WATER** section, are pertinent to resolution of Planning Problem #3, "How can the Forest's fish habitat, water quality, and soil productivity be maintained or improved?"

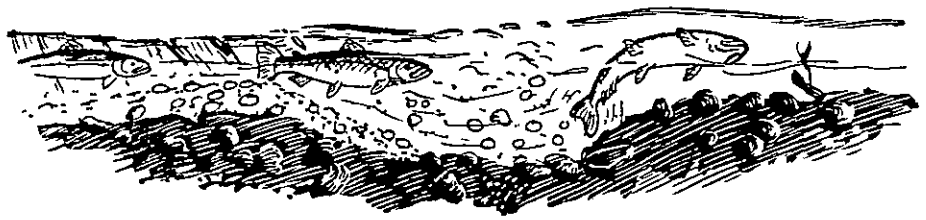
EXISTING CONDITION

Management responsibilities for the Forest's fish resources are shared between the Forest Service and state fish and wildlife agencies The state manages fish populations while the Forest manages fish habitat

Forest fish indicator species include fall chinook salmon, steelhead, and resident cutthroat trout. Habitat condition and population of these species directly correlates with all other Forest salmonids.

The Forest is known for its quality salmonid habitat Some of the highest quality anadromous fish habitat and fish populations in Oregon are located within the Siskiyou National Forest. Most of the salmonid habitat is provided by rivers and streams The Forest has a few small lakes which offer habitat for resident rainbow and brook trout.

All 19 of the Forest's Planning Basins contain streams that support salmonids (Figure III-17). Salmonids are known to occupy more than 1,150 stream miles on the Forest. Of this total, anadromous fish utilize at least 620 miles No major dams block upstream passage of fish to Forest streams.



The condition of Forest fish habitat is a critical factor in the establishment and maintenance of fish populations The following evaluation of existing conditions is based on our present knowledge of the stream systems·

1. Each of the Forest drainages has an adequate escapement potential for adult fish, to ensure sufficient reproduction and maintenance of salmonid stocks,

2 Forest spawning gravel quantity and quality is sufficient to provide for incubation and emergence of enough fry to fully stock existing rearing habitat; and

3. The quantity and quality of rearing habitat are critical components which influence the survival of juvenile salmonids and the carrying capacity in each stream

Many off-forest activities (e g , commercial ocean harvest) can also be important limiting factors for salmonid populations utilizing Forest streams

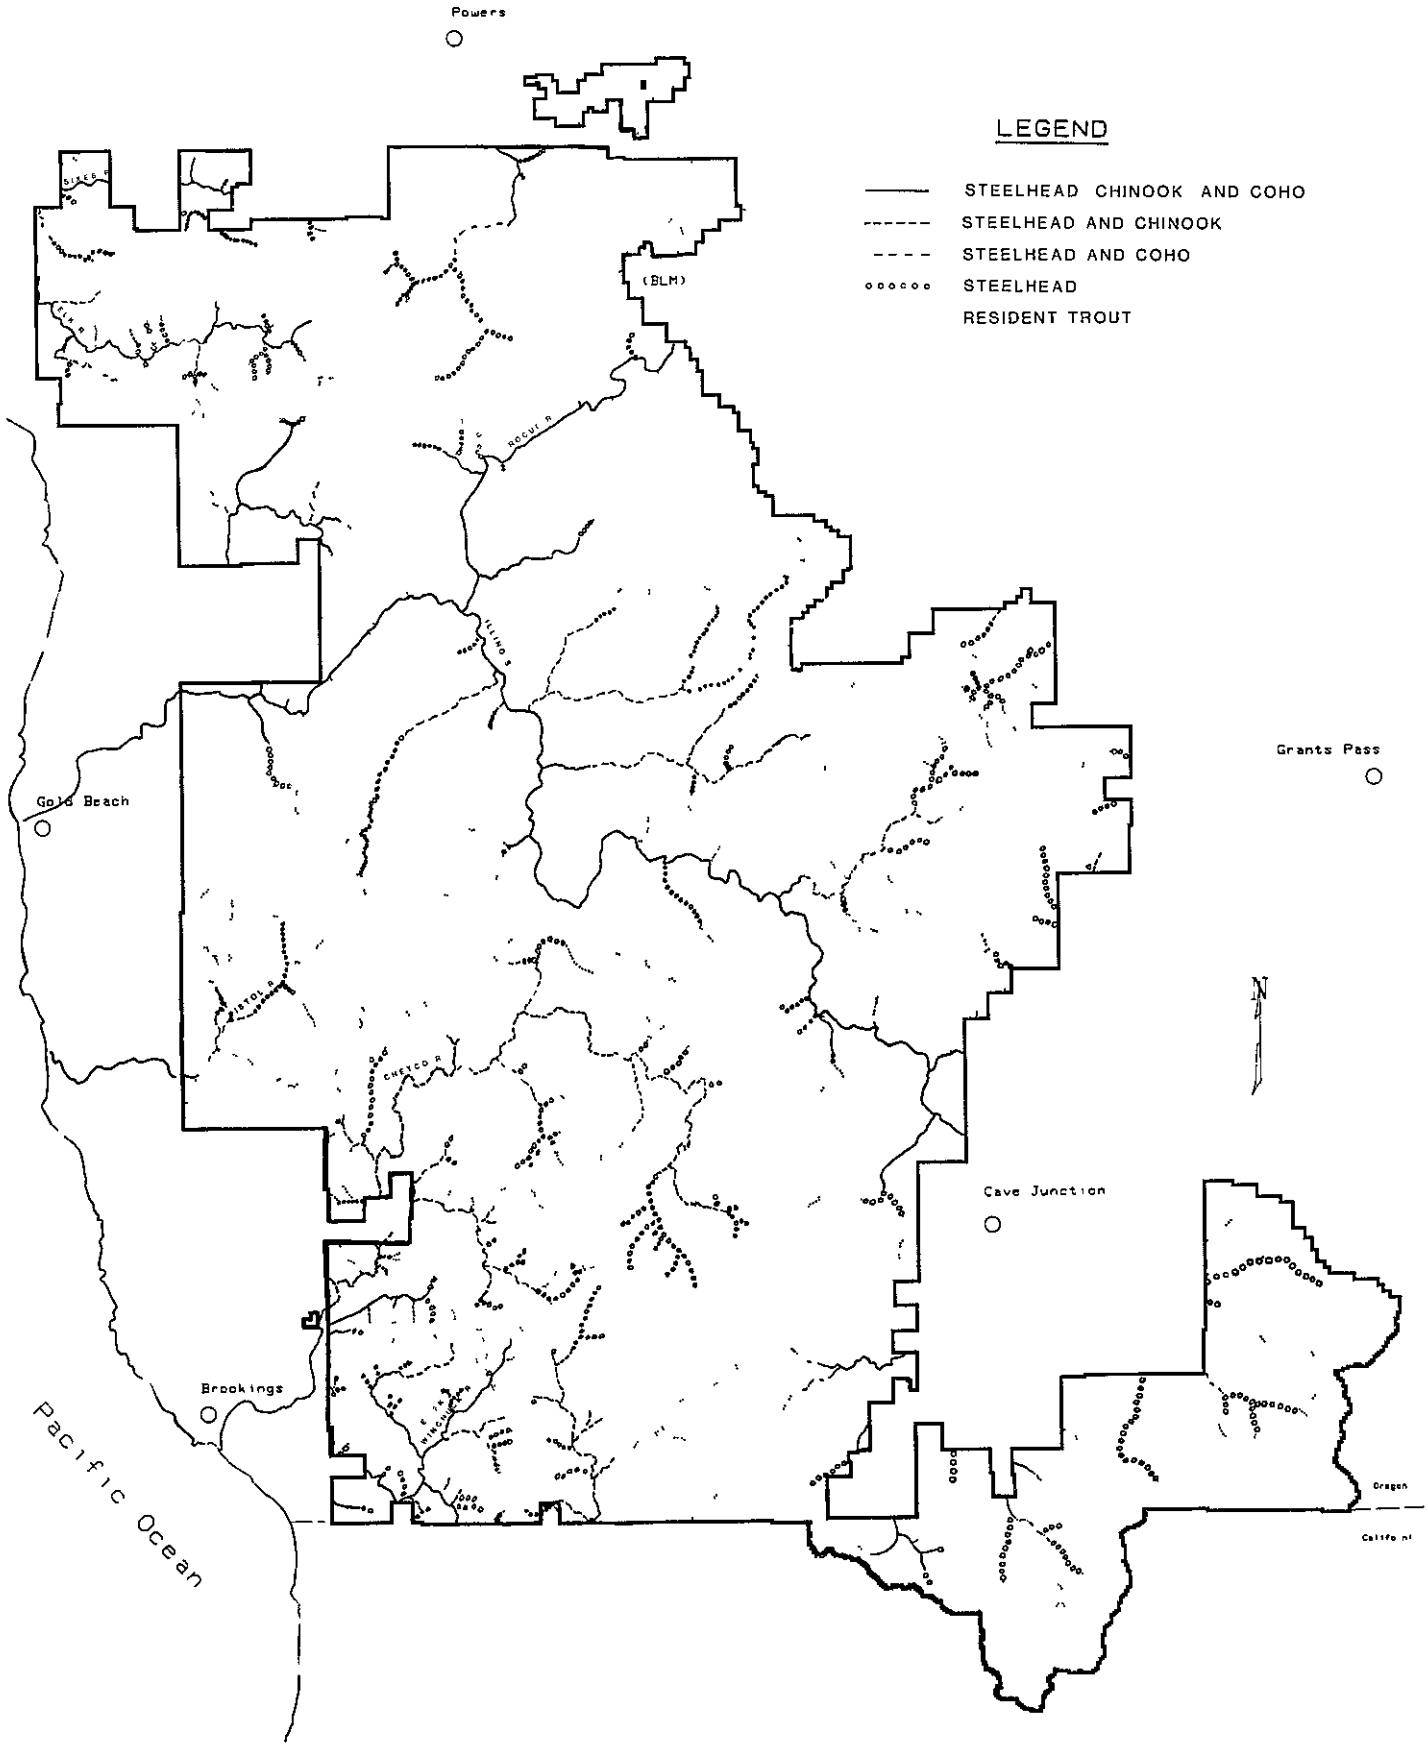


Figure III-17. Anadromous/Resident Fish Habitat Map

HABITAT CAPABILITY

In June of 1988 Forest biologists began a new inventory procedure for evaluating habitat capability of Forest streams. This procedure (Hankin and Reeves 1986) allows Forest biologists to evaluate fish habitat changes over time and provide them with a more extensive data set on key fish habitat factors. Such data is extremely valuable in determining salmonid habitat quality.

Recognized aspects of rearing habitat that present limitations to salmonid capability include flow, water temperature, pool depth, and instream cover (Physical and Biological Stream Survey 1935-1986). Major components of these limitations include the following.

Flow

Low summer flows are inherent to Siskiyou National Forest rivers and streams. Natural contributors to poor summer flow include geology, low elevation, and climate. The problems of natural low flows are today compounded by water withdrawal. Planning Basins currently having the most serious flow problems include the Upper Illinois, Lower Illinois, Galice/Slate, Rough/Josephine, and Sucker. Flow into and out of the Forest basins is essential to survival of salmonids in entire river systems. Juvenile salmonids which are excess to Forest rearing capability must rear off-Forest. However, as human demands for water increase, these displaced fish will face increasing stress and mortality.

Water Temperature

A serious threat to juvenile and adult salmonid survival during summer months is water temperature Forest water temperature problems are a result of geology, low elevations, low summer flows, high groundwater temperatures, and stream shade canopy. Forest summer stream temperatures are inherently high. Removal of stream shade and water withdrawals have increased temperatures in some streams

Stream survey reports in 1936 identified water temperatures of 78 degrees Fahrenheit at the mouth of the Illinois River (Ziesenhenne 1936). Optimum water temperature of 54 degrees Fahrenheit is listed for chinook salmon and 50 degrees Fahrenheit for steelhead (Reiser and Bjornn 1979) Summer water temperatures in portions of all nine major river systems exceed these temperatures In some Forest streams, the water temperatures exceed the upper lethal limits for salmonids. Of importance to *understanding impacts of water temperature upon aquatic life is the analysis of cumulative impacts from* natural and human activities upon aquatic habitat both on- and off-Forest.

Salmonid survival in all river systems transecting the Forest is highly dependent upon cooler inflow from well-shaded tributary streams Those Planning Basins mentioned as having flow problems also have serious water temperature problems for selected reaches. Other Planning Basins having serious temperature problems include the Lower Chetco and Coquille

Instream Cover

The more important instream cover components for survival of Forest salmonids include pool depth, instream woody material, large boulders, and surface turbulence. The interaction of these components are factors that determine the quality of rearing habitat Figure III-18 shows the relationship between fish density and temperature in Forest streams

1. **Pool Depth** During low summer flows, pool depth of medium and small Forest streams becomes *critical and is considered an important limiting factor for 1+ age class steelhead, coho, and resident* trout Forest stream surveys have identified the need for pool depths of three feet minimum for low-flow survival of juvenile steelhead and coho to the smolt stage (King and others 1984).

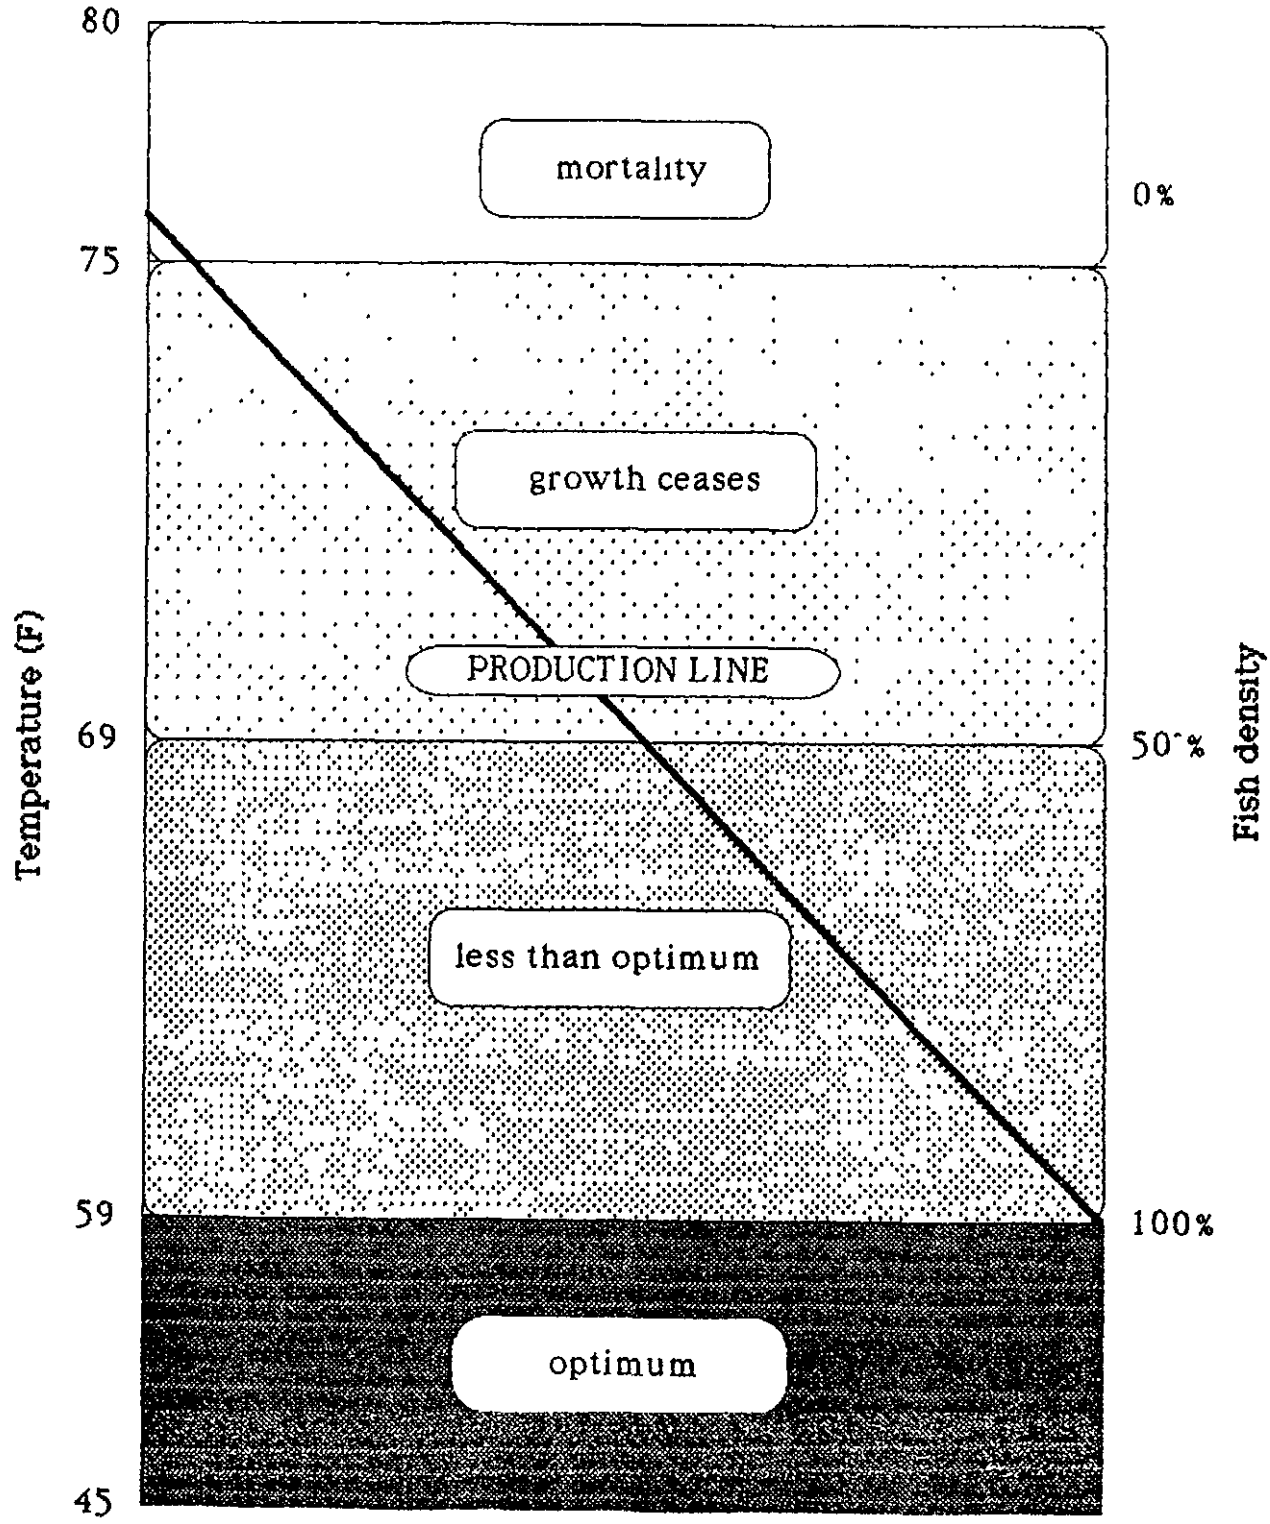

Figure III-18 Estimated Relationship between Stream Temperature and Fish Density for the Siskiyou National Forest

Pool depth is strongly associated with juvenile salmonid abundance, especially steelhead The average summer pool depths are less than three feet in most third, fourth, and fifth order Forest streams (Physical and Biological Stream Survey 1935-86)

2. **Large Woody Material.** Stream surveys have shown that large woody material, which is defined as material over 18 inches in diameter and 15 feet long, is an extremely important component of salmonid habitat The presence of woody material is positively correlated with juvenile fish abundance For a review of the importance of woody material to stream ecosystems, refer to Bisson and others (1986)

   Forest Class I and Class II streams generally have low levels of naturally-occurring large woody material. The retention of large wood is low in Forest streams due to high stream gradient, confined narrow channels, and high winter flows To varying degrees, lack of woody material in the Forest streams limits the ability to rear juvenile salmon, steelhead, and resident trout in all 19 Planning Basins.

3. **Large Boulders.** Large boulders are very important to maintaining channel stability by providing roughness, thereby reducing stream velocity during peak flows Large boulders benefit salmonid habitat much the same as large woody material, especially by providing escapement areas for small fish. Large boulders are generally abundant in Forest streams, particularly in the upper stream reaches

4. **Surface Turbulence.** In addition to depth and woody material, juvenile and adult salmonids are strongly associated with areas of increased surface turbulence. Turbulent areas provide cover, increased access to food, and more oxygen Surface turbulence is generally associated with riffles, cascades, and heads of pools

Bedload Sediment

Sediment, above background levels, can affect both spawning and rearing of salmonids. Stream bedload is closely correlated to soils, geology, climate and land management activities Excess sediment loading in lower gradient stream reaches promotes channel instability. This has been identified as a major factor which can contribute to the poor survival of salmonid eggs and fry Chinook salmon spawning success is especially vulnerable to stream channel aggradation and associated channel instability during high winter flows (Frissell and others 1987) Oregon Department of Fish and Wildlife (ODFW) biologists have found a direct correlation between Rogue River Basin chinook salmon juvenile production and intensity of winter storm events (Satherwaite 1988). Intense winter storm events can adversely affect spawning success for all salmonid species, especially chinook salmon

Excess bedload sediment can also affect salmonid rearing habitat by reducing the number, depth, and quality of pools, and thus reduce habitat complexity. Streams on Forest administered lands have generally higher energy or "stream power" due to steeper gradients, coupled with high winter stream flows and confined, narrow reaches Stream power is normally sufficient during winter months to move annual bedload sediment without excessive or adverse aggradation.

Wide, low gradient stream reaches are most susceptible to channel aggradation and meandering In particular, the lowest gradient reaches of small to medium-sized rivers (e g , Euchre Creek and Pistol River) on coastal alluvial plains are recognized as being extremely susceptible to cumulative impacts from excessive coarse sediment inputs and physical disturbance The potential for activities to cause channel aggradation will be evaluated both for direct and cumulative effects (Refer to Appendix D, Forest Plan)

Summary of Habitat Capability

Major habitat aspects currently limiting Forest salmonid rearing capability are shown by Planning Basin in Table III-20 Rearing habitat limitations are expressed as a high, medium, or low, along with estimated reduction in juvenile salmonid habitat capability potential. This table can be used to estimate the percent loss in salmonid rearing capability for Forest Planning Basins The numbers indicate the estimated percent reduction in rearing capacity The values are additive. For example, in Basin 20 (Sucker) the total estimated loss in capability would be 5+5+5+5 = 20 percent.

Table III-20 Major Habitat Aspects Currently Limiting Forest Salmonid Rearing by Planning Basin (in Percent) 1/

			Instream Cover	
Planning Basin	Flow	Water Temp	Pool Depth	Large Wood

1/ Species code: ST = steelhead; CH = chinook salmon; CT = cutthroat trout; and CO = coho salmon
2/ High sensitivity to impacts. 0-2 percent gradient.
3/ Relates to stability of spawning gravel; the factor rating is based on the energy of high flows and evidence of aggradation. (+) = Spawning habitat would be considered excellent; spawning gravel is expected to be relatively stable in most storm events. (0) = Spawning habitat of average quality. Spawning gravel would be stable in average winter flows. (-) = Spawning habitat would be considered poor. Spawning gravel would be unstable in most winter storms.
4/ (+) = Peak summer water temperatures are excellent for streams in this area; temperatures would rarely exceed 68 degrees F. (0) = Peak water temperatures are moderately high (68 to 72 degrees F) and would be expected to have some negative impacts on salmonid growth and density. (-) Peak water temperatures are often very high (> 73 degrees F); and extremely stressful for salmonids.
5/ Ratings with single entries (0) represent the average condition for all fish bearing streams within the basin Ratings with multiple entries (0/-/+) represent the range of conditions for various creeks, indicating that major differences occur between individual streams.
6/ Risk of water temperature increase, channel aggradation, or reduction of large woody material in various watersheds could detrimentally affect fish habitat. (H) = High Risk (M) = Moderate Risk (L) = Low Risk.

FISH POPULATIONS

The aquatic habitats of the Forest support several types of fish (see Table III-22) Anadromous salmonids utilizing Forest habitat for spawning, rearing, or migration include fall chinook salmon, spring chinook salmon, coho salmon, winter steelhead, summer steelhead, and searun cutthroat trout. Non-salmonid anadromous fish using Siskiyou National Forest habitat include green sturgeon, white sturgeon, and American shad.

Stream surveys verify 1,150 stream miles of resident trout use. Brook trout have been stocked by the Oregon Department of Fish and Wildlife in some Forest lakes

Four *warm water game fish* species are found on the Forest. Limited habitat presently restricts distribution to only a few areas. Ten *nongame fish* species occur on the Forest River and stream habitats support both native and introduced species. Invasion of new areas by nongame fish is often an indicator of habitat change.

Table III-22. Species of Fish Occurring on the Forest

Game Fish		Nongame Fish
Cold Water	Warm Water	
Salmonid Chinook Salmon Fall Chinook Spring Chinook Coho Salmon Rainbow Trout Anadromous Rainbow (Summer Steelhead) (Winter Steelhead) Resident Rainbow Brook Trout Cutthroat Trout Sea-run Cutthroat Resident Cutthroat Non-salmonids White Sturgeon Green Sturgeon American Shad	Largemouth Bass Bluegill Black Crappie Brown Bullhead	Redside Shiner Carp Sucker Klamath Small Scale Bridgelip Longnose Sculpin Coast range Prickly Reticulate Stickleback Squawfish

At least 400 miles of Forest stream contain populations of 8-inch (minimum length) fish. Average resident trout angler success on the Forest is approximately 1.6 hours per fish harvested Harvest is approximately 36,130 trout from Forest stream or river habitat per year (King 1985).

Ten lakes and one pond on the Forest produce approximately 8,200 trout per year; these waters are stocked by the Oregon Department of Fish and Wildlife Bolan, Babyfoot, and Tannen Lakes receive the majority of angler pressure.

The approximate annual production of adult anadromous salmonids attributed to Forest habitat is shown in Table III-23.

Table III-23. Annual Production of Adult Anadromous Salmonids Attributed to Forest Habitat

Species	Number of Smolts 1/		Smolt to Adult Survival (%) 2/		Adults
Chinook Salmon	2,025,275	X	5 8	=	117,466
Coho Salmon	83,345	X	5 5	=	4,584
Steelhead	335,700	X	10 0	=	33,570
1/2-lb Rogue Steelhead	600,000	X	10 0	=	60,000 3/
Sea-run Cutthroat	127,600	X	5 0	=	6,380

1/ Smolt production from Siskiyou habitat determined in cooperation with the ODFW was based on (1) Total miles of quality anadromous fish habitat, (2) Estimated escapement, and (3) Angler harvest
2/ Smolt to Adult Survival Fisheries Input, Forest Land and Resource Planning, USFS-Pacific Northwest Region, December 1981, plus consultation with ODFW Biologists R Hasselman and R Berry (1985) (Available in the Planning Records)
3/ Immature Steelhead

Contributions of individual Planning Basins to annual adult anadromous salmonid production are shown in Table III-24.

Table III-24 Current Adult Anadromous Salmonid Production Attributed to Forest Smolt Habitat Capability (Wild Fish Only) 1/

1/ Total average annual adult production including both catch and escapement Data compiled from ODFW catch to escapement records and personal correspondence with ODFW biologists Does not include catch and release (King 1985)
2/ Includes both summer and winter adult steelhead
3/ Immature steelhead of 14-20 inch length
4/ Spring chinook not produced on the Forest but reared in lower reaches of the Rogue River on Forest habitat

FOREST FISH HARVEST

Anadromous Salmonid Harvest

The approximate numbers of salmon, steelhead, and sea-run cutthroat trout derived annually from Forest habitat production which enter sport and commercial fisheries are shown in Table III-25.

Table III-25. Annual Anadromous Salmonid Harvest Derived from Forest Habitat

Species	Total Adults	Catch/Escapement 1/	Catch/Average Annual Harvest 2/
Chinook Salmon	117,466	3 1	88,100
Coho Salmon	4,584	5 1	3,820
Steelhead (adult)	33,570	0 55 1	11,912
1/2-lb Rogue Steelhead	60,000 3/	1.1	30,000
Sea-run Cutthroat	6,380	1 4	1,276

1/ Derived in consultation with the ODFW (King and others 1985) Harvest estimates and ODFW creek census data available in the Planning Records
2/ Includes both sport and commercial harvest for salmon and inland sport catch for steelhead and cutthroat
3/ Immature summer steelhead

Marine and Freshwater Catch

Division of marine and freshwater salmon sport catch (of fish production attributable to Siskiyou National Forest habitat) is approximately 66 percent ocean commercial harvest, 27 percent offshore harvest, and 7 percent inland sport harvest (developed from Pacific Fisheries Marine Council Records 1982-83). Division of commercial harvest and salmonid sport is shown by Planning Basin in Table III-26

Table III-26. Average Annual Salmonid Commercial and Sport Fishing Existing Capability by Planning Basin

Planning Basin	Pounds	WFUD's
01 - Elk/Sixes	49,734	3,418
02 - S F Coquille	7,967	3,928
03 - Lobster	12,961	1,909

Total (Base)	879,913	65,037

Resident Trout Harvest

The annual resident trout harvest from Forest river or stream habitat is over 36,000 fish, while the lakes and pond trout harvest is approximately 8,000 trout per year (King and others 1985).

CURRENT DEMANDS, WANTS, AND DESIRES

Both sport and commercial fishermen desire more fish from Forest habitat Desires relate not only to harvest, but also to the aesthetic values of seeing fish or just knowing that fish are in streams or rivers. Increasing numbers of people enjoy observing adult salmon or steelhead moving upstream over low falls or spawning on shallow rivers and stream riffles.

The demand for the anadromous fisheries has grown steadily A regional projection of a 1.6 percent annual growth results in an additional 16,900 WFUD's by the year 2000 This demand for sport and commercial fisheries greatly exceeds supply. State and Federal harvest restrictions, in terms of season lengths, gear, and total allowable tonnage, all regulate angler success and business expansion opportunity Even with stringent State harvest regulations, the future demand for Forest fisheries will increase.

Approximately 50 percent of the anadromous fish within the rivers of the four-county area are produced on-Forest Current average annual harvest in terms of commercial harvest and WFUD's, attributed to Forest habitat, is shown by Planning Basin in Table III-26.

OFFSHORE FISHERIES

Anadromous fish produced in Forest habitat provide a very prominent offshore sport and commercial fishery. Commercial fishing is one of the most important industries in terms of income and employment within Coos and Curry Counties. Coos and Curry Counties rank high in terms of total commercial salmon landing in the State Information provided by the ODFW shows that, of the Oregon Offshore Commercial salmon troll fishery for 1980-1987, 53 percent of the Chinook and 40 percent of the coho harvest come to Coos or Curry Counties (Osis 1988) Salmon derived from Forest habitat production contribute to offshore sport and commercial fishing from central California to Alaska Commercial harvest involves international planning efforts Recommendations for offshore harvest are presented by the Pacific Fisheries Management Council and ODFW based upon projections of ocean habitat conditions and stock size. Seasonal angling restrictions are a reflection of adult abundance

RECREATIONAL FISHERIES

The Forest provides sport fishing opportunities for local residents and tourists, thus contributing to the area's tourism-related employment. An important factor which enhances this recreational fishery is the access to Forest land provided by roads, trails, campgrounds, and boat launches. Off-forest, streams are more inaccessible due to private ownership along the banks

Resident trout and juvenile steelhead provide an important inland sport fishery. Native trout, and the habitats they occupy, provide high aesthetic value to recreationists Angler use of Forest lakes averages approximately 1,100 WFUD's per year Forest river and stream trout anglers enjoy approximately 4,000 WFUD's per year

ABILITY TO SATISFY DEMAND

Presently the demand for the salmon in offshore commercial and sport fishery far exceeds supply Availability of port docking and facility capacities during the peak angling seasons limit or discourage angler access The Forest's ability to satisfy the increasing demand for salmonid fish centers around resolution of Planning Problem #3, "How can the Forest's fish habitat, water quality, and soil productivity *be maintained or improved?*"

The following actions offer excellent means to potentially satisfy demand for salmonid fisheries derived from forest habitat production

Riparian Management

Retaining streamside vegetation for shade and other purposes will also maintain riparian zone integrity and minimize excessive entry of sediments into stream channels Important woody material sources will be retained. Distribution and transport of organic nutrient sources will also be provided, along with maintenance of instream productivity.

Riparian Prescription B is designed as the Management Requirement to meet water quality standards through maintaining current water temperature Integrity of the riparian area is achieved through limitations on activity within the Streamside Management Unit Both overall habitat capability and existing high quality habitat conditions would be maintained.

Application of Riparian Prescriptions C or Minimum Level would provide for varying reductions in summer water temperatures over the Planning Basins Fisheries habitat improvement would be achieved through increases in effective canopy cover (shade) By the end of the third decade in basins where timber harvest already occurs, temperature would drop by an estimated 2 degrees Fahrenheit for Prescription C Either Prescription C or Minimum Level would enhance riparian conditions in excess of Prescription B over time through reduction in water temperature and the addition of large woody material and organic detrital nutrients to stream and river systems. Application of Riparian Prescription C is modeled to increase salmonid capability by approximately 10 percent in those basins where it is applied (King and others 1984)

Supplemental Resource Management Areas

Thirty streams and rivers containing 39,606 acres have been identified as potential Supplemental Resource Management Areas These areas represent to varying degrees higher salmonid rearing capability, high risk landtypes, recreation values, and critical wildlife habitat Long-term salmonid habitat capability in these streams can be given added protection by providing a one-eight mile corridor on each side of the stream No programmed timber harvest within the riparian area and adjacent slopes (inner gorge) would provide an extra measure in protecting long-term salmonid habitat capability.

Capital Investment

Rearing habitat capability for anadromous salmonids can be increased through capital investments designed to improve features such as stream pool depth, gravel and fish passage Capital investments are planned to enhance the existing habitat Selection of areas for enhancement will consider predicted benefits to the fishery and existing habitat conditions. Streams with natural temperature or bedload conditions unfavorable for fish may not gain much from the addition of structures. The need and desirability for instream fish habitat work will be evaluated on a site-specific basis. Instream structure work on the Forest must be designed to be aethetically acceptable; thereby, native materials such as rock or logs are preferred.

Habitat enhancement includes not only instream structures, but incorporates total management of the riparian and upslope areas as well. Beyond land allocations, capital investments designed to improve salmonid spawning, rearing, and migration habitat offer opportunities to expand salmonid habitat capability In those Forest areas where capital investments have been made, salmonid capability and populations have been improved by approximately one-third above background levels.

Timber Harvest Activity

Utilizing BMP's (see Appendix G, Forest Plan), biologists generally agree that harvest evenly distributed in terms of time and space over suitable lands offers the best management options for maintaining fish habitat capability (conclusion reached by local biologists Jennings, Mullarkey, Riickula, and King in 1986) This option reduces the potential for accelerated sediment yields from Forest activity to Forest streams or offsite rivers and estuaries. When planning timber management and other resource activities, consideration must be given to the potential cumulative impacts on the aquatic environment. Good planning and implementation of land management practices offer the best options for maintaining and improving Forest salmonid habitat capability. Capital investment for instream project work would only be undertaken where land management practices are at least maintaining watershed conditions

Project-Level Planning

The Forest contains key habitat reaches that are extremely important. The identified key streams or stream reaches having special attributes in terms of salmonid production need full consideration for their protection and maintenance of capability during project-level planning.

SUMMARY OF POTENTIAL HABITAT IMPROVEMENT

The anticipated change in salmonid habitat capability due to habitat improvement is displayed in Table III-27

Table III-27. Management Option and Anticipated Gain in Salmonid Habitat Capability by Planning Basin 1/

Planning Basin No	Name	Riparian Rx C and Min Level	Supplemental Res Mgmt. Areas	Timber Harvest Dispersion	Capital Investment
01	Elk/Sixes	H 2/	H 3/	H 4/	L 5/
02	S F Coquille	H	M	M	M

19	E & WF Illinois	H	M	L	H
20	Sucker	H	M	M	M

1/ H-High, M-Moderate, L-Low, 0-Negligible (all in Wilderness)
2/ Gain primarily from water temperature reductions, naturally occurring woody material, and decreased risk of sedimentation
3/ Based on criteria which includes capability to rear juvenile salmonids, water temperature influence over offsite salmonid production, percent of Forest land within drainage being evaluated, and streamflow as it relates to fish habitat
4/ Based on percentage of tentatively suitable lands within each Planning Basin with high erosion hazard rating
5/ Based on Forest prioritization of Planning Basin for capital investment (Forest memorandum 1983, Planning Records)

WILDLIFE

EXISTING CONDITION

Management responsibilities for the Siskiyou National Forest's wildlife resources are shared between the Forest Service and state fish and wildlife agencies. The states manage individual animal species, while Forest Service responsibilities are fulfilled primarily through habitat management The Oregon Department of Fish and Wildlife (ODFW) provided criteria for use in developing and assessing DEIS alternatives (ODFW 1985a).

More than 250 wildlife species occur on the Forest, with only 22 classified as game animals or furbearers The Forest harbors 70 species of mammals, over 150 bird species, and 38 species of reptiles and amphibians Bird species include both migrants and residents These animals occupy a diverse array of habitats

ENDANGERED/THREATENED/SENSITIVE SPECIES

Two Siskiyou species, the bald eagle and peregrine falcon, are classified endangered or threatened. The bald eagle is discussed below Peregrine falcons are classified as endangered. They were not known to be present on the Forest until the first nesting pair was discovered in 1987; two additional pair were discovered in 1988. This bird is a cliff nester The species is managed in accordance with the *Recovery Plan for Peregrine Falcon (Pacific Population)* (USDI Fish and Wildlife Service 1982). As required by the Endangered Species Act, the Forest has consulted with the Fish and Wildlife Service during development of the FEIS and Forest Plan. Consultation in regards to endangered and threatened species is a crucial step in the planning process.

Of species found on the Oregon portion of the Forest, one bird is listed as sensitive, along with one amphibian, one reptile, and three mammals. The northern spotted owl is discussed below. The Siskiyou Mountain salamander is a resident of moist rock rubble areas east of Cave Junction The western pond turtle inhabits still waters of larger rivers such as the Rogue and Illinois. The white-footed vole, Townsend's western big-eared bat, and California wolverine occupy different habitats The vole resides in riparian habitat along small coastal streams. The bat feeds in a variety of habitats, but depends on caves (and sometimes buildings) for roosting The wolverine uses a variety of habitats, and does best in large undisturbed areas A wolverine was sighted on the Forest in 1985, and a handful of other sightings have been reported, beginning in the 1970s.

Sensitive species in California include the northern spotted owl, California wolverine, pine marten, fisher, and northern goshawk The first two species are also sensitive in Oregon. The marten, an indicator species, is discussed below. The fisher, rare on the Siskiyou, inhabits dense stands of many forest types The goshawk is an inhabitant of mature and old-growth coniferous forests

One species not listed as sensitive has generated considerable public interest in the last few years: marbled murrelet. This small seabird feeds in the ocean, but appears to nest in large conifers up to 30 or more miles inland. They have been detected flying in or around mature and old-growth forests at six locations in the Chetco River drainage. Research needs to be done to better locate and characterize forest habitat used by this species.

INDICATOR SPECIES

Forest management efforts consider all native vertebrate species. Several groups of species have special management needs These groups include: (1) species dependent on specialized habitat conditions, such as cavity-nesters; (2) species requiring early, mature, or old-growth forest conditions for optimum habitat; (3) popular game species; and (4) endangered, threatened, and sensitive species.

Eight Forest wildlife species have been selected as management indicator species (Table III-28). An indicator species represents all other wildlife which utilize the same habitat type. The species selected are commonly hunted, representative of specific habitats, or classed as endangered, threatened, or sensitive. Indicator species act as barometers for the health of various habitats and will be monitored to quantify habitat changes predicated by alternatives considered in this document.

Table III-28 Management Indicator Species - Wildlife

Species	Habitat Represented
Bald eagle 1/	Habitat corridors along major rivers
Osprey 2/	Habitat corridors along large creeks and rivers
Spotted owl 2/	Old-growth forest
Pileated woodpecker 2/	Mature forest
Pine marten 2/	Mature forest
Woodpeckers 2/	Wildlife trees (snags)
Black-tailed deer 3/	Early successional forest stages
Roosevelt elk 3/	Early successional forest stages

1/ Selected because of endangered/threatened status
2/ Selected because it represents specific habitat
3/ Selected because the species is commonly hunted

Bald Eagle

The bald eagle is Federally listed as threatened in Oregon and endangered in California A few of these birds are occasionally sighted on the Siskiyou National Forest, mainly along the Rogue and Chetco Rivers. Approximately 58,000 acres of the Forest are thought to be potential bald eagle habitat, however, extensive habitat inventories have not been conducted and only a small portion of the habitat is presently occupied. Sighting reports are collected and nesting sites are examined. Historically, these birds have nested along the Rogue River, and possibly the Chetco River In the past few years, two active nests were discovered on the lower Rogue River One nest is within the Wild Rogue Wilderness, the other is located on private land outside the Forest boundary.

The Pacific Bald Eagle Recovery Plan (USDI Fish and Wildlife Service 1986) lists the Rogue, Sixes, Chetco, and Illinois Rivers as key habitat areas. The Rogue is targeted for four recovery territories; the other Rivers for one each (targets are for all ownerships combined).

American Osprey

On a Nation-wide basis, the status of the American osprey is undetermined (USDI Fish and Wildlife Service 1973). At least 308 (+/-28) pairs of osprey nested within Oregon in 1976 (Henny and others 1978). In 1988 a minimum of 22 active osprey nests were located within the Forest boundaries. Most nests occurred along the Rogue River, but a few were located on the Illinois, Coquille, and Chetco Rivers Productivity figures for active nests are not known However, since 1975 the Forest osprey population has, at a minimum, remained stable, and may actually have increased. At least 58,000 acres of the Forest is osprey habitat, much of it occupied by nesting osprey. Osprey represent other species, such as river otter, which use the Forest's riverine habitat

Northern Spotted Owl

The State of Oregon classifies the northern spotted owl as threatened, while the California Department of Fish and Game considers it a "bird species of special concern " The Forest Service designates this owl as sensitive. Spotted owls are associated with multi-layered old-growth forests primarily confined to public lands. Old growth is defined in the Regional Guide (USDA 1984b, 3-40 to 3-41) A four-way interagency

agreement in August 1988 between the Forest Service, Bureau of Land Management (BLM), Fish and Wildlife Service, and National Park Service focuses on the fact that all Federal land managing agencies are integral to the success of maintaining spotted owl populations Spotted owl habitat areas on the Forest connect to networks on surrounding National Forests and BLM Districts

The Northern spotted owl represents over 150 other wildlife species which use old-growth forest habitat for all or part of their life cycles (Guenther and Kucera 1978, Brown 1985). Spotted owls have been sighted at over 150 different locations on the Forest from 1974 through 1988.

The Final SEIS for an Amendment to the PNW Regional Guide (USDA 1988b) provides a general description of suitable spotted owl habitat Specifically, the Siskiyou's spotted owl habitat occurs predominately in California Mixed Evergreen and Mixed Conifer vegetation types The Forest also supplies relatively small amounts of habitat for spotted owl in the Redwood and Cedar/Hemlock/Douglas-fir vegetation types. For a description of the Forest's spotted owl habitat, as related to the Spotted Owl Final SEIS, see Chapter IV of the Forest Plan (Management Area 8).

Lands mapped as mature or old growth in the 1979 timber inventory were generally considered to be spotted owl habitat. There were exceptions A significant proportion of the old-growth habitat in the Kalmiopsis Wilderness is fragmented; these stands were classified as not suitable for spotted owls. Most old-growth stands above 5,000 feet elevation were also classified as not suitable Because our planning data base does not differentiate between mature and old-growth forest, some mature forest stands are classified as spotted owl habitat However, this does not result in significantly skewed data; mature stands are few on the Siskiyou and are usually interspersed with old-growth Mature forest also serves well as feeding habitat. Approximately 90 percent of the mature and old-growth forest displayed in Figure III-15 is spotted owl habitat (a map showing the broad range of spotted owl habitat on the Forest is available at the Supervisor's Office)

Existing old-growth habitat on the Siskiyou can support approximately 153 pairs of spotted owls (maximum biological potential) (USDA 1988b) Although approximately 443,000 acres of mature and old-growth forest exist on the Forest, a maximum of 393,000 acres is considered suitable habitat for spotted owls

The Siskiyou National Forest SOHA network conforms to standards and guidelines established in the preferred alternative of the Final Supplement to the EIS for an Amendment to the Pacific Northwest Regional Guide: Spotted Owl Guidelines (USDA 1988b). The Siskiyou's SOHA's each contain 1,000 acres of suitable habitat, within 1.5 miles of the nest or suspected nest area. For more specifics on Standards and Guidelines for designated SOHA's, see Chapter IV, Forest Plan (Management Area 8).

To meet Management Requirements (MR's) for spotted owls, the Siskiyou National Forest needs to provide enough capable habitat to support a minimum network of 47 reproductive pair-sites Twenty-two sites are located in wildernesses and areas unsuitable for timber management; the other 25 (termed SOHA's) are located in areas which otherwise would support some level of programmed harvest (the effect on programmed harvest varies considerably from site to site). Wildernesses contain enough extra habitat (above MR needs) to support an additional 15 to 24 pair-sites Although extensive surveys have not been conducted in the 37 pair-sites in Wildernesses and areas unsuitable for timber management, owls have been found at 18 sites (Figure III-19, also See Chapter II for a more detailed discussion of MR's)

Most of the 25 non-Wilderness SOHA locations have been surveyed for spotted owls in the last five years The current status of these areas is listed in Table III-29. There are no viable alternatives to the three SOHA's listed as unknown; they are needed to insure proper distribution of habitat sites. The Forest will continue to monitor all sites (see Chapter V of the Forest Plan for details).

Table III-29 Status of Designated SOHA's (1984-1988)

Reproduction	Occupancy (pair)	Presence (single)	Unknown
5	10	7	3

Pileated Woodpeckers And Pine Marten

Pileated woodpeckers and pine marten represent the composite needs of over 160 wildlife species which utilize mature forest (Guenther and Kucera 1978, Brown 1985) For specific details on habitat needs of pileated woodpecker and pine marten, see Chapter IV of the Forest Plan (Management Area 8). The Forest contains an estimated 690 separate habitat areas suitable for breeding pairs of pileated woodpeckers (approximately 414,000 acres of suitable habitat) An estimated 2,700 separate habitat areas could support marten family groups, which include the female with young (approximately 432,000 acres of suitable habitat) Figure III-19 depicts habitat which must be allocated to meet MR's for pileated woodpeckers and pine marten The combined habitat networks for spotted owl, pileated woodpecker, and pine marten, along with intertwined Riparian areas, serve as an interlocking habitat system for all wildlife species which use mature and old-growth forest

Woodpeckers

The composite snag needs of woodpeckers represent all wildlife species which use cavities for nesting or denning. Over 75 of the Siskiyou's wildlife species use snag habitat (Guenther and Kucera 1978, Brown 1985)

In order to measure the ability to support cavity nesters, an index called "percent habitat capability" is used. It is based on data in Brown (1985) that indicates approximately 300 snags per 100 acres are required to support woodpeckers at the 100 percent level, or maximum population potential. For example, 150 snags per 100 acres would support woodpeckers at the 50 percent level.

Approximately 900,000 acres on the Forest are presently in an unmanaged condition and provide snags at background levels Of the remaining 192,000 acres, 52,000 acres are nonforested; the balance is cutover land. Timber stands harvested after installation of snag guidelines in 1976 retain enough wildlife trees to support woodpecker populations at 50 to 60 percent of potential. Areas harvested before installation of snag guidelines retain snags at various levels from 0 to 20 percent or more

Primary cavity excavators provide ecological diversity and habitat for many snag dependent species. By consuming forest insects, these birds may provide a suppressive influence on destructive forest pests. For these reasons a highly viable population of these birds is essential

Regional Management Requirements (MR's) for cavity excavators are set at 20 percent of their potential level (barely viable; not a functioning part of the ecosystem). An effective, highly viable, population level for these excavators is probably between 40 and 60 percent Consequently, the *Siskiyou Dead Tree (Snag) Guidelines* mandates that the Forest provide snags at the 60 percent level (the minimum acceptable population level for cavity nesters is 40 percent [FSM 1988]) See *Management of Wildlife and Fish Habitats in Forests of Western Oregon and Washington* (Brown 1985) and *Wildlife Habitats in Managed Forests, the Blue Mountains of Oregon and Washington* (Thomas 1979) for further discussion of management of this specialized habitat.

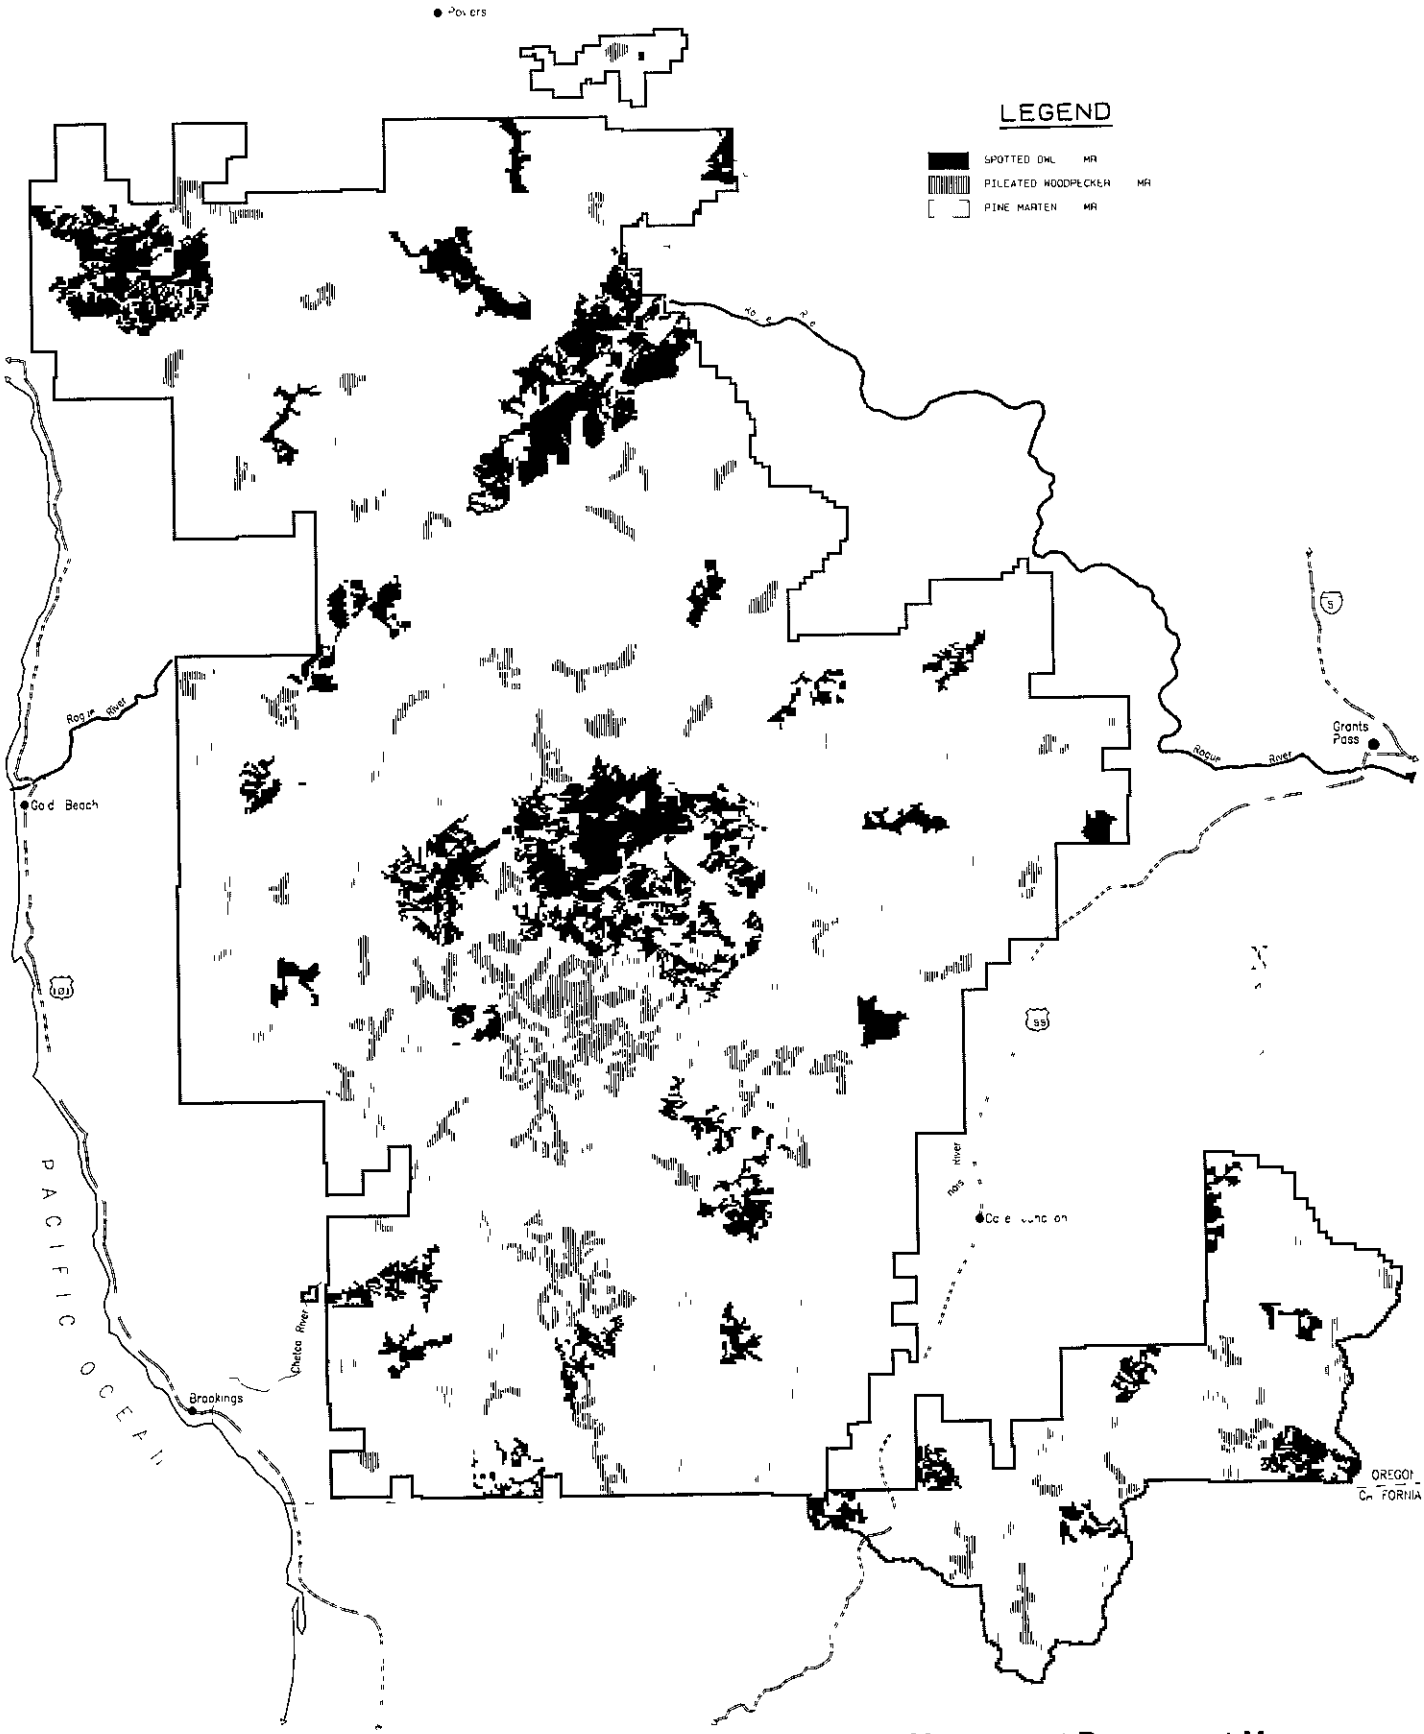

Figure III-19. Spotted Owl, Pileated Woodpecker, and Pine Marten Management Requirement Map

Blacktail Deer

Deer (and elk) use all successional stages, but natural or created openings provide the bulk of the feeding habitat (assumed to be the most restricted habitat component) Consequently, deer (and elk) represent over 180 other wildlife species needing young successional stages to meet all or some of their life requirements (Guenther and Kucera 1978, Brown 1985).

The actual size of the deer population is unknown, but the Siskiyou National Forest's habitat is probably capable of supporting 25-35,000 animals, based on the planned rotation of approximately 100 years for stands managed for timber harvest For planning purposes, habitat capability for the Forest's deer herd is estimated at 28,300 animals at the end of winter (April), private inholdings included This is approximately one deer per 42 acres. Areas managed for timber harvest have considerably higher deer populations; other areas have considerably less. Detailed information on modeled deer habitat capability is on file at the Supervisor's Office.

Oregon Department of Fish and Wildlife has suggested a population objective of 32,600 deer for the Siskiyou National Forest (ODFW 1980). Forest Service and ODFW estimates of habitat capability vary because different procedures were used to generate the numbers. Detailed criteria for forage/cover needs were outlined in a memo to the Forest Service (ODFW 1985a). In this document, the ODFW proposed a cover/forage ratio of 80 20 for the Siskiyou National Forest Both estimates recognize a stable cover/forage ratio of 80 20. The 80.20 ratio will be achieved in areas managed for timber, but generally will not be achieved in areas with no programmed harvest

The California portion of the Forest is not considered in the above calculations The deer population in this area is managed by the California Department of Fish and Game (McLaughlin 1984)

Approximately 905,000 acres (78 percent) are considered deer winter range, including private inholdings Included in the total are 514,000 acres (44 percent) of primary winter range. Winter range is not evenly distributed throughout the Forest. Primary winter range varies by Planning Basin from 2 to 97 percent; total winter range (primary and secondary) varies from 26 to 100 percent Aside from a few high elevation sites, the Forest has adequate habitat to support its deer population year round. A map of deer and elk winter range is available at the Supervisor's Office.

Roosevelt Elk

As with deer, elk represent a variety of other wildlife species. Elk provide exciting hunting and viewing experiences to many Forest users The ODFW (1980) suggested an April population objective of 6,700 elk for the Siskiyou National Forest The 80 20 cover/forage needs were detailed in a more recent letter (ODFW 1985a).

Elk presently inhabit one-third of the Forest, or approximately 388,000 acres, private inholdings included Approximately 329,000 acres (85 percent) of this total are considered winter range. Because so much of the Forest's elk habitat is at lower elevation and under a strong coastal influence, winter range is not a critical need On the Siskiyou, elk are still expanding their range; it is likely they will eventually inhabit as much as two-thirds of the Forest The Siskiyou's herd presently numbers approximately 1,350 animals, or an average of one elk for every 290 acres of occupied habitat.

A majority of the Siskiyou (private inholdings included) is classified as thermal (57 percent) and hiding (9 percent) cover for deer (and elk); foraging habitat accounts for 12 percent Planning Basins range from 18 to 80 percent total cover, cover percentages in some basins are naturally low because of the presence of serpentine plant communities.

Deer and elk do not fully utilize habitat along roads open to vehicle use (Brown 1985). Average density of roads in areas which are predominately roaded is 2.33 miles for each square mile of land (640 acres).

HABITAT TYPES NOT REPRESENTED BY INDICATOR SPECIES

Riparian Habitat

This habitat type includes all land within 150 feet of Class I and II streams or 100 feet of Class III streams Riparian habitat encompasses 175,500 acres, or 16 percent of the Forest, and is extremely important habitat for wildlife For instance, small-mammal communities in riparian ecosystems are more diverse and generally more dense than in neighboring habitats (Cross 1985). Riparian areas serve as habitat for over 180 wildlife species, they serve as protective travel corridors for animals moving between blocks of mature/old-growth habitat

Meadows

Meadows are an important component of habitat diversity for wildlife; 4,872 acres of meadow habitat were mapped during the 1979 timber inventory and 1,805 additional acres have been identified since that time. Suppression of wildfires has resulted in considerable habitat change, meadow habitat on the Siskiyou National Forest has decreased by at least one-third in the last four to five decades. Fifty years ago the Siskiyou National Forest contained over 9,000 acres of meadow habitat.

Wildlife Sites

During the past 10 years a number of important, but relatively small Special Wildlife Sites were identified by Ranger District employees during project-level planning for timber sales (184 sites, 6,932 acres). Those sites on land suitable for the production of timber were temporarily withheld from activities pending their disposition in the Forest Plan. Additionally, during the planning process Forest personnel identified many other special wildlife sites not associated with timber sale activities.

Special Wildlife Sites include meadows (discussed above), meadow buffers, lakes/ponds/wet sites, botanical sites, elk areas, osprey nest sites (those not in Wild and Scenic River corridors), band-tailed pigeon areas, rock bluffs, hardwood sites, wildlife areas, and dispersed old-growth. Special Wildlife Sites encompass 45,142 acres (approximately one-third classed as tentatively suitable for timber production).

Wildlife areas include sites with a variety of attributes important to wildlife. Examples include Fish Hook Peak (meadow/forest complex; important elk area), Pebble Hill (Jeffrey pine/grass meadow complex), Horse Creek (variety of habitats in close proximity), and Windy Valley (meadow/forest complex). Most dispersed old-growth sites are small areas unsuitable for timber management. As more and more of the forest is brought under rotation, this mature "connecting habitat" will begin to serve as "stepping stones" between some of the habitat areas for spotted owl, pileated woodpecker, and pine marten (Management Area 8).

Acres of Special Wildlife Sites are displayed by category in Chapter II, Table II-3 Management strategies *for Special Wildlife Sites are described in Chapter IV of the Forest Plan (Standards and Guidelines for* Management Area 9).

CURRENT DEMANDS, WANTS, AND DESIRES

Three Planning Problems pertain to management of wildlife resources and current demands, wants, and desires of the public:

1. "How Much Timber Should the Forest Produce?"

Most people realize that the level of timber harvest will have major effects on wildlife habitat. Timber harvest, if done within established guidelines, can result in increased habitat capability for deer and elk, and other species which utilize early seral stage vegetation. At the same time, however, populations of wildlife species dependent on mature and old-growth forest will be reduced. Many citizens feel the potential land base available for timber harvest should be managed to do more than just "meet" MR's for wildlife (the legal requirement under NFMA). Other people are concerned that the amount of timber available for harvest will be unduly restricted to meet overly considerate goals for wildlife habitat.

2. "How Much Old-Growth Forest Should Be Preserved?"

Some people feel that all existing old-growth stands should be protected and continue to serve as habitat for a variety of wildlife species. Many people think only enough old growth should be preserved to insure that there is little likelihood that dependent wildlife species will be extirpated from the Forest.

7. "How Should Wildlife Habitats on the Forest Be Managed?"

Wildlife and wildlife habitats are an important component of the Siskiyou National Forest ecosystem. The public and Forest managers realize that the Siskiyou must meet MR's for wildlife, and that we must maintain viable populations of all native and desirable nonnative wildlife species existing on the Forest. People disagree as to how this should be done. What should the levels be for populations of individual species, and how should land (habitat) be managed to meet population objectives? What are the potential maximum and minimum habitat levels?

CONSUMPTIVE USE

Hunted species on the Siskiyou collectively provide recreation for thousands of people. Based on license sales and participation rates, demand for all hunting in the Pacific Northwest is expected to increase by 1.3 percent annually from 1985 to 2030 (USDA 1984). Hunter-days attributed to hunting of game animals on the Siskiyou are estimated at 43,150 annually. At 1.3 percent per annum, demand would increase to 77,162 by the year 2030.

The black-tailed deer is the most important game animal on the Siskiyou. Deer hunting annually attracts more than 3,000 hunters, resulting in an annual average harvest of 1,000 deer. Hunter-days attributable to deer hunting on the Siskiyou have more than doubled in the last 25 years; total hunter-days increased by an average of 4.4 percent per year from 1960 to the mid 1980's.

In recent years, over 860 hunters have annually harvested an average of 74 elk. Each year, approximately 500 hunters harvest 45 black bear on the Siskiyou. An estimated 640 hunters harvest approximately 3,300 game birds including quail, grouse, and band-tailed pigeon. Although quail and grouse are under-utilized by hunters, they are an important component of the Siskiyou fauna.

Desires of big-game hunters are directed toward maintaining or increasing the numbers of deer and elk, especially the latter. Road closures are seen by some hunters to be a way of fostering quality hunting experiences; other hunters prefer access to as much of the road system as possible.

NONCONSUMPTIVE USE

Of the over 250 wildlife species inhabiting the Siskiyou, only 22 are classified as game animals or furbearers; and even these animals frequently serve the public in nonconsumptive ways. Nongame wildlife are recognized as an important natural resource by the ODFW (Marshall 1986).

Although no accurate figures for nonconsumptive use are available for the Forest, the 1975 National Survey of Fishing and Hunting showed that for every day a hunter spent in the field, three other individuals were bird-watching, photographing, or observing wildlife (USDI Fish and Wildlife Service 1977). During 1980, 2.2 million Oregon residents participated in some kind of nonconsumptive wildlife use activity (USDI Fish and Wildlife Service/USDC Bureau of the Census 1982).

Thousands of people boat or hike along the Rogue and Illinois Rivers every year; "watchable wildlife" are an important part of their recreation experience. On the Siskiyou, recreation-days attributable to nonconsumptive use of wildlife resources are at least as high as recreation-days attributable to hunting.

Most people enjoy seeing wildlife in their natural habitat. Most people agree that all wildlife species presently existing on the Forest should continue to be part of the Forest ecosystem People differ on how much of each vegetative type should be maintained to achieve the most desirable mix of habitats.

ABILITY TO SATISFY DEMAND

Three Planning Problems pertain to management of wildlife resources and the ability of the Forest and the Forest Service to satisfy demand:

1. "How Much Timber Should the Forest Produce?"

The Forest could adjust the allowable cut to meet a wide range of wildlife objectives. Specifically, in areas managed for timber the Forest is physically able to meet ODFW criteria for elk and deer cover/forage requirements (ODFW 1985a).

2. "How Much Old-Growth Forest Should Be Preserved?"

There is a wide range of options. Old growth can be reserved for wildlife that need this type of habitat; land allocations to meet MR's for wildlife can be expanded (increased from 159,949 acres; a minor portion is mature forest). If no more old growth is cut, the Forest could maintain approximately 393,000 acres of old-growth forest indefinitely (including dedicated areas). If present mature stands (50,000 acres) are allowed to progress into old growth, and if lands cut over in the last 40 years (138,000 acres) are allowed to grow back into old growth, an additional 188,000 acres could be managed as old growth.

7. "How Should Wildlife Habitats on the Forest Be Managed?"

Wildlife and their habitats are an important part of the Siskiyou ecosystem. If all wildlife species presently occurring on the Siskiyou are to remain as viable components of the Forest ecosystem, then this entails preservation of at least minimum amounts of the various habitats. Examples of the most essential habitats are meadows, riparian areas, snags, early successional stages, mature and old-growth forest, and hardwood stands.

Primary land allocations can be made to protect the various habitats supporting specific wildlife populations on the Forest, such as Designated Wildlife Habitat, Special Wildlife Sites, and Supplemental Resource Management Areas. Wildlife objectives can be furthered through secondary allocations such as Research Natural Areas and Botanical areas. Standards and Guidelines can be used to establish

management objectives to meet specific habitat needs (such as snags) Habitat improvement projects can be designed to meet wildlife objectives, such as increased carrying capacity for deer and elk (including transplanting elk to unoccupied habitat). Better opportunities for wildlife viewing could be developed The Forest's Comprehensive Fish and Wildlife Plan (Public Law 93-452) can be integrated into the capital investment program, and K-V funding (Knutson-Vandenberg) can be used to implement projects in timber sale areas (most projects are presently funded through the K-V program)

Bald Eagle and American Osprey

The objectives of the Pacific Bald Eagle Recovery Plan are to provide secure habitat and increase populations in specific geographic areas to levels where it is possible to delist the species (USDI Fish and Wildlife Service 1986) The Recovery Plan will govern habitat management for the bald eagle on the Siskiyou National Forest. A potential feeding area has been identified at the confluence of the Rogue River and a major tributary The Forest contains a minimum of 58,000 acres of primary bald eagle and osprey habitat along the Rogue, Illinois, and Chetco River corridors. Additional secondary habitat exists for osprey in the Rogue River drainage and along smaller rivers such as the Winchuck, Coquille, and Sixes.

Northern Spotted Owl, Pileated Woodpecker, and Pine Marten

Habitat for these three indicator species can be provided at various levels, from meeting MR's (159,949 acres, including habitat in Wildernesses) to preserving all existing mature and old-growth forest (443,000 acres) Figure II-10 displays the maximum number of sites *specifically* identified during the planning process as habitat areas for these three species (the maximum identified habitat network is approximately 200,000 acres).

Woodpeckers

Snag management guidelines have been in effect on the Siskiyou since 1976. One to two snags per acre (average 1 85), depending on habitat type, must be available to snag-dependent wildlife at any time during a rotation (minimum snag size 11" diameter). These snags provide for 60 percent of the maximum possible population levels of all woodpecker species (primary cavity excavators) on land suitable for the production of timber. Approximately three snags per acre provide for 100 percent levels; at that point territorial demands become limiting.

Wildlife trees are retained at the 100 percent level in areas not available for timber harvest Population levels for woodpeckers on land within timber management areas are reduced to 60 percent as stands are harvested and brought into a managed rotation. Some areas with a programmed timber harvest, such as Riparian areas or sites with Visual Quality Objectives of Retention or Partial Retention, may be able to support populations in excess of 60 percent

Deer and Elk Herds

If timber harvesting continues at the present rate, the size of the deer herd will remain relatively constant for the next three decades However, habitat capability will diminish in 40 to 50 years when the number of clearcut acres created each year begins to decline and commercial thinnings begin to comprise a significant proportion of the programmed timber harvest. Habitat capability for elk will follow the same general pattern as deer However, because elk presently occupy only one-third of the Forest land base, elk numbers will increase during the next few decades as new areas are colonized.

Higher levels of timber harvest (departure from an even-flow policy of timber production) would temporarily result in significantly increased deer and elk numbers. However, when future timber harvests are necessarily reduced, herd levels would decrease significantly A prolonged reliance on timber harvest within existing roaded areas will eventually create long-term fluctuations in the cover/forage ratio for deer and elk

One challenge facing the ODFW and Forest Service is how to meet the expected increase in demand for big-game hunting in the face of constant or declining habitat capability. A deline in habitat capability could be partially mitigated by installating shorter harvest rotations, allocating more land to timber harvest, prescribing fire to rejuvenate specific forage areas, or increasing capital investments in habitat improvement projects

Distribution of the deer and elk populations (and, concurrently, hunter distribution) may be improved when unroaded areas (nonreserved) are accessed by roads. However, as more logging roads are built, their adverse effect on deer and elk populations will be more pronounced. Forest managers could develop policies to alleviate the detrimental effects of open roads on deer and elk populations.

Special Habitats - Riparian, Meadows, and Wildlife Sites

The Forest's riparian ecosystem policy protects fish and wildlife habitat within Riparian areas. Meadows can be managed to maintain their wildlife values, and meadow acres lost in past decades can be reclaimed. Buffer areas (200 feet average width) surrounding the meadows can be managed for the benefit of wildlife species utilizing this type of habitat. Special Wildlife Sites can be withdrawn from timber harvest and managed to meet wildlife objectives. Many other identified wildlife sites undoubtedly exist on the Forest; a concerted effort can be made to find and manage these sites.

BIOLOGICAL DIVERSITY

EXISTING CONDITION

Biological diversity is the distribution and abundance of different plant and animal communities and species. Biological diversity should be gauged from several aspects: (1) spatial, such as throughout a forest stand, or across a forest landscape, (2) biological, such as genetic variation within a population of species; and (3) temporal, which relates to processes and conditions, such as short-term change, long-term productivity, and evolutionary change. Diversity is determined by ecosystem function, patterns of biotic communities, and human activities.

FLORAL AND FAUNAL DIVERSITY

The Siskiyou National Forest is the most floristically diverse Forest in the western United States and one of the most diverse in the Nation (Whittaker 1960) It supports over a quarter of all the sensitive species listed in the Pacific Northwest Region. It is the type locality for many rare species and supports well known endemics such as Brewer spruce, Saddler oak, kalmiopsis, and Waldo gentian.

In total, there are more than 1,400 plant species and 92 plant associations in the area of the Siskiyou National Forest The 92 plant associations were stratified into groups and separated by successional stages Table III-30 compares the abundance of each plant association group and successional stage by area (acres). The Siskiyou Mountains are the southern limit for northern conifers such as Alaska-cedar and silver fir, and the northern limit for southern species such as Jeffrey pine, redwood, and Andrew's bead lily Port-Orford-cedar, Pacific yew, and redwood are thought to have evolved in the area (Axelrod 1976, Detling 1961)

There is high species richness of both plants and animals on the Forest. There are more than 250 wildlife species occupying the diverse habitats in the area. The Siskiyou National Forest provides habitat for 70 species of mammals, over 150 bird species, and 38 species of reptiles and amphibians. An occurrence list of wildlife by seral stage and habitat type is available from the Supervisor's Office The list was prepared from data collected by Brown (1985), Guenther and Kucera (1978), and by Forest personnel and others

Several sensitive vertebrates occur in the area, such as the northern spotted owl, Townsend's western big-eared bat, and California wolverine. The bald eagle, a Federal threatened species, and the peregrine falcon, a Federal endangered species, both nest within the Forest. Grizzly bear and gray wolf once inhabited the area, but are now extirpated

Over 24 species of fish occur within the Siskiyou National Forest. Green and white sturgeon and various commercially important salmonids are included.

Four major factors play a role in the faunal and floral diversity of the Forest These are the transverse orientation of the Siskiyou Mountains, the geographic location (latitude), the diverse geology, and the fire history. The transverse orientation and rugged terrain of the Siskiyou Mountains provide a variety of drainage orientation, aspect, and elevation that add to environmental diversity and niche breadth. Latitude of the Forest assures a variety of weather; tropical and arctic influences both affect the weather throughout the year. Unique geological niches occur in serpentine areas and other geology complexes Evidence of fire exists in all areas. Vegetation in various successional stages, including relatively unaffected islands in late seral stages, provides structural diversity and testifies to the importance of fire.

Table III-30. Abundance of Successional Stage by Plant Association Group 1/

Plant Association Group	Successional Stages (Acres) Grasses & Forbs	Shrubs Low	Shrubs Tall	Trees Pole	Trees Young	Trees Mature	Trees Old	Series Total (Ac)	Percent

1/ Tables III-37 and III-38 are based on sampling by the Ecology Program. They estimate the present condition of the Forest relative to seral stages. Acreages were projected from 685 sample plots representative of the Forest as a whole. However, Wilderness areas were not sampled, making the projections somewhat biased. Rather than using all 92 Plant Associations, a stratification was used. The groups were based on Region-wide ecological analysis and were compiled collectively by Forest Service ecologists and inventory specialists. The groups will potentially be used in the upcoming resource inventory as strata and as a comparative base for monitoring changes in seral stages. The figures do not correspond to Table III-17 because: (1) ecological sampling is biased to later seral stages, (2) there are five seral classes in ecological sampling based on stand structure rather than the seven seral stages based on stand age, and (3) allocating ecological status to age classes, such as mature or old-growth, is subjective and is dependent on the definitions of each class and the vegetation under consideration

The existing diversity of the Forest is a valuable legacy of past geologic history and natural processes. Progenitors of species such as redwood, Pacific yew, and possibly Port-Orford-cedar and incense-cedar developed in the Klamath Mountains, the only local land area above sea level during the Jurassic Period, about 160 million years before present (MMBP). By the Cretaceous Period (135 MMBP), a mixture of ferns, palms, gingkos, cycads, conifers, and flowering plants occupied the landmass that we now call the Klamath Mountains

Long-term, sweeping climatic changes (including warm, dry and cool, wet eras) during the Tertiary period (60 to 2 MMBP) significantly changed the floral composition as the North American continent moved toward its present position The overall effect was mixing of flora from as far south as Mexico and as far north as Alaska, including oaks, locust, pines, hemlock, and fir

Before the Pleistocene (the epoch of the Ice Ages), the flora included old conifers (redwood, Pacific yew, and cedars), new conifers (pines, true firs, and Douglas-fir), and hardwoods and flowering plants from various origins (walnut, birch, beech, alder, maple, and ash). Hardwoods that could not tolerate dry summers or compete for moist niches gradually disappeared from the area Shrubby and herbaceous species also occurred, but left fewer fossil remains

During this period, species such as Alaska-cedar and Pacific silver fir began to occupy high elevation, north-facing, cold pockets during interglacial hot periods Species of southern origin requiring hot, dry conditions came to occupy low elevation, hot sites with shallow soils They expanded their range during the Xerothermic period (4 degrees Centigrade increase in average annual world-wide temperatures, Detling 1961) when elements of the California chaparral migrated as far north as the Columbia Gorge (4,000 years ago) Again the species requiring cold conditions took refuge in niches at the high elevations, and the Siskiyou Mountains received another influx of California species.

The 0.5 degrees Centigrade depression during the Little Ice Age (1,350 to 1,800 years ago) caused crop failure and famine throughout Europe and was the period when most of the old-growth forest stands of the Siskiyou originated. The most significant changes in species composition and structure since the onset of the Little Ice Age have been caused by fire, both natural and human-caused Most rare, endemic, and sensitive species have also survived the dramatic changes during the Ice Ages, Xerothermic Period, Little Ice Age, and the recent disturbances caused by trappers, miners, loggers, ranchers, and settlers.

ECOSYSTEM FUNCTION

Ecosystem functions can be categorized as physical and biological processes Examples of physical processes include weathering and erosion, while some biological processes include photosynthesis, nitrogen fixing, and reproduction. Many functions in an ecosystem, such as root activity, decomposition, and mychorrhizal associations, can be influenced by natural disturbances and human activity. Maintaining ecosystem function is key to long-term productivity. Forest management activities are thought to influence a number of ecosystem functions. For a full discussion of this topic refer to USDA 1988b.

Both natural and human-caused disturbances shape the biotic composition, structure, and function of the forest Disturbances can be catastrophic in nature, or periodic. They include insect outbreaks, disease, windstorms, flood, geologic actions, fire, and timber harvest Disturbances create mosaics of successional stages and forest patterns across the forest landscape

Fire has been the major agent of change in forest ecosystems (Omi and Laven 1982) Within the Siskiyou National Forest catastrophic wildfires occur, on the average, at 200 year intervals in the area influenced by coastal conditions East of the coastal area, but still west of the crest of the Siskiyou Mountains, the fire frequency is generally every 70 to 100 years East of the crest of the Mountains, in the rain shadow, the fire frequency is 50 years in white fir and 20 years in Douglas-fir communities.

In addition to fire, timber harvest also has a major effect on ecosystem function and productivity Timber harvest generally occurs in the late seral stages of coniferous forest These forests are complex ecosystems which have complex functions. The late seral stage coniferous forest consists of large long-lived trees forming a broken canopy with a variable distribution of dominants and codominants A vertical foliage distribution is present with a patchy understory which provides niches for vertebrates and invertebrates (Harris 1984)

These forests also contain snags and broken topped trees that provide roosting and nesting sites for birds and mammals. Underground mychorrhizal fungi provide food for many mammal species and assist trees in the uptake of nutrients for growth and survival. Fallen logs support insects, which serve as food for many vertebrates. Vertebrates, such as amphibians, also live in the decaying logs. The decaying logs, also provide sites of nutrient cycling and contribute to the maintenance of long-term site productivity (Harris 1984).

Patterns of timber harvest have consequences to diversity at the landscape level The contiguous nature of late seral stages is replaced by a patchwork interspersed with early seral stages. This condition has been referred to as "forest fragmentation." The degree of fragmentation may influence the abundance of forest interior species.

On the Siskiyou National Forest, much of the timber harvested has been on productive lower elevation sites, where vertebrate species density is generally higher The amount of late seral stage forest has also been reduced nearly 26 percent since 1940 The existing acres of late seral stage (mature and old growth) are displayed in Table III-30.

CURRENT DEMANDS, WANTS, AND DESIRES

The National Forest Management Act requires that Forest plans "preserve and enhance the diversity of plant and animal communities...so that it is at least as great as that which would be expected in the natural forest" (36 CFR 219.27). Additional direction states, "Management prescriptions, where appropriate and to the extent practicable, shall preserve and enhance the diversity of plant and animal communities, including endemic and desirable naturalized plant and animal species, so that it is at least as great as that which would be expected in a natural forest and the diversity of tree species similar to that existing in the planning area "

Several respondents to the DEIS mentioned the need to maintain the species diversity of the Forest, especially botanical resources Many comments mention establishment of Research Natural Area, Botanical, and Riparian Management Areas. Several species were mentioned specifically, including redwood, Brewer spruce, and Port-Orford-cedar

Perpetuation of old-growth forest ecosystems and the need to consider old growth preservation at the landscape scale were common themes Some respondents emphasized uneven-aged management Other public desires includes meadow maintenance, maintaining species viability, and retaining hardwood components in forest stands. Some respondents recognized that much is to be learned about providing biological diversity in the forest. They recommended inventories, monitoring, and research to develop future guidelines and practices.

ABILITY TO SATISFY DEMAND

Biologically, the Forest is capable of maintaining the present complement of species, barring an extensive catastrophe. Land allocations are one tool to maintaining viable populations of some plants and animals. Other tools, such as management plans and Forest-wide Standards and Guidelines, may be appropriate for some species. Redwood, Port-Orford-cedar, and Brewer spruce are examples of plant species that can be maintained by using more than one approach Table III-31 relates biological diversity to management issues and strategies

Botanical, Research Natural Areas, Special Wildlife Sites, Designated Wildlife Habitat, and selected Supplemental Resource Management Areas are all designated, in part, to maintain plant and animal diversity. There are plants and animals which also occupy land allocated to General Forest, Retention, and Partial Retention Visual Management Areas In these areas, sensitive plants and animals that thrive on infrequent disturbance will be considered on a case-by-case basis during project planning Emphasis is placed on the development of Species Management Guides for all of these species to allow evaluation, protection, and maintenance at the landscape scale. If plants requiring frequent disturbance are found in areas other than General Forest and Partial Retention Visual, a method of introducing disturbance in the proper frequency and intensity to assure species viability will be considered.

Remarkable groves of old-growth forest and unique plant habitats can be allocated to Botanical Management Areas In addition to these allocations, late seral stage forest would be provided in areas allocated to no harvest prescriptions (Management Areas 1-9) Mature and old-growth forest is also present on lands unsuitable for timber management within Management Areas 10-14

The combination of mature and old-growth forest on unsuitable lands and Management Areas 1-9 can be evaluated for each alternative to determine if late seral stages will likely be present in Planning Basins through the planning period. The potential pattern of late seral stages over the forest landscape can also be compared for each alternative.

The ability of the Siskiyou National Forest to provide significant quantities of old-growth forest in some plant associations may be impaired by the natural fire frequency in some areas of the Forest Fire frequencies are also affected by human activity. High fire frequencies on the lower slopes of the inland valleys were maintained by the Indians and are perpetuated by today's culture Many of these lower slopes have reburned as many as three times in the last two decades. Several plant associations of the Douglas-fir Series and the drier associations of the White Fir Series are not likely to persist in an old-growth condition for long periods of time.

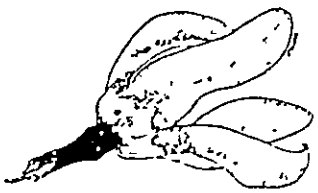

Table III-31. Management Strategies and Issues Related to Biological Diversity

Biological Diversity Considerations	Related Management Issue	Comments/Concerns	Strategies: Land Alloc.	S&G's	Monitoring	Other
MAINTAINING SPECIES DIVERSITY OF PLANTS AND ANIMALS

VISUAL RESOURCE

EXISTING CONDITION

Discussions presented in this section are pertinent to the resolution of Planning Problems 4, 6, and 8. Planning Problem #4, dealing with Wild and Scenic River corridors, was covered in that section. Planning Problems #6, "How, and to what degree, should Forest scenic values be protected through visual resource management?" and #8, "How will management direction affect recreation opportunities in the Wilderness and unroaded areas?" are treated below.

The characteristic landscape of the Siskiyou National Forest is identified with rugged, mountainous terrain with dissected drainage patterns The ridges are often narrow and similar in elevation, with canyons that are deep and narrow This landtype is clothed with a mixture of conifers and hardwoods These characteristics provide the basis for development of the current Visual Quality Objectives (VQO's) inventory.

Varying degrees of human-caused impacts exist Some are historic, the result of mining during earlier periods Others, such as road construction and timber harvest, are more recent. While visual conditions are not static, many impacts last long enough to affect the quality of the scenery for many Forest users.

VISUAL INVENTORY AND VISUAL QUALITY OBJECTIVES

The original Forest visual inventory in 1973 was modified to its present status in 1978 based on guidelines for the Forest Service Visual Management System (USDA 1974). The visual inventory is the result of the following independent variables (1) landscape variety classification; (2) viewer sensitivity; and (3) viewer distance (USDA 1974). The visual inventory provides measurable Standards and Guidelines for management of the Forest's visual resource.

Visual Quality Objectives are measurable degrees of acceptable deviation from a pristine environment and constitute the Forest's current visual inventory. The current inventory of VQO's is shown in Table III-32. The objectives are defined as:

Preservation - Management activities, except for very low visual impact recreation facilities, are prohibited. Ecological changes only continue uninterrupted

Retention - Management activities are not visually evident to the casual Forest visitor.

Partial Retention - Management activities are evident, but remain visually subordinate to the characteristic landscape

Modification - Management activities may dominate the characteristic landscape, but should be designed so as to resemble the natural appearance of the landscape when viewed in the background. This is a combined area with the *Modification/Maximum Modification* objective.

Table III-32 Visual Quality Objectives

Objective	Acres	Percentage of Forest
Preservation	235,310	22
Retention	81,480	7
Partial Retention	287,700	26
Modification	487,812	45

CURRENT FOREST VISUAL CONDITION

The Existing Visual Condition inventory (Pugh 1981; available in the Planning Records) provides a measure of the current condition of the Forest's visual resource. The Existing Visual Condition process used stratifies Forest lands into six landtypes that are shown in Table III-33.

Table III-33. Current Visual Condition Land Types as Defined by the Existing Visual Condition Inventory

Landtype	Acres	Percentage
I Untouched	483,355	41
II Unnoticed	192,514	17
III Minor disturbance	105,911	9
IV Disturbance	222,254	19
V Major Disturbance	139,545	12
VI Drastic disturbance	19,904	2

The Forest has identified 44 viewsheds as displayed in Figure III-20 (Pugh 1984, see Planning Records). The viewsheds can be described as *natural appearing* (landtypes I and II), *near natural* (landtype III), and *modified* (landtypes IV, V, and VI) Natural appearing implies little or no visible evidence of management activities; *near natural implies some evidence of management, but the natural character of the landscape* remains dominant; and Modified implies the evident modification of the natural character of the landscape. The visual condition of the viewsheds is shown in Table III-34.

Table III-34. Visual Condition

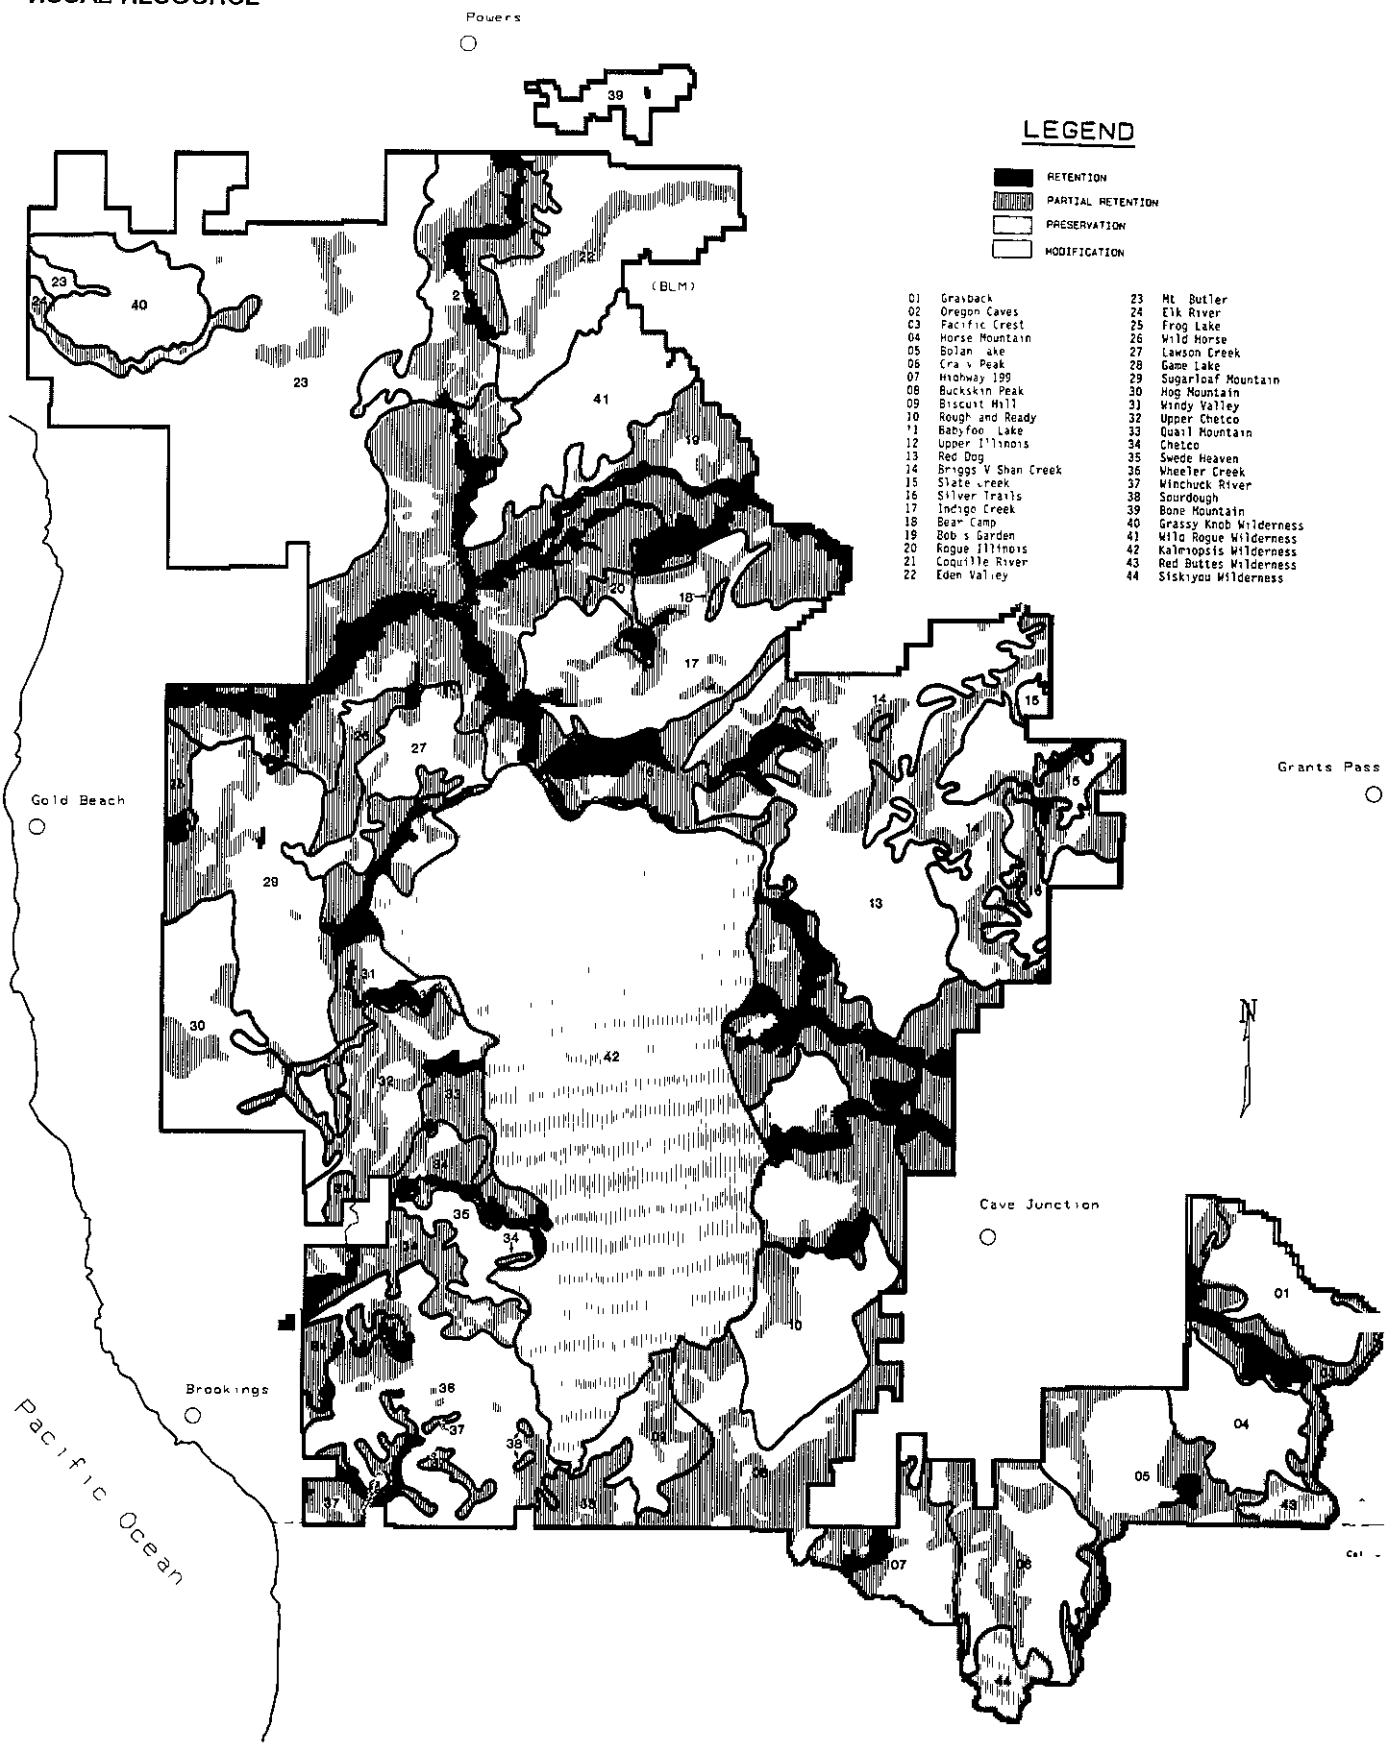
Viewshed Condition	No of Viewsheds	Acres
Natural Appearing	8	235,924
Natural/Near-Natural	11	277,278
Near-Natural/Modified	13	282,831
Modified	12	296,269

The final step in describing the current visual condition involves the overlay of the Existing Visual Condition with the visual inventory This process revealed that 47 percent of the acreage inventoried for Retention does not meet the criteria for that objective; 33 percent of the inventoried Partial Retention area is over-impacted; and 26 percent of the Modification area would not meet the criteria for the Modification objective To achieve the various visual objectives, all of these areas would require rehabilitation

CURRENT DEMANDS, WANTS, AND DESIRES

The demand for aesthetic values is difficult to quantify However, it is evident based on the level of recreation use and attendant concern for the recreational settings

As indicated in the **ECONOMIC AND SOCIAL** section of this chapter, population growth is expected to continue in southern Oregon This can be partially attributed to the ready availability of amenity resources. It is expected that the demand for visual resource management will continue. Demand, taken in this context, is not presented as a price-quantity relationship, but as a nonquantifiable attitude expressed by the public for the aesthetic quality of their Forest environment.



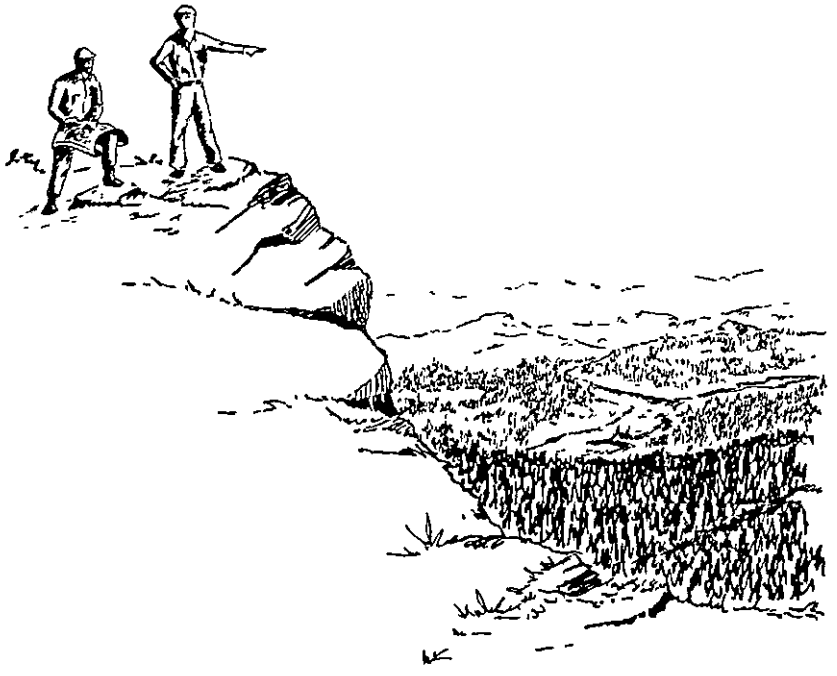


Figure III-20 Visual Quality Objective Map with Forest Viewsheds

ABILITY TO SATISFY DEMAND

The Forest can satisfy the concern for the quality of the visual resource by managing to meet or exceed the current inventory of Visual Quality Objectives Visual management can be reduced or increased depending on management emphasis. The Existing Visual Condition inventory indicates that the visual resource is in relatively good condition so that areas experiencing high levels of recreation use can be maintained in a natural or near-natural condition. In other areas of the Forest, the inventory can be reduced in response to relatively light use and managed more for other resource emphases.

RECREATION SETTINGS

EXISTING CONDITION

Discussions presented in this section are pertinent to the resolution of Planning Problems 4, 6, and 8. These Planning Problems deal with Wild and Scenic River and adjacent land management, the visual resource, and opportunities pertaining to Wilderness and unroaded areas

Recreation plays an important role in the management philosophy of the Forest However, relative to other National Forests in the Pacific Northwest, the Siskiyou is not considered to be a major recreation Forest However, river travel is the one recreation activity for which the Siskiyou National Forest is renowned The Rogue River draws the most attention and use Other rivers that have moderate to high recreational values are the Illinois, Chetco, Coquille, Winchuck, and Elk.

The Forest has four categories of recreation. (1) Developed; (2) Undeveloped, Dispersed, (3) Wilderness, and (4) Wild and Scenic Rivers.

Developed Recreation

The 46 developed recreation sites on the Forest range from very primitive (level I) to highly developed (level IV) These sites are located in areas of the Forest that exhibit a landscape character that is natural appearing, although evidence of management activities may be visible in the background from many of the sites Facilities are designed to blend with the Forest character and provide a setting that is appropriate for the types of recreation opportunities offered. User fees are charged for the more developed sites. The Forest has a developed capacity for approximately 1,960 people at any one time Current recreation use is at capacity at several developed sites and is expected to remain at or exceed capacity in the future Other sites are little used; they could be eliminated to provide more efficient use of recreation maintenance funds. Table III-7 in the **IMPROVEMENTS** section of this chapter displays the current inventory of developed recreation sites on the Forest

The trail system on the Forest began when people first inhabited the area Indians, early settlers, miners, and the military all contributed to the development. In more recent times, road building has displaced many trails. Others have become impassable due to lack of use and maintenance Presently, most of the trail system is maintained for recreation purposes. Table III-6 in the **IMPROVEMENTS** section displays mileages and the availability and suitability of trails for various uses.

Three National Recreation Trails (total of 36 miles) are located on the Forest These are the Boundary, Illinois River, and Upper Rogue River Trails. Two miles of interpretive trails (Japanese Bomb Site and Redwood Nature Trail) are located on the Chetco Ranger District. Three historic trails (totaling 38 miles), plus another 12 trails (58 miles) that have historic significance, are given consideration during project planning Eleven trails (99 miles) in undeveloped, non-Wilderness areas are closed to motorized use based on the need for public safety, resource protection, and law. The Rogue River Trail (15 5 miles) is restricted to hiker use only The Illinois River Trail (26 miles) is closed from May 15 to September 15 to ORV's

The recreation setting for the Forest's trail systems varies with the location of specific trails In general, trails located within Wilderness or Wild and Scenic River boundaries are natural appearing and generally uninfluenced by management. Some evidence of management activities may be in the background Other trails located in undeveloped, non-Wilderness areas will have a recreation setting that may be natural appearing or heavily altered depending on the intensity of management in proximity to the trail The reader can get a better "feel" for recreation settings by referring to Table III-33, Current Visual Condition, and comparing the trail location to the description of the viewshed (Figure III-20) through which the trail passes

Undeveloped, Dispersed Recreation

This category is used to describe recreation activities that are occurring in undeveloped areas outside of Wilderness or Wild and Scenic River corridors These activities may be motorized or non-motorized, or occur with or without significant levels of interaction with other users Dispersed recreation use exceeds developed recreation by a six-to-one ratio, and accounts for approximately 80 percent of recreation use on the Forest. These types of recreation opportunities can occur in a forest setting that ranges from an unroaded, unmodified, natural appearing landscape to a modified forest setting Popular recreation activities on the Forest are water-related, such as swimming, fishing, and floating in the river corridors, hiking and camping, sightseeing, and gathering forest products. Use statistics indicate that there are approximately 1,000 people involved in recreational activities each day on the Forest

Wilderness Recreation (Including Wilderness Potential)

The five Wildernesses have been inventoried according to criteria developed for the Wilderness Resource Spectrum (WRS); see next page for definitions The Kalmiopsis Wilderness provides the opportunity for Pristine, Primitive, and Semi-primitive recreation The other four provide Semi-primitive opportunities. Recreation use in all of the Wildernesses is low when compared to other Wildernesses in the Pacific Northwest Region. Of the total Wilderness use, 88 percent occurs in the Kalmiopsis, 8 percent in the Wild Rogue, 1 percent in Grassy Knob, 6 percent in Red Buttes, and 1 percent in the Siskiyou Wilderness (the latter two areas are for the Siskiyou National Forest portion only).

Portions of the inventoried North and South Kalmiopsis roadless areas offer Primitive and Semi-primitive recreation opportunities (See Table III-36 Undeveloped, Dispersed Recreation).

Wild and Scenic Rivers Recreation

Of the Forest's five designated Wild and Scenic Rivers, recreation use is heaviest on the Rogue, followed by the Chetco and the Illinois Recreation use is moderate on the Elk and low on the North Fork Smith There are approximately 22,400 RVD's of use occurring on the Chetco and 200 RVD's use on the North Fork Smith. Approximately 6,139 RVD's of use occur on the Elk River (See Table III-38).

CURRENT DEMANDS, WANTS, AND DESIRES

Developed Recreation

The demand for developed recreation is shown in Table III-35 Full utilization of a developed site is considered to be 30-40 percent, as theoretical capacity is based on every campsite being fully occupied for every day during the season of use Demand projections indicate that the Forest has the capacity to sustain use until approximately the seventh decade of the planning period. There is a consistent demand for trail-related recreation opportunities The desire for development of day hike trail systems within both the periphery of the Wilderness and in undeveloped areas have been expressed And, there has been a concern voiced for maintenance and preservation of the Boundary, Illinois River, and Hobson Horn/Silver Peak Trails

Table III-35 Developed Recreation Demand and Capacity (M RVD's)

Use	Forest Capacity	Percent Capacity
116	157	74

Undeveloped, Dispersed Recreation

Also, the demand for undeveloped, dispersed recreation opportunities will continue over the course of the planning period The Recreation Opportunity Spectrum (ROS), an inventory system which recognizes the quality aspects of recreation opportunities, is used to characterize demand (levels of use) over the range of available opportunities in undeveloped, non-Wilderness areas Current levels of recreation use are shown in Table III-36. Definitions of the ROS classes are:

Primitive - An area that is characterized by essentially unmodified natural environment of fairly large size. Interaction between users is very low and evidence of other users is minimal.

Semi-primitive Non-motorized - An area that is characterized by a predominantly natural or natural-appearing environment of moderate to large size User interaction is low, but there may be evidence of other users.

Semi-primitive Motorized - An area that is characterized by a predominantly natural or natural-appearing environment of moderate to large size Motorized use is permitted.

Roaded Natural (Modified) - An area that is characterized by predominantly natural-appearing environment with moderate to heavy evidence of the sights and sounds of man.

Table III-36. Undeveloped, Dispersed Recreation

ROS Class	Acres	Use (M RVD's)	Capacity (M RVD's)	Percent Capacity
Roaded Natural	625,272	369	679	54
Semi-primitive Motorized	95,050	69	122	57
Semi-primitive Non-motorized	101,197	12	21	57
Primitive	14,370	1	2	50

Wilderness Recreation (Including Wilderness Potential)

Concern has been expressed for the availability of dispersed motorized opportunities and for the quality of the environment in which these opportunities are available. Expressed, too, is the concern for the availability of Semi-primitive and Primitive recreation opportunities in the undeveloped, non-Wilderness areas These opportunities are available primarily in the North and South Kalmiopsis roadless areas Based on projected levels of use and growing popularity of primitive recreation experiences, the demand for Wilderness recreation opportunities is expected to continue over the course of the planning period. Wilderness recreation use (demand) is shown in Table III-37. Definitions of the WRS classes are:

Pristine - Unmodified wilderness character; cross-country recreation opportunities only Frequency of user interaction is very low

Primitive - Trail associated wilderness recreation opportunities on maintained systems Frequency of user interaction is low

Semi-primitive - Wilderness recreation opportunities in a predominantly unmodified environment. Frequency of user interaction is moderate

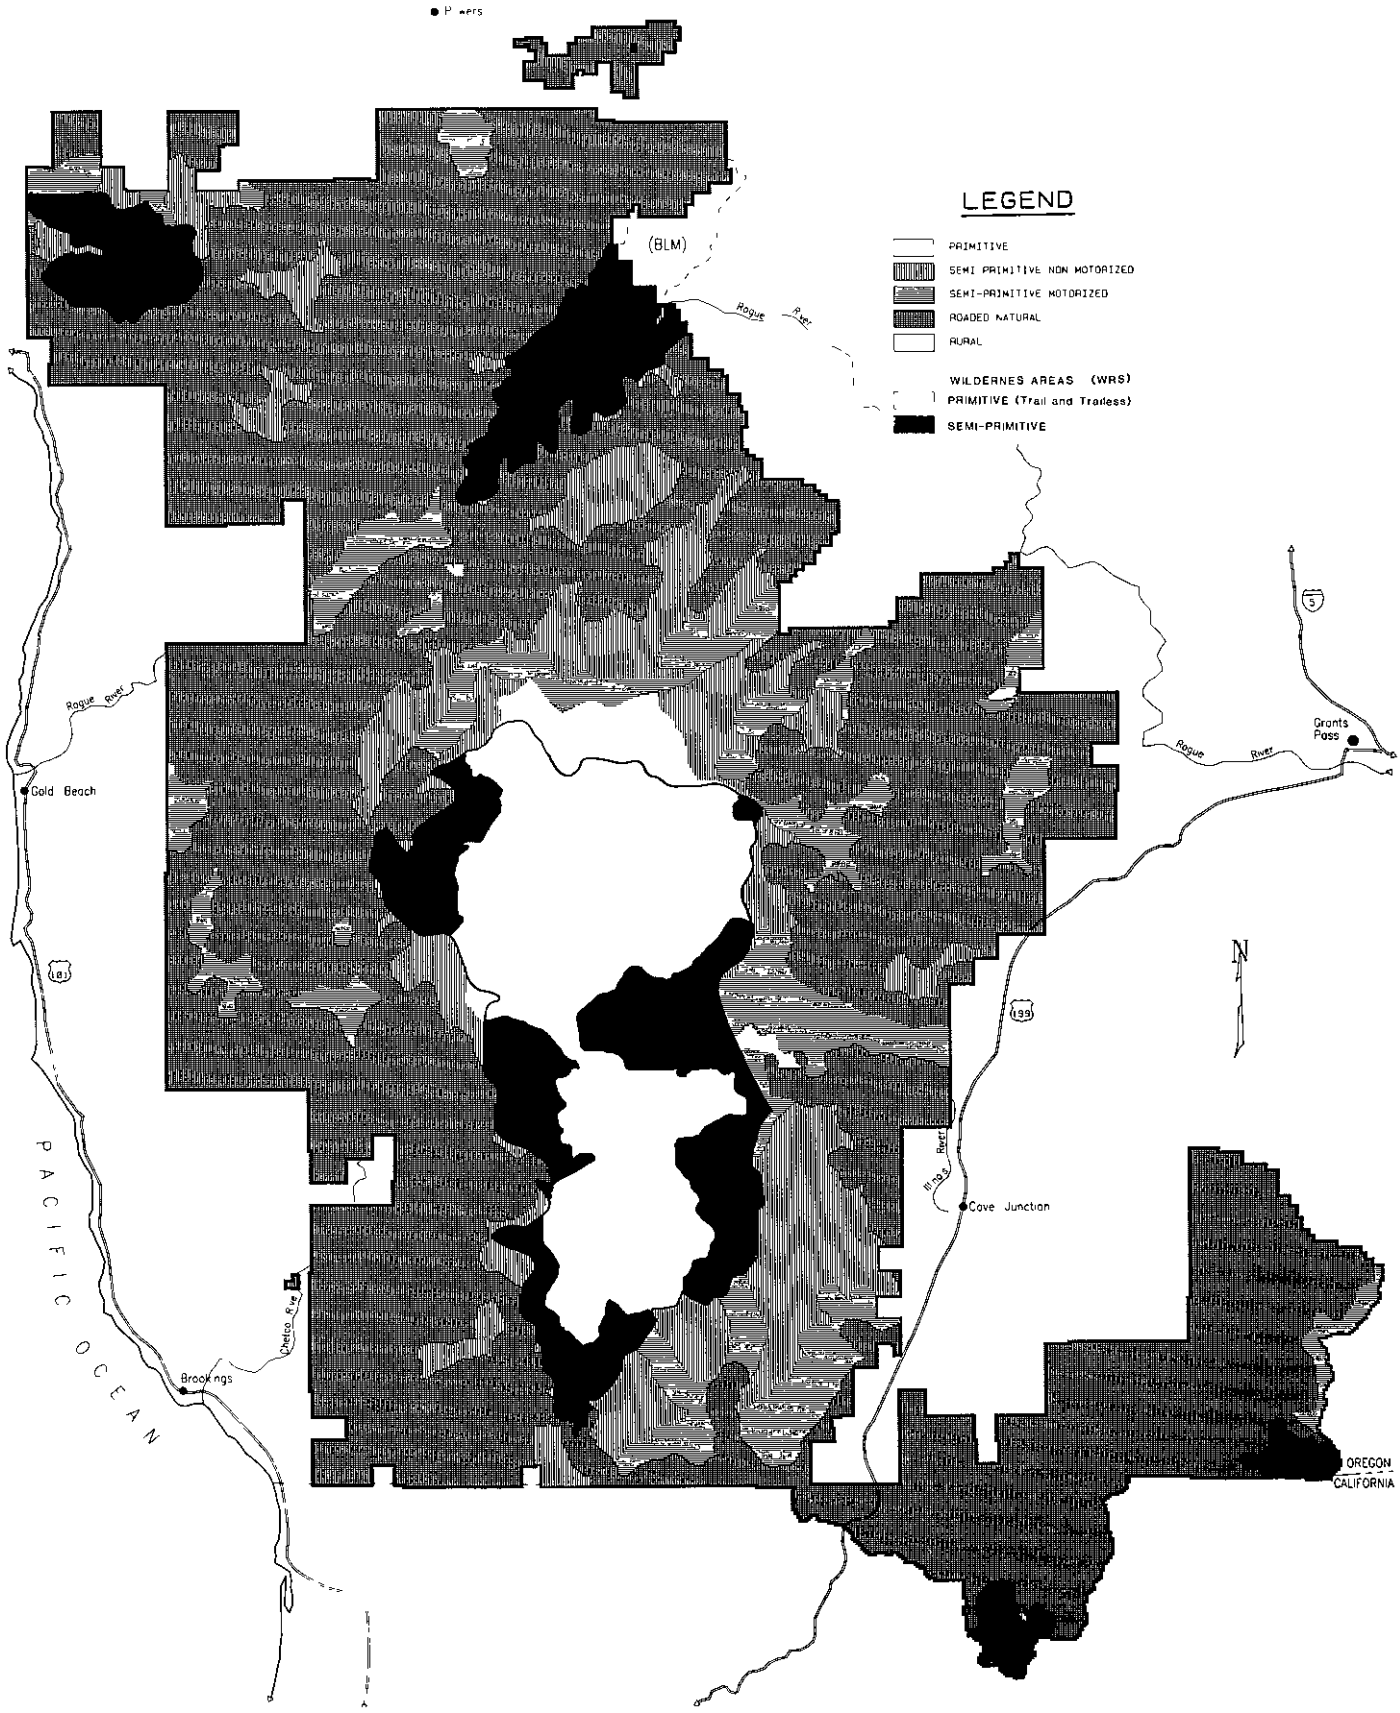

Figure III-21 Recreation Opportunity Spectrum Map

Table III-37. Wilderness Recreation Use

WRS Class	Acres	Use (M RVD's)	Capacity (M RVD's)
Primitive	93,462	1	1
Pristine	20,608	9	11
Semi-primitive	118,425	12	30

Wild and Scenic Rivers Recreation

Current use (demand) for the Forest's Wild and Scenic River system is shown in Table III-38 Use is assumed to increase at a projected rate of 0.5 percent per year over the course of the planning period

Table III-38 Wild and Scenic Rivers

ROS Class 1/	Acres	Use (M RVD's)	Capacity (M RVD's)	Percent Capacity
Roaded Natural	14,588	108	358	30
Semi-primitive Motorized	2,375	5	22	21
Semi-primitive Non-mot	11,986	2	25	8
Primitive	7,562	2	11	15

1/ See Table III-36 Undeveloped, Dispersed Recreation for the definitions of the ROS classes

ABILITY TO SATISFY DEMAND

The Forest has the ability to satisfy the demand for developed recreation opportunities over the course of the planning period. The Forest may not have the ability to sustain demand at specific campgrounds such as Quosatana, Grayback, and Cave Creek because of their location near attractions There are 18 potential developed sites on the Forest that can be constructed as the need arises. Some are scheduled for funding in the current investment program while the rest may be funded Furthermore, some of the existing sites can be reconstructed or rehabilitated to provide additional capacity.

Local counties and Federal agencies are entering into a number of partnerships to develop recreation and tourism opportunities The local counties chose tourism as their "Oregon Economic Comeback Strategy" which will result in lottery dollars coming to southwestern Oregon projects Several of the projects listed in the Recreation Capital Investments (see Forest Plan, Appendix B) reflect those the Forest is planning and funding jointly with the counties.

The Forest has the ability to satisfy the demand for trail-related recreation over the course of the planning period There are 122 miles of potential trails identified. Some are within Wilderness, others are located in other Management Areas Day hike opportunities exist at various areas in the Wilderness and throughout the rest of the Forest All or parts of the existing 457 mile trail system can be maintained or preserved depending on management emphasis

Based on projected levels of use, the Forest has the ability to satisfy the demand for the various recreation opportunities that are currently available The Forest has the capacity to sustain projected levels of use in the Semi-primitive Motorized and Roaded Natural ROS categories Under current direction, the Forest will not have the capacity to sustain the demand for Primitive and Semi-primitive recreation opportunities in the undeveloped, non-Wilderness areas over the planning period. Similar opportunities are available in the Wildernesses and on other Forests in southern Oregon and northern California

The Forest has the ability to satisfy the demand for wilderness recreation experiences within Wildernesses until approximately the fifth decade of the planning period when capacity will be reached for Primitive recreation. Other Primitive and Semi-primitive recreation opportunities are available on nearby National Forests in southern Oregon and northern California

The Forest has the ability to satisfy the demand for recreation opportunities associated with Wild and Scenic Rivers Recreation use of the rivers is within estimated capacities; demand can be satisfied over the course of the planning period.

ECONOMIC AND SOCIAL

EXISTING CONDITION

The purpose of describing the Forest's economic and social setting is to provide information on the existing condition, current demands, and the Forest's ability to meet those demands The major Planning Problems from Chapter I are used to focus the discussion. For additional details, refer to Appendix B

The Siskiyou National Forest is influenced by conditions occurring at National and regional levels However, the area most affected, and which most affects the Siskiyou, is quite local in nature. Coos, Curry, Jackson, and Josephine Counties (in Oregon) have been defined as the Siskiyou's primary area of economic and social influence (Peterson 1980) These counties roughly correspond to both the physical location of Forest lands and the geographic area within which the local populace relate to the Forest.

There are several types of communities within this influence area. Grants Pass, Coos Bay, and Medford represent the urban services and government centers Communities, such as Powers and Selma, represent the eastside rural communities that are dependent on wood products and agriculture. Westside rural communities, such as Bandon and Brookings, have more diversified economies with tourism and fisheries Communities such as Takilma are more self-contained and have alternate lifestyles with cottage industries as the primary economic enterprise.

POPULATION DYNAMICS

The total population of the four-county area is approximately 271,000 The decade of the 1970's witnessed rapid increases in the growth rates of Jackson and Josephine Counties, most being in-migration largely attributable to a large influx of retired people. Population projections for the four counties (Figure III-22) reflect the rapid growth during the 1970's and the more recent slower growth of the 1980's

SOCIAL OVERVIEW

Many different lifestyles exist in the four-county area. Residents depend on outdoor activities such as fishing, wood cutting, and gardening for income or leisure time supplements. The outdoor activities require natural resources and can foster distinct and strongly-held value structures which are relevant to the forest manager. One such view, the human-centered view, holds that the human's relationship to nature is one of dominance, i.e., natural resources exist for human use alone, to not fully utilize them is wasteful. Another view, the humanity-in-nature view, holds that the natural environment has value apart from human use These highly polarized views, and the nearly infinite intermediate views, result in conflicting opinions on Forest resource management issues.

Further pressure on resources, and increasing diversity of values, is likely to result from the in-migration of people who are either more economically aligned with nonconsumptive uses of the Forest such as recreation, or are retired and therefore are not reliant on economic growth at all The Forest is in the position of being able to contribute to local community stability by responding to these economic and social needs for a supply of all Forest uses

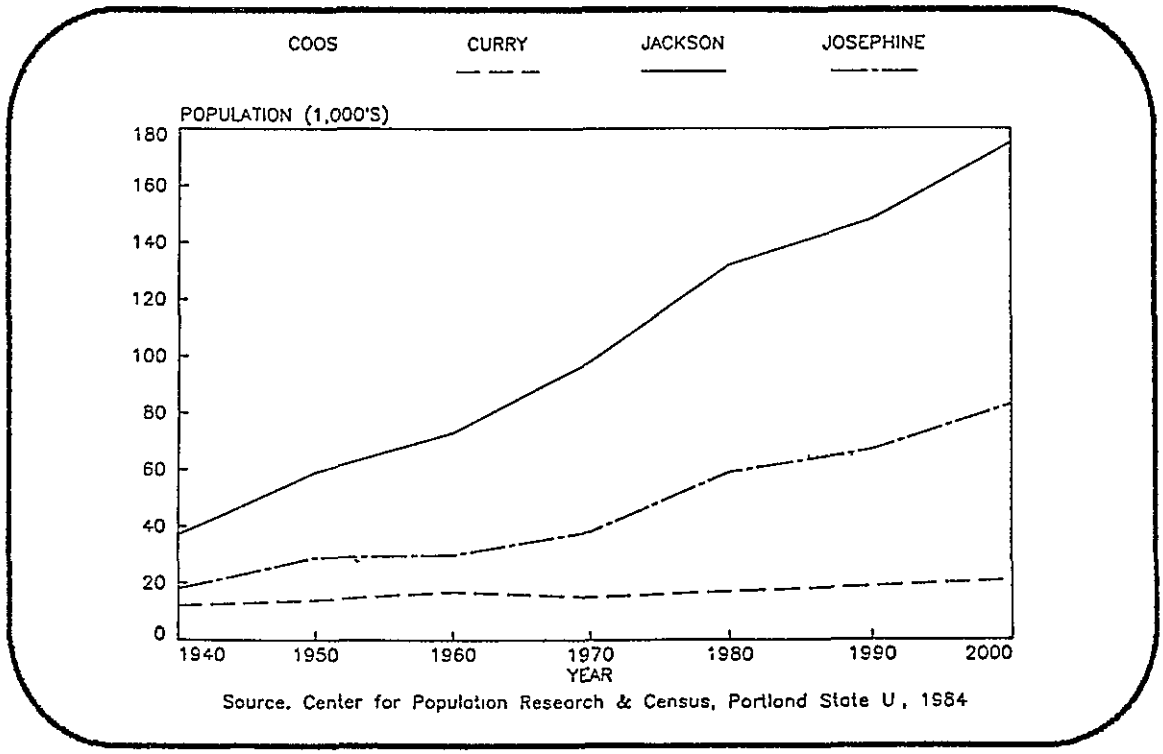

Figure III-22 Population Projections for the Four Counties

EMPLOYMENT

The most important employers are lumber and wood products, government, tourism, agriculture, and fisheries. Lumber and wood products manufacturing, which includes logging, is the largest employer, providing total employment of 17 to 18 percent in the four counties Lumber and wood products jobs have decreased in number from 1979 due to economic adjustments made by industry to remain competitive. Concurrently, other sectors have grown. In-migration (people moving into an area) has served to promote growth in finance, insurance, real estate, and other trade and service industries. Other industries which have provided basic employment growth include apparel, fiberglass, and electronics manufacturing. In Coos Bay, the transportation, communication, and utilities sector is relatively large primarily due to the shipping industry.

Government jobs provide a significant percentage of employment in all four counties, exceeding employment provided by the lumber and wood products industry in 1983. Covered employment, by economic sector in the four counties for 1979, 1982,and 1986, is displayed in Table III-39.

Table III-39. Nonagricultural Wage and Salary Employment for 1979, 1982, and 1986 1/

Coos - Curry Counties	1979		1982		1986

INCOME

Table III-40 displays payrolls by economic sector for 1980 and 1984. Lumber and wood products comprise the largest share of payrolls in all counties except Jackson. They provide 40 percent of Curry, 34 percent of Coos, and 28 percent of Josephine County payrolls, respectively. Not surprisingly, the proportion of total income in each sector is closely allied with employment by sector. Wood products is also ranked as the highest paying sector for individual employee income Coos County has the highest overall payroll levels (in agreement with other income data) Curry County is below average in many sectors Transfer payments, which are generally government assistance of some sort, accounted for 24 percent of total income in Josephine County in 1979.

COUNTY REVENUES

The Siskiyou contributes to revenues of Coos, Curry, and Josephine in Oregon, and Del Norte in California. The counties receive both O&C payments and National Forest Fund (NFF) payments

Table III-41 displays the NFF and O&C payments received by the counties from 1980 through 1986. Payments increased throughout the 1970's when timber bid prices were high and much timber was being harvested. From 1979 to 1982, they fell dramatically. This was due to the decline in bid prices and slowdown in timber harvest activity, resulting in a decrease in timber revenues received by the Forest Service. Future payment trends depend, again, on National demand for wood products and the resultant creation of demand for stumpage.

O&C payments come from timber revenue generated on O&C land. This revenue is then allocated to counties by a percentage established by Federal statute. Approximately 173,000 acres of O&C land are located on the Forest.

Table III-41. Payments to Counties (M $)

	County						
	Coos		Curry		Josephine		Del Norte
Year	NFF	O&C	NFF	O&C	NFF	O&C	O&C
1980	330	160	3,870	100	1,950	320	420
1981	260	90	3,050	50	1,540	180	230
1982	90	20	1,010	10	510	40	50
1983	150	30	1,710	20	860	50	70
1984	180	70	2,050	40	1,030	130	170
1985	290	90	3,350	60	1,690	190	240
1986	300	60	3,500	40	1,760	120	150

SALES BELOW COST

Sales below cost occur where the cost of planning, preparing, administering, and implementing timber sale projects exceed cash benefits. They occur infrequently on the Siskiyou. From 1979 to 1984, receipts from the volume harvested on the Forest have exceeded total costs (Table III-42)

Table III-42. Timber Sale Costs and Receipts

Fiscal Year	Timber Harvested		Timber Sale
	MMBF	Values (M $)	Costs (M $) 1/
1979	221	41,311	1,994
1980	129	24,767	2,433
1981	93	16,180	3,126
1982	39	3,223	2,939
1983	103	10,500	2,420
1984	134	17,909	2,262

1/ Costs include all those related to the timber sale program except road costs

The cost of road construction and reconstruction associated with the timber program is a capital investment which is used for the present and future timber program, as well as other uses such as recreation and forest protection. The asset value of this capital improvement is the cost of road construction, engineering, design, and inspection (Table III-43).

Individual years when road costs exceeded gross or net timber revenues reflect mostly the conditions where roads were built but the timber was not removed due to the wood products recession. The average sale sold on the Forest has revenues exceeding costs by approximately $1,000,000 (for details, see Planning Records). However, there are some conditions where below cost sales may occur. These areas are characterized by a combination of factors such as low-valued species, low volumes of commercial species per acre, high logging costs, high site preparation and regeneration costs, and expensive road building Cost reduction reviews, scheduling of sales, and organization of units within sales are presently used to minimize the timber sale program costs.

Table III-43 Road Costs Related to the Timber Sale Program

Fiscal Year	Asset Value (M $)
1979	6,582
1980	12,801
1981	14,428
1982	17,319
1983	9,290
1984	8,447

CURRENT DEMANDS, WANTS, AND DESIRES

The word "demand" is used in many different ways. Its use here will be confined to the following definition: a quantity of output that users are willing to take at a range of prices with given conditions. For many Forest products, no exact price relationship has been determined. Therefore, many assumptions are used and are discussed below.

The discussion of demand is essential to making an informed decision on allocation of the Forest resources and productive capacity. The demands of the public and interest groups for timber harvest, preserved old growth, fish habitat, water quality, soil productivity, river recreation, sensitive plant preservation, scenic vistas, wildlife habitats, wilderness and unroaded recreation, and mineral resources are important considerations when allocating the Forest resources.

TIMBER HARVEST

Regional Timber Supply And Projections

The principal projections used in developing long-range plans and programs for management of the National Forests are contained in the Forest and Rangeland Renewable Resources Planning Act (RPA) Assessment and 1984 Update (USDA 1984a) These projects focus on the situation for the long term (50 years) and do not necessarily recognize current short-term regional fluctuations. A summary of the projected RPA trends (year 2030) for timber supplies follows.

Hardwoods

The current balance between growth of wood and its removal shows that hardwood forests and eastern softwood forests can support additional timber harvests However, this balance will change, and future harvests, particularly in the decade beyond 2000, could vary over a wide range Nonetheless, if commercial timberland owners continue to respond to price and inventory changes, then timber harvests can be increased substantially during the next few decades. The largest hardwood increase will be in the South, with an increase of 6.0 billion cubic feet in 2030 (USDA 1984a)

Softwoods

Total projected softwood harvests would rise 24 percent from 1980 to 11.9 MMCF per year by 2030. There are important differences among the major softwood timber producing regions In the Douglas-fir subregion, projected annual harvest from 1980 to 1990 is about 2 3 MMCF per year, then declines to about 2 MMCF per year This level is roughly maintained through the rest of the 50-year projection period.

In contrast, the other major source of softwood timber harvest is the South, which is projected to rise from about 4.1 MMCF in 1980 to 7.3 MMCF per year in 2030. However, most recent forecasts are now showing a downward modification in the rate of economic supply This may indicate that the South could be expected to be shifting to a slower rate of increase above present levels until the year 2030. Much of the expansion in the South with softwoods, as well as hardwoods, is due to the fact that its wood products production has become more diversified as compared to other regions of the country.

Short-Term and Long-Term Demand Trends

Over the next ten years, timber demand from the Pacific Northwest geographic region will grow slowly. Although there is a backlog of unfulfilled housing demand, the future will depend primarily on the continuing strength in personal income and the availability of affordable housing and financing. In addition, projections of exports to the Pacific Rim countries show a continuing slow economic growth. The analysis acknowledges there will be a declining trend in the construction sector. Structure replacement, rather than new construction, will characterize the housing market. Projections for increase in demand may be described as considerably restrained and cautious (Nomura 1981).

Evaluation of recent data and information indicates that the demand for timber is changing to a moderate rate of increase as compared to the slowdown that occurred in the early 1980's. The ability to sustain this increase is linked to the critical issue of costs The short-term future of timber and wood products demand is clouded by the severity and length of the housing and wood products recession that began in 1980.

The long-term trends in housing demand, the growing popularity of construction methods that use less wood, the availability of wood substitutes, and a shift in business management strategies all contribute to a potential shift in future demand (Adams and Haynes 1985).

Wood supply will continue to be an issue because it will be highly dependent on the ability of producers to lower costs to be competitive with wood substitutes (Schallau 1986) Although overall current timber supply levels in the Pacific Northwest Region may be capable of meeting future demand, the shifting of industry within the region, the shifting emphasis on the types of wood products produced, and the ability of the subregion to supply the various kinds of wood needed are subregional problems.

An effort by the wood products industry to broaden the economic base may enable the Pacific Northwest to regain much of its previous economic strength, this will take time The opportunity to increase exports to international markets by modernizing facilities, adopting state-of-the-art technology, reducing costs, and diversifying into other sectors of production (similar to what the South has done) could help to rebuild and stabilize the wood based sectors of the region (Schallau 1985).

Private and Public Land Interrelationships

Currently, part of the timber formerly supplied by the Pacific Northwest Region is being supplied by the South and Canada However, the situation with Canada can be expected to change as there are indications that the economic supply may begin dropping off within 6 years, or at least by 15 years. The projected change indicates a potential drop in supply capability of 30 to 50 percent from the current relatively high levels. The South should be able to maintain or show a slow increase in harvest because of its remaining inventory and some substitution of hardwoods However, both the economic and physical supply of softwoods from that area may begin to show a decline by the year 2030.

At about the same time this drop in supply capability begins to occur for the other sources, the growth of wood fiber on private lands in the Pacific Northwest would again be increasing its capability. The private lands in the Pacific Northwest could then become a major source of supply for softwoods to meet National and international demand. Further, during the period before the private lands in the Region regain their full supply potential, the public forests would be looked upon as a major source for a relatively stable supply of wood fiber (Schallau 1986).

The demand for timber harvest in the area surrounding the Siskiyou National Forest is assumed to be infinitely elastic This means any increase or decrease in local timber supply will not affect long-term price trends which are determined by the prevailing market conditions such as mortgage rates, strength of the U.S. dollar, and other factors at the National and regional level.

The total amount of wood harvested within the four-county area of Coos, Curry, Jackson, and Josephine for 1984 was 960 MMBF. About 240 MMBF were harvested on National Forest land. Approximately 350 processing firms use that wood to produce a variety of products including sawtimber, plywood, shakes, pulp, arrows, and other miscellaneous products Douglas-fir is the species most often bought, although pines, hemlocks, western red-cedar, and Port-Orford-cedar are also utilized. The demand for Port-Orford-cedar is high due to its use in Japan.

Lumber and wood products are the most important manufacturing industry in the area. Estimates of log flows from Siskiyou National Forest lands to mills in the area are shown in Table III-44. In addition to being the most timber dependent of the four counties, Curry County is also the most dependent on the Siskiyou, receiving more than half of its timber supply from this source. Josephine County mills obtain about one-fourth of the timber they process from Siskiyou lands. Relatively minor proportions are processed in Coos and Jackson Counties.

Table III-44. Total Number of Logs Consumed by Mills within Zone of Influence from the Siskiyou National Forest 1/

	Number of Logs (Year)					
	1972		1976		1982	
County	MBF	Percent	MBF	Percent	MBF	Percent
Coos	49,797	6	37,136	6	33,278	6
Curry	148,390	73	83,364	54	17,845	25
Jackson	-	-	573	-	10,673	3
Josephine	75,612	26	44,300	26	28,282	28

1/ Source 1972 data derived from Schuldt and Howard, (1974), 1976 data derived from Howard and Hiserote (1978), and 1982 data derived from Howard, (1984). The volume and percent figures are those amounts attributable to the Siskiyou National Forest

LOCAL TIMBER SUPPLY AND PROJECTIONS

The importance of the Forest supply potential is linked with the overall timber supply picture for the local area of influence and the timber market areas. Demand for wood products has been the major factor affecting the health of the local timber industry in recent years. However, concern that a shortage of raw material may affect the future health of the wood products industry requires projections of future timber supply.

The Forest has historically supplied significant volumes of timber for harvest. The current Timber Management Plan was completed in 1962 and established an annual potential yield of 191 million board feet (MMBF). Amendments have adjusted the potential yield to account for changes in the land base, the major changes being primarily Wilderness additions. Table II-36 displays the potential yield, as amended, and the net chargeable volume sold and harvested by year from 1963 to 1987.

Two timbersheds exist in the area of influence surrounding the Siskiyou National Forest. The Medford timbershed, defined as being Jackson and Josephine Counties, utilizes timber from the Galice and Illinois Valley Ranger Districts of the Siskiyou National Forest as well as from private lands, the Rogue River National Forest, and BLM lands within the two counties. The south coast timbershed, defined as Coos and Curry Counties, receives timber from Powers, Gold Beach, and Chetco Ranger Districts as well as from private, BLM, and other public lands. Though some timber from the Forest goes outside of these areas, such log flows are insignificant. For this analysis, the log flows between timbersheds and with adjoining areas are assumed to be equal in both directions.

Coos and Curry Counties

In Coos and Curry Counties, industry ownership covers the largest area with over 30 percent of the forested lands, but contains less than 20 percent of the standing sawtimber in the timbershed. National Forest lands, though smaller in area, contain approximately 40 percent of the existing sawtimber. BLM lands have about 25 percent of the existing sawtimber on about 13 percent of the forested land. Other ownerships, including State and county forests, and miscellaneous property owners, make up the remaining areas (Table III-45).

Table III-45. Timber Stand Conditions for Coos and Curry Counties

Ownership Class	Percent of Total Forest Land	Percent of Standing Sawtimber
National Forest	30	39
BLM	13	23
Other Public	5	8
Forest Industry	32	19
Other Private	20	11

Approximately 19 percent of the raw materials harvested in the south coast timbershed during the 1970's originated on the Forest. In the early 1980's, the Siskiyou National Forest's share of harvested material declined to 11 percent (Table III-46). Many stands on private land are just reaching merchantable age and opportunities to harvest volumes on private land are postulated to expand somewhat from that harvested in the early 1980's for the first decade. In the second decade, harvest volumes from private industrial lands are projected to decline by approximately 50 percent from the projected harvest in the first decade.

Table III-46. Projected Timber Harvest for Coos and Curry Counties (MMCF) 1/

	Private			Public	
Period	Other Owners	Industrial	Total	Siskiyou National Forest	Total
1970-1979	396	763	1,159	275	1,434
1980-1984	229	505	734	94	828
1989-1998	369	745	1,114		
1999-2008	369	329	698		
2009-2018	369	640	1,009		

1/ Projected Volumes from Fox (1988), and Relationship of Forest Plans to Other Timber Owners, Region 6, USDA Forest Service, available in the Planning Records

Jackson and Josephine Counties

Within these counties, Siskiyou and Rogue River National Forests cover the largest area with over 34 percent of the forested lands, and contain half of the existing sawtimber in the timbershed. BLM lands have about 33 percent of the existing sawtimber within the timbershed on about 27 percent of the forested land. Industrial forest landowners manage approximately 20 percent of the forested lands and presently have 10 percent of the existing sawtimber. Other ownerships make up the remaining areas and standing volumes (Table III-47).

Table III-47. Timber Stand Conditions for Jackson and Josephine Counties

Ownership Class	Percent Total Forest Land	Percent Total Standing Sawtimber
National Forest	34	49
BLM	27	33
Other Public	2	1
Forest Industry	20	10
Other Private	17	6

In Josephine and Jackson Counties, the Siskiyou National Forest supplied approximately nine percent of the total timbershed harvest in the seventies (Table III-48) In the early 1980's, its share of the harvest decreased to eight percent

Future harvests on private lands are projected to decline dramatically in the second decade due to the age distribution of the timber stands and the growing stock available Harvest levels from the Rogue River National Forest are assumed to follow the preferred direction stated in the Rogue River National Forest DEIS. If these assumptions overestimate the supply of timber, then the following demand for Siskiyou National Forest timber will be greater than that stated. If these assumptions underestimate the area's supply of timber, then the demand presented below for Forest timber will be overestimated

Table III-48. Projected Timber Harvest for Jackson and Josephine Counties (MMCF) 1/

Period	Other Owners 2/	Private Industrial	Total Other	Siskiyou National Forest	Total
1970-1979	662	314	976	96	1,072
1980-1984	510	203	713	65	778
1989-1998	611	241	852		
1999-2008	612	42	654

2/ Includes all of the Rogue River National Forest

Total Supply and Consumption

The supply picture alone does not dictate the future condition of the timber industry, or the role of the Siskiyou National Forest in relation to this industry It is the interactions of supply and demand that establish the framework for future possibilities. As has been the case for Pacific Northwest Region demand as a whole, the demand for southwestern Oregon timber has been increasing back to historic levels. The combined effects of the influx of inexpensive timber from western Canada and the expansion of the wood products industry in the southern United States did precipitate a major slump in the southwestern Oregon market. However, the local market has revived in the last two years and is projected to grow at a slow to moderate rate over the next 10 to 20 years This growth may be sufficient to eventually return to a level close to that prevalent in the 1970's

When and if demand for timber grows to a level of that reached in the 1970's, the supply situation will become the critical factor for limiting the output of the local timber industry. Increased wood production from industrial land over that of the present situation is limited Private woodlot owners could increase their production. However, historically, they commonly have different objectives and respond to market conditions at levels far below the potential production

Another factor affecting supply conditions for local mills is the proportion of local harvest which is exported Of the volume harvested in 1982, approximately five percent was exported. That percentage has been increasing with increased market access to Japan, China, and other Pacific Rim countries. If log exports continue to increase, the supply shortage for local mills will be heightened, while a decrease in exports would serve to lessen the shortage

As the market conditions continue to improve, the supply situation in the four-county area of Josephine, Jackson, Coos, and Curry Counties could become the dominant factor in determining consumption for Forest timber. A quantitative estimate of future timber consumption, though highly uncertain, is useful for relating alternative Forest harvest levels to the four county area. Projections have been made for the future (Tables III-49, 50, and 51) based on the following assumptions:

1. The figures shown in Tables III-46 and III-48 will be used to estimate consumption. The average annual harvest level for the 1980-84 level and the 1970-79 level will be used to calculate the lower and upper limits of future consumption.

2. The lower limit of total consumption in the 1989-98 period, is postulated to gradually increase from the 1980-84 level to a point halfway between the 1980-84 level and the 1970-79 level. Similarly, the upper limit of consumption for the same period is postulated to be a point three quarters of the way between the 1980-84 level and the 1970-79 level. This increase reflects the initial stages of the anticipated recovery of demand for Pacific Northwest wood products.

3. In the second and third decades, demand continues to grow. The upper limit from the first decade now becomes the lower limit of consumption for the second and third decades. The 1970-79 level is regarded as peak consumption and is assumed to be the upper limit in the second and third decades.

4. Demand for Siskiyou National Forest timber can be projected by subtracting total other harvest from estimated total consumption. The projections of demand for National Forest timber represent estimates of the volume that would be purchased if it were available.

The above projected demand for the Siskiyou National Forest timber program varies from 90 to 316 MMCF for the first decade, and from 930 to 1154 MMCF the second decade (Table III-51). The demand for Forest timber will be higher in the future due to the projected inability of other ownerships to produce at levels equivalent to their production of the 1970's.

Table III-49. Projected Demand for Siskiyou National Forest Timber - Coos and Curry Counties (Million Cubic Feet per Decade)

Period	Estimated Total Consumption	All Other Harvest	Projected Demand Siskiyou Timber
1989-1998	1,131-1,283	1,114	17-169
1999-2008	1,283-1,434	698	585-736
2009-2018	1,283-1,434	1,009	274-425

Table III-50. Projected Demand for Siskiyou National Forest Timber - Jackson and Josephine Counties (Million Cubic Feet per Decade)

Period	Estimated Total Consumption	All Other Harvest	Projected Demand Siskiyou Timber
1989-1998	925-999	852	73-147
1999-2008	999-1,072	654	345-418
2009-2018	999-1,072	930	69-142

Table III-51. Projected Demand for Siskiyou National Forest Timber in Coos, Curry, Jackson, and Josephine Counties (Million Cubic Feet per Decade)

Period	Total Projected Demand for Siskiyou Timber
1989-1998	90-316
1999-2008	930-1,154
2009-2018	343-567

The projected demand for National Forest timber (Table III-51) represents estimates of the volume that would be purchased if it were available. The anticipated future supply conditions in the area are as follows:

1. An initial increase in harvest from industrial lands, compared to the early 1980's, will occur in the first decade with a subsequent drastic decrease in available harvest in the second decade.

2. As demand becomes greater in the second decade, increased demand is placed on harvests from the Siskiyou National Forest. The high demand continues into the third decade.

3 If supply becomes limiting, prices will increase because of the excessive competition on available supply. A disproportionate increase in price relative to Canada and other regions may make the local area less competitive in international markets until the economic adjustment of less mill capacity is achieved.

The average stumpage price weighted by species for the 1973-1982 period is $285/MBF (adjusted to 1982 dollars). For planning purposes, this price was projected to increase by one percent per year. This assumption is derived from the historic trends over the long term (Barnett and Morse 1963).

PRESERVED OLD GROWTH

Many resources other than timber have consumer demands including the desire for preservation of old-growth stands. The demand for preservation of old-growth timber is hard to quantify. Concern for retention of old growth and its perceived intrinsic value will intensify as old-growth stands are harvested and the human population increases. No quantification of this demand by corresponding changes in users' fees or recreational values was attempted. However, the concern is assumed to exceed existing supply levels as evidenced by public controversy, political lobbies, and national debates.

FISH HABITAT, WATER QUALITY, AND SOIL PRODUCTIVITY

As discussed in the **FISH** section, the demand for anadromous fisheries has grown steadily; the demand for sports and commercial fisheries greatly exceeds supply. Fish habitat, water quality, and soil productivity are interrelated. Maintenance of soil productivity and water quality results in quality fish habitat where the instream environment and upslope conditions can be maintained. As such, the demand for fish is used as a surrogate demand for the three resources.

For planning purposes, the expressed value of commercial anadromous fish was set at $1.05 per pound. The value of a fisherman's day for anadromous sport fishing was placed at $33 per day; for a resident sport fishing, $15 per day.

WILD AND SCENIC RIVERS

Recreational resources generate economic returns. Tourism is a key industry in all of the counties It has been growing in importance during the last decade Since tourism is not a homogeneous, or strictly-defined industry, measurement of its economic contribution is less precise than for other sectors. Economic support through tourist expenditures shows up in the trade and service sectors, primarily from the purchases of food, lodging, gasoline, and souvenirs

The Forest contributes to tourism-related employment mostly through the attraction of the Rogue River for rafting, boating, fishing, and hiking The recreational demand for Wild and Scenic Rivers use was estimated by projecting a one-half percent increase in annual use from the recorded use in 1980. Recently, a large increase in recreational use on the Rogue River required initiation of a permit system to properly manage the recreational impacts. The projected increase in recreational use appears to be a reasonable assumption due to National trends in lifestyles, personal habits, and available leisure time.

For all recreation including use of the Wild and Scenic Rivers, the following values developed Nationally by an RPA planning committee are used for a Recreation Visitor Day:

$11.30 per day for Primitive recreation,
$13.30 per day for Semi-primitive Non-motorized recreation,
$12 10 per day for Semi-primitive Motorized recreation,
$ 9 30 per day for Roaded Natural recreation,
$17.50 per day for Wilderness recreation, and
$ 6.00 per day for Developed recreation

RECREATION IN UNROADED AREAS

Unroaded areas, including Wilderness and non-Wilderness areas, contribute to the social environment and are important when describing the existing condition. Besides being useful for Semi-primitive and Primitive recreation, these areas can be considered attractions for the liveability of the area and are important to the mental attitudes of many people. Many of the area's features that draw tourists are not located on the Forest Many other recreation opportunities exist in the area of influence. Ocean beaches, snow and water skiing, hiking, camping, Shakespeare plays, and river and lake recreational opportunities exist within the area. Such specific attractions include the Shakespeare and Britt Festivals, Jacksonville Historic Landmark, Wildlife Safari, Crater Lake National Park, Redwood National Park, and five National Forests (Klamath, Rogue River, Siskiyou, Six Rivers, and Umpqua National Forest).

The actual demand for this form of recreation was estimated by projecting a one-half percent annual increase from the recorded use in 1980 Again, this assumption appears reasonable due to the trends in lifestyles, personal habits, and amount of recreation time. The same values for visitor days were used as documented for the Wild and Scenic Rivers recreational demand

SENSITIVE PLANTS

The contribution of sensitive plants found on-Forest is limited in its economic scope However, the social aspects of the sensitive plants, due to the public interest, is an important consideration in the existing environment. The demand for preservation of sensitive plants has been expressed by the public Anticipated concern is assumed to be reflected by existing condition and to increase as development encroaches on sensitive plant habitat. Increased human population will tend to increase pressure on the habitat of plant species.

VISUALS

Concerns expressed by the public for Forest aesthetic values will increase as the population increases The present demand level is assumed to increase as additional landscapes are modified by timber harvest. Most of this demand is connected with recreation. Such recreational use is also projected to increase at one-half percent annually from the actual recorded use in 1980. The values for such recreation use are similar to those used in the discussion under **WILD AND SCENIC RIVERS.**

WILDLIFE HABITAT

Many public groups are interested in wildlife habitat. Concern for wildlife habitat is assumed to include viable habitat for old-growth species (displayed as part of the preservation of old growth), dead and decadent tree habitat, and suitable areas for big-game habitat. Wildlife habitat diversity and protection of threatened and endangered species are also major concerns

The demand for big-game species habitat is assumed to increase at 1 3 percent per year as projected throughout the Pacific Northwest Region The demand for big-game habitat will exceed supply at the historic quality level given these assumptions, lower success rates may result For planning purposes, the following values derived from RPA planning are used·

$30 per day for a big-game user,
$19 per day for a small-game user, and
$25 per day for nongame wildlife use.

MINERAL RESOURCES

The anticipated demand for mineral resources is not available. However, present activity indicates potential for significant gold, nickel, cobalt, coal, and chrome mining depending on markets.

ABILITY TO SATISFY DEMAND

The major outputs and public expectations from the Siskiyou National Forest include areas related to timber production, fish habitat and watershed condition, old-growth preservation, sensitive plant areas, forest scenic values, wildlife habitat, recreation opportunities, and mineral development. "Benchmark alternatives" display the maximum supply of these resources (Table III-52). The Benchmark alternatives are constrained by legal requirements for managing National Forest land, such as those relating to the habitat needs for viable wildlife populations and multiple use requirements.

Table III-52. Benchmark Outputs and Effects

TIMBER PRODUCTION

The Forest's maximum supply of timber (first decade output) with a nondeclining flow is 33.4 MMCF annual sell The maximum long-term average sell over a 150-year period is 40 6 MMCF. The Forest's ability to supply timber is associated with (1) opportunity costs for timber and other resources including recreational opportunities, fisheries, and wildlife values, (2) production costs including road construction; and (3) administrative costs of planning, implementation, and contract administration Different options for production and associated costs vary from 0 to 40 MMCF average sell (150-year period), and 10 to 30 million dollars (Figure III-23). All costs are for a 150-year period discounted at 4 percent At the low average annual production of 28 to 30 MMCF, the high opportunity costs of foregoing timber harvest on commercial forest land becomes the dominant cost At relatively high production levels, budget costs and opportunity costs for fish make up the dominant costs.

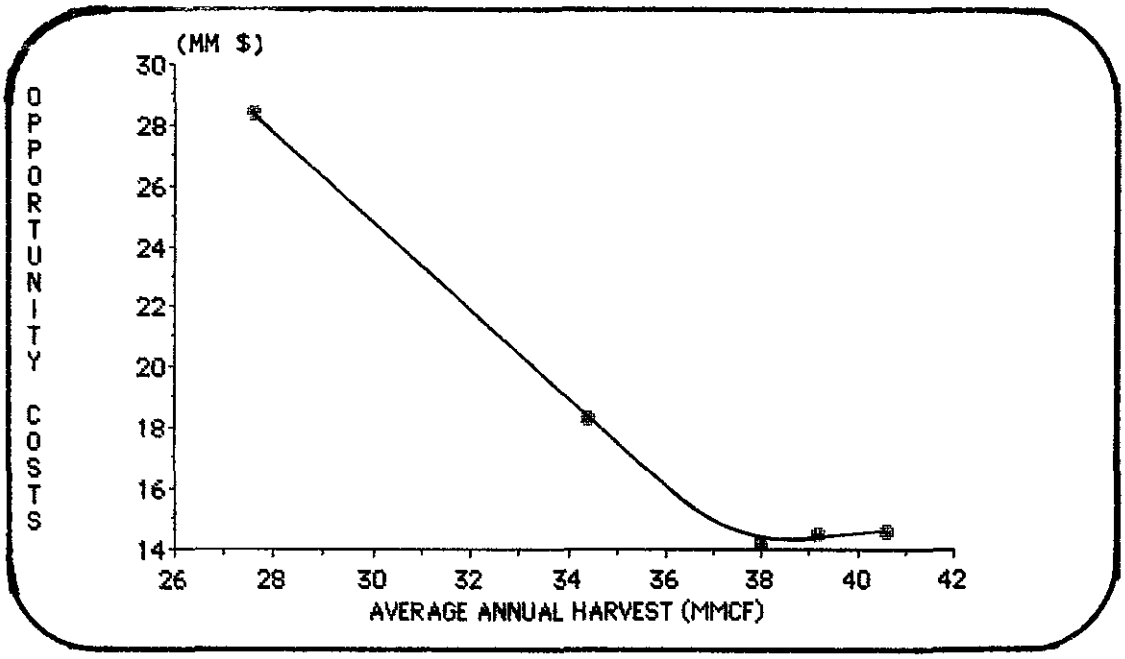

Figure III-23 Timber Production and Total Cost

OLD GROWTH HABITAT

The amount of old-growth habitat protected from harvest in all of Oregon and Washington is approximately 2 5 million acres The Siskiyou National Forest has a total of 0.4 million acres of existing mature and old growth In the local area, Crater Lake and Redwood National Parks, and the Umpqua, Rogue River, Six Rivers, and Klamath National Forests also have sizable acreages of old-growth forests However, the historic levels of old growth were much higher, particularly on much of the commercial forest land in the area of influence

The Forest's opportunity to protect forested areas containing old-growth characteristics is connected to opportunity costs of foregoing timber harvest on selected lands The range of production possibilities is illustrated in Figure III-24. The percentage of Forest in old growth in decade five is plotted against the opportunity cost of reducing the allowable harvest (discounted at 4 percent for 150 year period). Congressionally designated areas, such as Wilderness, and areas established to meet Management Requirements (MR's) provide protection of approximately 20 percent of the forest stands having old-growth characteristics. Since these areas leave the Forest few options, the resulting old growth has no opportunity costs displayed Opportunity costs previously calculated for wildlife MR's are provided in Appendix B As displayed, higher acreages of old growth involve higher opportunity costs of timber harvest. These opportunity costs are also associated with unroaded allocations (in general, Management Areas 1-9). Protecting areas of old growth may increase the amount of land allocated to an unroaded status.

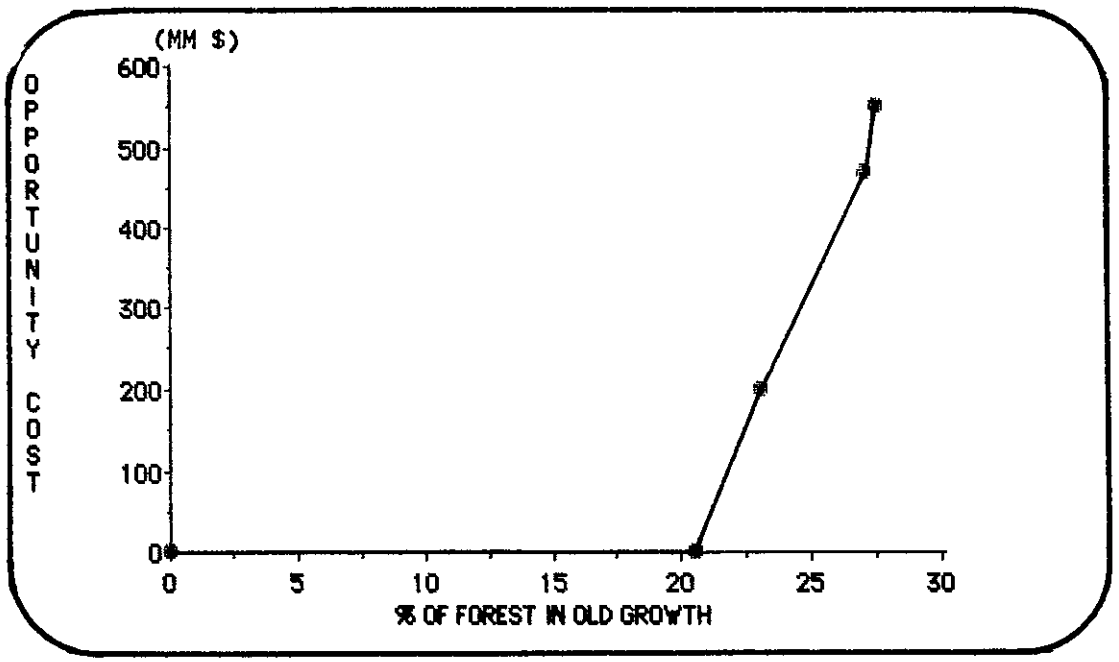

Figure III-24 Opportunity Costs of Foregone Timber Harvest in Preserved Old Growth

FISH HABITAT

The maximum amount of fish produced on the Forest is affected by both on- and off-Forest factors. Many off-site conditions affect the survival and return of the anadromous fish, including the commercial and sports fishing catch, seasonal streamflow extremes, and so forth Within the Forest there can also be wide swings in habitat capability by season or year. The Forest potential for providing fish habitat is affected by opportunity costs of foregoing harvests in Riparian Management Areas and capital investments At lower production capacity, capital investments provide increasing benefits To increase benefits even more requires reducing harvest along Riparian areas. At this point, the higher opportunity costs of foregoing timber harvest influence the steepness of the costs curve (Figure III-25). The potential for maximum production occurs over time when no timber is harvested in the Riparian areas and a high level of capital investments is maintained.

RECREATION

The recreational capacity of the Forest varies depending on land allocation. The Primitive and Semi-primitive recreational opportunities are the main concern The maximum amount of land that can be allocated, including existing Wilderness areas, to a condition suitable for Primitive or Semi-primitive recreational use is 547,000 acres

The Forest's ability to provide this type of experience outside of designated Wilderness has costs associated with foregoing timber harvest and the actual implementation costs (Figure III-26) These opportunity costs are also associated with the protection of old-growth. When areas are allocated to unroaded status, the protection of old-growth forests also occurs. Only implementation costs are associated with the lowest land allocation for Primitive recreation, while opportunity costs of foregoing timber harvest are associated with the maximum supply of Primitive recreation opportunities.

SENSITIVE PLANTS

The maximum acreage of land that may be allocated to Botanical and Research Natural Areas is 46,148 acres. The Forest capacity to provide adequate resources of sensitive plants is often associated with the opportunity costs of foregoing mineral extractions on selected Botanical and Research Natural Areas. These "costs" are presently not quantified due to uncertain markets and inadequate mineral surveys. However, the acres of mineral accessibility and restrictions to activity vary with the options of preserving sensitive plant habitat.

VISUALS

The maximum amount of area that may be allocated to Retention and Partial Retention Visual Management Areas is 88,000 and 300,000 acres, respectively. The supply of scenic vistas is directly related to the opportunity costs of timber harvest Slower rates of harvest on areas managed for scenic values are these opportunity costs. Increased amounts of pristine views are correlated with increased opportunity costs. These opportunity costs, therefore, may also be associated with the old-growth character of longer rotations. In other words, scenic vistas associated with a longer timber rotation also provide some old-growth characteristics

WILDLIFE HABITAT

Wildlife habitat measurements are varied depending on the objectives desired. Big-game habitat supply is more a result of Standards and Guidelines than major land allocations, assuming adequate openings are present Dead and defective tree habitat for species dependent on such habitat also varies with Standards and Guidelines There are few opportunity costs associated with such supplies, though higher logging costs, layout costs, and snag enhancement costs, such as tree topping, increase as one manages for an increased supply of dead and defective tree habitat.

MINERAL RESOURCES

Any change in Forest capacity to limit access for mineral extraction is primarily associated with areas allocated to an unroaded condition, conflicting resource values, and restrictive Standards and Guidelines Such restraints and requirements can affect the economic feasibility of mineral extraction.

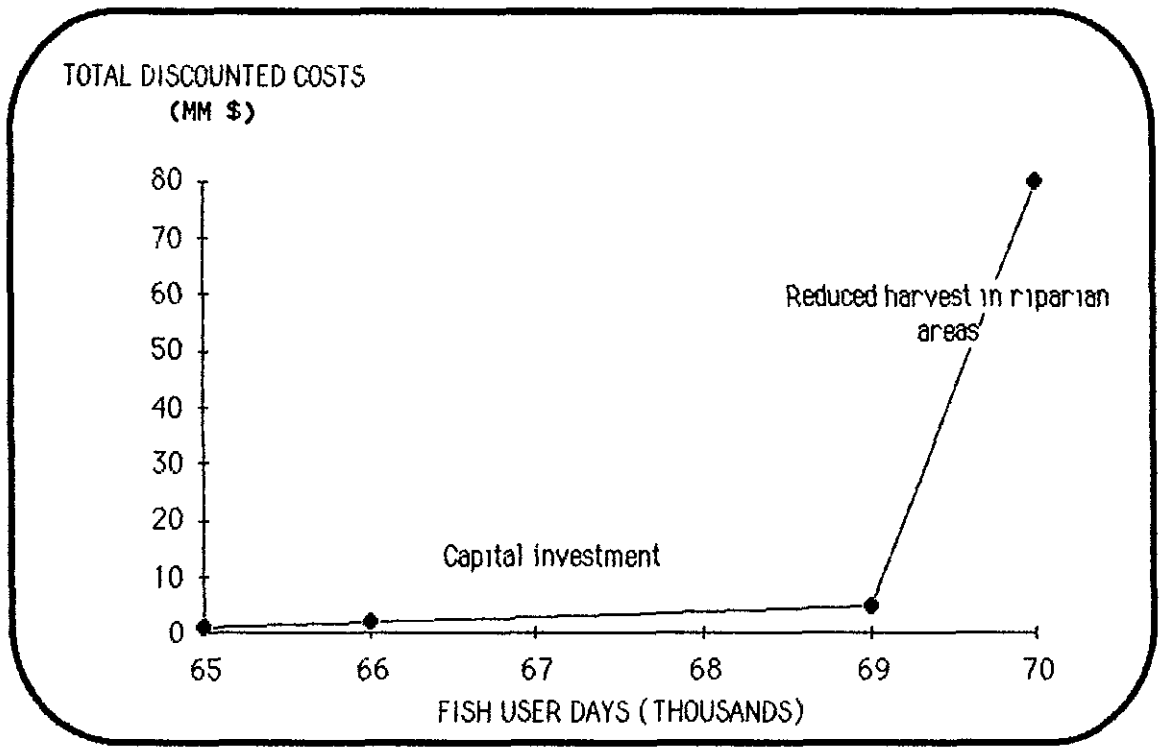

Figure III-25 Fish Production and Opportunity Costs of Reduced Harvest in Riparian Areas

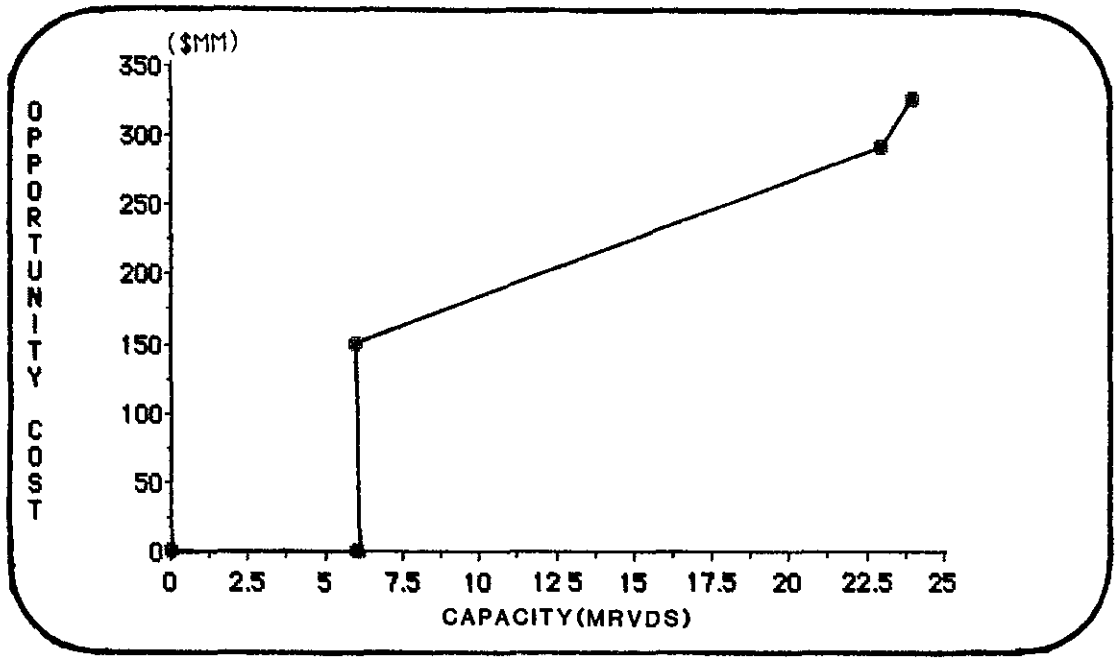

Figure III-26. Opportunity Cost of Reduced Timber Harvest in Primitive Recreation Opportunities Outside Designated Wilderness

1987 FIRES

During the public review period for the Forest DEIS, lightning ignited several major fires in southwestern Oregon Beginning August 30, 1987, and continuing for weeks and even months later, these fires swept over 128,252 acres, including 110,087 acres of Siskiyou National Forest land. During this period, several of the fires burned together forming the Silver, Galice and Longwood Fire Complexes. These fires burned a wide range of resources, including Wilderness, fisheries, and valuable timber and tree plantations.

Wide variation in burn intensity was characteristic throughout each complex Large areas within the fire perimeters were left unburned or merely underburned without killing the trees, leaving a mosaic of live and dead vegetation.

The environmental components most affected included soil and water, vegetation, fish, wildlife, visual resources, and recreation settings The discussion presented here concentrates on elements of these environmental components that specifically relate to the Planning Problems.

The most important resource changes relative to the planning analysis are changes in the timber inventory, the potential for changes in fish habitat and water quality conditions, and changes in wildlife habitat suitable for mature and old-growth dependent species. Other important considerations are the changes in other wildlife habitat and the recreation setting. Much of the area within the Silver Fire complex is unroaded (the inventoried North Kalmiopsis Roadless Area), the other fires have a moderately developed road system

For a full disclosure of the affected areas, a description of the resources impacted, site-specific management options considered in treating the resources and salvage of fire-killed trees, please refer to the following environmental documents (available in the Planning Records):

Silver Fire Recovery Project (FEIS and ROD, 1988);

Longwood Fire Salvage (Environmental Assessment and Decision Notice, 1988); and

Canfield-Chieftain (Galice) Fire Salvage Timber Sale (Environmental Assessment and Decision Notice, 1988).

VEGETATION TIMBER

The perception of the importance of the changes created by the fires based on the total fire area is quite misleading in terms of change in the timber resource Much of the Forest within the fire perimeter did not burn hot or long enough to kill the standing trees In addition, many of the areas burned were not suitable for timber production. Table III-53 displays the acres within each fire area, the acres within Wilderness, and the acres suitable for timber production

Table III-53. Land Status, 1987 Fires.

Fire Complex	Total Acres	NFS Acres	Wilderness	Unsuitable	Suitable
Galice	21,140	4,935	0	2,722	2,213
Longwood	10,572	8,912	656	3,861	4,395
Silver	96,540	96,240	53,340	20,463	22,437
TOTAL			53,996	27,046	29,045
Total NFS Acres		110,087			
Unavailable		53,996			
Net Available.		56,091			
Unsuitable		27,046			
Tentatively Suitable		29,045			

The intensity of the burn and the degree of change in the vegetation are important when assessing impacts on the timber resource. Table III-54 table displays the suitable acres within the fire perimeters by fire intensity, with a breakdown by vegetation class

Approximately 18,800 acres of tentatively suitable land burned at medium and high intensity Of this, 11,600 acres are mature timber and 5,600 acres are immature stands and plantations To put this in perspective, of the 624,240 acres of tentatively suitable Forest land, approximately 3 0 percent of the total has been impacted by fire. Tentatively suitable land contains 306,000 acres of mature timber; the burned portion represents 3.8 percent. The 5,600 acres of immature timber stands and plantations represent 2 2 percent of that category.

The volume of burned timber harvested in place of the normal green program will offset much of the inventory loss. The total volume of timber killed in all three fires was 332 MMBF. Volume planned for harvest that would offset green volume is approximately 190 MMBF. The estimated 142 MMBF lost from the inventory would affect the Forest's potential to produce timber in the future. Since the existing inventory must be metered out over 70-80 years to stay on a non-declining flow schedule, the maximum effect on the Forest's potential to produce timber is about 2 MMBF in Allowable Sale Quantity.

The salvage of burned timber in the immediate future will be balanced, in part, by shifting regular harvest activities to other parts of the Forest for the next few years This will result in a change in the scheduling of harvest activities under the Forest Plan.

Table III-54. Tentatively Suitable Timber Acres of High and Medium Burn Intensity by Vegetation Type

Galice Fire			
Vegetation Types	High	Medium	Total

WILDLIFE

The recent forest fires were an agent of positive change in wildlife habitat diversity. Although some areas were severely burned, many were not The fires have created a mosaic of habitats which has markedly increased habitat diversity. Populations of species dependent on older forest stages are expected to decrease (e g., spotted owls, hermit warblers, and red tree voles) Populations of species that utilize younger forest habitat (e.g., bluebirds, brush rabbits, blacktail deer, and elk) should increase. Resetting of the cycles in meadows and creation of more openings will benefit many species. Forage quantity and quality will increase in burned areas with deer and elk as the major beneficiaries. Overall, populations of wildlife species do not appear to be seriously affected, either positively or negatively by the fires.

Forest-wide, there is no serious impact as a result of the fires on the habitat network proposed to maintain minimum viable populations of wildlife species dependent on mature and old-growth forest. An interesting footnote to the Silver Fire during the summer of 1988 spotted owls responded to imitated calls in two locations where fire intensity was less severe.

Of particular concern in light of the planning issues are the changes in habitat suitable for wildlife dependent on mature and old-growth forest As part of the Forest Planning process, a network of suitable habitats has been identified for spotted owls, pileated woodpeckers, and pine martens. Where identified

habitat areas within the network no longer contain suitable habitat as a result of the fires, opportunities for adjustment of areas within the network have been evaluated. Only additional areas which would be a logical part of the network were designated. All necessary adjustments have been made, resulting in only minor effects on the alternatives considered in this FEIS. Summaries of the evaluations of identified habitat areas within the fire perimeters are described below.

Gallce Fire Complex

No management areas for Spotted Owl, Pileated Woodpeckers, or Pine Marten proposed in the habitat networks were within the fire area.

Longwood Fire Complex

Two SOHA's are within the Longwood Fire One was not severely affected; however, the other was severely burned and has been replaced by another area. In the area where the SOHA was replaced, a marten area has been mapped (established) in the burned area. The boundaries of one proposed Pileated habitat area and two Pine Marten areas have been adjusted slightly to fit suitable habitat.

Silver Fire Complex

One SOHA and four pileated areas are located outside the Wilderness; all are still suitable habitat. The burned portion of the Kalmiopsis Wilderness is capable of supporting 12 separate home ranges for spotted owls. Six of the habitat areas were not significantly affected by the fire; the other six have been affected to various degrees and some may not contain adequate habitat.

SENSITIVE PLANTS

Research Natural Areas were not impacted by the fires The Craggies Botanical Area is within the perimeter of the Silver Fire and the inventoried Chrome Ridge Botanical Area (a candidate area in several alternatives) was partially burned in the Galice Fire The fire did not eliminate a significant number of rare individuals or affect their viability. On the contrary, these plant communities evolved with fire and most of the sensitive species benefit from the reduction in competition from shrubs and trees. Thus, the fire helped to maintain species diversity within the Botanical Areas

FISHERIES/WATERSHED

Much of the shade producing vegetation on the perennial streams is still in place. Many small streams in the upper reaches of the watershed and a few principal tributaries to Silver and Indigo Creeks, however, were severely burned and the vegetative shade canopy lost. These changes will impact both stream temperatures and sedimentation as they affect the primary beneficial use, fish habitat. Critical summer stream temperatures are expected to increase by one to eight degrees Fahrenheit in some drainages. This will affect fish habitat capability to some extent since these streams currently reach temperatures exceeding 70 degrees Fahrenheit The projected increase resulting from the fire will push them to near critical thresholds Regrowth of streamside vegetation has already begun; full recovery is expected in 15 to 20 years on smaller streams, with larger streams requiring more time.

Sediment delivered to some of the severely burned streams is expected to be as much as triple pre-fire base levels. The significance of increased sedimentation was evaluated relative to characteristics of the specific watersheds involved. Silver, Indigo, Galice, and Tincup Creeks are steeper gradient systems with high flow energy capable of moving large amounts of material during winter storms. Even with the increase in sediment production, significant channel aggradation or siltation of anadromous fish spawning gravels is not expected to occur. Resident trout populations in upper reaches of some streams could be impacted,

particularly where large areas of the watersheds are severely burned or local stream gradients are subject to sediment deposition. Most of these streams are quite remote and receive scant fishing use

Cumulative effects analysis of the Silver Fire area indicates a first year post-fire reduction of approximately 6,500 steelhead smolt from the Silver and Indigo Creek drainages. Again, this will only be a temporary loss as full recovery will occur within a decade. Based on Forest Plan data, total steelhead smolt attributed to Forest production is approximately 948,000 fish. Reduction of steelhead smolt resulting from the Silver Fire is less than one percent.

The Longwood Fire occurred in the mid-reach of the East Fork Illinois River drainage. Riparian areas of the main stem East Fork received only minor damage during the burn. Tributaries in the burn areas of the East Fork flow very little in the summer season and are either dry or flowing under gravel as they enter the East Fork. Assuming a 10 percent reduction in steelhead capability of the East Fork drainage as a result of the Longwood Fire, total capability loss would be approximately 900 steelhead smolts per year, or about one tenth of one percent of the total Forest production

RECREATIONAL SETTING

Major portions of the Wilderness have burned, changes in the vegetative character will be obvious to recreationists These changes do not affect the primitive nature of the experience and may, over time, enhance the visual variety through creation of snags and openings, and rejuvenation of meadows. The view along the Wild segment of the Illinois River has changed slightly, but management options are essentially unaffected The mosaic of vegetative changes outside of Wilderness in the Bald Mountain area has also been changed, but again this will not have any appreciable long-term effect on the nature and type of recreation opportunity

The greatest impact on visuals was localized in areas of the Longwood Fire which face toward the community of Takilma Visual considerations accompanied the project-level environmental analysis of the proposed salvage harvest of fire-killed trees.

The resulting changes in recreational setting and use in the aftermath of the fires do not appear to have any major implications in terms of the resolution of the issues addressed in this environmental analysis. In fact, the present setting is strongly influenced by evidence of earlier fires. In addition, substitution of opportunities in one area for another has not been a part of resolution of this issue (the issues center on individual areas more than the total supply of opportunities).

While the fires themselves did not appreciably change the recreation opportunities on the Forest, the proposed salvage logging and associated road construction of the Silver Fire Recovery Project would affect the roadless area and unroaded recreation opportunities. The Selected Alternative of the Silver FEIS and Record of Decision, as amended by the 1989 Appropriations Act, schedules construction of approximately 13 miles of road in selected parts of over 42,000 acres burned in the unroaded portions of the North Kalmiopsis. The decision affected change in the inventoried unroaded boundaries, with impacts on the Primitive and Semi-primitive Non-motorized recreation opportunities as noted above.

The roads have been built in the Bald Mountain and Indigo Creek areas Maps showing the changes in the unroaded boundary and changes in the ROS inventory are provided in Appendix C The former North Kalmiopsis Roadless Area would be reduced from 110,175 acres to 88,582 acres. The decision to road and salvage portions of the Silver Fire would contribute approximately 19,000 acres to the reduction in Forest-wide roadless area inventory. See **WILDERNESS AND ROADLESS AREAS** and Appendix C for an indepth discussion of changes in the inventoried roadless area. The changes in ROS class resulting from the Silver Recovery Project are shown for the project area in Table III-55 The changes in ROS inventory Forest-wide are shown in Table III-56.

Table III-55. Changes in ROS Class Inventory within Silver Recovery Project Boundary

ROS Class	Previous	Current
Primitive	5,200	0
Semi-primitive Non-motorized	20,400	5,700
Semi-primitive Motorized	11,800	2,500
Roaded Natural	5,500	34,700
Total	42,900	42,900

Table III-56. Forest-wide Changes in ROS Class Inventory Resulting from the 1987 Fires and Related Recovery Projects

ROS Class	Previous	Current
Wilderness Primitive	114,000	114,000
Wilderness Semi-primitive	118,000	119,000
Primitive	22,000	17,000
Semi-primitive Non-motorized	97,000	82,000
Semi-primitive Motorized	113,000	104,000
Roaded Natural	628,000	656,000
Total	1,092,000	1,092,000

Chapter IV
ENVIRONMENTAL CONSEQUENCES

INTRODUCTION

The purpose of this chapter is to disclose the environmental consequences of implementing the alternatives described in Chapter II Relative to the existing conditions and affected environment described in Chapter III, each alternative potentially impacts various components of the environment. Those environmental effects are presented in this chapter, and form the scientific and analytic basis for the comparison of alternatives examined in Chapter II.

Impacts on components of the environment are discussed in terms of their significant direct, indirect, and cumulative effect(s). *DIRECT EFFECTS* are generally the result of land allocations to Management Areas that prescribe permissible activities on lands within the area's perimeter. Agency activities and the inherent capability of the land provide goods and services that may be consumed by the public. Government expenditures that finance agency activities are treated as a direct effect in the economics section of this chapter.

INDIRECT EFFECTS generally occur when the public takes advantage of the opportunities provided in each alternative. Public use of the Forest for recreation (including hunting and fishing), timber harvest, and mineral withdrawal, for example, can have adverse effects on various components of the environment. The value to society (benefits) of goods and services are treated as indirect effects in the economics section of this chapter, as are the impacts on revenues, jobs, and income

CUMULATIVE EFFECTS deal with both the synergistic effects over time and the incremental change from existing conditions given the combined actions of the agency and other ownerships in southwest Oregon and northwest California. The net effect on individual program efficiencies, jobs, income, and social parameters (such as community stability), are treated as cumulative effects in the economics section of this chapter Some of the effects are described in qualitative terms, while others are described in quantitative terms.

All effects disclosed in this chapter assume complete compliance with the Standards and Guidelines summarized in the FEIS, Appendix D, and the Forest Plan, Chapter IV. Environmental consequences would be far more severe, or unacceptable, in the absence of Standards and Guidelines and accompanying Best Management Practices (BMP's) These Standards and Guidelines contain many of the mitigations that avoid, minimize, restore, replace, reduce, or eliminate probable or potential environmental impacts. Standards and Guidelines also include the Monitoring and Evaluation Program requirements (detailed in the Forest Plan, Chapter V) that serve as the enforcement mechanism for achieving desired future conditions

The environmental effects that are expected to result from timber harvest are based on the use of even-aged timber management regimes and assume predominant use of the clearcut harvest method. Use of other systems is not precluded; final selection of silvicultural systems will be based on site-specific analyses. Appendix G - Selection of Silvicultural Systems describes the process and factors involved in making this determination.

The organization of this chapter is similar to that of Chapter III. Environmental components become the subject of analysis. The "existing condition" description of each component in Chapter III provides the foundation for the impacts discussed in this chapter. A thorough reading of Chapter III, Affected Environment, will improve the reader's understanding of material in this chapter. The structure of Chapter IV is designed to trace the natural progression of consequences (resulting from an agency action, such

as road construction) through the physical and biologic components of the environment, ending with the social and economic implications of the action.

Each environmental component is introduced with a description of the significant interactions which summarize the relationship between site-disturbing activities and impacts on the component Table IV-1 indicates the more important effects expected between causative agents (e g , land allocation proposals, agency activities, public consumption of goods and services) and environmental components Interactions shown are specific to the Siskiyou National Forest. The reader is encouraged to review the entire chapter in order to understand the complete ramifications of the proposed actions in this FEIS

Several special summaries follow the disclosure of impacts by environmental component. A review of potential conflicts with plans and policies of other jurisdictions for alternatives considered in this FEIS is provided, followed by a discussion of the adverse impacts that cannot be avoided, the relationship between short-term use and long-term productivity, and the irreversible and irretrievable commitment of resources associated with implementation. Environmental effects or conditions common to, or unchanged by the alternatives, are also outlined The chapter concludes with a series of specific disclosures required by NEPA and CEQ regulations for the proposed action.

Mitigation, as referenced in the above discussion of Standards and Guidelines, is extremely important in the design of the alternatives and during the implementation of any alternative. In general, "mitigation" is a measure taken to cause an action to become less harsh or less severe From the CEQ Regulations (40 CFR 1508 20), "mitigation" includes.

1. *Avoiding* the impact altogether by not taking a certain action or parts of an action;
2. Minimizing impacts by *limiting* the degree or magnitude of the action and its implementation,
3. *Rectifying* the impact by repairing, rehabilitating, or restoring the affected environment;
4. *Reducing* or eliminating the impact over time by preservation and maintenance operations during the life of the action; and
5 *Compensating* for the impact by replacing or providing substitute resources or environments

In the design of alternatives in Chapter II and throughout the discussion of environmental consequences by resource component in this chapter, mitigations have been thoroughly incorporated and evaluated. For the actions analyzed in this programmatic EIS, both the means to resolving the issues (Planning Problems) and mitigations are primarily addressed through **land allocations, standards and guidelines**, and **capital investments.**

Mitigations are easily found in this chapter if the concept is understood. Some examples may help to highlight their use Where a sensitive nest site of a falcon is known to exist, a land allocation (such as Special Wildlife Site) or guideline requiring that any proposed management activity remain at several hundred yards distance can be applied to *avoid* the potential disturbance of that site and its occupants However, if the falcons only use the site for rearing of young, then a standard which requires a seasonal closure to activities in the vicinity of the nest may be most appropriate for *limiting* or minimizing the impacts during the occupancy period

Quite often soil and water improvements through capital investments are utilized in *rectifying* prior impacts (as in restoration of an old, badly eroding road) or in preventing erosion (such as grass seeding, mulching, or paving a newly constructed road) Programmed road maintenance for the level and type of use and other resource considerations is valuable in *reducing* many resource impacts while providing protection to the capital investment (the road itself) over the life of that facility.

Numerous examples of mitigations can be listed However, if the use of land allocations, capital investments, and standards and guidelines are tracked closely, the various forms of mitigation should be readily apparent.

CHANGES BETWEEN DRAFT AND FINAL

Several areas of change have occurred since the DEIS These changes are noted in previous chapters and in the formulation of Alternative S, in particular The changes primarily resulted from the Omnibus Wild and Scenic Rivers Act of 1988 (which added the Chetco, Elk, and North Fork Smith Rivers to the National System), the 1987 fires, roadless area inventory adjustments, and public and other agency input relative to many of the resource components The greatest concerns revolved around environmental impacts associated with biological diversity and old growth, overall forest productivity, water quality, and fisheries

In evaluation of alternatives, only Alternative S fully represents the existing and newly designated Wild and Scenic Rivers. Other alternatives presented different management options to assess Wild River and Scenic/Recreation River allocations. The very recent legislation has negated the need for disclosing these potential effects and has effectively altered Planning Problem #4 (see Chapter I) Alternatives (other than Alternative S) which disclose environmental consequences associated with the Chetco, Elk, and North Fork Smith Rivers should be viewed in light of their recent change in status

The 1987 fires did affect the environmental setting for portions of the Forest (see Chapter III). In this Chapter, components which would change by alternative have been evaluated and the consequences provided under **1987 FIRES** Adjustment in the inventory resulting from the fires has not been applied to the alternatives evaluated in the FEIS. However, any alternative selected would be updated for these changes in the Forest Plan.

Considerable public input centered around the roadless area issue Comments focused on the "Custodial (Roadless)" Management Area which emphasized protection of these areas in an essentially preserved state. Management Area 6 goals and prescription have been changed to emphasize a greater array of recreational opportunities, and lesser restrictions on mineral entry and development (see Chapter II). The Management Area "Backcountry Recreation" replaces Custodial (Roadless). Backcountry Recreation better represents the intent and focus of management direction. For Alternative S, individual allocations to Backcountry Recreation are assigned to either motorized or non-motorized use

As noted in Chapter III, acres of inventoried roadless areas have changed since 1984 The effects on the new inventory of 284,000 acres are disclosed in **WILDERNESS AND ROADLESS AREAS** The decision for the Silver Fire Recovery Project created the largest adjustment in the inventory. Analysis of the affected wilderness characteristics for this site-specific project are provided in the Silver Fire Recovery Project FEIS and Record of Decision (USDA 1988). Specific changes in inventory and a analysis of each alternative by inventoried roadless area are provided in Appendix C.

The environmental consequences associated with the alternatives as addressed by resource component have been re-evaluated and changed, where necessary, to represent or respond to public and other agency input. One component, **BIOLOGICAL DIVERSITY**, has been added. Treatment of biological diversity, however, is addressed within several resource components in other sections of Chapter IV

Parts of the **SOIL AND WATER** and **FISH** sections have been combined to better disclose their interactions and potential effects. In addition, the process and application of Best Management Practices (BMP's) that accompany the Standards and Guidelines common to all alternatives have been further described and developed (see Forest Plan, Appendix F).

LAND ALLOCATIONS

SIGNIFICANT INTERACTIONS

The allocation (assignment) of land to various Management Areas may change existing land status because it establishes the permissible activities and uses that can occur on an acre of land, as described in Chapter III. Taken collectively, the land allocation "decision," with its associated activities and uses, provides the primary mechanism for creating environmental effects. Agency activities permitted within each Management Area are treated as the causative agent for all direct environmental impacts presented in this chapter Agency activities also produce, or make available, the goods and services necessary to resolve most planning problems The public's consumption of those opportunities creates, in turn, indirect environmental effects, removed in time and space from most initial agency actions.

Relative to the General Forest Management Area, lands assigned to other Management Areas limit site-disturbing activities by varying degrees. Depending upon the objective of each Management Area, Standards and Guidelines establish the acceptable degree of site disturbance and the kinds of uses permitted on lands within its perimeter Standards and Guidelines governing Wilderness, for example, greatly limit site disturbance Even activities such as trail construction are restricted to primarily the use of hand tools. General Forest Standards and Guidelines, on the other hand, permit a considerable degree of site disturbance to accommodate a broad range of multiple uses, subject to the provisions included in Forest-wide Standards and Guidelines.

ENVIRONMENTAL EFFECTS AND MITIGATION

Environmental consequences on land status, as defined in Chapter III, are presented in this section. *DIRECT EFFECTS* on land status are characterized by the number of acres represented by each Management Area (Table IV-2) and the Standards and Guidelines that define acceptable practices and permissible uses The amount of use anticipated, such as timber harvest and recreation, is presented in Chapter II, and reflects the number of acres allocated to each Management Area. The significance of use, or public consumption, of the opportunities provided in each Management Area is evaluated as indirect environmental consequences, and is presented in the subsequent sections of this chapter.

Because each alternative generally has some land represented by all Management Areas, the organization of this section differs from the format in the remainder of Chapter IV Direct effects of the alternatives on land status are presented by Management Area Following a statement of the objective for each Management Area, a summary of the Standards and Guidelines that define the permissible degree of site disturbance, access restrictions, and acceptable uses and activities is presented. The number of acres allocated to each Management Area (displayed in Table IV-2) indicates the direct effect of each alternative

Land allocations to the first nine Management Areas are designed to limit site-disturbing activity that can occur. Motorized access is generally restrained to one degree or another, and mineral and energy operating plans contain strict requirements and mitigative measures to protect the features and primary values of the Management Area. On occasion, withdrawal from mineral entry is requested. Lands in these Management Areas are rarely offered in land adjustments or exchanges. Agency activities are designed to provide basic resource protection (e.g , fire suppression and insect and disease control) and facilitate recreational use Land assigned to Management Areas 1-9 ranges from 280,863 acres (28 percent of the Forest) in Alternative NC to 670,117 acres (61 percent) in Alternative M.

Table IV-2. Acreage in Management Areas by Alternative

Management Area No.-Name	ALTERNATIVE

1/ Alternative M includes 97,661 acres not accessible from existing roads [illegible]

Land assigned to the last five Management Areas provides a much broader range of uses. A greater degree of site disturbance is allowed. The visual emphasis in three of the five areas, however, does limit the methods, scheduling, and locations of some site disturbing activities. Motorized access is prevalent in these Management Areas in support of the timber harvest program, some forms of recreation, and hunting use. Overall, energy and mineral development opportunities are not encumbered by overly-restrictive requirements and mitigations for access and development. Land assigned to Management Areas 10-14 ranges from 422,185 acres (39 percent of the Forest) in Alternative M to 811,439 acres (72 percent) in Alternative NC.

No indirect or cumulative effects on land status have been identified.

Wilderness Management Area (1)

These areas were established by Congress to provide opportunities for solitude and recreation in a natural state. Standards and Guidelines for Wilderness limit site disturbance to that which can be accomplished with hand tools *With the exception of mining activity on valid claims established prior to December* 31, 1984, no motorized access is permitted. Land within the Wildernesses is not available for energy and mineral development, except as previously noted. Total acreage within the Wilderness Management Area (232,495 acres) remains fixed by alternative Where two or more Management Area allocations overlap (e.g , Big Craggies Botanical Area in the Kalmiopsis Wilderness), the Wilderness effects and constraints on land status take precedence.

Levels of agency activity that vary by alternative are generally limited to trail construction/reconstruction and activities related to resource protection. Natural fuels treatment within Wilderness is permitted to varying degrees in all alternatives, except Alternatives NC, A, and A-Departure.

Wild River Management Area (2)

With the exception of permits, structures, and practices that were established prior to legislative designation, site disturbance within the Wild River Management Area is generally limited to that which would preserve the river in a natural, wild, and primitive condition. No motorized access is permitted unless provided for in the legislation (e g., Rogue River as cited in P L. 90-542). Subject to valid existing claims, lands in Wild River are withdrawn from mineral and energy development

Trail development, fish and wildlife habitat improvement projects, and primitive campsites illustrate the extent of agency activities permitted in the Wild River Management Area Treatment of natural fuels through prescribed burning is also permitted in all alternatives except NC, A, and A-Departure.

Research Natural Area Management Area (3)

RNA's are established (or recommended to be established) to represent typical and distinctive natural ecosystems and habitats for scientific or educational use in an unmodified condition. Standards and Guidelines for RNA's generally prohibit site disturbance unless consistent with the objectives of the area. Site-disturbing activities beyond trail development and maintenance are not permitted in this Management Area. Special use permits may be approved by the Pacific Northwest Experiment Station when directly related to the objective of the RNA Lands within this Management Area would have high levels of access restrictions for mineral and energy development However, withdrawals from mineral and energy development can only be considered through the NEPA process.

Three existing RNA's total 1,957 acres. Recommended additions to this Management Area of approximately 1,300 acres occur under Alternatives E, G, K, M, and S.

Botanical Management Area (4)

Similar to RNA's, these areas provide educational or recreational opportunities to observe exceptional plants and plant communities in a natural setting. A limited amount of site disturbance is permitted when it will not adversely affect endangered, threatened, or sensitive plants, and is consistent with the area's management objectives. Both motorized and trailed access are permitted to facilitate recreational opportunities. Withdrawal from energy and mineral entry may be considered through the NEPA process if development would jeopardize plant values emphasized in the area. Lands classified (36 CFR 294 1) as Botanical Area are unavailable for land adjustments or exchanges.

Three established areas total 4,475 acres Recommended additions to this Management Area range from 4,581 acres in Alternatives B, C, D, and D1, to 34,591 acres in Alternatives G and M

Unique Interest Management Area (5)

Lands allocated to this area provide recreation and education opportunities for observing unique or exceptional geologic features and cultural sites with historical significance Site disturbance that does not jeopardize the particular feature for which the area was recommended is generally permitted Access to the Management Area may be by road or trail. Where unique features are jeopardized, withdrawals from energy and mineral entry would be requested, if justified, and evaluated through the NEPA process Special-use permits may be granted that are consistent with the objectives of the individual areas. Lands classified (36 CFR 294.1) in this Management Area are generally not available for land adjustments or exchanges.

Allocations to these areas range from no acres in Alternatives NC, A, and A-Departure to 2,015 acres in Alternative S.

Backcountry Recreation Management Area (6)

Other than mineral activities, land allocated to this Management Area is managed to provide motorized and/or non-motorized recreation opportunities in an undeveloped setting. Other than mineral activities as noted, site-disturbing activities are not planned except for those activities described below. Unless associated with approved operating plans for mineral activity, motorized public access is restricted to designated travelways. Mineral access and site impact restrictions may be considered if they exceed the inventoried Visual Quality Objectives (VQO's) for the specific area, and mitigative measures are deemed ineffective

Fire prevention, presuppression, and suppression activities, trail construction and maintenance, treatment of major catastrophic losses, and control of insect and disease problems are the extent of agency activity in this Management Area. Motorized uses will generally occur where such use currently exists

Allocations to Backcountry Recreation range from no acres in Alternatives NC, A, A-Departure, B, C, D, and D1, to 301,737 acres in Alternative E.

Supplemental Resource Management Area (7)

Lands allocated to this Management Area possess inherently high watershed, recreation, fish, and wildlife values Site disturbance is limited to those activities which can be completed without adverse effects on the emphasized resources. As necessary, road access is occasionally permitted using techniques and locations that have the least impact on the watershed. Special requirements or mitigative measures may be necessary for energy and minerals development to comply with watershed objectives Lands in this Management Area are not available for land adjustment or exchange.

Agency activities within the Supplemental Resource area include development and maintenance of trails, watershed restoration, fish and wildlife habitat improvements, and developed recreation sites when compatible with primary resource objectives No timber harvest is programmed and firewood cutting is generally prohibited. Roads that comply with the Standards and Guidelines for this management area may be built and maintained.

Allocations to Supplemental Resource Management Area range from 1,285 acres in Alternative C, to 50,453 acres in Alternative G

Designated Wildlife Habitat Management Area (8)

Supporting plants and animals dependent upon mature and old-growth habitat, these areas are distributed throughout the Forest in a manner that facilitates population dynamics and long-term viability. Site-disturbing activities are limited to those that do not significantly alter existing old-growth characteristics, or occur beyond 1,000 feet of spotted owl nests or roost trees. Motorized and trailed access *is located to minimize impacts on indicator species, especially in the vicinity of nest trees Requirements* will be included in mineral and energy operating plans to minimize impacts on old-growth vegetation and nest sites.

Fire prevention, presuppression, and suppression activities, treatment of catastrophic losses, and control of insect and disease problems are examples of management activities typical to this area Most road and trail construction would occur to access other destinations. There is no programmed timber harvest and firewood cutting is prohibited

For alternatives which meet Management Requirements (MR's), land assigned to the Designated Wildlife Habitat Management Area ranges from 39,242 acres in Alternative E to 70,858 acres in Alternative G Alternative NC, which does not carry the current MR array, contains 5,082 acres of designated habitat; these acres are allocated in conformance with a memorandum (April 20, 1981) from the Regional Forester which establishes interim direction for management of spotted owl habitat (32 pairs; 300 acres per pair).

Special Wildlife Site Management Area (9)

Representing an array of unique plant and animal conditions that contributes to overall habitat diversity, these lands include meadows, water-dominated habitat, hardwood stands, rock cliffs, and small blocks and stringers of old-growth forest used as travel corridors by many animal species. The degree of site disturbance in this Management Area varies depending upon the specific area objective and condition. While no timber harvest is programmed in these areas, some activity is permitted as noted below. Motorized and trailed access is generally permitted, but discouraged in meadows Mineral activity is generally not encouraged as these sites are normally quite limited in size. Operating plans for mineral and energy development would be designed to minimize impacts on special site values.

A variety of agency activities designed to improve or enhance wildlife habitat may occur depending upon the characteristics and objectives of the individual site Road and trail construction is usually designed to access other destinations. Prescribed burns and removal of tree encroachments in meadows are typical of the activities oriented to enhancement of the resource.

Allocations to Special Wildlife Sites range from 5,883 acres in Alternatives A and A-Departure, to 27,450 acres in Alternative S.

Scenic/Recreation River Management Area (10)

Established to provide river-oriented recreation in an area of high scenic quality and largely undeveloped shorelines, lands allocated to this Management Area are limited in degree of site disturbance by VQO's of Retention as seen from the river itself, and/or Partial Retention within the 1/4 mile corridor on either side

of the river Scenic segments limit activity to that which will maintain visual quality and undeveloped shorelines, while development activity in Recreation segments may result in a substantially modified appearance.

Motorized and trailed access is permitted in both sections, but VQO's are generally more restrictive in the Scenic sections. High access restrictions may be imposed where necessary to protect river values.

A wide range of management activities, including construction and maintenance of trails and campsites, fish and wildlife habitat improvements, and timber harvest may occur in this Management Area. The amount of timber harvest activity and associated road construction varies by alternative Recreation use of the river may be controlled to maintain the character of each river.

Allocations to Scenic/Recreation River range from 3,557 acres in Alternative K, to 15,248 acres in Alternative NC

Riparian Management Area (11)

Bordering all perennial streams, rivers, and other bodies of water, lands occurring in the Riparian area are allocated to one of three different management regimes depending upon the emphasis in the alternative. Riparian vegetation in a particular basin is managed as an entire system over space and time. Planning Basins are allocated to one of three management prescriptions· Riparian Prescription B, Riparian Prescription C, or Minimum Level.

For the Minimum Level, there is no programmed harvest; little disturbance is permitted within the Riparian area. Basins managed with Prescription B permit some site disturbance and removal of trees where other riparian objectives can be concurrently met. Prescription B is designed to maintain existing water temperatures over the whole planning basin Site disturbance under Prescription C is limited to that activity which, over time, results in an improvement in summer water temperature.

A wide range of management activities, including construction and maintenance of trails, roads, and campgrounds, fish and wildlife habitat improvement projects, watershed restoration, and timber harvest may occur in areas allocated to Prescriptions B and C. The intensity of harvest activity will vary with Prescriptions B and C; site-specific environmental analysis is accomplished during implementation at the project level.

Allocations to Prescription B range from no acres in Alternatives E, G, and M, to 84,517 acres in Alternative NC. No land is allocated to Prescription C in Alternatives NC, A, A-Departure, C, E, and M, while Alternative G has 45,212 acres allocated to Prescription C The Minimum Level prescription applies to the Upper Chetco Planning Basin in all alternatives because it is entirely in the Kalmiopsis Wilderness. Over 56,000 acres are allocated to the Minimum Level prescription in Alternative E and M.

Retention Visual Management Area (12)

The maintenance of natural or near natural scenic quality during timber harvest, road construction, and other activities in areas of high recreational value is the objective of lands allocated to this Management Area Site disturbance is limited to those activities which result in visual impacts that are subordinate to the characteristic landscape Special mitigative measures may be necessary in energy and mineral operating plans to comply with the visual quality emphasis of this Management Area

No restrictions on agency activities apply to lands in this Management Area as long as techniques and locations that meet the VQO are utilized. Timber harvest opportunities are generally adjusted at the project level by area of activity, specific boundary adjustments, and condition of the viewshed relative to past management practices.

Allocations to the Retention Visual Management Area range from no acres in Alternative C, to 50,715 acres in Alternative NC

Partial Retention Visual Management Area (13)

Lands allocated to this Management Area are visible from major and secondary travel routes, rivers, and other high-use recreation areas Site-disturbing activities utilize techniques and locations that result in a visual impact that is subordinate to the characteristic landscape. Special measures may be necessary in energy and mineral operating plans to comply with the visual quality emphasis of this Management Area.

No restrictions on agency activities apply to lands in this Management Area as long as techniques and locations that meet the visual quality objective are utilized. Timber harvest activity is designed at the project level to meet the applicable guidelines.

Allocations to Partial Retention Visual areas range from 86,551 acres in Alternative C, to 229,802 acres in Alternative NC

General Forest Management Area (14)

Remaining Forest Service lands, following the allocations discussed above, are retained in this Management Area Other than Standards and Guidelines governing the Forest as a whole, no other restraints on site disturbance affect land in this Management Area. The basin-specific harvest constraint does apply, however, to the total area that can be disturbed in any one decade. This constraint occurs on six basins in Alternatives B, D, and D1, and on all basins in Alternatives E, G, K, M, and S. An extensive road system provides access for harvest, haul, timber stand management, other administrative needs, and public uses.

No special measures for mineral and energy operating plans are generally necessary in this Management Area. The entire range of management activities and practices that meet Forest-wide Standards and Guidelines are permitted in this Management Area.

General Forest Management Area acreage ranges from 233,269 acres in Alternative M, to 570,681 acres in Alternative C.

CULTURAL RESOURCES

SIGNIFICANT INTERACTIONS

Land management decisions which significantly affect the cultural resources component are those under the General Forest, Scenic/Recreation River, Riparian, Retention Visual, and Partial Retention Visual Management Area allocations. The factors considered in determining the nature of resource interactions are: the level of significance of the cultural resource, its suitability for scientific research or interpretive opportunities, its value to a community or ethnic group, its accessibility, and the level of compatibility with other management activities. Specifically, the ground-disturbing activity and increased access to remote areas are what generate potential effects to historic and prehistoric sites. In Table IV-3, the relationships between the causative agents and cultural resources are summarized.

Table IV-3. Relationship Between Activities and Affected Cultural Resources

Activity	Affected Cultural Resources (Site Types)
Recreation Development (Direct) Recreation Use (Indirect)	Prehistoric village sites, campsites, and food-procurement sites, historic trails, mining features, and homesteads occur in areas common to this activity. Sites are being affected by users of Forest recreation, particularly along the Rogue River corridor.
Trail Construction (Direct)	Same as above with the addition of potential quarry sites and Vision Quest sites. Sites may be affected by trail construction, particularly in identified high probability areas.
Road Construction (Direct) Timber Harvest (Indirect)	When road construction and harvest occur in areas of high probability, historic trails and prehistoric campsites are the most likely sites affected.
Minerals, Geology and Energy Use (Indirect)	Historic mining sites and prehistoric village sites, hunting camps and toolmaking sites are those most likely affected by this activity.
Fire - Wildfire and Prescribed (Direct)	Potential to destroy above-ground cultural resources, such as log cabins or other historic structures. May also reveal cultural sites previously overgrown with dense vegetation.

As initial development activity takes place in these Management Areas, the probability of adverse impacts on cultural resources may occur. Secondly, as alternatives allocate higher proportions of land to these Management Areas, the potential for adverse impacts correspondingly increases.

Studies on the Forest indicate certain locations which have the greatest probability for cultural resources. These include flat or gently rolling terrain, river terraces, meadows, ridgetops, saddles, springs, and southerly aspects (West and Steinfeld 1983). Table IV-4 indicates, by alternative, how many acres of ground-disturbing activities are permitted and how many acres possess a high, moderate, or low probability of containing cultural resources.

Table IV-4 Acres of Cultural Resource Probability by Alternative

Alternative	Total Acres 1/	High	Moderate	Low
NC/A/A-Dep	751,000	7,000	82,000	662,000
B	763,000	7,000	82,000	674,000
C	773,000	8,000	85,000	680,000
D/D1	763,000	7,000	82,000	674,000
E	443,000	4,000	42,000	397,000
G	529,000	3,000	51,000	475,000
K	713,000	6,000	76,000	629,000
M	416,000	4,000	50,000	362,000
S	617,000	5,000	56,000	557,000

1/ Acreage for Management Areas 11-14

ENVIRONMENTAL EFFECTS AND MITIGATION

Ground-disturbing activities, such as road construction, timber harvest, and recreation developments are permitted in Management Areas 10 through 14 and may have an effect on cultural resources. The degree of modification to the environment created by such management activities and the potential effect these activities have on cultural resources vary by alternative

Effects to cultural resources range from disturbance, destruction, or loss of part or all of the resource, to modification of the environmental setting around a site such that its basic sense of feeling or place is altered or destroyed. The greater the number of known or potential cultural sites or use areas that fall within the areas where ground disturbance is permitted, the greater the risk of adversely affecting cultural resources

Standards and Guidelines provide a means to minimize or mitigate adverse effects on cultural resources incurred by Forest management activities, vandalism or natural deterioration. However, situations may arise where site damage occurs without knowledge or discovery by the Agency.

Approximately 25,000 acres (2 5 percent) of the Forest are inventoried annually These acres are usually selected in conjunction with ground-disturbing activities During the past six years, an average of 25 new sites have been recorded annually, principally in proposed project areas.

For all alternatives, mining activity and forest fires may result in either discovery or disturbance of cultural resources. For fire, the risk of discovery for accessed areas is similar to those in remote areas For accessed areas, the ability to control wildfire is better, thereby reducing the degree of exposure. Simply the distance from people will reduce the probability of finds in remote, unroaded terrain.

Alternatives NC, A, A-Departure, B, C, D, and D1

DIRECT EFFECTS These alternatives have a high probability for identifying new cultural resource sites, and also present a likelihood for affecting existing cultural properties. Between 751,000 to 773,000 acres are potentially subject to ground-disturbing activities under these alternatives; 7,000 to 8,000 acres of which are characterized as high probability acres for containing cultural resources. Based on past inventory data, approximately 35 to 40 new sites will be identified annually and four or five sites will require mitigation, as prescribed in the Standards and Guidelines, to offset project impacts.

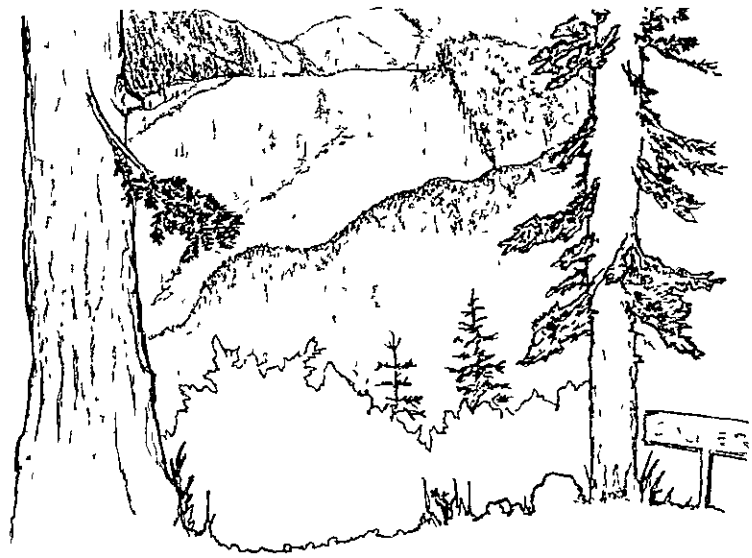
INDIRECT EFFECTS. With the area of ground-disturbing activity allowed under these alternatives, there is a high potential for destroying or altering sites during a given undertaking Furthermore, the increased access to sites in once-remote areas may promote an increase in site theft and vandalism Four or five sites may be adversely affected due to the indirect effects.

Alternatives K and S

DIRECT EFFECTS. Potential ground-disturbing activities under these alternatives could total 713,000 acres (Alternative K) and 617,000 acres (Alternative S), of which 6,000 acres (K) and 5,000 acres (S) are classified as high probability for containing cultural resources. Based on previous findings, 30 new sites will be recorded annually and three sites will require mitigation work to offset project impacts

INDIRECT EFFECTS. The same discussion applies from the above alternatives However, the potential for these effects to occur is moderate Some increased access may increase site vandalism and theft. Three sites may be adversely affected due to the indirect effects

Alternatives E and G



DIRECT EFFECTS. The potential to locate new cultural resources and conduct data recovery efforts or other mitigation measures is low for these alternatives because only 443,000 to 529,000 acres are subject to ground-disturbing activities over time Based on previous findings, 20 new sites will be recorded annually and two sites will require mitigation work to offset project impacts

INDIRECT EFFECTS The likelihood of altering or destroying sites due to ground-disturbing activities is low Vandalism and theft will occur; however, a low increase in access to presently remote areas is expected Two sites may be adversely affected due to the indirect effects of activities and vandalism.

Alternative M

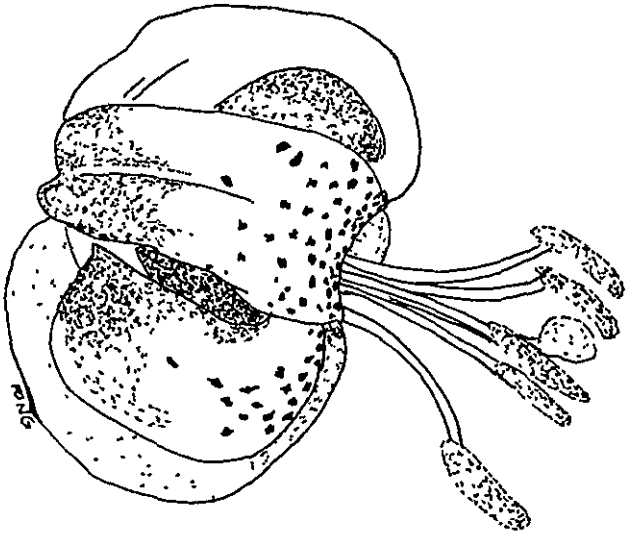
DIRECT EFFECTS. Potential disturbances total 319,000 acres, 3,000 of which are classified as high-probability acres for containing cultural resources. The 250-year rotation provided in this alternative results in fewer acres harvested per decade and thus a low potential impact to cultural resource sites. Furthermore, no new roads are constructed Therefore, the potential to locate new sites and conduct data recovery projects or other mitigation work is very low. Based on previous findings, 15 new sites will be recorded annually and one site will require mitigation work

INDIRECT EFFECTS. The likelihood of altering or destroying sites due to activities is very low. Vandalism and theft may occur; however, no increase in access to presently remote areas is expected. One site may be adversely affected due to the indirect effects of ground-disturbing activities, vandalism, or modification to the environmental setting of a cultural resource.

ENERGY

SIGNIFICANT INTERACTIONS

The significant effects on nonmineral energy are a result of: (1) the different harvest levels of the alternatives which affect the amount of fuelwood generated as well as the energy required to implement the alternative; and (2) land allocation and associated Standards and Guidelines changes by alternative that affect hydropower development potential.



Energy required to implement the alternatives is discussed in the **SPECIFICALLY REQUIRED DISCLOSURES** section at the end of this chapter. Significant interactions and effects on energy minerals are discussed in the **MINERAL DEPOSITS** section of this chapter.

ENVIRONMENTAL EFFECTS AND MITIGATION

DIRECT EFFECTS There are no direct effects on fuelwood Direct effects on hydropower result from the changing of land allocations by alternative and the Standards and Guidelines associated with those allocations. These Standards and Guidelines have the effect of restricting access. The access (direct effect) is displayed by alternative in Table IV-5.

INDIRECT EFFECTS. The indirect effects on fuelwood result from residue of timber harvest and, as harvest levels fluctuate, cords of fuelwood change Cords of wood per year resulting from the harvest residue in the first decade range from a high of 60 cords in Alternative B to a low of 11 in Alternative M. Volumes of fuelwood by Alternative are listed in Table II-5.

CUMULATIVE EFFECTS. No significant effects are expected for fuelwood.

MINERAL DEPOSITS

Exploration and development of mineral resources on the Forest have varying effects on the environment. The potential environmental effects are dependent upon methods, duration, and extent of operations. Ground disturbance associated with mineral and energy activities can have important direct and indirect interactions with most of the environmental components described in this chapter (see Table IV-1) Conversely, land allocations designed to protect various resources from adverse effects of ground-disturbing activities can exclude or constrain mineral exploration and development, limiting mineral resource use.

SIGNIFICANT INTERACTIONS

Proposals for mineral exploration and development are negotiated on a case-by-case basis It would be impossible to describe all the potential significant interactions that could take place without knowing the actual plans of operation for mineral or energy proposals. However, one way the Forest can deal with such proposals is by allocating specific lands for protection of important resources. When a proposal is then received, the Forest Service can work with the proponent and other agencies to minimize or mitigate adverse impacts on those resources requiring some degree of protection Only reasonable restrictions to mining can be legally imposed on areas not withdrawn

Examples of possible significant interactions might include proposals to test drill for ore in Wilderness, Wild River, or Backcountry Recreation areas. If roads were needed to transport the drilling equipment and a site needed to be leveled and cleared in order to operate, the integrity of these areas could be compromised To mitigate these impacts, the operator may be required to build roads with costlier standards or in less-than-optimum locations. Or, drilling equipment and personnel may need to be flown in at a much greater cost The economic viability of the operation may be reduced

Another example might be a proposal to test drill for oil and gas in a Research Natural Area, Botanical Area, or Unique Interest Area. Sensitive plants are known to inhabit such areas. In order to protect the plants, the operator may be required to slant drill from an off-site location. Slant drilling is a much more time-consuming and costly method

Another significant interaction could result from a prospector that discovers valuable ore in a Special Wildlife Habitat area. Suppose the initial proposal threatens to drive the protected species from the site and jeopardize the site for future use To mitigate this impact, the proposal must be scaled down, reducing economic efficiency In addition, no operations can take place during the mating, birthing, and rearing seasons for the species. The economic viability of the operation would likely decrease.

Finally, a mining company decides to capitalize on a long-standing claim which is now located within a Scenic/Recreation River. Processing facilities are located a long distance from the claim and the company needs a site to mill the ore prior to transport. The mine and most feasible mill site are within the 1/4 mile river corridor which seriously threatens the visual qualities which brought about the Scenic designation To mitigate this impact, the mill site must be located elsewhere; the nearest suitable location being several miles away. New road construction will be required as well as significant upgrading of existing roads Considerations of water transmission, use, and treatment, mill waste disposal; and particulars of mine rehabilitation may become more complex. Mitigation costs coupled with the added transportation costs could jeopardize the operation's profitability

RESPONSE TO PLANNING PROBLEMS

Concerns with respect to mineral development are focused on Planning Problem #9, "How should mineral resources of the Forest be developed in coordination with management of other resources?" The key

indicator in resolution of this problem is the area remaining available for development with limited (low and moderate) restrictions imposed by various land allocations

ENVIRONMENTAL EFFECTS AND MITIGATION

The primary adverse effects on mineral and energy exploration and development relate to land allocations that either severely limit access and/or ground-disturbing activities or withdraw lands entirely from mineral entry.

The discussion of environmental effects on minerals is presented in two sections The first section, **ENVIRONMENTAL EFFECTS BY LAND ALLOCATION**, describes the impacts of the various land allocations on accessibility of Forest lands to mineral and energy exploration and development. The second section, **ENVIRONMENTAL EFFECTS BY ALTERNATIVE**, summarizes the direct and indirect effects of the Alternatives with respect to Forest land accessibility. Cumulative effects were considered, but were not found to be significant with respect to mineral and energy activities.

ENVIRONMENTAL EFFECTS BY LAND ALLOCATION

Restrictions imposed by various land allocations differ in severity depending on applicable laws and regulations Sensitivity of the resource being protected and the magnitude of the proposed ground-disturbing activity also influence the degree of restriction needed. For analysis in this document, the various land allocations were placed in one of four access restriction categories· *Withdrawn*, *High*, *Moderate*, or *Low* These access restriction categories are defined below.

Restriction	General Characteristics of the Restriction
Withdrawn	Lands withdrawn from mineral entry Includes statutory and administrative withdrawals In comparing land management alternatives, this category will also include areas where preservation of other resource values require subsequent withdrawal from mineral entry
High	Lands where mineral activities are permitted, but administrative designations preclude or highly restrict access and/or ground-disturbing activities This category includes statutory or regulatory designations where mineral development is permitted, but access is highly restricted due to resource constraints. Also included are lands where, through changes in landownership status, some or all of the mineral rights were retained by a prior landowner Leases usually would contain no surface occupancy stipulations
Moderate	Lands where management designations or other resource considerations require special mitigative measures Special lease stipulations or plan of operation considerations are needed to accomplish resource coordination
Low	Lands where management designations would not require special mitigative measures over extended areas Restrictive lease stipulations or operating conditions may be required to mitigate site-specific resource coordination needs For the most part, however, standard field practices for mining and mineral lease activities can be utilized

The effects of Management Area allocations on mineral and energy exploration and development are as follows.

Wilderness

Designated Wilderness has both direct and indirect effects on minerals However, there is no change from present as no additional Wilderness is proposed in any alternative. Direct effects are mandated by law; designated Wilderness has been withdrawn from new prospecting and mineral entry and location since December 31, 1984. However, pre-existing claims are still valid, but subject to restrictions on mining operations. Indirect effects are likely to grow, over time, in the form of increasing restrictions on mining

activities that conflict with wilderness values Public demand for removal of the activity from Wilderness could result

Wild and Scenic/Recreation Rivers

Allocations to or designations of Wild, Scenic, or Recreation Rivers could have significant direct effects on mineral activities due to high or withdrawn access restrictions The Illinois and Rogue River are partially withdrawn from mineral entry under the current situation Allocations to Wild segments will generally result in the withdrawal of land from mineral activities within 1/4 mile either side of the river In some cases, withdrawal may be recommended in Scenic segments Access restrictions on Recreation segments are generally high. Protection of visuals on lands adjacent to the 1/4 mile corridor (i e , within the viewshed) may impact mineral activities on a much larger area due to public demand for protection of those areas. Development of reservoirs and powerlines, and other types of intensive use, are generally not permitted on Wild and Scenic Rivers Removal of sand and gravel will usually be prohibited

Botanical, Unique Interest, and Research Natural Areas

The potential for major direct effects on minerals can occur in these areas Because of the potential conflict with sensitive plants and unique plant communities, all three allocations impose high restrictions relative to access and development. If protection cannot be assured during mining, the need for withdrawal will be considered through environmental analysis of specific operating plans Known deposits of strategic minerals such as nickel, laterites, and chromite could be significantly affected.

Existing Research Natural Areas (RNA's) and Botanical Areas are withdrawn (or are in the process of being withdrawn) from mineral entry. Impact will vary by alternative and by individual area depending on the mineral potential (see Appendix F for site specific information for RNA's and Botanical Areas). Unique Interest Areas are quite limited in number and area

Backcountry Recreation

This Management Area assignment could lead to significant direct effects on mineral activities. The level of access restrictions is low to moderate, depending on whether the individual area is motorized or non-motorized In general, though, areas of higher mineral potential have existing primitive jeep roads and motorized trails. Where these occur, the established use would likely continue under either the Management Area prescription or an approved operating plan.

Designated Wildlife Habitat and Special Wildlife Habitat Areas

Allocations to Wildlife Management Areas could have moderate or high restrictions on mineral access and development depending on the sensitivity of the species affected While not prohibitive, some of the more sensitive wildlife habitats and species may carry restrictions on mineral activities that could make mining uneconomical.

Riparian and Supplemental Resource Management Areas

Assignments to these areas could have a significant direct effect on mineral activities. A moderate access restriction has been applied to the acreage of Riparian areas A high restriction will apply to Supplemental Resource areas, depending largely on the proposal and sensitivity of the area and its related resource values The potential for major conflict exists between placer mining and fish habitat, water quality, recreation use, and other values and uses This could lead to more severe access restrictions, however, to date, this has not been the Forest's experience

Retention and Partial Retention Visual Management Areas

Allocations to these Management areas generally require moderate restrictions on mineral activities Retention will usually produce a moderate restraint on activities. Partial Retention provides more than the normal restrictions, but not overly so when compared to General Forest (the least restrictive).

General Forest

The General Forest allocation is the least restrictive to mineral access However, there are some circumstances where visual concerns may require moderate restrictions. Lands allocated to General Forest have the least effect on mineral and energy exploration and development.

ENVIRONMENTAL EFFECTS BY ALTERNATIVE

Table IV-5 displays the estimated mineral potential and accessibility restrictions by alternative. When considered together, these two factors (potential and restrictions) tend to indicate the potential for development of mineral resources. The combination of high or moderate potential for locating minerals with low or moderate access restrictions is the most favorable for mineral development

Table IV-5. Estimated Mineral Potential and Accessibility Limitations by Alternative

	Mineral Potential (M Acres)			
Access Restrictions	High	Moderate	Low	Total
Alternative NC:				
Withdrawn	34	83	149	266
High	3	10	27	40
Moderate	22	44	108	174
Low	86	163	363	612
Alternatives A and A-Departure:				
Withdrawn	34	83	150	267
High	3	10	26	39
Moderate	25	52	126	203
Low	83	154	347	584
Alternatives B, D, and D1:				
Withdrawn	34	83	149	266
High	4	4	20	28
Moderate	23	45	100	168
Low	84	167	379	630
Alternative C:				
Withdrawn	33	83	149	265
High	4	3	10	17
Moderate	21	44	103	168
Low	87	170	385	642
Alternative E:				
Withdrawn	35	83	150	268
High	10	15	34	59
Moderate	58	120	233	411
Low	42	80	232	354
Alternative G:				
Withdrawn	35	83	150	268
High	17	21	54	92
Moderate	46	90	171	307
Low	49	104	272	425
Alternative K.				
Withdrawn	34	83	149	266
High	7	10	41	58
Moderate	25	50	104	179
Low	80	156	354	590
Alternative M:				
Withdrawn	35	83	150	268
High	15	19	44	78
Moderate	58	121	232	411
Low	37	76	222	335
Alternative S:				
Withdrawn	34	83	152	269
High	9	14	45	68
Moderate	16	49	118	183
Low	85	152	334	571

In the following discussion, Alternatives were grouped in terms of similar direct and indirect effects. *DIRECT EFFECTS* are simply the access restrictions imposed by the various land allocations In general, Alternatives with more acres allocated to Management Areas 10 through 14 are the most favorable and have the least potential for adverse impacts on mineral and energy activities *INDIRECT EFFECTS* are simply the amount of roads proposed by the various alternatives. Increased roading is assumed to benefit *mineral and energy interests since roads facilitate exploration and prospecting opportunities.*

Alternatives NC, A, A-Departure, K, and S

The area with low or moderate access restrictions varies from 754,000 acres in Alternative S to 786,000 acres in Alternatives A and A-Departure The percentage of these acres with low access restrictions ranges from 74 to 78 percent. These figures represent a moderately adverse direct effect on potential mineral and *energy activities All five of these alternatives provide for development of an extensive road system* with a good start being made in the first decade. This provides a favorable indirect effect on mineral and energy exploration and prospecting.

Alternatives B, D, D1, and C

The area with low or moderate access restrictions varies from 798,000 acres in Alternatves B, D, and D1 *to 810,000 acres in Alternative C. The percentage of these acres with low access restriction is 79 percent* for all four alternatives. These figures represent a minimally adverse direct effect on potential mineral and energy activities. All alternatives provide development of a very extensive road system with an aggressive start being made in the first decade. This provides a highly favorable indirect effect on mineral and energy exploration and prospecting

Alternatives E and G

Low to moderate access restrictions range from 732,000 acres in Alternative G to 765,000 acres in Alternative E. However, the percentage of these acres with low access restrictions is 58 percent for Alternative G and 46 percent for Alternative E. These figures represent a highly adverse direct effect on potential mineral and energy activities Both alternatives provide for development of a moderate transportation system with a modest start being made in the first decade. This provides a slightly favorable indirect effect on mineral and energy exploration and prospecting

Alternative M

Low to Moderate access restrictions amount to 746,000 acres with 45 percent of these acres in the low access restriction category These figures amount to a severely adverse direct effect on potential mineral and energy activities Alternative M provides for no new road development with numerous road closures and thus a limited transportation system. This provides a negative indirect effect on mineral and energy exploration and prospecting

IMPROVEMENTS

SIGNIFICANT INTERACTIONS

Effects on improvements from the implementation of land management alternatives are described in this section. Improvements are an important part of the human environment, these include such facilities as roads, trails, developed recreation sites, administrative sites, utility and transportation corridors, water storage developments, and miscellaneous improvements. These are described in the **IMPROVEMENTS** section of Chapter III.

Roads, in particular new construction and reconstruction, have significant interactions with nearly all environmental components discussed in this chapter A multitude of direct, indirect, and cumulative effects on various resources are associated with roads, and these are discussed at length under respective environmental components in this chapter Significant interactions and their associated environmental effects in this discussion are limited to those that affect the improvements themselves and their management

Public use of Forest resources along with Forest Service use and protection activities have significant direct and indirect effects on man-made improvements on the Siskiyou National Forest Land allocations which attract people can cause traffic on existing roads and trails. Vehicles, pack animals, and people cause wear on these facilities and, along with vegetative encroachments into the traveled way, require recurring maintenance to protect the initial investment. When excessive traffic wear resulting from deferred maintenance or storm damage has occurred, reconstruction may be required to provide a suitable facility Where people will have limited access to a resource use opportunity, a new road or trail could be constructed to satisfy the identified transportation need, e g., access for recreation, mining, fire suppression, or timber harvesting.

Some roads are closed to meet resource management objectives. Closures are used to discourage or eliminate all use by motorized vehicles over 40 inches in width. And, a few road closures may altogether eliminate traffic where resource sensitivity is of particular concern. The purposes for closures include providing for water quality, erosion control, public safety, reduction of road user conflicts, reduction of maintenance costs, legal mandates, managing recreation opportunity, and protection/management of wildlife and wildlife habitat. Road closures can result in reduced disturbance to big game and help meet demand for increased "quality" hunting experiences Changes made to accommodate recreation demand could cause closure of existing developed recreation sites or construction of new ones. Closures may be permanent or periodic Road closures are authorized in the Code of Federal Regulations, *Title 36 Part 261.*

ENVIRONMENTAL EFFECTS AND MITIGATION

The alternatives and their associated land allocations have varying effects on the improvements found on the Forest While road construction can have important cumulative effects on a number of resources including soil and water, no significant adverse cumulative effects were found to impact improvements Forest-wide Standards and Guidelines, as they apply to location, design, operation, and maintenance of facilities, assure that improvements will accommodate their intended use over time As demand and use changes with time, capital investments can be used to mitigate those changes An example might be paving a road to accommodate increased winter traffic In cases where capital investments are not justified, improvements such as roads or campgrounds might be closed to prevent degradation

A number of effects common to all alternatives are described at the end of this chapter under the section titled **ENVIRONMENTAL EFFECTS UNCHANGED BY ALTERNATIVES.** The remainder of the discussion is focused on direct and indirect effects, both in general terms and by alternative.

New road construction within the first decade offered by the alternatives range from none (Alternative M) to 308 miles (Alternative C). The long-term road system will require from zero to 1,577 additional miles. The final road system varies from the present 2,645 miles (Alternative M) to 4,222 miles (Alternative C) Completion of the system could take up to eight decades. Alternative M, however, utilizes the existing road system only.

Road closures under the alternatives during the first decade would vary from 89 to 475 additional miles of road for wildlife, recreation, watershed, or road management purposes. As the final road system is attained, the alternatives provide for a proportionate increase in road closures This varies from a maximum of 1,127 more miles of road closures to 271 additional miles. This information can be found by comparing Tables II-11 and II-12 with Table III-5.

Road reconstruction varies from 23 miles (Alternative M) to 172 miles (Alternative C) per year during the first decade. In subsequent decades, there is a general upward trend in miles per year in road reconstruction. Table II-10 shows these variations.

Trail construction in Wilderness areas during the first decade varies from zero (Alternative E) to 47 miles (Alternative C). Trail construction in non-Wilderness areas during the first decade varies from zero to 44 miles (Alternative S). The long-term trail system could add between 32 miles (all outside Wilderness) to 130 miles (nearly equally divided between Wilderness and non-Wilderness) to the existing 450 trail miles. Trail construction and reconstruction data is found in Table II-14. The potential trail improvements by alternative are in Table II-4.

The number of recreation sites provided varies from 47 sites (Alternatives NC and A) to 65 sites (Alternative M). Most of the 21 existing developed recreation sites are retained for public use in all alternatives. In several of the alternatives, closure of some existing minimum developed sites is proposed. Four currently closed sites would be reopened under four alternatives. A summary of recreation site status is found in Table II-18. Detailed alternative assignments are found in Table II-4.

For all alternatives, the *INDIRECT EFFECTS* are primarily those related to road and trail maintenance. While these effects are essentially the same by alternative, they vary by the amount of construction, reconstruction, and total system at a specific point in time. Various levels of maintenance will be performed on existing and added miles of road during the first decade, and will continue for all miles under the final road system. Likewise, maintenance would be programmed for all trails on the system.

The following are the *DIRECT EFFECTS* of each alternative:

Alternatives NC, A, and A-Departure

During the first decade, 230 miles of road will be added. Almost all (218 miles) will be constructed in support of timber sale needs. Ultimately, 1,545 miles will have to be built to satisfy this need. It will take until the seventh decade to attain 95 percent of the long-term (4,190 miles) road system. During the first decade, there will be 89 additional miles of road closure; ultimately, 613 additional miles over present will be closed During the first decade, 1,460 miles of road reconstruction will be required to satisfy user needs and road management objectives.

Within the first decade, less than a half mile of trail access will be constructed in Wilderness; none will be built in non-Wilderness areas. Ultimately, 57 miles of trail construction will be completed before the end of the third decade; less than half (24 miles) will be in Wilderness.

All 46 existing developed and minimum developed recreation sites are retained for public use at their present capacity. The four existing closed sites will remain closed. A visitor information center will be constructed at Agness during the first decade.

Alternatives B, D, and D1

During the first decade 277 miles of road will be added to the road system Almost all (252 miles) will be constructed in support of timber sale needs. Ultimately, 1,553 miles will have to be built to satisfy this need. It will take until the sixth decade to attain 95 percent of the long-term (4,198 miles) road system During the first decade, there will be 110 additional miles of road closure; in the long-run, 620 additional miles over present will be closed. During the first decade 1,670 miles of road reconstruction will be required to satisfy user needs and road management objectives.

Within the first decade, 21 miles of trail access will be constructed in Wilderness, and five miles in non-Wilderness Ultimately, 88 miles of construction will be completed before the end of the fourth decade, almost all (81 miles) in Wilderness.

Forty-two of the existing recreation sites are retained for public use at their present development scale. In addition to the existing four closed sites, three of the low use sites will be closed. As the demand for developed recreation facilities increases over the first four decades, seven new recreation sites will be constructed where concentrations of recreation use are expected. One existing site will be reconstructed to a higher standard this will be done in the first decade. One additional site will also be constructed during the first decade.

The description and effects are essentially the same as those of Alternative B, except 1,560 (Alternative D) and 1,720 (Alternative D1) miles of road reconstruction will be required during the first decade.

Alternative C

During the first decade 308 miles of road will be added Almost all (288 miles) will be constructed in support of timber sale needs Ultimately, 1,577 miles will have to be built to satisfy this need. It will take until the fifth decade to attain 95 percent of the long-term (4,222 miles) road system During the first decade, 119 additional miles of road closure, ultimately, 627 additional miles over present will be closed During the first decade, 1,720 miles of road reconstruction will be required to satisfy user needs and road management objectives

Within the first decade, 47 miles of trail access will be constructed in Wilderness; and five miles constructed in non-Wilderness. Ultimately, 99 miles will be constructed before the end of the second decade, almost all (92 miles) in Wilderness.

All 46 existing developed and minimum developed recreation sites are retained for public use at their present development scale. The four existing closed sites will be reopened as demand for these facilities increases

Alternative E

During the first decade, 110 miles of road will be added to the road system Almost all (107 miles) will be constructed in support of timber sale needs. Ultimately, 665 miles will have to be built to satisfy this need. It will take until the fifth decade to attain 95 percent of the long-term (3,310 miles) road system During the first decade, there will be 475 additional miles of road closure; ultimately, 834 additional miles over present will be closed. During the first decade, 820 miles of road reconstruction will be required to satisfy user needs and road management objectives

Within the first decade, no new trail access will be constructed in Wilderness, 14 miles will be constructed in non-Wilderness Ultimately, 32 miles will be constructed by the end of the fifth decade, all outside Wilderness.

Forty-five of the existing recreation sites are retained for public use at their present development scale. As the demand for developed recreation facilities increases over the first four decades, all four of the existing closed sites would be reopened and seven new sites constructed where concentrations of recreation use are expected. Also, one existing site will be reconstructed to a higher standard in the first decade. One additional site will also be constructed during the first decade

Alternative G

During the first decade 142 miles of road will be added to the road system. Almost all (136 miles) will be constructed in support of timber sale needs. Ultimately, 963 miles will have to be built to satisfy this need. It will take until the seventh decade to attain 95 percent of the long-term (3,608 miles) road system. During the first decade, there will be 225 additional miles of road closure, ultimately, 719 additional miles over present will be closed. During the first decade, 1,010 miles of road reconstruction will be required.

Within the first decade, 22 miles of trail access will be constructed in Wilderness and six miles in non-Wilderness. Ultimately, 85 miles will be constructed before the end of the fourth decade, over half (45 miles) being in non-Wilderness.

Forty-three of the existing recreation sites are retained for public use at their present development scale. As the demand increases over the first four decades, all four of the existing closed sites will be reopened and 15 new recreation sites will be constructed where concentrations of recreation use are expected. Also, three existing sites will be reconstructed to a higher standard, one being completed in the first decade. One additional site (a visitor information center at Agness) will also be constructed during the first decade.

Alternative K

During the first decade, 206 miles of road will be added to the road system. Almost all (190 miles) will be constructed in support of timber sale needs. Ultimately, 1,433 miles will have to be built to satisfy this need. It will take until the eighth decade to attain 95 percent of the long-term (4,078 miles) road system. During the first decade, there will be 391 additional miles of road closure; ultimately, 1,127 additional miles over present will be closed During the first decade, 1,311 miles of road reconstruction will be required.

Within the first decade, 15 miles of trail access will be constructed in Wilderness and five miles in non-Wilderness. Ultimately, 95 miles will be constructed before the end of the third decade, over half (50 miles) being in Wilderness.

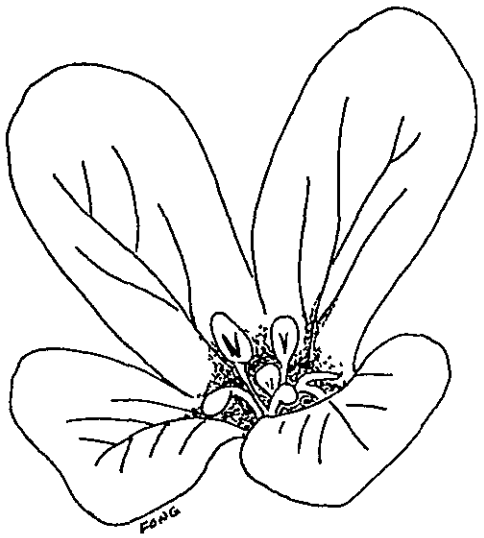
Forty-three of the existing recreation sites are retained The four existing closed sites will remain closed As the demand increases over the first five decades, seven new sites will be constructed where concentrations of use are expected. Also, three existing sites will be reconstructed to a higher standard, one of which will be done in the first decade.

Alternative M

No roads will be constructed during any decade. The existing system will be the ultimate road system During the first decade, there will be 271 additional miles of road closure, there will be no subsequent road closure. During the first decade 230 miles of road reconstruction will be required to satisfy user needs and road management objectives

Within the first decade, 22 miles of trail access will be constructed in Wilderness and six miles in non-Wilderness Ultimately, 85 miles will be constructed before the end of the fourth decade, less than half (40 miles) in non-Wilderness.

Forty-three of the existing recreation sites are retained. As the demand increases over the first four decades, all four of the existing closed sites will be reopened and 15 new recreation sites will be



constructed where concentrations of recreation use are expected. Also, three existing sites will be reconstructed to a higher standard, one of being done in the first decade. One additional site (a visitor information center at Agness) will also be constructed during the first decade

Alternative S

During the first decade, 228 miles of road will be added to the road system Almost all (212 miles) will be constructed in support of timber sale needs. Ultimately, 1,343 miles will have to be built to satisfy this need. It will take until the seventh decade to attain 95 percent of the long-term (3,988 miles) road system. During the first decade, there will be 404 additional miles of road closure; ultimately, 1,072 additional miles over present will be closed. During the first decade, 1,353 miles of road reconstruction will be required to satisfy user needs and road management objectives

Within the first decade, 42 miles of trail will be constructed in Wilderness and another 44 miles in non-Wilderness. Ultimately, 130 miles will be constructed before the end of the third decade, slightly more than half (68 miles) being in non-Wilderness.

Forty-three of the existing recreation sites are retained for public use at their present development scale. The four existing closed sites will remain closed. As the demand for developed recreation facilities increases over the first five decades, nine new sites will be constructed where concentrations of recreation use are expected. Also, four existing sites will be reconstructed to a higher standard, three being in the first decade A visitor information center at Agness will also be constructed during the first decade.

WILDERNESS AND ROADLESS AREAS

SIGNIFICANT INTERACTIONS

Impacts to the Wilderness resource and the potential for Wilderness on the Forest will vary through the range of alternatives The agent that will affect Wilderness most is the alternative prescriptions with varying degrees of management in the Wildernesses

For those unroaded areas with undeveloped characteristics (i e , Wilderness potential), the most significant impact would be development. With development, the existing values, attributes, or inherent characteristics that provided the option for wilderness opportunities would be foregone if an unroaded area was roaded and management activities, such as timber harvest, took place

There are no additions to the Forest's existing Wilderness System proposed within any of the management alternatives considered.

RESPONSE TO PLANNING PROBLEMS

Planning Problem #8, "How will management direction affect recreation opportunities in the Wilderness and Unroaded Areas?" This is one of the most polarized issues identified during scoping Analysis of the alternatives in response to the problem deals with both management of existing Wildernesses, and allocation and management of the remaining unroaded areas.

ENVIRONMENTAL EFFECTS AND MITIGATION

WILDERNESS MANAGEMENT

Management activities that are proposed within the Wildernesses under any alternative will be implemented using the Wilderness Management Guidelines. Management activities within any of the alternatives that would affect the Wilderness are primarily those associated with trail construction and fire, most activities are highly restricted as specified in the Standards and Guidelines.

Other potential effects relative to the quality of a wilderness recreation experience are management activities planned in areas adjacent to designated Wilderness that may be seen or heard by recreationists in the Wilderness. Proposed activities adjacent to a Wilderness are evaluated at the site-specific project level and appropriate measures taken to mitigate the potential effects.

Alternatives NC, A, A-Departure, and E would continue the existing management policy for the Wildernesses and implement a modest program of trail construction in the Kalmiopsis Wilderness There would be no new trail construction programmed for the Wild Rogue or Grassy Knob Wildernesses

Alternatives B, C, D, and D1 would implement an aggressive program of trail construction in the Kalmiopsis and Wild Rogue Wildernesses. Alternatives G and K would implement a moderate level of trail construction in these Wildernesses Alternative S would implement a more aggressive trail construction program in the Kalmiopsis, Wild Rogue, and Grassy Knob Wildernesses.

Alternative M would maintain all Wildernesses in their existing condition No additional activity is proposed.

The Red Buttes and Siskiyou Wildernesses will not be significantly affected by any alternative. These two areas are essentially developed.

Wilderness Management Plans will be developed for each area Plans for the Kalmiopsis, Wild Rogue, and Grassy Knob Wildernesses are included in the Forest Plan, Appendix A The Siskiyou National Forest will

implement management plans developed by the lead Forests for both the Red Buttes and Siskiyou Wildernesses.

ROADLESS AREAS

Alternatives NC, A, A-Departure, B, C, D, and D1 would assign all, or nearly all, of the roadless areas to Management Areas which allow for some level of development. Except for the large blocks of unsuitable land in the South Kalmiopsis, any undeveloped characteristics (Wilderness potential) within these areas would be permanently lost by the end of the first or second decades. The inventoried Siskiyou and Kangaroo Roadless Areas, and the lower Illinois River viewshed within the Wild segment are the exceptions They are managed in whole or part as Supplemental Resource Management Areas in Alternatives NC, A, and A-Departure.

Alternatives E, G, K, S, and M would allocate varying amounts of the inventoried roadless areas to Backcountry Recreation and other Management Areas which have very limited activity and no programmed harvest. Wilderness potential would be maintained in those areas allocated

Determination of demonstrable Wilderness potential is subject to varying interpretations For the purposes of this document, Wilderness potential (or "undeveloped characteristics") is based on the criteria identified in the Wilderness Management Act These are areas in which the natural integrity of the ecosystems are intact and uninterrupted, and offer the opportunities for solitude and primitive experiences.

For site-specific descriptions of the environment, opportunities, and environmental consequences by alternative for each of the 18 inventoried roadless areas, refer to Appendix C.

Table IV-6 (Table C-4 in Appendix C) provides a summary of the 18 inventoried roadless area attributes. The wilderness characteristics and key resource values are identified by area The primary characteristics evaluated for Wilderness potential were (1) manageability, (2) natural integrity, (3) opportunity for solitude, (4) primitive experience, and (5) special factors. Accessibility, resource use conflicts, and relevance of need were also appraised. From these, the potential for Wilderness has been used to make an objective separation of those roadless areas which have strong wilderness attributes from areas with lesser qualities. Those with strong wilderness attributes are discussed here; the remaining are included in Appendix C.

Table IV-6. Summary of Roadless Area Attributes - Description, Capability, Availability, and Need

		EXISTING CONDITIONS AND POTENTIALS							
				Key Resource Values - Potentials					
Name of Area	RARE II Number	Accessibility	Use Conflicts	Mining	Grazing	Fish	Wildlife	Timber	Recreation

KEY to Attributes:
HIGH - High
Mod - Moderate
L - Low
0 - None, or negligible

Grassy Knob Unroaded Area

This area has a moderate level of manageability due to size, location, and potential for conflict with management activities on adjacent land The area has a moderate level of natural integrity due to some evidence of human activity (westside of the North Fork Dry Creek and Butler Creek). The area demonstrates a low level for Semi-primitive recreation experiences with the opportunity for only localized solitude due to the influences of the sights and sounds of motorized activities and harvest units on adjacent lands. However, the western (Anvil and Rock Creeks) and eastern (Bee Creek) portions of the unroaded area provide a good opportunity to further separate the interior of the designated Grassy Knob Wilderness from sights and sounds of activities on adjacent lands.

North Kalmiopsis Roadless Area

This roadless area demonstrates a moderate level of manageability due to its irregular boundaries The area's large size inherently protects the character and values of the interior environment, especially where contiguous with the Kalmiopsis Wilderness. The area demonstrates a high level of natural integrity due to lack of human influences on natural appearance or long-term ecological processes A moderate level of solitude is demonstrated throughout much of the area, but is occasionally limited by the sights and sounds of activities on adjacent lands However, there is ample opportunity for both solitude and Primitive and Semi-primitive recreation experiences on approximately 30,000 acres in the Silver and Horse Sign Creek drainages

The area demonstrates a moderate level of special features, the most notable being the Kalmiopsis Wilderness to the south and the Illinois Wild and Scenic River which runs through the northwestern portion There is a very high level of public interest in the disposition of the North Kalmiopsis.

Approximately 42,000 acres in the north central part of the inventoried roadless area was impacted by the 1987 Silver Fire. The salvage of fire-killed trees and other resource activities planned under the subsequent Silver Fire Recovery Project FEIS and Record of Decision in 1988 will result in a 19,000-acre reduction in the inventoried roadless area The inherent wilderness attributes have been changed to varying degrees by nonconforming features of new roads (13 miles) and numerous helicopter and skyline timber salvage units proposed and being implemented. Even with this reduction in inventory, nearly 88,000 acres of unroaded condition remains For further discussions, see sections covering **1987 FIRES** and **RECREATION SETTINGS**, and Appendix C

Siskiyou Roadless Area

This roadless area demonstrates a moderate level of manageability due to it's location adjacent to the newly created Siskiyou Wilderness Maintaining the roadless characteristics would aid in the retention of the Siskiyou Wilderness character. There is a potential for conflict with management activities on lands in lower areas to the west. The natural integrity of the area within the roadless boundary is intact. The area demonstrates the opportunity for localized solitude and Semi-primitive experiences that would be influenced by the sights and sounds of management activities The area demonstrates a moderate level of special features, although the high elevation and the character of the landscape offer vistas that are quite limited on other areas of the Forest The area demonstrates the most Wilderness potential through the moderate level of public use and interest.

Kangaroo Roadless Area

This roadless area demonstrates a moderate level of manageability. Boundaries are well defined, but the presence of activities on adjacent lands to the east and west would affect the ability to manage the area in a natural state. A significant portion of this roadless area lies to the east of the divide on the Rogue River National Forest The natural integrity is nearly intact although there are human influences within the area due to old campsites and grazing The area provides opportunities for localized solitude and Semi-primitive

experiences, though both would be influenced by the sights and sounds of activities on adjacent lands. The area demonstrates a high level of special features that include wildlife, several mountain peaks, subalpine vegetation, and a scenic character that is unusual for the Forest

South Kalmiopsis Roadless Area

This area demonstrates a moderate level of manageability Boundaries are irregular and, in some places, abut private land Numerous access points are located on private land and would be difficult to control. There are numerous roads within the area being used to access active mining claims. The area's large size inherently protects the natural character of the area in the eastern interior portions adjacent to the Kalmiopsis Wilderness The natural integrity and appearance of the area is near natural.

Mining development (both past and present) and other miscellaneous activities have relatively little impact on the area's natural characteristics. Significant portions of the area exhibit an undisturbed landscape character. The potential for solitude and Semi-primitive recreation experiences is high, particularly for those portions adjacent to the Kalmiopsis Wilderness. Moderate levels of special features are exhibited, including the adjacent Kalmiopsis Wilderness, the Illinois Wild and Scenic River, abundant plant species, and unusual rock formations Perhaps the greatest attribute for Wilderness potential is the area's ability to further separate the interior of the Kalmiopsis Wilderness from sights and sounds of management activities on adjacent lands.

Table IV-7 delineates the disposition of the five areas cited above through the range of the alternatives.

Table IV-7. Backcountry Recreation Allocations by Alternative, in Roadless Areas with Demonstrable Wilderness Potential (Thousands of Acres)

	M Acres								
Roadless Area Name	NC/A/ A-Dep/ B	C	D/D1		E	G	K	M	S
Grassy Knob	-	-	-	-	6	1	-	6	2
North Kalmiopsis	-	-	-	-	110	88	11	110	42
Siskiyou	-	-	-	-	3	3	-	3	1
Kangaroo	-	-	-	-	7	7	-	7	3
South Kalmiopsis	-	-	-	-	105	52	2	105	57

A few other roadless areas (notably Shasta Costa and Copper Mountain) demonstrate attributes that are similar to the five areas cited above. However, they are isolated from other unroaded areas and Wildernesses. All are heavily influenced by the sights and sounds of activities on adjacent lands which would detract from desired wilderness qualities.

ENVIRONMENTAL EFFECTS BY ALTERNATIVE

The following evaluation deals primarily with *DIRECT EFFECTS* of management direction and activities on the character of Wildernesses For roadless areas, direct effects are associated with the Management Area allocations by alternative, and accompanying activities related to the development or non-development of the unroaded area. *INDIRECT EFFECTS* of management activities associated with these alternatives include the effects of adjacent land allocations, Wilderness use (people), mineral exploration and development, and road closures on adjacent lands The range of effects is not expected to vary by

alternative although the degree of the effects will For *CUMULATIVE EFFECTS*, see **ENVIRONMENTAL EFFECTS UNCHANGED BY ALTERNATIVES.**

Alternatives NC, A, and A-Departure

The current management direction for recreation would continue to be implemented under these alternatives, resulting in construction or reconstruction of 38 miles of trail in Wilderness. The construction of these trails is not expected to materially alter the existing character of the Wilderness

The potential for Wilderness that exists in the Forest's roadless areas would not be maintained under these alternatives. These areas would be allocated to varying degrees of development. Road construction and related harvest activities would significantly alter the character of the area and result in the loss of Wilderness potential. The Siskiyou and Kangaroo Roadless Areas and lower Illinois River viewshed are managed as Supplemental Resource Management Areas under these alternatives. Only 3,000 acres of the Kangaroo area, however, is managed as Supplemental Resource (called "Craggy Mountain" in this Management Area assignment). The undisturbed character of these areas would be retained

The quality of recreation experiences within existing Wilderness is likely to be affected by the management activities in adjacent areas. Development of the Silver Creek drainage will affect approximately 4,000 acres of area currently inventoried as Primitive (ROS) in the Kalmiopsis Wilderness. Although additional impacts may occur, the Forest expects to be able to provide approximately 110,000 acres of Primitive or Pristine recreation opportunities within the Kalmiopsis Wilderness over the course of the planning period.

The direct effects of management activities within the Wildernesses associated with these alternatives include trail construction and fire management The range of these effects is not expected to vary by alternative. The impacts, accompanied by their respective Standards and Guidelines, are deemed minor

The direct effects of management activities within the roadless areas identified as having Wilderness potential include road and trail construction, timber harvest, and other facility construction The range of effects is not expected to vary by alternative, although the degree (miles of trail, miles of road, acres harvested, etc.) of the effects will.

For these alternatives, the area remaining unroaded (non-Wilderness) at the end of the first decade would be 102,000 acres; at the end of the fifth decade and beyond, approximately 85,000 acres These figures are estimates of the remaining undeveloped areas in blocks generally (a) greater than 5,000 acres, and/or (b) contiguous to designated Wilderness. The largest residual is attributable to the South Kalmiopsis Roadless Area where the large block of land unsuitable for the production of timber exists, this is assumed to remain unroaded over time

A different scenario exists if the land allocated to Management Areas 2 through 9 within the inventoried unroaded areas is added. For Alternatives A and A-Departure, 47,000 acres has been assigned to Management Areas which have no programmed timber harvest and whose management goals are strongly oriented to little or no roading Approximately 28,000 acres are allocated in Alternative NC to Management Areas 2-9.

Alternatives B, C, D, and D1.

Approximately 97 miles of trail would be constructed or reconstructed in the Kalmiopsis and Wild Rogue Wildernesses. No trail construction is programmed in the Grassy Knob Wilderness The character of portions of these Wildernesses without trails would be altered by the construction of the trails, however, these effects are not expected to be significant. Primitive and Semi-primitive capacities will be expanded under these alternatives (see Table IV-10 in **RECREATION SETTINGS** section) Within the Wildernesses,

the quality of recreation experiences are expected to be influenced heavily by the sights and sounds of management activities on adjacent lands

None of the Forest's roadless areas would be allocated to the Backcountry Recreation under these alternatives The Wilderness potential of these areas would be permanently lost as described in Alternative A above

For these alternatives, the area remaining unroaded (non-Wilderness) at the end of the first decade would be 86,000 acres; at the end of the fifth decade, approximately 68,000 acres. Again, these figures are estimates of the remaining undeveloped areas in blocks generally (a) greater than 5,000 acres, and/or (b) contiguous to designated Wilderness.

Alternatives B, D, and D1 has 36,000 acres and Alternative C has 28,000 acres if land allocated to Management Areas 2 through 9 within the inventoried unroaded areas is added These Management Areas have no programmed timber harvest and management goals are strongly oriented to little or no roading

Alternative G

Approximately 50 miles of trail would be constructed or reconstructed There would be no trails programmed in the Grassy Knob Wilderness. The character of the Pristine portions of the Kalmiopsis Wilderness would be altered by construction of trails, however, these effects are not expected to be significant. Primitive and Semi-primitive recreation capacities would be expanded as a result of the trail construction Recreation experiences within the Kalmiopsis Wilderness are expected to be moderately influenced by a reduction in sights and sounds of adjacent activities due to Backcountry Recreation allocations on contiguous lands.

Alternative G would assign all or portions of eight roadless areas (Grassy Knob, Copper Mountain, North Kalmiopsis, Siskiyou, Kangaroo, North Fork Smith, Packsaddle, and South Kalmiopsis) to Management Areas with no programmed development. Maintenance of viable wilderness character is achieved due to the size of the allocations and the location (this alternative would allocate significant portions of the roadless areas in the viewshed adjacent to the Wild and Scenic sections of the Illinois River) The Primitive and Semi-primitive opportunities available in the Silver Creek drainage would be maintained

For Alternative G, the area remaining unroaded (non-Wilderness) at the end of the first decade would be 185,000 acres At the end of the fifth decade and beyond, approximately 173,000 acres would remain These figures do not include over 25,000 acres allocated to Backcountry Management under this alternative which would require restoration to a nonroaded, undeveloped setting.

If land allocated to Management Areas 2 through 9 within the inventoried unroaded areas is added, Alternative G has 178,000 acres. These areas have no programmed timber harvest and remain essentially unroaded

Alternatives E and M

All of the Wildernesses would be maintained in their present condition. No trails would be programmed for construction or reconstruction other than those on the current capital investment program (approximately 50 miles). Naturally occurring ecosystems in all of the Wildernesses would be uninterrupted by further development The integrity of the recreation experiences within the Wildernesses is expected to be minimally influenced by the sights and sounds of activities on adjacent lands due to the large Backcountry Recreation Management Area assignments

The Wilderness potential in all of the roadless areas would be maintained under these alternatives, since all would be allocated to Backcountry Recreation. For these alternatives, the area remaining unroaded

(non-Wilderness) at the end of the first decade and beyond would be 284,000 acres Again, these figures are estimates of the remaining undeveloped areas in blocks generally (a) greater than 5,000 acres, and/or (b) contiguous to designated Wilderness. An additional 30,000 acres that is included under the Backcountry Recreation allocation would require restoration to a nonroaded, undeveloped setting. These acres are not included in the above 284,000 acre figure.

Alternatives B, D, and D1 have 36,000 acres and Alternative C has 28,000 acres if land allocated to Management Areas 2 through 9 within the inventoried unroaded areas is added These Management Areas have no programmed timber harvest and management goals are strongly oriented to little or no roading.

Alternative K

A moderate increase in trails (66 miles) in the Kalmiopsis and Wild Rogue Wildernesses would occur under this alternative No new trail construction is proposed within the Grassy Knob Wilderness Primitive and Semi-primitive recreation capacities would be expanded as a result The recreation experiences within the designated Wilderness are expected to be moderately influenced by the sights and sounds of activities on adjacent lands. Some of the influences will be offset by the Backcountry Recreation Management Area allocations in these alternatives.

Portions of the Briggs and North Kalmiopsis Roadless Areas (approximately 16,000 acres) would be allocated to the Backcountry Recreation. Some Primitive recreation opportunities would be maintained in areas outside of the Kalmiopsis Wilderness. The allocated portion of the North Kalmiopsis would offer positive benefits to the Kalmiopsis Wilderness since the area is contiguous. The most significant effect of these allocations is the maintenance of the viewshed (approximately 5,400 acres) adjacent to the last six miles of the Wild section of the Illinois River.

For Alternative K, the area remaining unroaded (non-Wilderness) at the end of the first decade would be 109,000 acres. At the end of the fifth decade, the residual unroaded area would be maintained at approximately 91,000 acres.

If land allocated to Management Areas 2 through 9 within the inventoried unroaded areas is added, Alternatives K has 70,000 acres. These Management Areas have no programmed timber harvest and management goals are strongly oriented to little or no roading.

Alternative S

There would be a substantial increase in trails (128 miles) in the Kalmiopsis, Wild Rogue, and Grassy Knob Wildernesses under this alternative. Primitive and Semi-primitive recreation capacities would be expanded as a result. The recreation experiences within the designated Wildernesses are expected to be moderately influenced by the sights and sounds of activities on adjacent lands Much of this influence, however, will be offset by the Backcountry Recreation Management Area allocations adjacent to the Kalmiopsis Wilderness.

Portions of eight roadless areas (Grassy Knob, Copper Mountain, North Kalmiopsis, Windy Valley, Siskiyou, Kangaroo, Packsaddle, and South Kalmiopsis) would be allocated to Backcountry Recreation. As a result, the Forest will maintain opportunities for Primitive, Semi-primitive Non-motorized, and Semi-primitive Motorized opportunities in these areas. Portions of the North and South Kalmiopsis would offer positive benefits to the contiguous Kalmiopsis Wilderness The most significant effect of these allocations is the maintenance of the unroaded recreation opportunities (both motorized and non-motorized) in a natural/near-natural forest setting, and the maintenance of the undisturbed viewshed (approximately 5,400 acres) adjacent to the last six miles of the Wild section of the Illinois River.

The area remaining unroaded (non-Wilderness) at the end of the first decade in Alternative S would be nearly 135,000 acres; at the end of the fifth decade and beyond, approximately 126,000 acres. These figures are estimates of the remaining undeveloped areas in blocks generally (a) greater than 5,000 acres, and/or (b) contiguous to designated Wilderness

Alternative S has 146,000 acres if lands allocated to Management Areas 2 through 9 within the inventoried unroaded areas are added These Management Areas have no programmed timber harvest and management goals are strongly oriented to little or no roading.

WILD AND SCENIC RIVER

SIGNIFICANT INTERACTIONS

Management plans for the Rogue and Illinois Wild and Scenic Rivers will not be affected through the range of the alternatives Land allocation decisions and activities on the periphery of Wild and Scenic Rivers corridors, however, have a potentially significant impact on the Wild and Scenic River attributes. Depending on the specific land allocations within the alternatives, the potential for adverse effects varies greatly The allocations can affect the quality of the recreation experiences available (Clark and others 1984) Timber harvest and related road construction, and other facility construction are the management activities within any of the alternatives that would have the greatest affect on the quality of the river experience and the inherent attributes The degree of visual resource protection offered in the viewsheds adjacent to the rivers becomes the means to evaluate acceptable levels of activity. Resource activities are mitigated through the use of Standards and Guidelines applicable to the visual resource.

RESPONSE TO PLANNING PROBLEMS

Planning Problem #4, "How, and to what extent, should lands in and adjacent to river corridors be managed to protect, preserve, and enhance Wild and Scenic River attributes?" is addressed by alternative in this section The problem has two parts.

The first part deals with establishing or reaffirming management direction for the five designated rivers Management Plans exist for both the Rogue and Illinois Rivers. However, as a result of the Omnibus Oregon Wild and Scenic Rivers Act of 1988, management plans are required for the Chetco, Elk, and North Fork Smith River. Development of the three new plans and review of the two existing River Management Plans will not occur under the analysis and documentation provided herein These plans will be prepared within the next three years under separate documents.

Also as a consequence of the new legislation, the Planning Problem was basically reduced to the question dealing with management of lands adjacent to the corridors The alternatives presented are evaluated based on the visual management objectives assigned to lands within and adjacent to the river corridors which indirectly affect recreational experiences

Wild and Scenic River designations have an immediate effect on water quality standards too, through change to the more restrictive antidegradation policy applied by the State of Oregon As the impacts are already in place by virtue of the 1988 Act, there is little need to dwell on the beneficial or adverse effects of the river designations on other resources. Refer to the **SOIL AND WATER** section for treatment of water quality and application of Standards and Guidelines, including BMP's, to proposed management activities

The DEIS treatment of inventoried and eligible rivers for inclusion into the National Wild and Scenic Rivers System is moot. The Chetco, Elk, and North Fork Smith Rivers were intentionally assigned differing designs in the array of alternatives so that a full range of management options could be offered to adequately analyze the environmental impacts and tradeoffs. In the FEIS analysis, the rivers still are allocated as originally designed (per alternatives presented in the DEIS), however, discussion will be brief The new Alternative S carries the five rivers as they are Congressionally designated. If another alternative is recommended as the Preferred, then the changes per recent status would have to be incorporated From a Forest-wide perspective, the changes are relatively minor as to acres and effects

ENVIRONMENTAL EFFECTS AND MITIGATION

DIRECT EFFECTS. The direct effects of management activities associated with these alternatives include land allocations, road construction, construction of developed recreation sites, and trail construction

These effects are common to all alternatives, except Alternative M (no new road construction), and are not expected to vary, though the intensity of the effects may

INDIRECT EFFECTS The indirect effects of management activities associated with these alternatives include timber harvest and related activities, the effects of recreation users, and mineral development These effects are common to all alternatives and are not expected to vary except by intensity of the effects.

CUMULATIVE EFFECTS See **ENVIRONMENTAL EFFECTS UNCHANGED BY ALTERNATIVE** at the end of this chapter.

Alternative NC, A, and A-Departure

Current conditions would be maintained in the Rogue and Illinois River corridors. The current visual inventory would be allocated in all viewsheds resulting in maintenance of natural/near-natural landscape character. A limited reduction in the natural character of the landscape within the Rogue corridor would result from allocation of parts of the Quosatana, Potato Mountain, and Rogue Roadless Areas to development. These areas are inventoried for Retention and Partial Retention, thereby the potential visual impacts of activities as seen from the Rogue River would be largely mitigated. It is noted, however, that the majority of these areas are located within the Recreation sections of the river where open extended views are offered recreationists traveling on the river, the Agness Road, and on portions of the Upper and Lower Rogue River Trails

Past analysis (available in Planning Records; Rogue River Corridor Visual Study 1982) indicates that unroaded areas in viewsheds bordering the Rogue present problems related to color contrast that would make it difficult to achieve the inventoried VQO's on a site-specific basis. Coupled with the topography, the potential for impacts to the visual resource from management activities would neither benefit the recreation setting for the river corridor nor the attendant experiences offered

Similar effects could result from the allocation of Squaw Mountain and the eastern portion of the North Kalmiopsis roadless areas in the Upper Illinois viewshed to General Forest The susceptibility of portions of these areas to adverse visual impacts has not been verified And, the viewshed adjacent to the last six miles of the Wild section of the Illinois could be impacted to a limited degree as a result of being assigned to Supplemental Resource.

Both the Illinois and Rogue corridors are expected to remain in a natural/near-natural condition as a result of their Wild and Scenic designation, the large area of Wilderness through which both rivers flow, visual resource allocations in viewsheds of both corridors, and other assignments to Management Areas 1-9.

The inventoried Chetco and North Fork Smith Rivers would be managed to maintain Wild and Scenic River attributes The character of both river corridors is expected to remain in a natural/near-natural condition resulting from the maintenance of the corridor and assignment to Supplemental Resource. The upper reaches of both rivers are bounded by Wilderness. The natural/near-natural character of the Elk River will be maintained largely through the inventoried VQO's within the viewshed.

Alternatives B, C, D, and D1

Outside of the river corridors within the Kalmiopsis and Wild Rogue Wildernesses, there would be a reduction in the existing character of the landscape in both designated Wild and Scenic River corridors and in the two inventoried river corridors The Elk River would be allocated to a combination of Supplemental Resource and Riparian Prescription C in Alternatives B, D, and D1. The river would be managed under only Riparian Prescription B in Alternative D. Visual resource assignments would be reduced in viewsheds adjacent to the designated and potential river corridors, resulting in a near-natural/modified landscape character. Under Alternative C, 38,000 acres of inventoried Retention in

the five viewsheds adjacent to the rivers would be managed to achieve the Partial Retention objective. Under Alternatives B, D, and D1, approximately 26,000 acres inventoried for Retention would be managed to achieve Partial Retention.

The effects on the quality of the recreation settings and attendant experiences are expected to be similar to those described in Alternative A. Reductions to the character of the landscape result from a combination of the allocation of adjacent viewsheds to management for Partial Retention and Modification, and the allocation of unroaded areas to General Forest Allocations that benefit the two designated rivers include Supplemental Resource, Partial Retention Visual, and other allocations that have no programmed timber harvest

None of the rivers eligible for inclusion into the Wild and Scenic River System would be recommended for designation or further study. The character of the river corridors would be somewhat reduced The viewshed adjacent to the Chetco would be managed to achieve the Partial Retention. The character of the landscape would vary between near-natural appearing and modified. The viewshed adjacent to the North Fork Smith is expected to be modified as a result of allocation to General Forest Alternative C would result in a significant impact to the potential rivers since they are managed only under the Riparian Prescription.

Alternatives E, G, and M

Recreation settings in all five river corridors would be maintained in a natural/near-natural condition. Alternatives E, G, and M would meet or exceed the inventoried VQO's, and allocate all unroaded areas to Backcountry Recreation. No changes to the character of the landscape are expected.

The viewshed adjacent to the last six miles of the Wild section of the Illinois River would be allocated to the Backcountry Recreation. Alternative M would enhance the character (i.e , create a natural appearance) within all river corridors since timber management would be subject to a 250-year harvest rotation. Additional allocations that benefit the Wild and Scenic River resource include visual resource assignments in viewsheds along both river corridors and allocations to Management Areas 1-9.

The Chetco and North Fork Smith Rivers would be recommended for designation in all of these alternatives resulting in effects similar to those identified in Alternative A. The Elk River would be managed under Riparian Prescription Minimum Level and allocated to Supplemental Resource in Alternatives E and M. Riparian Prescription C would be applied in Alternative G. The Wild and Scenic attributes of the rivers are expected to be fully protected under these three alternatives

Alternative K

The existing character of the landscape within the designated Wild and Scenic River corridors would be maintained in its current condition Recreation settings in the Rogue and Illinois River corridors would be maintained in a natural/near-natural condition due to assignments of their viewsheds to inventoried VQO's. The three roadless areas would be allocated to General Forest; effects would be similar to those described in Alternative A In addition, the inventoried foreground Retention along the Scenic and Recreation sections of the Rogue River would be removed from the lands suitable for timber production in order to protect or maintain the old-growth character in view of the river. The land within the viewshed adjacent to the last six miles of the Wild section of the Illinois River (approximately 5,400 acres) would be allocated to Backcountry Recreation, resulting in maintenance of the landscapes natural character.

None of the potential rivers would be recommended for designation or further study in this alternative. Both the Chetco and the North Fork Smith Rivers would be allocated to management as Supplemental Resource areas, providing protection to a 1/8 mile strip on either side of the river. In addition, visual resource allocations in the immediate viewsheds would be reduced (the foreground being managed to achieve Partial Retention objectives), resulting in near-natural/modified Forest settings which may effect the quality

of the recreation experiences available. However, the upper reaches that extend into the Kalmiopsis Wilderness would remain unchanged. Elk River would be managed under Riparian Prescription C. The viewshed adjacent to the Elk River would be assigned Partial Retention so that the river corridor retains its natural/near-natural character.

Alternative S

The existing character of the landscape within all five designated Wild and Scenic River corridors would be maintained in their current condition. Recreation settings in the Rogue and Illinois river corridors would be maintained in a natural/near-natural condition due to the allocation of these viewsheds to their inventoried VQO's. Portions of the three roadless areas adjacent to the rivers would be allocated to General Forest; effects similar to those described in Alternative A would occur. In addition, the inventoried foreground Retention (nearly 10,000 acres) along the Scenic and Recreation sections of the Rogue River would be removed from the land base suitable for the production of timber in order to protect the old-growth character as seen from the river. The land within the viewshed adjacent to the last six miles of the Wild section of the Illinois River (approximately 5,400 acres) would be allocated to the Backcountry Recreation, maintaining the undisturbed character of this area.

SOIL AND WATER

SIGNIFICANT INTERACTIONS

The interaction between components of the hydrologic cycle and erosion is very complex, with resource management activities adding further complexity (Brown 1980) Significant interactions with the soil and water resource are possible from any resource management activity that disturbs the soil, reduces root strength on steep slopes, reduces organic matter, disrupts watershed drainage, or reduces riparian vegetation. Road construction, timber harvest, fuels treatment, and the development of energy or mineral deposits are the principal resource management activities with potential for significant interactions with the soil and water resource.

Water quality, soil erosion, mass-wasting (landslides), and long-term productivity are the forest components that would most likely be affected by interactions of both management activities and natural conditions. Stream temperature and stream sedimentation are the two water quality parameters most sensitive to management activities. Water temperature is affected primarily by loss of stream canopy cover, while sediment is delivered to streams by surface erosion, channel erosion, and mass wasting

Erosion of surface soils is a natural process on steep lands of the Forest Exposure of mineral soil on steep slopes, however, allows direct raindrop impact, causing erosion and puddling of the soil which reduces infiltration and increases runoff. Mass wasting occurs when the shear strength of rock or soil is exceeded by the shear stress imposed by gravity Slope failure of soil and rock involves a reduction in strength or an increase in stress in those earthen materials. Responsible factors usually include increased water loading (pore pressure), weathering of soil and rock, oversteepened slopes, and delay or absence of root replacement Increases in groundwater during storms contributes to reduced strength and increased stress.

All of these processes occur naturally, however, ground disturbance, removal of soil-anchoring vegetation, and concentration of water caused by management activities, would tend to accelerate the interactive processes Increases in water temperature and sediment can reduce the quality of anadromous fish habitat Excessive turbidity can affect the quality of angling in the Forest's streams and rivers, as well as water utility for domestic uses.

Long-term productivity of forest ecosystems is highly dependent on the interactions of management activities with natural variables including soil, bedrock, plant community, and climate.

Considering the above factors, the potential risk of adverse cumulative watershed effects from resource management activities, irrigation, and domestic water use definitely exists The interaction of Forest Service activities that create soil disturbance or remove stream shading, alone, or in combination with those of other agencies and landowners, may result in cumulative watershed effects

SEDIMENTATION

Each alternative produces a different amount of sediment Road construction is a major source of sediment (Fredriksen 1972), while activities related to timber harvest produce a much smaller amount of sediment per acre of disturbance. Increased sediment delivery to streams resulting from soil erosion and mass wasting is a potential consequence of timber harvest and road construction in steep terrain. Large inputs of sediment can aggrade stream channels if stream power is insufficient to transport the material downstream The limited areal extent of mining activity and the resultant impacts, while numerous, are neither major nor significant

Erosion

Soil erosion is often accelerated by road construction, timber harvest, site preparation, and fuels treatments on steep slopes and slopes adjacent to streams. Road construction may divert and concentrate surface water, increasing erosion of ditches, slopes, stream banks, and channels Prescribed burning to prepare a site for reforestation may produce a significant loss of soil cover on steep slopes where litter and duff layers are naturally thin Mineral soil exposure on steep slopes can greatly increase erosion, with corresponding effects on soil productivity and stream sedimentation. Off-site effects can include channel scour and streambed aggradation Streambank failures are secondary downstream effects.

Mass Wasting

Many slopes on the Siskiyou National Forest, especially those near streams, are oversteepened (i e., greater than 70 percent) and, as a result, most major landslide activity occurs along the inner gorges of major streams

The removal of vegetation by timber harvest, site preparation, or fuels treatment increases the potential for landslides. Accelerated rates of mass wasting are a potential consequence of building roads and harvesting timber in steep, rugged terrain. All alternatives that contain road building and timber harvesting will accelerate the occurrence of landslides above the background level Best Management Practices will be implemented to minimize the amount of management-related mass wasting and protect the beneficial uses of water The consequences of slope failures may include.

Increased sediment to streams and reservoirs;
Decreased water and fish habitat quality;
Potential impacts on structures and facilities;
Loss of growing sites and decreased site productivity;
Visual impacts of landslide scars, and
Potential loss of life.

Sediment from slope failures associated with road construction are directly related to.

The area of land dedicated to roads;
The types of rock and soil through which the road passes,
The frequency of high intensity and large storms;
Distance of the failure to an active stream,
Length of time since road construction; and
Road design and construction techniques.

Debris slides of noncohesive soil and rock fragments have potential for rapid, but temporary, increases in stream sedimentation. Thick slow-moving earthflows of cohesive soil provide low initial amounts of sediment, but contribute sediment for long periods. Earthflows commonly grade into debris slides at the toe of the failure, and periodically produce large amounts of sediment

Geology, topography, and soils directly affect the location and cost of roads, rock quarries, and timber harvest units Conversely, timber harvest and road construction can cause significant changes in slope stability causing damage and increasing the costs of structures Buildings, bridges, culverts, fences, etc. are subject to impacts from slope failures

Slope failures on the Forest do not normally result in the loss of human life. Safety is, however, of prime importance when constructing roads through steep, rocky terrain, or land particularly susceptible to slope failure Failures on Forest have occurred with sufficient intensity that Forest workers or visitors could have

been killed or injured had they been in the path of these rapid landslides Population centers and residences located outside the Forest boundary have a low probability of risk to mass wasting

WATER QUALITY

Water Temperature

Water temperature can be affected by removing the vegetation that shades streams, or by summer water withdrawals for irrigation, domestic consumption, or other uses For many Siskiyou streams, summer water temperatures are at critical levels for the survival of cold water game fish This condition exists due to both natural and activity-induced impacts. Natural conditions can range from very low summer stream flows, to a geology-related lack of stream shading A combination of streamside conditions resulting from past activity, from activity of others, or indirectly through upstream diversions (water withdrawals), blend to create a potential impact on instream uses The **FISH** section of this chapter provides a discussion of water temperature for each alternative

Water Clarity

As described above, primary sources of sediment are natural and management-related surface erosion, channel erosion, and mass wasting An increase in the amount of delivered sediment to streams can affect the clarity or turbidity of the water Turbidity (cloudiness) is a measure of the capacity a given volume of water to transmit light. When sediment rates increase, turbidity will increase. The amount of turbidity produced per unit of suspended sediment concentration depends on the size, shape, and refractive index of the sediment particles (Lloyd 1987). Whereas a strong relationship between sediment and turbidity can be developed within a watershed, this relationship can vary significantly between drainages (Beschta 1980).

Turbidity usually drops off rapidly after the triggering storm events; however, reservoirs and lakes may experience increased turbidity for an extended period of time Earthflows are often major contributors to turbidity because of high clay contents.

WATER YIELD AND PEAK FLOWS

The harvest of mature timber increases water yield up to 20 inches per year per unit area harvested. This additional water yield results in small increases in summer flows and modest increases in fall peak flows. The additional water yield gradually diminishes over the first 20 years following timber harvest due to regrowth of trees and brush. The total amount of additional water yield produced by timber harvesting is not significant when compared to the total water yield from a large river basin, and is estimated to be smaller than the five percent accuracy of stream flow measurement (Harr 1976; Harr and others 1979).

When soils are saturated, the magnitude of larger peak flows will normally be similar with or without timber harvest and roads (Wright 1985) However, in the less frequent "rain on snow" events, harvested areas may contribute to increased peaks. Some of the Forest is within the "transient" snow zone, i.e., snowpacks being generally less in depth, but lower in elevation and warmer. A major storm event, coupled with a heavy snowpack in the transient zone, may produce higher peak flows which increase the potential for both hillslope and channel erosion. The drainage size will normally influence and normalize the peak flows to the extent that downstream values and structures are not placed at risk. A more thorough discussion of water yield and peak flows is provided at the end of this chapter and entitled **ENVIRONMENTAL EFFECTS UNCHANGED BY ALTERNATIVES**

SITE PRODUCTIVITY

Forest productivity is dependent on continual gains and losses of organic materials and nutrients from roots, dead and down trees, and other organic material. Nitrogen, the most limiting soil nutrient in the

forests of southwestern Oregon, is mineralized or made available by biological decomposition of organic matter Organic material supply the habitat and energy for these processes It also aids in moisture retention, soil aggregate stability, and surface protection. Levels and distribution of phosphorus, a second critical element, is also affected by loss and redistribution of organic residues, duff, and litter during timber harvest, site preparation, and fuels treatment

Site productivity can also be affected by loss of organic matter due to harvest of logs, site preparation, and fuels treatments, all of which transport nutrients off-site Low intensity prescribed burns preserve more on-site nutrients, duff, litter, and large woody material than high intensity burns Woody residues, duff, and litter concentrated close to the ground that act as moisture storage reservoirs are preserved following low intensity burns. High intensity burns expose more mineral soil than low intensity burns. Nutrient availability following fuels treatment is high in the short term, and low in the long term with high demand by a fast growing new forest.

Site productivity can further be affected by soil compaction during timber harvest and site preparation Moderate and severe compaction has the potential to reduce soil porosity, water storage and release, and plant root growth. Further, it has potential to reduce infiltration of precipitation and to increase storm runoff.

Site productivity is affected by mass wasting, soil erosion, and by losses of organic matter in timber harvest units. Failures that occur within harvest units, above the top of road cuts, or below the toe of the fill slopes, may directly impact productivity of forest land Most soil nutrients and moisture storage are found in the surface soil horizons, and any loss of topsoil impacts site productivity.

Best Management Practices are implemented to reduce the impact to site quality. Soil compaction by heavy equipment during timber harvest or site preparation may also be minimized by limiting the area of tractor use

MANAGEMENT AREA ALLOCATIONS

Land allocations have a direct bearing on soil and water resources Management Areas 1-9 have no programmed harvest, as such, a higher percentage of land allocated to these Management Areas result in less impact on soils and water. By contrast, Management Areas 13 and 14 allow for development, principally through timber harvest and road construction, and therefore present the greatest risk to soil and water. Management Areas 10-12, while allowing for limited harvest and associated roading, spread impacts over space and time Guidelines for management of these areas provide for smaller unit size and other requirements which, in effect, substantially reduce the risk to the soil and water resource

Management Areas 7 and 11 are especially important to maintaining critical soil and water resources. Management Area 7 (Supplemental Resource) generally restricts activity from the inner river gorge environment where the risk of mass slope instability is high. Management Area 11 (Riparian) similarly restricts or limits activities adjacent to streams and rivers (see the **FISH** section in this chapter). Impacts on soil and water values are further mitigated through the Riparian Standards and Guidelines which provide for area constraints (an average of 11 percent activity per decade), limited harvest to no harvest depending on prescription, an initial suitability determination, and Best Management Practices (BMP's) described in the Siskiyou National Forest's policy for riparian ecosystem management and Appendix F of the Forest Plan.

On areas designated Management Area 14 (General Forest), all timber harvest activity is governed by Standards and Guidelines and associated BMP's. Some of the more important Standards and Guidelines deal with the first step, that of the suitability determination Here, areas susceptible to adverse impacts due to high risk soil, water, and geologic conditions are removed from the land base In the second step, specific requirements are applied to numerous practices within all phases of planning, location, design, implementation, and post-treatment activity Surveillance and monitoring before, during, and after helps

to assure that the effects are those that were anticipated, or that changes in practices are required to meet the soil and water quality standards incorporated into the site-specific projects.

RESPONSE TO THE PLANNING PROBLEMS

Planning Problem #3, "How can the Forest's fish habitat, water quality and soil productivity be maintained or improved?," is addressed here Changes, by alternative and by basin, are addressed for selected measures most relevant to soil productivity and the beneficial uses of water throughout the Forest's 19 Planning Basins Stream temperature and sediment, as related to fish habitat, is addressed under the **FISH** section of this chapter.

ENVIRONMENTAL EFFECTS AND MITIGATION

The discussion of environmental effects is divided into three sections The first section, **ANALYSIS CONSIDERATIONS**, explains several factors that influence how effects were determined These include Short- and Long-Term Effects, Cumulative Effects Analysis, Standards and Guidelines, and Mitigations The second section, **ENVIRONMENTAL EFFECTS BY ALTERNATIVE**, describes the direct, indirect and cumulative effects with respect to each alternative. The last section, **SEDIMENT INCREASE BY BASIN AND ALTERNATIVE**, provides a series of bar charts illustrating the increase in sediment predicted for each alternative. The section **ENVIRONMENTAL EFFECTS BY PLANNING BASIN** describes the risks to watersheds in each Planning Basin posed by management activities prescribed for each alternative, and is located under the **FISH** section of this chapter. Since anadromous fisheries are a major beneficial use in nearly all Planning Basins and the only use which occurs in all basins, the analysis and discussions for water quality and fish were combined.

ANALYSIS CONSIDERATIONS

Short- and Long-Term Effects

The relationship between short- and long-term effects is complex. Short-term effects range from increases in water yield which gradually diminish over a twenty-year period as vegetation grows, to long-term cumulative effects such as the potential for soil productivity loss over multiple rotations of harvests and fuels treatments Both the short-term and long-term effects are discussed in more detail below.

Cumulative Effects

Interactions of land management activities with soil and water resources contribute to soil erosion, mass wasting, nutrient losses, and stream sedimentation They may also contribute to cumulative impacts to fisheries, site productivity, and water quality Considering these direct and indirect effects, there is a potential risk of cumulative effects from resource management activities such as timber harvest and road construction, or from consumptive uses of water such as irrigation and domestic uses For example, channel sedimentation and aggradation may be tied directly and indirectly to landslide size and frequency and, in turn, to timber harvest and road building

The analysis of cumulative effects takes into consideration past, present, and future impacts on National Forest and adjacent lands Cumulative impacts are reviewed in terms of timing, location, and significance Analysis of cumulative effects often requires a threshold value above which the cumulative effects may be significant, and below which the effects are judged to be insignificant The accepted methods or models to establish threshold values for determining the significance of cumulative impacts from sediment delivered to streams from surface erosion, channel erosion, and mass wasting are not highly reliable relative to accuracy (absolutes) This is particularly true when applied to differing physiographic and climatic conditions in which the model was neither designed to replicate particular natural processes (systems) nor based on local, empirical information

Second, and just as important, the relationship of the activity to the direct effect may be good, but the secondary (indirect or cumulative) effects may not be as strong From extensive literature review, coupled with on-site measurements and field knowledge gained over time, a good quantative estimate may closely represent actual processes, outputs and effects Quantitative estimates may not be absolute, but may be appropriately used in comparing relative differences between alternatives wherein a good assessment of effects can be made In many cases, a model may assist simply through providing the means in which immense data can be processed and outputs generated in a consistent manner. Furthermore, because mass failures cannot be predicted from storm magnitudes or frequencies with a high degree of reliability, the estimate of when threshold values might be exceeded is mostly professional judgment Only the probability may be calculated.

A model that relates stream power and the percent increase in sediment over natural conditions to fish habitat was developed on the Siskiyou National Forest in 1988 by the Silver Fire Recovery Project's "Cumulative Effects Assessment Team" (Vanderheyden and others 1988). The model holds considerable promise for Forest-wide use in making cumulative effects assessments at the project-level; monitoring data is currently being gathered in the Silver Fire area to help validate and improve the model.

Concentrating timber harvest and road-building activities may result in an increase in landslide frequency. The concentration of intensive management (roads and timber harvest) in very steep or marginally stable terrain can cause greater impacts than in flatter or more stable terrain. These effects become important when, as a result of management activities, storms of lesser intensity cause equivalent damages that were previously sustained only under major storms and/or natural conditions. The accumulation of numerous failures may become important after an extended period of time For example, many small failures can result in the loss of growing sites, eventually adding to a substantial loss of timber production

Applying restrictive basin-specific timber harvest constraints will result in a greater dispersion of activity. Consequently, as harvest acres are constrained, total sediment yield is reduced And, more importantly, sediment is more evenly distributed over both space and time. This distribution diminishes the potential risk for cumulative effects on stream morphology and degradation of established beneficial uses of water.

The sum of all soil and stream disturbances in a watershed has the potential to produce adverse cumulative impacts due to increased frequency of landslides, altered stream channels, and increased stream temperature. The alternatives provide for various levels of dispersion of timber harvest and roading by application of "basin constraints" (basin-specific timber harvest dispersion constraints) and "Watershed Analysis Areas" (Standards and Guidelines 7-15). Riparian Prescriptions B, C, and Minimum Level for Management Area 11 are designed to either maintain or, in selected watersheds, reduce water temperatures to prevent adverse cumulative impacts to the downstream aquatic environment

For selected alternatives, the basin timber harvest dispersion constraints on acres suitable for timber production range from 9 to 13 percent per decade in Planning Basins ranging in size from 34,600 to 93,800 acres. Several alternatives contain a 20 percent per-decade basin constraint on timber harvest, while one alternative contains a 7 to 17 percent constraint. To prevent concentrating too much harvest in smaller watersheds, projects proposing to harvest 20 percent or more in a Watershed Analysis Area of up to 2,500 acres in area require a more indepth analysis of watershed condition, past and proposed activities, and the potential for significant cumulative effects.

The reduction in variation of sediment yield over time also results in lower peaks of sediment production. For the Planning Basin analyses, a lower sediment yield variance results in a reduced potential risk for adverse effects. Higher mean decade sediment increases indicate greater risk for on-site impacts due to soil loss, and off-site impacts related to beneficial uses of water as affected by both sediment and turbidity.

Similarly, increasing the magnitude of the "pulse" or peak sediment output will require that the watershed absorb this impact over a short time The risks of cumulative effects are measurably increased Use of the

basin-specific harvest dispersion constraint has a tremendous bearing on averting potentially significant direct, indirect, and cumulative impacts on soil, water, and other associated resource values within a Planning Basin

When sediment rates are discussed, it should be kept in mind that these figures are not absolutes, but are estimates based on the best tools and professional inputs available. However, they are reasonably good estimates of the values anticipated for the resource conditions and activities found on the Forest. For relative differences and comparative purposes, they are excellent For project level application, sediment values would need to be developed from existing data, monitoring, site-specific conditions, and proposed activity

The application of basin constraints is evaluated below (Forest-wide) by alternative. A comparison of the relative differences in risk for cumulative effects between alternatives is made under the **SOIL AND WATER** section of Chapter II The potential risk for cumulative effects by Planning Basin is analyzed under the **FISH** section of this chapter.

Standards and Guidelines

The Standards and Guidelines and BMP's contained in the accompanying Forest Plan (Chapter IV and Appendix F) have been designed to minimize the impacts to the soil and water resource, and thereby provide a strong degree of protection to the established beneficial uses of water. A discussion of the requirements in accordance with the Clean Water Act for the protection of waters of the State of Oregon and State of California is contained in the **SOIL AND WATER** section of **POTENTIAL CONFLICTS WITH PLANS AND POLICIES OF OTHER JURISDICTIONS** near the end of this chapter.

Mitigations

Mitigation measures are used in preventing or restoring those direct, indirect, and cumulative effects previously discussed The applicable Standards and Guidelines designed to mitigate these effects contain requirements for maintaining soil cover, classifying land for suitability, maintaining riparian vegetation and minimizing disturbance for both stream temperature and stability, avoiding or restricting activity in areas of potential mass instability, and qualifying type, degree, and timing of soil disturbance

Best Management Practices (Appendix F of the Forest Plan) will be implemented on National Forest lands to comply with State requirements for protection of waters of the State of Oregon and California. Sullivan and others (1987) suggest that adopting BMP's provides the needed basis for reducing effects of forest management activities The monitoring and evaluation plan in Chapter V and Appendix D (Forest Plan) describes the BMP's implementation and effectiveness monitoring

For private lands in watersheds with multiple ownerships, the BMP's for timber harvest are contained in the Oregon Forest Practice regulations These are designed to protect water quality and beneficial uses following timber harvest on private lands

Capital investments, applied through watershed improvement projects, vary primarily by acres harvested These resource improvement activities are oriented to preventing, mitigating, or enhancing the soil and water resources

Approaches to evaluating non-point source impacts from silvicultural activities on water and soil are discussed in the WRENS document (EPA 1980) Other overviews of erosion, sedimentation, and water quality relationships are covered in *Forestry and Water Quality* (Brown 1980), *Forest and Water. Effects of Forest Management on Floods, Sedimentation, and Water Supply* (H.W. Anderson and others 1976), and *Logging Roads and Protection of Water Quality* (EPA 1975)

ENVIRONMENTAL EFFECTS BY ALTERNATIVE

Potential effects on soil and water vary between alternatives due to differences in Management Area allocations (development and nondevelopment areas), basin timber harvest dispersion constraints, and Riparian prescriptions. Differences are also strongly correlated to activity acres (timber harvest and associated road construction), timing of the activity, and soil and slope sensitivity within the basins

All alternatives have been evaluated utilizing the full set of mitigation measures provided in the Standards and Guidelines and associated BMP's.

The alternatives provide for a range of first-decade annual timber sale volume of 6.1 to 36 8 million cubic feet (MMCF). For road construction, the alternatives range from no new construction to 308 miles within the first decade Acres of timber harvest by alternative varies from 754 to 6,713 acres each year in the first decade.

The intensity and extent of activities are primary determinants of potential risks to soil, water, and geologic resources. A more complete discussion of potential risk can be found in the subsection titled **ENVIRONMENTAL EFFECTS BY PLANNING BASIN**, located in the **FISH** section of this chapter. The beneficial uses of water considered below may include the anadromous fishery, public and domestic water supplies, irrigation, wildlife, fishing, boating, water-contact recreation, visual quality, and navigation where applicable. The following terms for rating the potential risks to the beneficial uses of water are used in the analysis·

> **negligible** -- the existing beneficial uses of water are expected to be maintained or improved; water quality standards are expected to be met.
>
> **minor adverse** -- the predicted change in sediment or turbidity results in increased risk to a beneficial use without significant impacts. There is a slight risk of exceeding water quality standards on a short-duration, localized basis
>
> **moderate adverse** -- the predicted change in sediment or turbidity results in increased risk, with potential for localized impacts to beneficial uses. Water quality standards for an identified use may be exceeded.

Under alternatives where risks are defined as **negligible,** water quality and instream conditions for beneficial uses are expected to be maintained or improved. Where the potential for improvement over current condition exists, the ratings are enclosed by parentheses, e.g., **(minor improvement)** or **(moderate improvement)**; this rating applies to the long term potential for improvement of existing conditions For current conditions, refer to Chapter III, **FISH** and **SOIL AND WATER** sections

For each alternative, under the *CUMULATIVE EFFECTS* heading, the average variation in potential accelerated sediment over the first five decades is used as an indicator of the potential for cumulative effects A combination of the variation in both the basin timber harvest constraint and the total amount of accelerated sediment for each alternative results in a smaller or larger value for this coefficient. A smaller value for the average variation in potential accelerated sediment results in a correspondingly reduced potential risk of adverse cumulative effects, such as channel aggradation and occurrence of landslides.

Besides the average variation in potential accelerated sediment over the first five decades, the potential risk from sediment and turbidity identified for each Planning Basin under the **FISH** section of this chapter is another indicator of the potential risk of cumulative effects Planning Basins with either a minor or moderate potential risk from sediment and turbidity are listed below for each alternative under the *CUMULATIVE EFFECTS* heading The potential risk associated with increased stream temperature for all alternatives and Planning Basins is negligible (see **FISH** section of this chapter)

The environmental consequences to soil and water for each alternative are described below The overall assessment by alternative is a composite rating of the 19 Planning Basins.

Alternative NC

DIRECT AND INDIRECT EFFECTS. The level of timber harvest and road construction necessary to produce 31.0 MMCF per year of wood for decades 1-5 would result in a 964,000 tons per decade mean increase in potential accelerated sediment to streams and rivers.

All Planning Basins would be managed with Riparian Prescription B which is designed to maintain stream water temperature Fourteen rivers and streams allocated to Supplemental Resource areas provide soil and water protection to the high-risk inner-gorge areas

The mean increase for decades 1-5 in potential accelerated sediment for this level of activity varies moderately by Planning Basin, ranging from below five percent for the Upper Illinois (5 percent) and Rough/Josephine (4 percent) to over 30 percent for the Indigo (33 percent) and Winchuck (34 percent)

The estimated risk of a potential increase in accelerated sediment and turbidity to the beneficial uses of water for all Planning Basins ranges from **negligible** to **minor adverse** The majority of the estimated risks are **negligible**; existing conditions are maintained (see **ENVIRONMENTAL EFFECTS BY PLANNING BASIN** in the **FISH** section of this chapter)

CUMULATIVE EFFECTS. For Alternative NC, the 20 percent per-decade basin limit on disturbed acreage due to timber harvesting and road construction would result in a 35 percent average variation in potential accelerated sediment over the first five decades For this alternative, the Indigo, Silver, Briggs, Rough/Josephine, and Winchuck Planning Basins would have an estimated **minor adverse** risk from sediment and turbidity.

Alternative A

DIRECT AND INDIRECT EFFECTS The level of timber harvest and road construction necessary to produce 30 1 MMCF per year of wood for decades 1-5 would result in a 944,000 ton per decade mean increase in potential accelerated sediment to streams and rivers.

All Planning Basins would be managed with Riparian Prescription B, designed to maintain stream water temperature. Twelve rivers and streams allocated to Supplemental Resource areas to provide soil and water protection to the high-risk inner-gorge areas.

The mean increase for decades 1-5 in potential accelerated sediment for this level of activity varies moderately by Planning Basin, ranging from below five percent for the Upper Illinois (5 percent) and Rough/Josephine (3 percent) to over 30 percent for the Indigo (33 percent) and Winchuck (31 percent)

The estimated risk of a potential increase in accelerated sediment and turbidity to the beneficial uses of water for all Planning Basins ranges from **negligible** to **minor adverse**. The majority of the estimated risks are **negligible**; existing conditions are maintained

CUMULATIVE EFFECTS For Alternative A, the 20 percent per-decade basin limit on disturbed acreage due to timber harvesting and road construction would result in a 34 percent average variation in potential accelerated sediment over the first five decades. For this Alternative, the Briggs, Indigo, and Silver Planning Basins would have a **minor adverse** risk from sediment and turbidity.

Alternative A-Departure

DIRECT AND INDIRECT EFFECTS. The level of timber harvest and road construction necessary to produce 31 2 MMCF per year of wood in the first decade and 29 4 MMCF per year in the fifth decade would result in a 962,000 ton per-decade mean increase in potential accelerated sediment to streams and rivers.

All Management Area allocations, Riparian prescriptions, and basin dispersion constraints are the same as Alternative A The mean 1-5 decade percent increase in potential accelerated sediment is essentially the same as Alternative A, for the minor differences, see Figures IV-2 and IV-3.

The estimated risk of a potential increase in accelerated sediment and turbidity to the beneficial uses of water for all Planning Basins ranges from **negligible** to **minor adverse.** The majority of the estimated risks are **negligible**, existing conditions are maintained.

CUMULATIVE EFFECTS For Alternative A-Departure, the 20 percent per-decade basin limit on disturbed acreage due to timber harvesting and road construction would result in a 28 percent average variation in potential accelerated sediment over the first five decades For this Alternative, the Briggs, Indigo, and Silver Planning Basins would have an estimated **minor adverse** risk from sediment and turbidity.

Alternative B

DIRECT AND INDIRECT EFFECTS The level of timber harvest and road construction necessary for harvesting the average annual wood output of 36 8 MMCF per year in the first decade and 25.0 MMCF per year in the fifth decade would result in a 990,000 ton per-decade mean increase in potential accelerated sediment to streams and rivers

Riparian Prescription B (12 Planning Basins) will maintain stream temperature, and Prescription C (6 Planning Basins) will improve stream temperature. Fourteen Supplemental Resource areas are allocated to provide soil and water protection to the high-risk inner-gorge areas.

The mean increase for decades 1-5 in potential accelerated sediment ranges by Planning Basin from below five percent for the Upper Illinois (5 percent) to over 30 percent for Indigo (39 percent).

The estimated risk of a potential increase in accelerated sediment and turbidity to the beneficial uses of water for all Planning Basins ranges from **moderate adverse** to **negligible (minor improvement).** Half of the estimated risks are **negligible**, existing conditions are maintained

CUMULATIVE EFFECTS For Alternative B, the 9-12 percent per-decade limit on disturbed acreage due to timber harvesting and road construction in six Planning Basins and 20 percent per decade in the remaining 12 Planning Basins results in a 35 percent average of variation in potential accelerated sediment over the first five decades. For this alternative, the East and West Forks Illinois, Rough/Josephine, Indigo, Lower Illinois, Galice/Slate, Silver, and Briggs Planning Basins would have an estimated **minor adverse** risk from sediment and turbidity. Indigo Planning Basin would have an estimated **moderate adverse** risk.

Alternative C

DIRECT AND INDIRECT EFFECTS. The level of timber harvest and road construction necessary for harvesting the average annual wood output of 31.8 MMCF per year for decades 1-5 would result in a 1,076,000 ton per-decade mean increase in potential accelerated sediment to streams and rivers.

Riparian Prescription B would be implemented in all Planning Basins to maintain stream temperature Two Supplemental Resource areas are allocated to provide soil and water protection to the high-risk inner-gorge areas

The mean increase for decades 1-5 in potential accelerated sediment for this level of activity varies greatly by Planning Basin, ranging from below five percent for the Upper Illinois (5 percent) and Rough/Josephine (5 percent) to over 30 percent for the Indigo (39 percent) and Winchuck (34 percent)

The estimated risk of a potential increase in accelerated sediment to the beneficial uses of water for all Planning Basins ranges from **moderate adverse** to **negligible** Half of the estimated risks are **negligible,** existing conditions would be maintained

CUMULATIVE EFFECTS. For Alternative C, the 20 percent per-decade basin limit on disturbed acreage due to timber harvesting and road construction would result in a 44 percent average variation in potential accelerated sediment over the first five decades. For this Alternative, the Upper Rogue, Indigo, Galice/Slate, Lower Illinois, Briggs, Rough/Josephine, Winchuck, and East and West Forks Illinois Planning Basins would have an estimated **minor adverse** risk from sediment and turbidity. Indigo and Silver Planning Basins would have an estimated **moderate adverse** risk.

Alternative D

DIRECT AND INDIRECT EFFECTS The level of timber harvest and road construction necessary for harvesting the average annual wood output of 30 4 MMCF per year for decades 1-5 would result in a 970,000 ton per-decade mean increase in potential accelerated sediment to streams and rivers

All Management Area allocations, Riparian prescriptions, and basin constraints are the same as Alternative B. The mean 1-5 decade percent increase in potential accelerated sediment is essentially the same as Alternative B; for the differences, see Figures IV-4 and IV-6

The estimated risk of a potential increase in accelerated sediment to the beneficial uses of water for all Planning Basins ranges from **moderate adverse** to **negligible (minor improvement).** The majority of the estimated risks are about equally distributed between **minor adverse** and **negligible**

CUMULATIVE EFFECTS For Alternative D, the 9-12 percent per-decade limit on disturbed acreage due to timber harvesting and road construction in six Planning Basins and 20 percent per decade in the remaining 12 Planning Basins results in a 41 percent average variation in potential accelerated sediment over the first five decades For this alternative, the East and West Forks Illinois, Silver, Rough/Josephine, Lower Illinois, Galice/Slate, Briggs, and Pistol Planning Basins would have an estimated **minor adverse** risk from sediment and turbidity. Indigo Planning Basin would have an estimated **moderate adverse** risk.

Alternative D1

DIRECT AND INDIRECT EFFECTS. The level of timber harvest and road construction necessary for harvesting the average annual wood output of 33 2 MMCF per year in decades 1-5 would result in a 942,000 ton per-decade mean increase in potential accelerated sediment to streams and rivers

All Management Area allocations, Riparian prescriptions, and basin constraints are the same as Alternatives B and D. The mean 1-5 decade percent increase in potential accelerated sediment is essentially the same as Alternative B and D, for the differences, see Figures IV-4, IV-6, and IV-7

The estimated risk of a potential increase in accelerated sediment to the beneficial uses of water for all Planning Basins ranges from **moderate adverse** to **negligible (minor improvement).** The majority of the estimated risks are about equally distributed between **minor adverse** and **negligible.**

CUMULATIVE EFFECTS The same description applies from Alternative B and D, except the average variation is 42 percent For this alternative, the Lobster, East and West Forks Illinois, Silver, Rough/Josephine, Lower Illinois, Galice/Slate, Briggs, and Pistol Planning Basins would have an estimated

minor adverse risk from sediment and turbidity Indigo Planning Basin would have an estimated **moderate adverse** risk

Alternative E

DIRECT AND INDIRECT EFFECTS. The level of timber harvest and road construction necessary for harvesting the average annual wood output of 16 2 MMCF per year for decades 1-5 would result in a 510,000 ton per-decade mean increase in potential accelerated sediment to streams and rivers.

Riparian areas (Minimum Level Prescription) and all 30 Supplemental Resource areas would be allocated to a level of management which precludes programmed timber harvest in stream and inner-gorge river areas The risk of potential adverse impacts on the water resource and values would be greatly minimized adjacent to most waterways.

The mean increase for decades 1-5 in potential accelerated sediment for this level of activity varies by Planning Basin, ranging from below five percent for the Silver (1 percent), Upper Illinois (2 percent), Rough/Josephine (1 percent), and North Fork Smith (3 percent), to less than 30 percent for all other basins

The estimated risk of a potential increase in accelerated sediment to the beneficial uses of water for all Planning Basins ranges from **negligible** to **negligible (moderate improvement)**. The majority of the estimated risks are **negligible (minor improvement)**.

CUMULATIVE EFFECTS. For Alternative E, the 9-13 percent per-decade basin limit on disturbed acreage due to timber harvesting and road construction would result in a 17 percent average variation in potential accelerated sediment over the first five decades. The potential risk from sediment and turbidity for all Planning Basins is **negligible.**

Alternative G

DIRECT AND INDIRECT EFFECTS. The level of timber harvest and road construction necessary for harvesting the average annual wood output of 20.5 MMCF per year in decades 1-5 would result in a 614,000 ton per-decade mean increase in potential accelerated sediment to streams and rivers.

Riparian areas and 31 Supplemental Resource areas would be allocated to a level of management which precludes programmed timber harvest in stream and inner-river gorge areas. The risk of potential adverse impacts on the water resource and values would be greatly minimized adjacent to most waterways.

The mean increase for decades 1-5 in potential accelerated sediment for this level of activity varies by Planning Basin, ranging from below five percent for the Silver (2 percent), Upper Illinois (2 percent), North Fork Smith (4 percent), and Rough/Josephine (2 percent), to less than 30 percent for all other basins.

The estimated risk of a potential increase in accelerated sediment to the beneficial uses of water for all Planning Basins ranges from **negligible** to **negligible (moderate improvement)**. The majority of estimated risks are **negligible (minor improvement)**.

CUMULATIVE EFFECTS. For Alternative G, the 9-13 percent per-decade basin limit on disturbed acreage due to timber harvesting and road construction would result in a 14 percent average variation in potential accelerated sediment over the first five decades. The potential risk from sediment and turbidity for all Planning Basins is **negligible**

Alternative K

DIRECT AND INDIRECT EFFECTS The level of timber harvest and road construction necessary for harvesting the average annual wood output of 27 8 MMCF per year for decades 1-5 would result in a 800,000 ton per-decade mean increase in potential accelerated sediment to streams and rivers.

All Planning Basins, with the exception of the Elk-Sixes (Prescription C), would be managed with Riparian Prescription B Twenty-three Supplemental Resource areas that are of particular benefit to fish also reduce the potential risks of adverse impacts to soil and water values in the inner-river gorges

The mean increase for decades 1-5 in potential accelerated sediment for this level of activity varies by Planning Basin, ranging from below five percent for the Silver (5 percent), Upper Illinois (4 percent), Rough/Josephine (3 percent), and North Fork Smith (5 percent), to less than 30 percent for all other basins.

The estimated risk of a potential increase in accelerated sediment to the beneficial uses of water for all Planning Basins ranges from **minor adverse** to **negligible (minor improvement)** The majority of estimated risk is **negligible**, existing conditions maintained.

CUMULATIVE EFFECTS. For Alternative K, the 9-13 percent per-decade basin limit on disturbed acreage due to timber harvesting and road construction would result in a 16 percent average variation in potential accelerated sediment over the first five decades The potential risk from sediment and turbidity for Indigo and Silver Planning Basins is **minor adverse**; all other Planning Basins are **negligible.**

Alternative M

DIRECT AND INDIRECT EFFECTS. The level of timber harvest and road construction necessary for harvesting the average annual wood output of 6.1 MMCF per year for decades 1-5 would result in a 174,000 ton per-decade mean increase in potential accelerated sediment to streams and river.

Riparian areas (Minimum Level Prescription) and all Supplemental Resource areas would be allocated to a level of management which precludes programmed timber harvest. Potential impacts to soil and water values from risk of mass failures would be minimized.

The mean increase for decades 1-5 in potential accelerated sediment for this level of activity is below 10 percent for all Planning Basins

The estimated risk of a potential increase in accelerated sediment to the beneficial uses of water for all Planning Basins ranges from **negligible (minor improvement)** to **negligible (moderate improvement)** The majority of estimated risks are **negligible (moderate improvement)**

CUMULATIVE EFFECTS For Alternative M, the 9-13 percent per-decade basin limit on disturbed acreage due to timber harvesting and road construction would result in a 96 percent average variation in potential accelerated sediment over the first five decades. A smaller average variation in potential accelerated sediment could result in a reduced potential for adverse cumulative effects; however, the total acres impacted under this alternative for all basins are insignificant. The potential risk from sediment and turbidity for all Planning Basins is **negligible**

Alternative S

DIRECT AND INDIRECT EFFECTS. The level of timber harvest and road construction necessary for harvesting the average annual wood output of 29.0 MMCF per year for decades 1-5 would result in a 828,000 ton per-decade mean increase in potential accelerated sediment to streams and rivers. Fertilizer would be applied to increase commercial forest growth

Eleven Planning Basins would be managed with Riparian Prescription B, seven would be managed with a Prescription C. Twenty of the most productive Supplemental Resource areas for fish would be allocated to provide soil and water protection to the high-risk inner-gorge areas. Five other key streams and rivers are given additional protection through other land allocations with no programmed harvest

The mean increase for decades 1-5 in potential accelerated sediment for this level of activity varies by Planning Basin, ranging from below five percent for the Silver (4 percent), Upper Illinois (4 percent) and Rough/Josephine (3 percent), to less than 30 percent for all other basins.

The estimated risk of a potential increase in accelerated sediment to the beneficial uses of water for all Planning Basins ranges from **minor adverse** to **negligible (minor improvement)**. The majority of estimated risks are **negligible**; existing conditions maintained.

In a summary of six fertilization studies in the Douglas-fir region, Fredriksen and others (1975) concluded that peak concentrations of nitrogen never reached toxic levels. The observed peak concentrations were associated with direct application to water. No effect from fertilizer application is anticipated since precautionary project-level Standards and Guidelines will be taken to prevent direct application or fertilizer to streams, as well as buffer zones between treated areas and the streams.

CUMULATIVE EFFECTS. For Alternative S, the 7-17 percent per-decade basin limit on disturbed acreage due to timber harvest and road construction would result in a 16 percent average variation in potential accelerated sediment over the first five decades. The potential risk from sediment and turbidity for Indigo and Silver Planning Basins is **minor adverse**; all other Planning Basins are **negligible.**

SEDIMENT INCREASE BY BASIN AND ALTERNATIVE

Figures IV-1 through IV-12 show the mean decade percent increase (decades 1-5) in potential accelerated sediment, and the maximum percent decade increase (decades 1-5) for each alternative by basin The mean and peak decade percent increase in sediment shown in Figures IV-1 through IV-12 was used to help estimate the potential risk from increased sediment and turbidity by alternative for each Planning Basin. See **ENVIRONMENTAL EFFECTS BY PLANNING BASIN** located in the **FISH** section for these ratings.

The percent increase in the figures is computed based on an estimate of current sediment production on the Forest Current sediment production consists of natural erosion and human-induced erosion from existing road systems. Of the 20 original Planning Basins, only 19 remain. Basin 18 was combined with two other Planning Basins. Basin 14, the Upper Chetco, is entirely within the Kalmiopsis Wilderness. The Planning Basins are shown in Figure III-8

The sediment yield estimates should not be considered as absolute amounts, but rather as an **index** for comparing the relative risk to water quality and beneficial uses between alternatives. Sediment yield estimates were made based on geomorphic indices for natural surface and channel erosion, an aerial photograph inventory of landslides on the Forest between 1956 and 1976 for estimating the natural and management-related rate of landslides, and literature to estimate potential surface erosion for management activities. Considering the fact that several major floods, including the 1964 flood (a 100-year runoff event), occurred within the aerial photograph landslide inventory period, the estimate of mass movement-related sediment for management activities is probably greater than would be expected under a normal long-term average. Additionally, the sediment calculations do not totally account for current BMP's for road construction and timber harvesting in use today.

FIRE

SIGNIFICANT INTERACTIONS

The various land allocations and the associated agency activities and public consumption will interact with the Fire environmental component by increasing or decreasing the "risk" and "hazard" associated with the fuels component of the fire environment Microclimate, an element of the weather component of the fire environment, will also be affected The interactions are complex and range from short-term to long-term and may produce positive or negative impacts on the Forest's resources and the ability to protect those resources.

For example, General Forest, Partial Retention Visual, Retention Visual, Riparian, and Scenic and Recreation River allocations (Management Areas 10-14), allow timber harvest operations In the short term, these operations present a significant risk and generate large amounts of slash which contribute to the development and rapid spread of high intensity wildfires The harvest operations also open up the vegetative canopy, creating a hotter and drier microclimate which affects fire behavior In the long term, however, timber harvest activities and the associated fuels treatment will create a mosaic pattern in the vegetation (diversity) which will serve to reduce the potential development and spread of large fire, its intensity, and the potential for resource damage and high suppression costs

Even-aged management is the predominant silvicultural system utilized in General Forest. Good spatial distribution of the units will, over time, develop a mosaic of age classes and non-uniform fuel profiles that will be more resistant to the spread of a major wildfire than will a homogeneous stand condition. The large tracts of existing even-aged timber with interlocking crowns, large accumulations of surface fuels, and understory vegetation which provide an excellent fire ladder, would be broken up by an array of areas with relatively low flammability ranging in size from 2 to 60 acres, with an anticipated average of 20 to 30 acres. The post-treatment fuel loadings left on these sites would be less than 30 tons per acre. The effectiveness of a fire suppression organization would be increased as a result of the discontinuous fuel profiles.

The units would remain relatively fire resistant until silvicultural activities, such as chemical or manual release, and precommercial thinning begin to contribute to the buildup of fuels in the 0 to 3 inch size classes within the first decade in the stand rotation. Harvest clearcuts will eventually develop into even-aged, dense conifer plantations with a potential for high rates of spread. The plantations create a more hazardous fuels complex when these dense stands cover old logging slash. The potential rate of spread will drop sharply and then start to increase again after each commercial thinning operation and accompanying fuels treatment

Silvicultural systems, such as shelterwood, seed tree, single-tree selection, and group selection, will also serve to modify the vegetation. This in turn will serve to reduce the spread of a major fire, but to a lesser degree than clearcutting These systems will be more predominant in the Retention Visual, Partial Retention Visual, Riparian, and Scenic/Recreation River Management Area allocations

Site-specific microclimates will be modified as a result of the activities associated with land allocations. Road construction, timber harvest, and thinning will open up the forest canopy and increase the amount of sunlight and wind at ground level. Countryman (1955) estimated that opening a virgin mixed-conifer stand could increase the rate of fire spread up to 4.5 times. This considers only the changes due to microclimate and not any additional rate of spread increase due to the additional fuels on the site. Morris (1941) reports that the fire weather in harvest clearcut Douglas-fir units in western Oregon will be seven times more severe than in adjacent, uncut timber under similar conditions. The potential for an ignition source (lightning strike, spark, etc) causing a detectable fire is increased in the hotter and drier microclimates

One of the paradoxes of modern fire exclusion and over-protection practices is that those areas most protected become the most susceptible, and dangerous for fires. Numerous small fires create both diversity and protection against the worst ravages of fire storms which devastate more uniform, climax forests (Lewis 1982).

Fuels complexes are dynamic and based on the cyclic nature of vegetative types and stages in the area (Martin and Brackebusch 1974) Continued suppression of wildfires frequently leads to the development of timber stands dominated by shade-tolerant species (Spurr and Barnes 1973). Species composition of the stand and fire suppression result in fuel accumulations above natural levels A climatic pattern of warm, dry summers and wet, cool or cold winters leads to maximum accumulations of dead fuels (Dodge 1972) Past suppression activities and inadequate fuel management programs, too, have enhanced the threat of wildfires by allowing fuel loads in the forest to accumulate to unnaturally high levels (Davis and Cooper 1963; Vogl 1971; Hall 1977).

The treatment or reduction of natural fuels accumulations goes a long way toward reducing the intensity and potential spread of wildfire Selected fuels complexes can be treated to reduce the fuel continuity and protect resources in critical areas Large areas can be treated with prescribed fire which would result in a mosaic of fuels complexes.

Recreation opportunities, timber harvest, and harvest-related activities affect the risk of human-caused fires. No specific numbers are available to correlate the relationship between activities and use, and the number of human-caused fires, but it is generally accepted that as activities and uses increase, the risk of an ignition also increases. Industrial operations present a high risk of ignition. This high risk is compounded by the high fuel hazard that concurrently exists on the site

Prescribed fire, as an agency activity, also constitutes a legitimate risk of ignition. The risk is twofold. First, there is the risk of fire escaping at the time of fire application. Later, there is the risk of ignition due to holdover embers

The risk associated with motorized recreation is related to the miles of road maintained for public use. Areas not presently available become so as timber harvest activities expand the road network. This improved access would then increase the risk of a human-caused fire in areas where this previously has not been a problem. The risk is compounded by motorcycle and all-terrain-vehicle (ATV) users who would still make use of the many miles of nonmaintained roads.

Dispersed recreation facilitates a broader distribution of risk than developed recreation. With dispersed recreation, the Forest visitor will be using natural or otherwise-unimproved areas Forest-wide. Developed recreation will focus risk in specific locations such as campgrounds or day-use areas

ENVIRONMENTAL EFFECTS AND MITIGATION

The effects of the distribution of land allocations across the alternatives on fire is best approached through an analysis of risk and hazard Risk and hazard are terms that are not easily quantified. The analysis is broad scale and the effects are based on the "best professional judgement" of fire management professionals. The analysis also assumes that fire management direction spelled out in the Standards and Guidelines are followed, especially those relating to fuels treatment. More detailed assessments are possible, however, for site-specific areas The reference point for the analysis of effects is the existing condition discussed in Chapter III.

Alternatives NC, A and A-Departure

DIRECT EFFECTS. About 35 percent of the Forest will be allocated to General Forest. Harvest activities will develop a mosaic of nonuniform fuel complexes by the end of the eighth decade. An additional 36 to 38 percent of the Forest will be modified to a lesser degree in the Management Areas 10-13.

The acres of fuels mosaic generated through the land allocations will be supplemented by 60 acres annually of natural fuels treatment in General Forest beginning in the first decade and up to 750 acres annually of hardwood conversion Prescribed fire will be utilized to treat approximately 3,400 acres of activity fuels annually in the first decade.

INDIRECT EFFECTS. The risk of a human-caused ignition will be affected by the 2,528 miles of road open to the public. Industrial operations will distribute the risk of an operations-related fire over 70 percent of the Forest

CUMULATIVE EFFECTS The expected annual loss to wildfire (based on 1970-1979 data) will be 215 acres The potential for large fires (fires of several thousand acres) will be reduced in allocations having timber harvest activities Fuels accumulations and the potential for a major fire will continue to increase in Wildernesses due to fire exclusion. The hazard presented by fuels accumulations in the Wild Rogue Wilderness will be compounded by recreation use in the river corridor.

Alternatives B, D and D1

DIRECT EFFECTS. About 50 percent of the Forest will be allocated to General Forest Harvest activities will complete a mosaic of nonuniform fuel complexes by the end of the ninth decade An additional 20 percent of the Forest will be modified to a lesser degree in Management Areas 10-13.

The acres of fuels mosaic generated through the land allocations will be supplemented by 400 acres annually (250 acres for Alternative B) of natural fuels treatment. This program will emphasize treatment of Wilderness, particularly the Kalmiopsis and Wild Rogue Planned ignitions and limited use of unplanned ignitions (lightning) will play a role Hardwood conversions up to 1,400 acres annually may also make a contribution to the vegetation or fuels mosaic on General Forest lands

Prescribed fire will be utilized to treat approximately 4,000 to 4,200 acres of activities fuels annually in the first decade.

INDIRECT EFFECTS The risk of a human-caused ignition will be affected by 2,554 miles of road open to the public. Industrial operations will distribute risk over 72 percent of the Forest.

CUMULATIVE EFFECTS The expected annual loss to wildfire will be 171 acres The potential for large fires will be reduced in allocations dominated by timber harvest activities The potential for large damaging fires in the Wilderness, or the potential for a fire escaping from the Wilderness and causing extensive resource damage to surrounding General Forest lands, will also be reduced

Alternative C

DIRECT EFFECTS. About 52 percent of the Forest will be allocated to General Forest. Harvest activities will complete a mosaic of nonuniform fuel complexes by the end of the eighth decade. Another 19 percent of the Forest will be modified to a lesser degree in Management Areas 10-13.

The acres of fuels mosaic generated through the land allocations and hardwood conversions are the same as described in Alternatives D and D1. Prescribed fire will be utilized to treat approximately 5,000 acres of activity fuels annually in the first decade.

INDIRECT EFFECTS. The risk of a human-caused ignition will be affected by 2,578 miles of road open to the public Industrial operations will distribute risk over 72 percent of the Forest.

CUMULATIVE EFFECTS. The expected annual loss to wildfire will be 171 acres The potential for large fires will be reduced in allocations dominated by timber harvest activities The potential for large damaging fires in the Wildernesses, or the potential for a fire escaping from Wilderness and causing extensive resource damage to surrounding General Forest, will also be reduced.

Alternative E

DIRECT EFFECTS. About 22 percent of the Forest will be allocated to General Forest Harvest activities will develop a mosaic of nonuniform fuel complexes by the end of the seventh decade Another 19 percent of the Forest will be modified to a lesser degree in Management Areas 10-13.

Almost 49 percent of the Forest would be assigned to Wilderness and Backcountry Recreation Much of this area would be considered old growth by the end of the fifteenth decade. Fuel accumulations will be heavy and continuous, and the vegetative canopy will be closed and continuous over large acreages. The old-growth stands will be vulnerable to a large, high intensity wildfire

The acres of fuels mosaic generated through allocations will be supplemented by 400 acres annually of natural fuels treatment. This program will emphasize treatment of lands under Backcountry Recreation and fuels in other high risk areas outside of Wilderness Prescribed fire will be utilized to treat nearly 2,200 acres of activity fuels annually in the first decade.

INDIRECT EFFECTS The risk of a human-caused ignition will be affected by the 2,022 miles of road open to the public. Industrial operations will distribute risk over only 41 percent of the Forest as all existing unroaded and undeveloped areas will remain in a roadless condition.

CUMULATIVE EFFECTS. The expected annual loss to wildfire in the first decade will be 171 acres The potential for large fires will be reduced in allocations dominated by timber harvest activities. The potential for large damaging fires in Wildernesses will increase due to the combination of fire exclusion and the lack of natural fuels treatment

Alternative G

DIRECT EFFECTS. About 26 percent of the Forest will be allocated to General Forest. Harvest activities will develop a mosaic of nonuniform fuel complexes by the end of the seventh decade. Another 23 percent of the Forest will be modified to a lesser degree in Management Areas 10-13

Another 35 percent of the Forest would fall under Wilderness and Backcountry Recreation management. Most of these acres would be considered old growth by the end of the fifteenth decade. Fuel accumulations will be heavy and continuous; vegetative canopy will be closed and continuous over large acreages. The old-growth stand will be vulnerable to a large, high intensity wildfire.

The acres of fuels mosaic generated through allocations will be supplemented by 400 acres annually of natural fuels treatment. Fuels treatment will be emphasized in Wilderness and other high risk areas outside of Wilderness Planned ignitions, as well as unplanned ignitions (lightning) will play a role in Wilderness. High intensity prescribed fires ignited by lightning would be acceptable in those portions of the Kalmiopsis with a Primitive ROS classification. Only low-intensity lightning fires would be managed as prescribed fires in the Wild Rogue Wilderness. Hardwood conversions up to 400 acres per year could contribute to the vegetation or fuels mosaic on General Forest lands Prescribed fire would be utilized to treat approximately 2,600 acres of activity fuels annually in the first decade

INDIRECT EFFECTS The risk of a human-caused ignition will be affected by 2,304 miles of road open to the public. Industrial operations will distribute risk over 49 percent of the Forest.

CUMULATIVE EFFECTS. The expected annual loss to wildfire in the first decade will be 171 acres. The potential for large fires will be reduced in allocations with timber harvest activities The potential for large damaging fires in Wilderness will decrease as will the resource impacts of fires in the areas receiving treatment The potential exists for damage to forest resources (primarily the soil resources) in Wilderness where high intensity prescribed fire is permitted.

Alternative K

DIRECT EFFECTS. About 43 percent of the Forest will be allocated to General Forest. Harvest activities will develop a mosaic of nonuniform fuel complexes by the end of the seventh decade. An additional 23 percent of the Forest will be modified to a lesser degree in Management Areas 10-13.

Another 23 percent of the Forest would be allocated to Wilderness and Backcountry Recreation. Most of these acres would be considered old growth by the end of the fifteenth decade. The fuels accumulations will be heavy and continuous; the vegetative canopy will be closed and continuous over large acreages. The old growth will be vulnerable to a large, high intensity wildfire.

The acres of fuels mosaic generated through allocations will be supplemented by 400 acres annually of natural fuels treatment This program will emphasize fuels treatment on lands in Wilderness and other high risk areas outside of Wilderness. Planned ignitions, as well as unplanned ignitions (lightning), will play a role in the Wildernesses. High intensity prescribed fires ignited by lightning would be acceptable in those portions of the Kalmiopsis with a Primitive ROS classification Only low-intensity lightning fires would be managed as prescribed fires in the Wild Rogue Wilderness. Limited amounts of hardwood conversions up to 750 acres annually would also contribute to the fuels mosaic on General Forest lands. Prescribed fire will be utilized to treat approximately 3,600 acres of activity fuels annually in the first decade.

INDIRECT EFFECTS. The risk of a human-caused ignition will be affected by the 2,202 miles of road open to the public Industrial operations will distribute risk over 66 percent of the Forest.

CUMULATIVE EFFECTS. The expected annual loss to wildfire in the first decade will be 171 acres. The potential for large fires will be reduced in allocations having timber harvest activities. The potential for large damaging fires in Wilderness will decrease as will the resource impacts of fires in the areas receiving treatment. The potential exists for damage to forest resources (primarily the soil resources) in the Wildernesses where high intensity prescribed fire is permitted.

Alternative M

DIRECT EFFECTS Approximately 21 percent of the Forest will be allocated to General Forest Harvest activities will complete a mosaic of nonuniform fuel complexes in some future decade. The rate of conversion as old-growth stands and areas accessed by existing roads would not be managed the same as the other alternatives. An additional 17 percent of the Forest will be modified to a lesser degree Management Areas 10-13.

About 48 percent of the Forest would be allocated to Wilderness and Backcountry Recreation. Most of these acres would be considered old growth by the end of the fifteenth decade The fuels accumulations will be heavy and continuous, the vegetative canopy will be closed and continuous over large acreages. The old growth will be vulnerable to a large, high intensity wildfire

The annual 400 acres of natural fuels treatment will not contribute significantly to the overall reduction in the potential of a major wildfire, but the treatments will enhance the ability to protect sensitive resources

and improvements from fire damage. Prescribed fire will be utilized to treat approximately 600 acres of activity fuels annually in the first decade.

INDIRECT EFFECTS. The overall risk of a human-caused ignition should not increase. No new roads, accompanied by road closures, will limit access to many areas, thereby concentrating the risk in general areas. Only 2,116 miles of road will be open. The risk associated with dispersed recreation may increase Risk associated with industrial operations will be limited to 39 percent of the Forest.

CUMULATIVE EFFECTS The expected annual loss to wildfire in the first decade will be 171 acres. This objective will become harder to sustain in future decades as the amount of old growth increases and becomes more vulnerable to a stand replacement type of fire. Fuels accumulation and the potential for a major fire will continue to increase in Wilderness with fire exclusion. The hazard presented by fuels accumulations in the Wild Rogue Wilderness will be compounded by recreation use in the corridor.

Alternative S

DIRECT EFFECTS. About 35 percent of the Forest will be allocated to General Forest. Harvest activities will develop a mosaic of nonuniform fuel complexes by the end of the seventh decade An additional 22 percent of the Forest will be modified to a lesser degree in Management Areas 10-13.

Another 31 percent of the Forest would in Wilderness and Backcountry Recreation Most of these acres would be considered old growth by the end of the fifteenth decade. The fuels accumulations will be heavy and continuous; the vegetative canopy will be closed and continuous over large acreages The old-growth stand will be vulnerable to a large, high intensity wildfire.

The acres of fuels mosaic generated through allocations will be supplemented by 400 acres annually of natural fuels treatment This program will emphasize fuels treatment on lands in Wilderness and other high risk areas outside of Wilderness. Planned ignitions, as well as unplanned ignitions (lightning), will play a role in Wilderness High intensity prescribed fires ignited by lightning would be acceptable in portions of the Kalmiopsis with a Primitive ROS classification Only low intensity lightning fires would be managed as prescribed fires in the Wild Rogue Wilderness. Limited hardwood conversion, up to 750 acres annually, would also contribute to the fuels mosaic on General Forest Prescribed fire will be utilized to treat approximately 3,600 acres of activity fuels annually in the first decade

INDIRECT EFFECTS. The risk of a human-caused ignition will be affected by 2,211 miles of road open to the public. Industrial operations will distribute risk over 66 percent of the Forest

CUMULATIVE EFFECTS. The expected annual loss to wildfire in the first decade will be 171 acres. The potential for large fires will be reduced in land allocations having timber harvest activities The potential for large damaging fires in Wilderness will decrease as will the resource impacts of fires in the areas receiving treatment. The potential exists for damage to forest resources (primarily the soil resources) in the Wildernesses where high intensity prescribed fire is permitted

VEGETATION

SIGNIFICANT INTERACTIONS

Almost all land allocations and their ensuing activities have a direct or indirect effect on the vegetation For example, the General Forest allocation indirectly affects the age-class distribution of tree species. The actual harvest activity, in turn, directly affects the amount and distribution of old-growth stands only as consumption of the stand is realized. Such an interaction is significant because the amount, and the rate, of liquidation of old-growth stands is an important planning issue that affects southwestern Oregon.

Hardwood Conversion

Conversion of hardwood stands to conifer stands will affect species abundance, forest structure, and overall diversity Species composition is only slightly affected since most hardwoods will resprout after treatment The major change is relative cover or dominance Conifers, not hardwoods, will dominate the site. In coastal sites where tanoak is climax, manzanita and ceanothus will be part of the preconversion complement of shrub species. Most of the herbs will still exist in the area, but in isolated patches where disturbance was minimal. Normally, pioneer species are introduced and overall diversity is higher immediately following conversion However, the pioneers are usually short lived and quickly rot while the preconversion species begin to reach previous levels after approximately ten years It is in this period that vegetation management activities are most needed on General Forest acres. Heavy competition from resprouting hardwoods would otherwise affect survival and growth of the crop trees. Twenty-five years following burning, the invading pioneer species are significantly reduced (Kraemer 1977) This immediate effect is of local significance.

Effects on biological diversity depend on the amount and location of land converted and scale Viewed as a local basin effect, the impacts may be significant; but viewed as a Forest-wide process, the effects may be insignificant. Of importance is the juxtaposition of areas converted Silvicultural considerations as well as the number of acres converted should follow the Standards and Guidelines in order to minimize cumulative impact. If areas converted are distributed such that the remaining uncut hardwood stands remain well connected either to each other or via riparian areas, impacts are likely to be insignificant. Managers should be looking for the most productive sites for conversion (tanoak series). Under those alternatives that provide for hardwood conversion, the overall effect on diversity is insignificant.

Land Allocation

The most significant interaction is brought about by the activities related to the land allocations. The status of vegetation relative to old growth, diversity, timber, and sensitive plants are indirectly, but significantly, affected by the land allocation process and the site-disturbing activities permitted Management Areas 1-9 allow natural processes to shape forest composition and structure more so than Management Areas 12-14 For a full discussion of the alternatives as they relate to sensitive plants, Botanical Areas and Research Natural Areas, refer to the **SENSITIVE PLANTS** section of this chapter.

RESPONSE TO PLANNING PROBLEMS

Several Planning Problems relate to vegetation; however, Planning Problem #1, "How much timber should the Forest produce?," and #2, "How much old-growth forest should be preserved?" have the greatest impact on vegetation This analysis takes a holistic approach to vegetative management and diversity in response

ENVIRONMENTAL EFFECTS AND MITIGATION

The effects of alternatives and consequent management activities on the vegetative component of the environment are directly related to the intensity of consumption set by the particular alternative. Timber

harvest activities are significant, direct and cumulative. Alternative M, the least consumptive relative to timber, has the least direct effect on the vegetation, but the greatest indirect effect Indirectly, the existing vegetative character is at risk of high intensity wildfire and/or epidemics It will be difficult to prolong the character of older age classes without an active program of fuel and stand maintenance. Another option is to accept the effects of natural disturbances, such as fire and epidemics, on the vegetation in these areas, and their influence on adjacent areas with different land allocations Alternatives C and D1 have the greatest direct effect on age-class distribution.

Harvest levels are the highest among Alternatives NC, B, C, D, and D1 and the rate of conversion of older, less productive age classes to managed status is the fastest. Streamside vegetation is managed in all the alternatives except E and M. The intensity of activity in riparian areas is governed by the Standards and Guidelines, but the option to remove volume and manage for structure and disturbances exists Harvesting requires roads. The alternatives that have the highest level of harvest have the highest level of road construction Road and trail construction have a direct effect on the vegetation, but are concentrated and usually of only local significance to the vegetation composition and structure

IMPACTS COMMON TO ALL ALTERNATIVES

Although harvest levels differ by alternative, the direct effects of timber management activities are basically the same for each. Only the spatial extent to which they are applied and the rate of harvest differ. Harvest rates by alternative are dealt with in detail in Chapter II. The major cumulative effect is the change in age-class distribution as the old growth is harvested. The composition of those areas allocated to management that include harvest (Management Areas 10-14) would continue to shift from mature and old-growth stands toward more seedling, sapling, and pole stands. Continuing this management for several decades would result in a dispersion of stands from newly regenerated seedlings to mature stands at harvest age

The absolute amount of younger age classes will not have significant effects on the vegetation or site potential. Only local effects, such as minor changes in microclimate, will be experienced. Such changes will have indirect effects on the growth and survival of both planted and natural vegetation. The placement of harvest units, for example, affects the flow of heat or cold. Cold air pockets and exposed southern slopes can be difficult to reforest.

Arrangement of harvest units may also be used to facilitate animal travel and associated seed dispersal. Where patches of old growth are being saved to provide habitat for sensitive plants, consideration of the size, amount, and quality of edge is important Generally, the smaller the patch and the greater the amount of edge, the less the total patch will climatically resemble old-growth environment. In many cases, managers can use harvest unit arrangement to modify microclimate in favor of sensitive species. In all cases, application of the Standards and Guidelines related to basin-cutting levels will assure species viability.

Wildfires have been a key process in creating a diversity in composition and structure. Low intensity fires are common in nature and often effect composition and structure of the vegetation. High intensity fires, on the other hand, do not often totally destroy vegetation over a great extent. Islands of trees or individual trees are often left in the wake of such fires. Patches are usually left, particularly in riparian zones and on north slopes. These stands or individuals usually provide natural seed for regeneration. Over the first rotation, potential effects of wildfire on vegetation differs through the alternatives High preservation alternatives greatly increase the risk of large intense fires, whereas alternatives that create more roaded areas provide more opportunity for fuel management.

SPECIAL MANAGEMENT CONSIDERATIONS

Port-Orford-cedar

Management of Port-Orford-cedar is consistent through all the alternatives. Application of Standards and Guidelines is intended to minimize or negate any artificial increase in the rate of root disease spread Appropriate practices identified from experience and research will be applied on a site or drainage-specific basis to prevent or reduce the spread and severity of Port-Orford-cedar root disease

Port-Orford-cedar management is based on a Forest Service manual supplement and standards developed from work by Harvey, Hadfield, and Greenup (1985); "Ecology, Pathology, and Management of Port-Orford-cedar (*Chamaecyparis lawsoniana*)" by Zobel, Roth, and Hawk (1985); and by the Port-Orford-cedar consensus group, whose membership included industry, agency, and university personnel as well as conservation-minded citizens.

Of special significance to the management of Port-Orford-cedar is the Region Five-Region Six Port-Orford-cedar Root Disease Action Plan dated June 29, 1988. In short, this document provides the support and the direction to manage for the viability and continued presence of Port-Orford-cedar in the ecosystem throughout its native range on Forest Service lands.

For Port-Orford-cedar, the major differences between alternatives are related to the harvest and recreation level, because it is suspected that the rate of root rot spread is related to road construction, road travel, and harvest activities. Thus, Alternatives NC, A, A-Departure, B, C, D, D1, K, and S have the highest potential for spreading the rot; Alternatives E, G, and M have the lowest potential

Redwood

The management of redwood is consistent through the alternatives. The effects of the present management regime will be to slightly increase its present range and possibly increase genetic variability. The Wheeler Creek RNA is an important part of the system because it represents a tenable redwood stand at the species' northern environmental limits. However, Alternatives E, G, K, M and S include the Snake Tooth Redwood Botanical Area (21 acres), an isolated stand of old-growth redwood approximately 5 miles north of the Wheeler Creek RNA. It is possible that this stand represents diversity not included in the Wheeler Creek RNA Alternative S also includes an additional Botanical Area called Redwood Groves, this area preserves prime examples of old-growth redwood stands which are otherwise unprotected.

Meadows

There are few true meadows on the Forest; most are denuded forest land that will eventually return to forest composition and structure if the natural process is not interrupted. However, the Forest-wide Siskiyou Standards and Guidelines dictate the maintenance and enhancement of meadow habitat. In areas where "meadows" are being reclaimed by trees, efforts will be made to prevent forest encroachment There are no differences in effects among the alternatives

Forage

Big game and livestock forage areas are constantly changing The vast majority of sites on the Forest are categorized as "transitory." That is, grasses and forbs present in the early stages of succession following harvest are the source of forage As harvested areas mature and potential forage production wanes, animals shift to other newly harvested areas. Alternatives NC, B, C, D, K, and S have the highest potential for producing transitory forage areas, Alternative A is moderate; and Alternatives E, G, and M have the lowest potential

Riparian Areas

Riparian areas will be managed to maintain their health and integrity, adding to the diversity of the Forest. No significant differences occur between alternatives with respect to riparian areas. Approximately one-third of the riparian acres in Class I and II streams have old-growth characteristics.

Alternative NC

DIRECT AND INDIRECT EFFECTS. Approximately 26 percent of the Forest land is allocated to nonconsumptive management where site-disturbing activities are generally prohibited. The remainder is under Management Areas 10-14 and is available for harvest.

Existing Research Natural Areas (RNA's) and the proposed Hoover Gulch RNA (3,247 acres) are allocated under this alternative. No new Botanical Areas are established

The conversion of hardwood sites to conifer production could eventually increase timber output when the stands mature. All hardwood stands planned for conversion represent less than 7 percent of the suitable timber acres and the maximum rate of conversion is less than 2 percent per year of the suitable hardwood acres (approximately 48,000 acres per year).

All of the existing unroaded areas will be roaded and open for motorized travel. The direct effect on vegetation by construction is insignificant. The indirect effect of the forest visitor on the vegetation is also insignificant.

CUMULATIVE EFFECTS. Generally, Alternative NC does not allocate lands for special habitats or sensitive species. The potential for maintaining Forest-wide diversity may be slightly affected However, the viability of the populations of sensitive species may not be affected. More specific information is provided in the **SENSITIVE PLANTS** section of this chapter

By the tenth decade (the length of an average rotation), approximately 10 percent of the Forest would remain as mature or old growth This appears to be more than enough to meet Management Requirements (MR's) for wildlife species dependent on mature or old-growth forest. However, there are no wildlife MR's in the alternative; habitat dispersion requirements for mature/old growth Management Indicator Species will not be met.

Alternatives A and A-Departure

DIRECT AND INDIRECT EFFECTS. Approximately 30 percent of Forest land is allocated to nonconsumptive management where site-disturbing activities are generally prohibited The remainder is under Management Areas 10-14 and is available for harvest.

Existing RNA's and proposed Hoover Gulch RNA (3,247 acres) are allocated under this alternative. No new Botanical Areas are established

The conversion of hardwood sites to conifer production (up to 750 acres per year) will eventually increase timber output when the stands mature. Hardwood stands converted annually represent less than 7 percent of the suitable timber acres and the maximum rate of conversion is less than 2 percent per year of the suitable hardwood acres (approximately 48,000 acres per year).

All of the existing unroaded areas will be roaded and open for motorized travel. The direct effect on vegetation by construction is insignificant. The indirect effect of the forest visitor on the vegetation is also insignificant.

CUMULATIVE EFFECTS. Generally, Alternative A does not allocate lands for special habitats or sensitive species. The potential for maintaining Forest-wide diversity may be slightly affected. However, the viability of the populations of sensitive species should not be affected More specific information is provided in the **SENSITIVE PLANTS** section of this chapter

By the tenth decade (the length of an average rotation), approximately 12 percent of the Forest would remain as mature or old growth The Forest would more than meet MR's for wildlife species dependent on mature or old-growth forest.

Alternative B

DIRECT AND INDIRECT EFFECTS. Approximately 29 percent of the Forest (about 319,000 acres) is allocated to nonconsumptive management. As in Alternative A, the remainder of the land is available for full or partial harvest.

Seven new Botanical Areas totalling 4,581 acres would be added Hoover Gulch and Craggy Peak RNA's would also be added.

The conversion of hardwood sites to conifer production, up to 1,400 acres annually, will eventually increase timber output when the stands mature. Hardwood stands converted annually represent less than 7 percent of the suitable timber acres and the maximum rate of conversion is about 3 percent per year of the suitable hardwood acres.

All of the existing unroaded areas will be roaded and open for motorized travel. The direct effect on vegetation by construction is insignificant The indirect effect of the forest visitor on the vegetation is also insignificant.

CUMULATIVE EFFECTS. Generally Alternative B does not fully allocate lands for special habitats or sensitive species. The potential for enhancing Forest-wide diversity is relatively low. However, the viability of the populations of sensitive species should not be affected

The amount of mature and old growth remaining after tenth decade is 11 percent of the current total, similar to Alternatives A, C, D, K and S.

Alternatives C, D, and D1

DIRECT AND INDIRECT EFFECTS. Approximately 28 percent (29 percent in Alternatives D and D1) of the Forest land (about 319,000 acres) is allocated to nonconsumptive management. As in Alternatives A and B, the remainder of the land is available for full or partial harvest

The same Botanical Areas and RNA's allocated under Alternative B would be allocated under alternatives C, D, and D1.

The conversion (up to 1,400 acres per year) of hardwood sites to conifer production will eventually increase timber output when the stands mature Hardwood stands converted annually represent less than one-fifth of one percent (0 2 percent) of the suitable timber area and the maximum rate of conversion is about 3 percent per year of the suitable hardwood acres

All of the existing unroaded areas will be roaded and open for motorized travel The direct effect on vegetation by construction is insignificant. The indirect effect of the Forest visitor on the vegetation is also insignificant

CUMULATIVE EFFECTS. Generally, Alternatives C, D, and D1 do not fully allocate lands for special habitats or sensitive species The potential for incorporating Forest-wide diversity is relatively low. However, the viability of the populations of sensitive species should not be affected

The amount of mature and old growth remaining after decade 10 is 11 percent of the Forest total, similar to Alternatives A, B, K, and S.

Alternative E

DIRECT AND INDIRECT EFFECTS. Approximately 59 percent of Forest land is allocated to non-consumptive management. The remainder is under Management Areas 10-14 and is available for partial or full harvest.

All or part of 15 potential Botanical Areas would be established in addition to establishment of all four proposed RNA's

There is no conversion of hardwood dominated sites to conifers.

Thirty-two percent of the Forest (approximately 352,000 acres) will remain unroaded in addition to Wilderness. Without access to these areas, opportunity to manage fuel and stand structure is limited. *Ability to suppress wildfire is poor. There is an extreme risk of wildfire damaging or altering the composition* and structure of large tracts of vegetation within the first rotation. As such, the potential for indirect but significant effects on vegetation is high

CUMULATIVE EFFECTS. Alternative E allows for setting aside many diverse habitats for sensitive species. The potential for maintaining Forest-wide diversity is high. The viability of the populations of sensitive species should not be affected.

At decade 10 (the length of an average rotation), approximately 25 percent of the Forest would remain as mature or old growth, approximately three times the amount needed to meet MR's for wildlife species dependent on mature or old-growth forest.

The character of existing old-growth stands is dependent on the trees' ability to ward off insect attacks and pathogens. Stand health depends on tree density, the site's ability to provide resources, and it's ability to withstand wildfire. Access facilitates the use of prescribed fire to safely reduce fuel loads and manipulate vegetation in favor of tree longevity. The lack of access provided by Alternative E will make it increasingly difficult to maintain the health of old-growth stands over succeeding rotations.

Alternative G

DIRECT AND INDIRECT EFFECTS. Approximately 51 percent (558,000 acres) of the Forest land is allocated to nonconsumptive management. The remainder is under Management Areas 10-14 and is available for partial or full harvest

Twenty-two Botanical Areas would be established in addition to all four proposed RNA's.

The conversion (up to 400 acres per year) of hardwood sites to conifer production will eventually increase timber output when the stands mature. Hardwood stands converted annually represent less than one-fifth of one percent of the suitable timber area and the maximum rate of conversion is about one percent per year of the suitable hardwood acres.

Thirty-two percent of the Forest (approximately 344,000 acres) will remain unroaded in addition to Wilderness. Without access to these areas, opportunity to manage fuel and stand structure is limited and

potential for large intense wildfires and subsequent indirect but significant effects on the vegetation is high (see Alternative E)

CUMULATIVE EFFECTS. Alternative G allows for setting aside many diverse habitats for sensitive species. The potential for maintaining Forest-wide diversity is high. The viability of the populations of sensitive species should not be affected

At decade 10 (the length of an average rotation), approximately 20 percent of the Forest would remain as mature or old growth, well above the the amount needed to meet MR's for wildlife species dependent on mature or old-growth forest

Lack of access will make the character of existing old growth stands increasingly difficult to maintain over succeeding rotations (see Alternative E).

Alternative K

DIRECT AND INDIRECT EFFECTS Approximately 34 percent of the Forest land (approximately 375,000 acres) is allocated to nonconsumptive management The remainder is under Management Areas 10-14 and is available for partial or full harvest.

Eight Botanical Areas would be established in addition to all four proposed RNA's.

The conversion of hardwood sites to conifer production (up to 750 acres per year) will eventually increase timber output when the stands mature Hardwood stands converted annually represent less than one-fifth of one percent of the suitable timber area and the maximum rate of conversion is less than two percent per year (750 acres) of the suitable hardwood acres.

Approximately three percent of the Forest (about 29,517 acres) will remain as unroaded in addition to Wilderness. Because increased access allows more effective fire control and fuels management, the risk of wildfire damaging or completely altering the composition and structure of the vegetation within the first rotation is low.

CUMULATIVE EFFECTS. In Alternative K, the potential for maintaining Forest-wide diversity is moderate. The viability of the populations of sensitive species should not be affected.

At decade 10 (the length of an average rotation), approximately 13 percent of the Forest would remain as mature or old growth, which more than meets MR's for wildlife species dependent on mature or old-growth forest.

Alternative M

DIRECT AND INDIRECT EFFECTS. Approximately 61 percent (670,000 acres) of the Forest is allocated to nonconsumptive management The remainder is under Management Areas 10-14 and is available for partial or full harvest There is no conversion of hardwood-dominated sites to conifers.

Twenty-seven percent of the Forest (approximately 297,000 acres) will remain unroaded in addition to Wilderness. There would also be another nine percent (98,000 acres) in General Forest not accessible by existing roads that would not have programmed timber harvest. Without access to these areas, opportunity to manage fuel and stand structure is limited and potential for indirect but significant effects on the vegetation is high (see Alternative E).

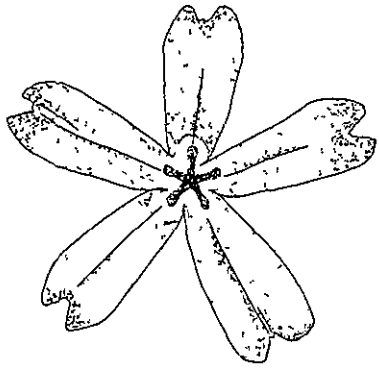
CUMULATIVE EFFECTS. Alternative M allows for setting aside many diverse habitats for sensitive species. The potential for maintaining Forest-wide diversity is high The viability of the populations of sensitive species should not be affected

At decade 10, approximately 31 percent of the Forest would remain as mature or old growth, well over the amount needed to meet MR's for wildlife species dependent on mature or old-growth forest. Today's mature and old growth is approximately 36 percent of the Forest.

Lack of access will make the character of existing old-growth stands increasingly difficult to maintain over succeeding rotations (see Alternative E).

Alternative S

DIRECT AND INDIRECT EFFECTS. Approximately 43 percent of the Forest land (approximately 465,000 acres) is allocated to nonconsumptive management. The remainder is under Management Areas 10-14 and is available for partial or full harvest



Nineteen Botanical Areas are established in addition to the four proposed RNA's.

The conversion of hardwood sites to conifer production (up to 750 acres per year) will eventually increase timber output when the stands mature. Hardwood stands converted annually represent less than one-fifth of one percent of the suitable timber area and the maximum rate of conversion is less than two percent per year (750 acres) of the suitable hardwood acres

In addition to Wilderness, approximately 12 percent of the Forest (about 136,000 acres) will remain essentially unroaded Because increased access allows more effective fire control and fuels management, the risk of wildfire damaging or completely altering the composition and structure of the vegetation within the first rotation is low.

CUMULATIVE EFFECTS. In Alternative S, the potential for maintaining Forest-wide diversity is moderate The viability of the populations of sensitive species should not be affected.

At decade 10 (the length of an average rotation), approximately 14 percent of the Forest would remain as old growth, which more than meets MR's for wildlife species dependent on mature or old-growth Forest.

SENSITIVE PLANTS

SIGNIFICANT INTERACTIONS

Timber harvesting, road building, and mining are all land-disturbing activities that affect sensitive plants Road building and logging can severely impact small populations of sensitive species. Surface mining activities present the potential for elimination of localized concentrations of some sensitive plant communities Economically important metals such as nickel and chromium are found associated with 44 sensitive species (Webb 1988). Land-disturbing activities may also disrupt site conditions which sustain sensitive plant communities (such as changes in water flow or introduction of disease organisms) For example, water flow into Darlingtonia bogs can be altered by road building However, in such cases, roads have been relocated and the effects mitigated The Elk Wallow Road with *Bensoniella oregana* and Bald Mountain Road with *Kalmiopsis leachiana* are examples of road relocation which avoid such impacts.

Livestock grazing can detrimentally affect populations of sensitive plants. Specific sites may be over-used by people

Conversely, some sensitive plants rely on the habitat provided by early seral stages Timber harvesting can be beneficial to some sensitive plants, although the vegetative changes may have to be designed to benefit the intended plant species Natural and prescribed fire can be detrimental, neutral, or beneficial, as with Kalmiopsis.

Land allocations affect sensitive plant communities; designations such as RNA, Botanical, or Supplemental Resource Management Areas can provide protection to sensitive plant sites and help maintain genetic viability In all cases, Standards and Guidelines can be established to mitigate detrimental effects of other environmental components on sensitive plants.

RESPONSE TO PLANNING PROBLEMS

The following alternative descriptions relate directly to Planning Problem #5. "How should sensitive plant resources be addressed?" Two additional planning problems are addressed indirectly. #2, "How much old-growth forest should be preserved?"; and #9, "How should mineral resources of the Forest be developed in coordination with management of other resources?"

ENVIRONMENTAL EFFECTS AND MITIGATION

There are two methods of managing sensitive plant resources: designation and standards. Designation involves allocation of specific sites as Botanical areas. Important concentration areas of sensitive or rare plants are logical candidates for designation Certain areas on the Forest, such as Eight Dollar Mountain, are more unique than others. In concentration areas of lesser importance, or where sensitive/rare plants are more widely dispersed, management standards will guide timber management, road building, mining activities, and livestock grazing.

The management objective for botanical resources is to provide habitat capable of indefinitely supporting all native plants and plant communities. All alternatives are designed to meet this objective in at least a minimally adequate fashion Alternatives that allocate relatively large amounts of land for preservation of sensitive plants or specific plant communities (RNA's) result in the best long-term protection for these resources, although this results in a somewhat lower annual allowable timber harvest Alternatives that allocate the most land to categories other than General Forest also result in the best level of protection for sensitive plants and plant communities (potential RNA's) Alternatives with lower timber harvests also have fewer roads, and this means less potential impact on sensitive plants/plant communities

Potential Botanical areas and RNA's described in this FEIS represent an incomplete inventory Although major concentration areas for sensitive plants have been identified, additional potential Botanical areas will

undoubtedly be found on the Forest. Also, much remains to be discovered about the range and abundance of individual plant species Known plant communities needing representation in the RNA system are included in the proposed RNA's. Research in progress on the plant associations of the Siskiyou Mountain Province (Atzet and Wheeler 1984) will undoubtedly result in the identification of additional plant communities needing representation in RNA's

Over the short term, there is a low risk that sites not designated will be precluded from receiving future consideration as RNA's or Botanical areas For most sites, a decision to withhold RNA or Botanical status can be reversed at the end of the first planning period (10-15 years) This would not be true of the old-growth sites, which might be harvested (at least partially) before the Forest Plan is revised Over the long term (by the fifth decade), grazing, road building, timber harvesting, and mining activities will have taken their toll and many sites will no longer retain the qualities necessary to meet the criteria for designation as RNA or Botanical areas The Forest's rare plant resources would be best managed by assigning Botanical areas status to high priority sites Plant resources in sites with lower priorities would be intensively inventoried before this Forest Plan is revised in 10-15 years. For a description of the RNA's and Botanical areas (existing and proposed) refer to Appendix F (FEIS).

Alternatives NC, A, and A-Departure

DIRECT EFFECTS. No potential Botanical areas are established with these alternatives. In areas with a significant amount of land allocated to General Forest (see Table II-3), site conditions will change from natural to managed over the long term as road building and logging take place This means most of these sites will eventually be unsuitable for designation as Botanical areas. This is especially true for old-growth sites; all of these sites are allocated in whole or in part to General Forest Individual sensitive plant populations within potential Botanical areas (and elsewhere) will be managed through application of Standards and Guidelines; however, the natural features of individual areas may not be protected in the long term.

Existing RNA's and the proposed Hoover Gulch RNA (3,249 acres) are allocated (14 plant communities protected) Present cell needs (Dyrness and others 1975) will not be met. Thus, future needs will have to be found in Wilderness or in other compatible management areas If they are not found, cells will not be *represented and baseline information will be unavailable.*

Lemmingsworth Gulch and Cedar Log Flat contain both mineral resources and land allocated to General Forest. Up until the next revision of the Forest Plan in 10-15 years, these two sites may not be heavily impacted by mining, road building, and timber harvesting activities In the long term, logging and road building will inevitably make the sites unsuitable for designation as RNA's The portion of the proposed Craggy Peak RNA on the Siskiyou National Forest has no known mineral resources and no timber available for harvesting; the option to designate this site as an RNA would probably be available indefinitely.

Many sensitive species are present in existing Wilderness, RNA's, and Riparian areas. Without specific information on environmental requirements of sensitive species, the effects of this alternative on specific sensitive plants is unknown over the long term. Refer to Appendix F (FEIS) for additional information.

Alternative A-Departure is the same as Alternative NC and A, except that accelerated timber harvest activities may change the character of individual areas sooner.

INDIRECT EFFECTS The public will still be able to visit potential Botanical and RNA's; however, at some sites inherent natural values may be lost over time because of grazing, road building, timber harvesting, and mining activities Although few allocations were made in this alternative for Botanical or RNA's, some of the areas will still be relatively unchanged and available for designation during the next one or two decades.

CUMULATIVE EFFECTS Over time, the range of options for allocating lands for Botanical areas diminishes.

Alternatives B, C, D, and D1

DIRECT EFFECTS Seven new Botanical areas totaling 4,581 acres are established in this alternative; most were selected not on a priority basis, but because they exist on serpentine sites or otherwise have little harvestable timber (see Table II-3 for list of specific sites) Important sensitive plant areas such as Iron Mountain and Bigelow Lakes were not selected. Even so, the seven selected sites contain at least 25 sensitive species and candidates for the Regional Forester's sensitive list, out of 73 known to exist on the Forest. Eight Dollar Mountain, probably the site best known to the general public, is selected

All nonselected areas contain a significant number of acres tentatively suitable for timber production (see Table II-3). Site conditions in these areas will change from natural to managed over the long term as road building and timber harvest occur. This means most of these sites will eventually be unsuitable for designation as Botanical areas This is especially true for the old-growth sites, all of these areas except the Page Mountain Grove are allocated in whole or in part to General Forest Individual sensitive plant populations within potential Botanical areas (and elsewhere) will be managed through the application of Standards and Guidelines; however, the natural features of individual areas may not be protected in the long term.

Existing RNA's, Hoover Gulch, and Craggy Mountain are allocated as RNA's in this alternative (16 plant communities protected; 3,349 acres). Present or projected cell needs will not be covered. Non-representation of a cell may result in loss of baseline areas as reference points to monitor and compare Forest activities

The two other potential RNA's are not designated, and their natural ecosystems are not protected; Lemmingsworth Gulch and Cedar Log Flat contain both mineral resources and land allocated to General Forest. Up until the next revision of the Forest Plan in 10-15 years, these two sites may not be heavily impacted by mining, road building, and timber harvesting activities. In the long term, logging and road building will inevitably make the sites unsuitable for designation as RNA's

INDIRECT EFFECTS. The public will still be able to visit potential Botanical and RNA's not selected in these alternatives; however, at some sites inherent natural values may be lost over time because of grazing, road building, timber harvesting, and mining activities Some of the areas not selected in these alternatives will still be relatively unchanged and available for designation during the next one or two decades. However, the accelerated harvest programmed for these alternatives in the first two decades will eliminate this option relatively sooner

Alternative D is slightly different in that timber harvest is not accelerated in the first two decades. The character of individual areas will not change as quickly and thus the option to apply Botanical or RNA status may be available for a longer period of time. Alternative D1 has an average rotation age of 80 years instead of 100 This means that 25 percent more acres will be harvested every year, which in turn means that the character of individual areas will change more rapidly. The option to apply Botanical or RNA status will dissipate more rapidly than in Alternative D (about the same as B for the first two decades).

Alternative C is the same as Alternative B, except that timber harvest is not accelerated in the first two decades The character of individual areas will not change as quickly and thus the option to apply Botanical or RNA status may be available for a longer period of time

CUMULATIVE EFFECTS Over time, the range of options for allocating lands for Botanical areas diminishes

Alternative E

DIRECT EFFECTS Fifteen new Botanical areas totaling 23,251 acres are established in this alternative (see Table II-3 for a list of specific sites). This is nearly 70 percent of the land identified within potential Botanical areas A minimum of 37 sensitive plants and candidates for the Regional Forester's sensitive list, are present in allocated Botanical areas, out of 73 known to be present on the Siskiyou Eight Dollar Mountain is selected in this alternative areas selected represent a good cross-section of the Forest's different plant habitats. The range of plant diversity, both coastal and inland, will be quite well covered. Bear Camp, Bigelow Lakes, Chrome Ridge, Iron Mountain, Oregon Mountain, and Snow Camp are other noteworthy areas selected Sensitive plant resources are well protected in this alternative. Three of the old-growth sites are selected, including Lobster Grove and Page Mountain Grove.

A few non-selected areas contain a significant number of acres tentatively suitable for timber production (see Table II-3). Site conditions in these areas will change from natural to managed over the long term as road building and timber harvest take place, most of these sites will eventually be unsuitable for designation as Botanical areas. This is especially true for the old-growth sites not selected. Although sensitive plant populations within non-selected Botanical areas (and elsewhere) will be managed through application of Standards and Guidelines, natural features of individual areas may not be protected in the long term.

Existing RNA's and all four potential RNA's identified on the Siskiyou by the Pacific Northwest Experiment Station are designated (4,756 acres; 25 plant communities protected). They, along with existing RNA's, account for present needs; the distribution of the Botanical areas allows for future needs. Lemmingsworth Gulch and Cedar Log Flat contain both mineral resources and land allocated to General Forest. These sites are thus protected from potential mining impacts, road building, and timber harvest which might have taken place before the next revision of the Forest Plan.

INDIRECT EFFECTS The public will be drawn to visit sites designated as RNA and Botanical areas; there could eventually be problems with over use in some areas. The public will still be able to visit non-selected potential Botanical; however, at some sites inherent natural values may be lost over time because of grazing, road building, timber harvesting, and mining activities. Some of the areas not selected in this alternative will still be relatively unchanged and available for designation during the next one or two decades

CUMULATIVE EFFECTS. Over time, the range of options for allocating lands for Botanical areas diminishes.

Alternative G

DIRECT EFFECTS. Twenty-two new Botanical areas, including three old-growth sites, totaling 34,526 acres are established (see Table II-3 for a list of specific sites). A minimum of 41 out of 73 known sensitive plants and candidates for the Regional Forester's sensitive list are present in allocated Botanical areas. Eight Dollar Mountain is selected, along with other well-known sensitive plant areas such as Bear Camp, Bigelow Lakes, Chrome Ridge, Iron Mountain, Oregon Mountain, Snow Camp, and Vulcan Peak. areas selected represent a good cross-section of the Forest's diverse plant habitats. All potential sensitive plant Botanical areas identified to date are protected. Three of the five old-growth Botanical areas are protected including Lobster Grove, Page Mountain Grove, and Snaketooth Redwood. Forest-wide Standards and Guidelines are used to manage sensitive plant resources located outside of Botanical areas

All four potential RNA's identified on the Siskiyou National Forest by the Pacific Northwest Experiment Station are designated in this alternative. See DIRECT EFFECTS, Alternative E

INDIRECT EFFECTS. The public will be drawn to visit sites designated as RNA and Botanical areas; there could eventually be problems with over-use in some areas

CUMULATIVE EFFECTS. None

Alternative K

DIRECT EFFECTS. Eight new Botanical areas, totaling 6,214 acres, are established in this alternative (see Table II-3 for a list of specific sites), this is 18 percent of the land identified within potential Botanical areas. A minimum of 31 sensitive plants and candidates for the Regional Forester's sensitive list are present in allocated Botanical areas, out of 73 known to be present on the Siskiyou. The areas selected are the most important botanical sites on the Forest, and represent a cross section of the habitats which support sensitive plants on the Siskiyou Eight Dollar Mountain is selected in this alternative, along with Bear Camp (two parts), Bigelow Lakes, Days Gulch, and Iron Mountain (two parts). Three of the old-growth sites are selected, and include Lobster Grove, Page Mountain Grove, and Snaketooth Redwood. This alternative provides good protection of botanical resources The Forest's unique plants are managed through a blending of two courses of action. Forest-wide Standards and Guidelines and designated Botanical areas.

Some nonselected areas contain a significant number of acres tentatively suitable for timber production (see Table II-3). Site conditions in these areas will change from natural to managed over the long term as road building and timber harvest take place; most of these sites will eventually be unsuitable for designation as Botanical areas This is especially true for the old-growth sites not selected Although sensitive plant populations within potential Botanical areas (and elsewhere) will be managed through application of Standards and Guidelines, the natural features of individual areas may not be protected in the long term.

All four potential RNA's identified on the Siskiyou National Forest by the Pacific Northwest Experiment Station are designated in this alternative. See Alternative E.

INDIRECT EFFECTS. Same as Alternative E

CUMULATIVE EFFECTS Same as Alternative E.

Alternative M

DIRECT EFFECTS. Same as Alternative G. Also, given the relatively low amount of land devoted to timber management, most sensitive plants not in Botanical areas are inherently well protected. Some plants which live in habitats maintained by periodic fires may be at a disadvantage.

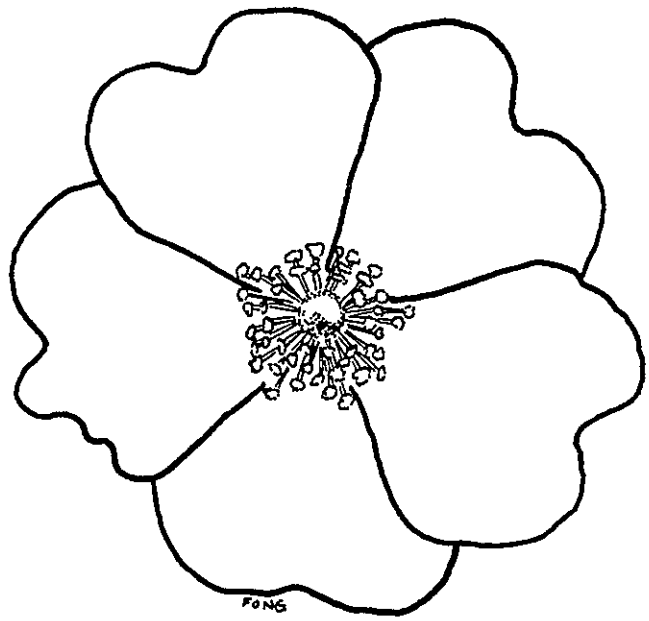
INDIRECT EFFECTS. Same as Alternative G. Also, given the very low amount of land tentatively available and suitable for timber production, there will be opportunities to designate additional Botanical areas (there would be no more timber harvested from areas of the Forest not already roaded)

CUMULATIVE EFFECTS None.

Alternative S

DIRECT EFFECTS Nineteen new Botanical areas, totaling 15,157 acres, are established in Alternative S This is approximately 43 percent of land identified within potential Botanical areas (see Table II-3 for list of specific sites). Fourteen of the selected areas are Sensitive Plant sites; five are old-growth sites.

Out of 73 known sensitive plants and candidates for the Regional Forester's sensitive list on the Forest, at least 40 are present in Botanical areas recommended in Alternative S The areas selected include the most important concentrations of sensitive plants on the Forest.



Many of the sensitive species present in nonselected sites are represented in the selected Botanical areas. One area (Cleopatra) was not selected because the species of concern was far more abundant on the adjacent Six Rivers National Forest. In some cases, boundaries of potential Botanical areas have excluded some sensitive plant populations, but the most important populations have been retained

Some nonselected areas contain a significant number of acres tentatively suitable for timber production (see Table II-3). Site conditions in these areas will change from natural to managed over the long term as road building and logging take place; most of these sites will eventually be unsuitable for designation as Botanical areas. Although individual sensitive plant populations within the Forest will be managed through application of Standards and Guidelines, the natural features of individual areas may not be protected over the long term

Existing RNA's and all four potential RNA's identified on the Siskiyou National Forest by the Pacific Northwest Experiment Station are designated (4,608 acres, 25 plant communities protected) See Alternative E.

INDIRECT EFFECTS Same as Alternative E.

CUMULATIVE EFFECTS. Same as Alternative E.

AIR QUALITY

SIGNIFICANT INTERACTIONS

The principal impact to air quality on the Forest and the surrounding area generated by the various land allocations and associated activities will be the temporary visibility impairment caused by smoke from prescribed fires and wildfires

An important impact on air quality in some areas adjacent to the Forest is that caused by the residential use of firewood produced on the Forest. Butcher and Sorenson (1979) suggest that the particulate emissions from a total community may contribute to particulate levels as high as 100 micrograms per cubic meter of air in a worst-case 24-hour average ambient concentration Data from various research shows an emission range for particulates from 15 to 75 pounds per cord of firewood burned with an average of 28 1 pounds per cord (Duncan and others 1979)

No emissions from forestry burning have yet been identified by the Environmental Protection Agency (EPA) as hazardous (Cook and others 1978), and no threshold limit values have been set for compounds in forest smoke (Sandberg and others 1979). Breysse (1984) does, however, outline health hazards associated with the inhalation of smoke. Emissions of polycyclic organic matter (POM) have been reported from burning pine needles (Ryan and McMahon 1976) and from agricultural burning (Darley and Lerman 1974). POM is of special interest in smoke management because it is a class of compounds containing many physiologically active substances. Benzo(a)pyrene (BaP) and other implicated carcinogens are usually found in POM (Tangren and others 1976).

Cook and others (1978) report that emissions from prescribed burning are highly complex, consisting of hundreds of gaseous chemical compounds and particulates, which vary greatly in composition and physical properties. They also report that a number of the compounds emitted are photochemically reactive and thus the physical and chemical properties of smoke change with increasing residence time in the atmosphere

Sandberg and others (1979) report that there are few studies on the effects of smoke on forest ecosystems in the vicinity of fire or upon long-range smoke transport and transformation. There is also little information on the effects of smoke on forest animals

The effect of reduced visibility on the amenity-related resources, e.g., recreation, visual resource, Wild and Scenic Rivers, and Wilderness will be to detract from the experience provided by those resources Vistas and panoramas normally enjoyed by Forest users could be temporarily obscured by smoke and haze. Rural communities and human resources could be inconvenienced by smoky conditions for relatively short periods of time.

Emission factors, relating quantity of effluent released to mass of fuel consumed, have been derived through laboratory burning studies and a limited number of field measurements. However, emission factors for burning forest fuels are anything but precise because of the great variation in fuels, fuel arrangement, moisture, ventilation, and type of burning--flaming versus glowing, and head fire versus backing fire (Cramer 1974)

The following emission ranges for the major effluents have been suggested by leading experts in prescribed fire and represent the best general estimate of expected normal field emissions based on current data (Cook and others 1978)

Carbon dioxide	-	2,000 to 3,500 lbs per ton of fuel consumed
Water	-	500 to 1,500 lbs. per ton of fuel consumed
Carbon monoxide	-	20 to 500 lbs. per ton of fuel consumed
Particulates	-	17 to 67 lbs. per ton of fuel consumed
Hydrocarbons	-	10 to 40 lbs. per ton of fuel consumed
Nitrogen oxides	-	2 to 6 lbs per ton of fuel consumed

Particulates are the major contributor to visibility reduction The suspended particles 0.3 to 1 microns in diameter are the principle factor in visibility impairment. Experimental data developed by Sandberg and Martin (1975) shows that more than 80 percent of the smoke mass is contained in particles 1 micron in diameter or less. Deeming (1980) reports that only two micrograms of these small particulates per cubic meter of air is enough to produce a change in the clarity of clear air to be perceivable to the human eye. The small size of the particles also compounds the visibility problem because of their very slow fall velocity Because of this tendency to stay aloft, the particles can be transported great distances by even relatively light winds creating vast areas of uniform haze

The largest contribution to TSP (total suspended particulates) production will come from the broadcast burning of final harvest units and the burning associated with the hazard reduction efforts in commercial thinning operations The hardwood conversion program, which is not included in all of the alternatives, will be the second largest contributor to TSP, followed by the burning of landing piles and road right-of-way piles The TSP production associated with the treatment of natural fuels will not be a major factor in annual TSP production

The particulate emission problem is less severe with prescribed fire than with wildfire Prescribed fires consume less fuel per unit area and therefore produce less particulates per unit of fuel, than wildfire (Cooper 1976) The ratio of wildfire to prescribed fire particulate production of roughly 3·1 has been suggested by Ward and others (1976).

Wildfire smoke will also affect air quality and air quality-related values throughout the array of alternatives Since the occurrence of wildfires is a random event in both time and space, the severity of the air quality impact will vary, depending upon fire intensity, fuel type and conditions, size of the fire, and meteorological conditions. Wildfires, and lightning fires in Wilderness that are managed as prescribed fires, are not considered in TSP production estimates.

ENVIRONMENTAL EFFECTS AND MITIGATION

Air quality will be affected by the array of forest resource management activities proposed through the range of alternatives Smoke from prescribed fire operations and wildfires will create a significant, but temporary, impact on the forest environment Mitigation measures designed to maintain air quality at a level adequate for the protection and use of National Forest resources, and meet or exceed applicable Federal and State standards and regulations are detailed in the Air Quality section of the Forest-wide Standards and Guidelines (Chapter IV, Forest Plan)

The direct effect of the alternatives will be measured by the amount of TSP produced on an annual basis. Indirect effects on air quality will be the impacts created in local urban areas from the burning of firewood obtained from the Forest Cumulative effects common to all alternatives include the downwind increases in TSP, in particular fine particulates, when the smoke from prescribed burning operations on the Forest combines with the smoke from prescribed fire operations on adjacent downwind ownerships. Other effects common to all alternatives are described in the **ENVIRONMENTAL EFFECTS UNCHANGED BY**

ALTERNATIVES section at the end of this chapter. Specific outputs by alternative are presented in Chapter II

Alternatives NC, A and A-Departure

DIRECT EFFECTS. Prescribed burning operations will produce a moderate amount of TSP annually in the first decade, ranging from 4,280 to 4,445 tons. This will increase to between 7,500 and 7,631 tons annually in the fifth decade

INDIRECT EFFECTS. Between 688 and 878 tons of particulates could be added annually to local urban airsheds from burning of firewood produced as a by-product of timber harvest on the Forest

Alternatives B and D1

DIRECT EFFECTS Prescribed burning operations under Alternatives B and D1 will produce a moderately high amount of TSP annually in the first decade (5,804 and 5,386 tons, respectively) This will increase to 7,649 (Alternative B) and 7,554 (Alternative D1) tons annually in the fifth decade

INDIRECT EFFECTS. An estimated 843 (Alternative B) and 773 (Alternative D1) tons of particulates could be added to local urban airsheds from the burning of firewood produced as a by-product of timber harvest operations on the Forest

Alternative C

DIRECT EFFECTS Prescribed burning operations will produce a very high amount of TSP annually in the first decade (9,159 tons). This will decrease to approximately 6,703 tons annually in the fifth decade.

INDIRECT EFFECTS An estimated 745 tons of particulates could be added annually to local urban airsheds from the burning of firewood produced as a by-product of timber harvest operations

Alternative D

DIRECT EFFECTS Prescribed burning will produce a high amount of TSP annually in the first decade (7,265 tons), decreasing to approximately 5,892 tons annually in the fifth decade.

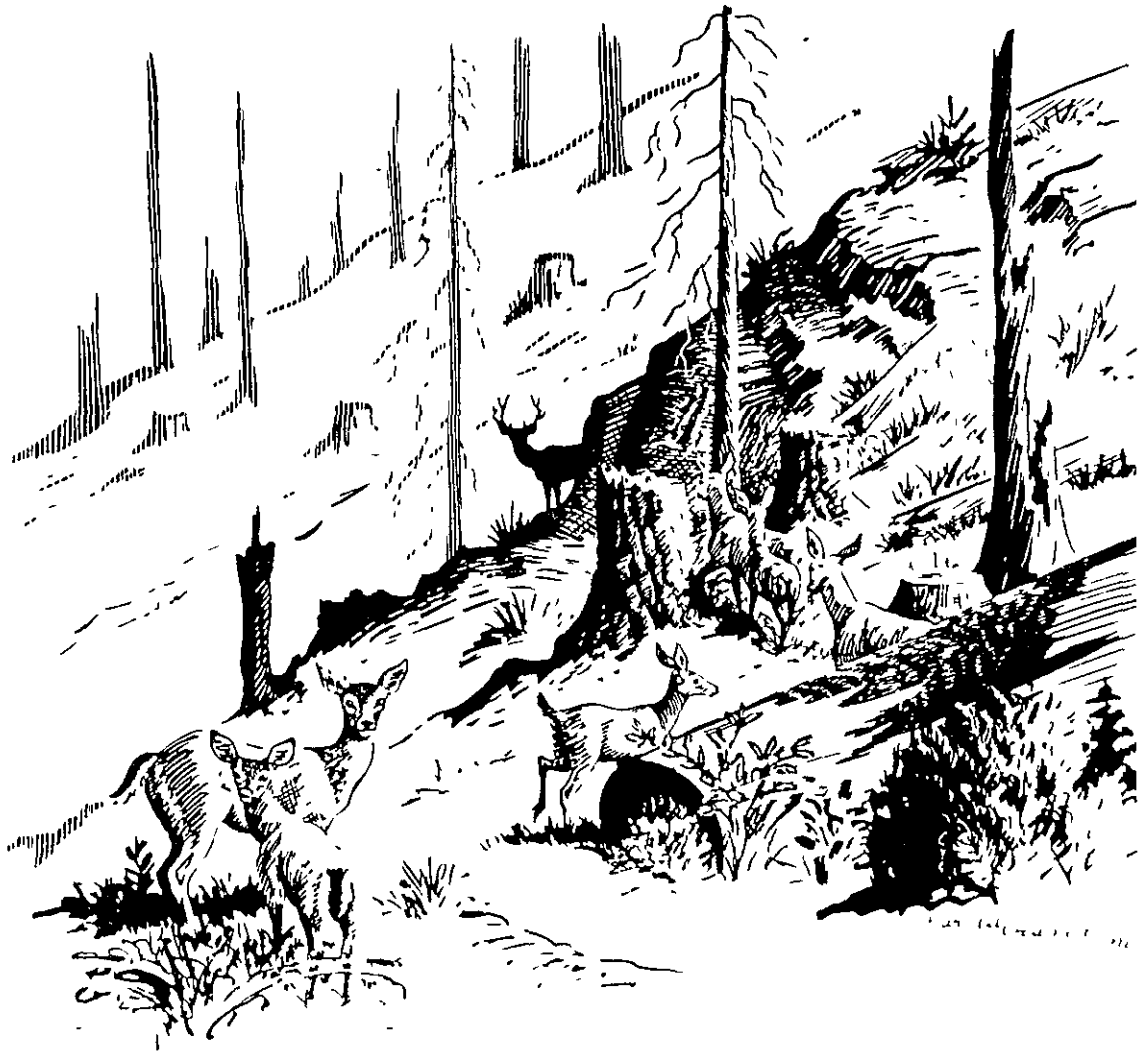
INDIRECT EFFECTS. An estimated 717 tons of particulates could be added annually to local urban airsheds from the burning of firewood produced as a by-product of timber harvest operations

Alternatives E and G

DIRECT EFFECTS. Prescribed burning operations under Alternatives E and G will produce a low amount of TSP annually in the first decade (2,700 and 3,344 tons, respectively) This will increase to 3,330 (Alternative E) and 3,913 (Alternative G) tons annually in the fifth decade

INDIRECT EFFECTS An estimated 393 (Alternative E) and 491 (Alternative G) tons of particulates could be added to local urban airsheds from the burning of firewood produced as a by-product of timber harvest operations on the Forest

Alternatives K and S



DIRECT EFFECTS Prescribed burning operations for Alternatives K and S will produce a moderate amount of TSP annually in the first decade (4,430 and 4,579 tons, respectively) This will increase to 5,663 (Alternative K) and 5,218 (Alternative S) tons annually in the fifth decade

INDIRECT EFFECTS An estimated 618 (Alternative K) and 759 (Alternative S) tons of particulates could be added annually to local urban airsheds from the burning of firewood produced as a by-product of timber harvest operations on the Forest

Alternative M

DIRECT EFFECTS Prescribed burning operations for this alternative will produce a negligible amount of TSP annually in the first decade (748 tons). This will increase to approximately 1,093 tons annually in the fifth decade.

INDIRECT EFFECTS An estimated 155 tons of particulates could be added annually to local urban airsheds from the burning of firewood produced as a by-product of timber harvest operations on the Forest.

FISH

The success of the Forest fish habitat is directly dependent upon maintaining or improving water quality, instream cover, pool quality, streambed stability, quality of spawning gravel, and riparian zone integrity. Impacts upon these resources affect Forest habitat capability to rear juvenile anadromous salmonids to the smolt stage and resident salmonids through juvenile and adult stages. However, the anadromous salmonid life cycle involves both on- and off-Forest habitats, from headwater streams to the ocean. Any weak link within the cycle can have major influence upon population. Excess harvesting of fish, poor ocean food conditions, competition from hatchery stock, and off-Forest water withdrawals are factors beyond Forest control.

SIGNIFICANT INTERACTIONS

Management of salmonid fish habitat interacts significantly with nearly all other Forest resources By improving or maintaining salmonid habitat capability and production, fish habitat objectives complement water quality goals and the desires of recreational and commercial fishermen Increasing numbers of people enjoy fishing and the aesthetic values of observing fish in streams However, fisheries objectives can directly interfere with the maximization of timber production capability, and options for road and mineral development. The ability to rear resident trout and juvenile anadromous salmonids, attributable to the Forest, is a direct reflection of how well both aquatic and terrestrial habitat is managed.

Land management activities which have the highest probability of affecting Forest fish habitat capability include a mix of land allocations, Standards and Guidelines, and capital investments. Relationships between these activities and their influence over Forest salmonid habitat capability are shown below·

Activity	Affected Prime Fish Habitat
Riparian Area Management	Water quality (temperature, turbidity), streambed and bank, slope stability; nutrient source; instream cover, interspecies competition
Supplemental Resource Areas	Water quality (temperature, turbidity); streambed and bank, slope stability, nutrient source, instream cover
Timber Management and Road Construction	Water quality (turbidity), streambed and bank stability; nutrient source, instream cover, streambed sedimentation; interspecies competition
Off-Forest Water Use	Water quality (temperature), instream cover, water availability (flow), riparian area stability, interspecies competition.
Capital Investments	Instream cover, pool depth, water quality (temperature), streambed and bank stability, stream shade canopy, habitat availability

RIPARIAN MANAGEMENT AREA

Streamside areas (riparian areas), contain some of the most valuable Forest resources in terms of human needs for high quality water, recreation, and economic gain Many harvested riparian areas on private lands are now recovering, with overhead canopy cover improving along many streams Benefits from this recovery would exist in all alternatives.

There are three options for management of riparian vegetation on Forest lands suitable for the production of timber These are provided for under Riparian Management Area allocations, and are referred to as Riparian Prescription B, Prescription C, and Prescription M (see FEIS, Chapter II, "Management Area 11") These prescriptions restrict the amount of vegetation that can be removed from riparian areas within a given Planning Basin Prescription B is the least restrictive and Prescription M (Minimum Level) is the most

restrictive Alternatives with Prescription C or Prescription M riparian management would allow more long-term stream shade retention and recovery than Prescription B

Application of any of the prescription options will provide flexibility to retain sufficient old-growth conifer species in the riparian areas for long-term input of large organic material to stream systems For modeling purposes, these prescriptions represent an average for conditions and application throughout the Forest. During project implementation, however, the variability of trees removed from the riparian areas (from no harvest to a specified amount) will largely depend on site-specific conditions and resource protection objectives for the given stream. Maintenance or expected decrease in stream temperatures over time, too, is a function of past, present, and future activity. Where Planning Basins are largely undeveloped, the goal is to maintain existing stream temperatures Where entry and timber harvest has been heavy in the past, the goal will be to reduce stream temperature within two to three decades.

Prescription B

Prescription B allows a light to moderate level of commercial-sized conifer tree removal from the riparian area It is designed to maintain existing water temperatures within the Planning Basin as regrowth of shade in past activity units balances removal associated with new projects It must be remembered that these prescriptions are applied to an entire Basin; the expected results are viewed as a net change over time. Prescription B is considered the Management Requirement (MR's) for riparian areas. Removing more conifers from the riparian area would lead to net increases in water temperature during the critical summer period resulting in unacceptable adverse impacts to the fisheries resource.

Prescription C

Prescription C allows minor removal of the vegetation that provides stream shading. The net effect is estimated to produce up to a two degree Fahrenheit reduction in the summer water temperature by the end of the third decade. A decrease in water temperature would improve salmonid habitat quality Prescription C reduces risk slightly from Prescription B for activity-related impacts on all perennial streams (Class I, II, and III), adding some increase in protection to the riparian ecosystem. The long-term availability of large woody material input to streams and the densities of overhead shade canopies would be maintained or increased above current levels. On-the-ground implementation of Prescription C will result in very limited or no harvest of trees within 25-50 feet of stream edges.

Prescription M (Minimum Level)

Prescription M does not allow for removal of vegetation that provides stream shade. There is no programmed timber harvest Reductions in stream temperatures beyond those predicted by Prescription C have not been projected. This option provides little risk to fish habitat by further minimizing the potential for activity-related impacts on riparian areas.

SUPPLEMENTAL RESOURCE MANAGEMENT AREA

Supplemental Resource areas were designated on some larger streams and rivers to address concerns for fish habitat and other high values and uses associated with the riparian ecosystem. Some of the factors influencing the choice of these areas were: (1) water quality, (2) salmonid rearing capability, (3) geologic risk, and (4) other high value riparian resources. The Supplemental Resource area designation provides important protection of fish habitat in inner-gorge areas (refer to FEIS, Chapter II, "Management Area 7").

TIMBER MANAGEMENT AND ROAD CONSTRUCTION

Past timber harvest, road construction, and early mining practices, both on- and off-Forest, were responsible for considerable localized degradation of salmonid fish habitat. Today, for all alternatives,

activities in the General Forest, Partial Retention and Retention Visual Management Areas have the most significant influence on the potential for erosion and sedimentation of streams Without question, the greatest source of sediment comes from road construction and, to a lesser degree, landslides associated with tree removal (timber harvest). Coupled with the Standards and Guidelines and associated (BMP's), the basin-specific timber harvest constraints are designed to decrease management-related erosion and sediment by dispersing activities in both space and time over the Planning Basin Alternatives which are reasonably constraining to site disturbances, particularly on the higher risk landforms, generally offer the most protection to water quality and fish habitat Refer to the **SOIL AND WATER** section for additional discussion of basin timber harvest constraints

OFF-FOREST WATER USE

Off-Forest water uses present either a current or potential threat to Forest-derived salmonids in several Planning Basins Human water needs are expected to increase due to population growth projected for the region. Water withdrawal currently presents a serious threat to salmonid populations in the Illinois River drainage (Refer to Chapter III, **FISH**). Since salmonids spend critical life stages in habitats both on- and off-Forest, gains in anadromous salmonid habitat capability on-Forest can be offset by losses off-Forest. State water appropriation laws do not assure that adequate summer flows will be maintained for rearing salmonids This problem is common to all proposed alternatives for the Siskiyou.

Background water temperatures, both for natural and human-affected conditions, are near threshold limits for salmonid survival and growth in several rivers. Temperature problems are particularly severe in the mainstem Illinois River and several of its tributary streams. This problem is common to all alternatives. Possible measures that might mitigate this condition and increase fish production include: water storage impoundments, purchase of water rights, and riparian management practices that increase streamside shade

CAPITAL INVESTMENTS

Some streams that lack suitable salmonid habitats or contain habitat which has been degraded as a result of past activity, will benefit from in-stream projects that improve these conditions. The stream habitat enhancement activity may reduce competition among juveniles and adults, and prevent them from being forced downstream to less desirable areas off-Forest. Habitat enhancement opportunities are limited in some basins due to poor access, low flows, high water temperatures, or existing conditions already near maximum capability. Improvement of salmonid rearing habitat capability will be conducted under basin priority selection (see Planning Records for 2630 Fish Habitat memorandum by D. King 1983) This method for choosing priority areas will be used with all alternatives. Instream habitat enhancement work is only beneficial if land management practices are complementary in not seriously impacting water quality and stream channel conditions

RESPONSE TO PLANNING PROBLEMS

Planning Problem #3, "How can the Forest's fish habitat, water quality and soil productivity be maintained or improved?," is addressed here for response to fish habitat concerns. Changes by alternative and by basin are addressed for selected measures most relevant to fish habitat and beneficial uses of the fisheries resource.

ENVIRONMENTAL EFFECTS AND MITIGATION

All alternatives are designed to maintain or improve existing fish habitat capability. However, some alternatives can place individual Planning Basins at risk of minor adverse impact (moderate for one basin for one alternative) Where this occurs, water quality standards could be exceeded on a short duration, localized basis The Standards and Guidelines and accompanying BMP's, which are found in Chapter IV of the Forest Plan, include many mitigating measures and/or enhancements that would be applied to future

activities. These are considered an integral part of all alternatives and their implementation (the planning, location, design, construction, and subsequent monitoring and evaluation for project-level activity). Criteria used for evaluation include: timber harvest (acres), Riparian prescriptions, Supplemental Resource area allocations, basin timber harvest constraints, and capital investments

CUMULATIVE EFFECTS associated with Forest Service, private land, and other ownerships relative to past, current, and reasonably foreseeable future activities have been considered in the following discussions. However, the most specific evaluation of cumulative effects appears in the section titled **ENVIRONMENTAL EFFECTS BY PLANNING BASIN.** For additional discussion of the interrelated watershed cumulative effects, refer to the **SOIL AND WATER** section of this chapter.

Anticipated effects on fish habitat and production capability are presented in four parts:

1. **CHANGES IN YEARLY FISHERIES OUTPUTS.**
2. **DIRECT AND INDIRECT EFFECTS BY ALTERNATIVE.**
3. **ENVIRONMENTAL EFFECTS BY PLANNING BASIN.**
4. **SUMMARY OF FOREST-WIDE EFFECTS ON FISH HABITAT BY ALTERNATIVE**

CHANGES IN YEARLY FISHERIES OUTPUTS

Table IV-8 shows the differences between alternatives in relation to predicted fisheries outputs.

Table IV-8. Anticipated Changes in Yearly Fisheries Output Based on Fisheries Habitat Management and Capital Investment by Alternative.

Alternative	Riparian Management		Investment 3/ (M $)	Yearly Fisheries Output	
	Prescription B 1/ (No of Basins)	Prescription C 2/ (No of Basins)		Pounds	(WFUD's)
NC	19	0	227	978,000	67,050
A	19	0	227	978,000	67,050
A-Dep	19	0	227	978,000	67,050
B	13	6	350	1,047,915	72,546
C	19	0	260	992,000	68,231
D, D1	13	6	250	1,004,951	68,973
E	1	18	250	1,011,533	69,578
G	1	18	260	1,014,533	69,816
K	18	1	350	1,028,143	71,295
M	1	18	260	1,014,533	69,816
S	12	7	350	1,044,000	72,300

1/ Continuation of existing riparian management practices
2/ Minimal timber harvest from riparian areas, combined with gains in overhead canopy shade in areas which were previously harvested, results in decreased temperatures
3/ Includes spawning, rearing, and migration habitat improvements Does not include projects planned for the soil and water recovery program (Refer to FEIS, Chapter II, Table II-21)

DIRECT AND INDIRECT EFFECTS BY ALTERNATIVE

Alternatives NC, A, and A-Departure

DIRECT EFFECTS. These alternatives represent today's management situation and existing salmonid habitat condition as shown in Tables III-24 and III-26. Alternative A-Departure has slightly greater risks associated with accelerated timber harvest activities

Timing of timber harvest and road construction in Alternative A-Departure will be accelerated over the base level for the first two decades, resulting in a predicted sediment increase of two percent The increased sediment level presents a slight increase in risk to salmonid habitat capability, but is not considered significantly different than current direction nor detrimental to overall salmonid production There are no specific timber harvest basin constraints applied to these alternatives; however, the watershed dispersion constraint of 20 percent does apply as a Management Requirement (MR)

Riparian habitat is managed under Prescription B within 18 planning basins, and Minimum Level for the Upper Chetco (that basin being entirely within Wilderness) This array will result in maintenance of current water temperatures, long-term organic material input to streams, and instream habitat stability

Alternatives NC and A include 14 Supplemental Resource areas which favorably influence salmonid habitat

Capital investments of $227,000 per year are programmed to increase salmonid habitat capability.

INDIRECT EFFECTS. During the first decade, potential fish harvests are expected to gradually increase from current levels, providing an additional 8,100 wildlife/fish user days (WFUD's) per year in the inland and offshore sport fishery and an additional 98,000 pounds per year in the offshore commercial salmon fishery.

Alternative B

DIRECT EFFECTS. Alternative B offers moderate salmonid capability in terms of smolt and fisheries output potentials. The application of Riparian Prescription C on the Elk/Sixes, Upper Rogue, Lower Rogue, Silver, Lower Chetco, and Winchuck Planning Basins is expected to decrease water temperatures in these basins. Water temperatures will be maintained in other basins with application of Riparian Prescription B.

Alternative B has predicted sediment outputs at five percent above the current level (Alternative A) This increase in sediment level presents slightly higher risk to salmonid habitat capability, but is not expected to significantly decrease overall salmonid production Timber harvest basin constraints have been applied to five Planning Basins; the watershed dispersion constraint applies to the remainder.

Fourteen Supplemental Resource areas of special importance to fish habitat were selected from the candidate areas.

Capital investments of $350,000 per year are programmed. This high investment option is the primary reason for the high potential fisheries outputs.

INDIRECT EFFECTS. During the first decade, potential fish harvests are expected to gradually increase from current levels, providing an additional 13,600 wildlife/fish user days (WFUD's) per year in the inland and offshore sport fishery and an additional 167,000 pounds per year in the offshore commercial salmon fishery. If improvement projects are not funded, the increase attributed to the application of Riparian Prescription C alone would be 1,100 WFUD's and 17,900 pounds

Alternative C

DIRECT EFFECTS Alternative C represents an option for high timber outputs. Riparian Prescription B is utilized for all basins available for timber management Current water temperatures will be maintained in all basins

Sediment is predicted to increase by 14 percent over the current level (Alternative A). This increased sediment poses a greater risk to salmonid habitat capability than any of the other alternatives The potential

for localized aggradation and adverse impacts on fish habitat and production exists Only the watershed dispersion constraints (MR's) apply to this alternative

Two Supplemental Resource areas are allocated. This low number limits protection of many key streams.

Capital investments of $260,000 per year for Alternative C represents a moderate investment option. Improvement of salmonid rearing habitat capability, as shown in Table IV-8, was predicted based on these investments For Alternative C, capital investment offers the only identified opportunity for improving salmonid habitat capability

INDIRECT EFFECTS During the first decade, potential fish harvests are expected to gradually increase from current levels, providing an additional 9,300 wildlife/fish user days (WFUD's) per year in the inland and offshore sport fishery and an additional 112,000 pounds per year in the offshore commercial salmon fishery.

Alternative D and D1

DIRECT EFFECTS. Alternative D offers moderate salmonid capability in terms of smolt and fisheries output potentials. The application of Prescription C is expected to improve habitat in the Elk/Sixes, Upper Rogue, Lower Rogue, Silver, Lower Chetco, and Winchuck Planning Basins. Current water temperatures will be maintained in 12 basins with application of Prescription B. Sediment increases in some basins approach levels predicted for Alternative C.

Alternative D1 is essentially the same as Alternative D with the exception of shorter timber-harvest rotation. Impacts on the fishery are not substantially different from those discussed under Alternative D. Alternative D has predicted sediment outputs of three percent above the current level (Alternative A), while Alternative D1 is essentially the same as current outputs. The increase in sediment level for Alternative D presents slightly higher risk to salmonid habitat capability, but is not expected to significantly decrease overall salmonid production. Timber harvest basin constraints have been applied to five Planning Basins; the watershed dispersion constraint (MR's) applies to the remainder.

Fourteen Supplemental Resource areas of special importance to fish habitat were selected from the candidate areas.

Capital investments of $250,000 per year for Alternative D represent a moderate investment option

INDIRECT EFFECTS. During the first decade, potential fish harvests are expected to gradually increase from current levels, providing an additional 10,000 wildlife/fish user days (WFUD's) per year in the inland and offshore sport fishery and an additional 125,000 pounds per year in the offshore commercial salmon fishery. If improvement projects are not funded, the potential increase would be 1,100 WFUD's and 17,900 pounds (attributable to application of Riparian Prescription C only).

Alternative E

DIRECT EFFECTS. Alternative E offers high salmonid capability in terms of smolt and fisheries output potentials. Through application of the Minimum Level Prescription to Riparian Management Areas in all 19 basins, habitat capability will increase in 18 basins.

Sediment production is predicted to decline by 46 percent below current levels This significantly reduces the risk of sediment effects on streams (from current levels of activity) Timber harvest basin constraints have been applied to all Planning Basins.

Supplemental Resource area designation is prescribed for 30 key streams.

Capital investments of $250,000 per year for Alternative E represent a moderate investment option.

INDIRECT EFFECTS During the first decade, potential fish harvests are expected to gradually increase from current levels, providing an additional 11,600 wildlife/fish user days (WFUD's) per year in the inland and offshore sport fishery and an additional 131,500 pounds per year in the offshore commercial salmon fishery. If improvement projects are not funded, the expected increase would be 1,500 WFUD's and 19,000 pounds (attributable to application of Minimum Level standards).

Alternative G

Alternative G is similar to Alternative E, with the exception of differences in scheduled timber harvest, the additional of Supplemental Resource areas, and a special category of Fisheries-Watershed Areas as described below.

DIRECT EFFECTS Alternative G offers high salmonid capability in terms of smolt and fisheries output potentials. The application of Riparian Prescription C to 18 basins would reduce stream temperatures below current levels in these basins.

Sediment production is predicted to decline by 35 percent below current levels. Timber harvest basin constraints ranging from 9-13 percent have been applied to all Planning Basins. These constraints distribute harvest among the basin and reduce risks to fisheries habitat. The effects are similar to Alternative E.

Thirty-one Supplemental Resource areas are allocated. A number of major streams are protected by 1/8 mile corridors in Fisheries-Watershed areas These corridors measurably reduce the potential for risks associated with activity in the inner-gorge areas. The 1/8 mile corridors, which are twice the width of Riparian Management Areas for Class I and II streams, reduce the probability of activity-induced landslides, but add little improvement in stream temperature over Riparian Prescription C It is again noted that stream temperature is the most limiting factor for salmonids in the majority of Siskiyou National Forest streams.

Basin-specific timber-harvest constraints ranging from 9-13 percent are applied to the 18 planning basins.

INDIRECT EFFECTS. During the first decade, potential fish harvests are expected to gradually increase from current levels, providing an additional 10,900 wildlife/fish user days (WFUD's) per year in the inland and offshore sport fishery and an additional 134,500 pounds per year in the offshore commercial salmon fishery. If improvement projects are not funded, the potential increase would be 1,400 WFUD's and 19,500 pounds (attributable to application of Prescription C)

Alternative K

DIRECT EFFECTS Alternative K offers high salmonid capability in terms of smolt and fisheries output potentials. Application of Riparian Prescription C, which will aid in salmonid habitat capability recovery, applies only to the Elk/Sixes Basin. Water temperature will be maintained in 17 basins with application of Riparian Prescription B.

Sediment production is predicted to decline by 15 percent below current levels. Timber-harvest basin constraints ranging from 9-13 percent have been applied to all Planning Basins. These constraints distribute harvest among the basin and reduce risks to fisheries habitat.

Capital investment of $350,000 per year for Alternatives B, K, and S represent the highest investment option

Twenty-three Supplemental Resource areas with no programmed timber harvest are allocated

INDIRECT EFFECTS. During the first decade, potential fish harvests are expected to gradually increase from current levels, providing an additional 12,400 wildlife/fish user days (WFUD's) per year in the inland and offshore sport fishery and an additional 148,000 pounds per year in the offshore commercial salmon fishery. If improvement projects are not funded, the potential increase attributable to application of Riparian Prescription C would be 79 WFUD's and 1,100 pounds.

Alternative M

Anticipated fishery outputs are the same as Alternative G. There is considerably less risk, however, due to measurably reduced timber harvest and no new road construction. Sediment production is predicted to decline by 81 percent from current levels, representing a significant decrease in potential impacts to salmonid habitat capability.

Alternative S

DIRECT EFFECTS Alternative S offers high salmonid capability in terms of smolt and fisheries output potentials. Water temperatures would gradually decrease and salmonid fish habitat capability would increase over present levels in the seven planning Basins with Riparian Prescription C. These basins include: Elk/Sixes, Lobster, Lower Rogue, Indigo, Silver, Pistol, and Lower Chetco. The temperature in the 12 basins with Riparian Prescription B would remain at current levels

Sediment production is predicted to decrease by 12 percent from current levels (Alternative A) for decades 1-5 This will have effects similar to those described for Alternative K Basin-specific timber-harvest basin constraints of 7 to 17 percent have been applied.

Salmonid capability is expected to increase through fish habitat improvement projects. Capital Investments of $350,000 represent the high investment option.

Twenty key streams are allocated to Supplemental Resource Management Areas. Five other key streams are given additional protection through other land allocations with no programmed harvest.

INDIRECT EFFECTS. During the first decade, potential fish harvests are expected to gradually increase from current levels, providing an additional 13,400 wildlife/fish user days (WFUD's) per year in the inland and offshore sport fishery and an additional 164,000 pounds per year in the offshore commercial salmon fishery. If improvement projects are not funded, the expected increase attributable to application of Prescription C would be approximately 1,000 WFUD's and 15,000 pounds

ENVIRONMENTAL EFFECTS BY PLANNING BASIN

The potential for sediment and water temperature impacts on anadromous salmonid fish are also key indicators for the **SOIL AND WATER** section of this chapter. The recognized environmental effects for both fish and water are combined herein. For each Planning Basin, an estimate is made of the risk of the proposed management activities on salmonid habitat capability and other selected beneficial uses of water. The beneficial uses selected were those considered most sensitive to forest management activities, and/or at least those with the status of a minor beneficial use for the Planning Basin, as shown on Table III-11.

For Siskiyou National Forest streams, the most critical potential sources of risk from management activities are related to:

1. Sediment and turbidity increases, above background levels, by timber harvest and road construction (refer to the **SOIL AND WATER** section in this chapter), and

2. Temperature increases due to removal of streamside shade canopies

The water quality standards established by the Oregon Department of Environmental Quality and the California Water Resources Control Board are intended to provide for water quality sufficient to maintain existing levels of beneficial uses.

The intensity and extent of activities are the primary determinants of potential risks to the water and fisheries resource The following terms for rating the potential risks to salmonid habitat capability and selected beneficial uses of water are used in this analysis. The beneficial uses of water considered below always include the anadromous fishery, and may include public and domestic water supplies, irrigation, wildlife, fishing, boating, water-contact recreation, visual quality, and navigation where applicable.

negligible -- the existing salmonid habitat capability and beneficial uses of water are expected to be maintained or improved; water quality standards are expected to be met.

minor adverse -- the predicted change in temperature, sediment, and turbidity results in increased risk to salmonid habitat capability and beneficial uses without significant impacts. There is a slight risk of exceeding water quality standards on a short-duration, localized basis.

moderate adverse -- the predicted change in temperature, sediment, and turbidity results in increased risk, with potential for localized impacts to salmonid habitat capability and beneficial uses. Water quality standards for an identified use may be exceeded.

Under alternatives where risks are defined as **negligible**, water quality and instream conditions for salmonid capability and beneficial uses are expected to be maintained or improved. Where the potential for improvement over current condition exists, the ratings are enclosed by parentheses, e.g , either **(minor Improvement)** or **(moderate Improvement)**. This rating applies to long-term potential for improvement over existing conditions. For current conditions, refer to the **FISH** and **SOIL AND WATER** sections of Chapter III.

The potential for on-site and downstream cumulative effects resulting from all (National Forest and other) proposed management activities in the basin is shown by the relative rating of potential risk from increased sediment, turbidity, and temperature identified below for each Planning Basin. The estimates of potential risk from increased sediment and turbidity were made considering the estimated mean and peak decade percent increase in sediment shown in Figures IV-1 through IV-12, land allocations, the beneficial uses of water, current watershed condition and water quality, and past, present, and future (anticipated) levels of management activity on National Forest and other lands The estimates of potential risk from increased temperature were made considering current and future water temperatures and trends, land allocations, as well as the Riparian Prescriptions (B, C, or M) identified by alternative for each Planning Basin. The estimates of potential risk for Indigo, Silver, Galice/Slate, and East and West Fork Illinois Planning Basins considered the impacts associated with the 1987 fires on both watershed condition and water quality.

In order to track the following discussions, two tables in previous chapters will be particularly helpful. Table II-3 (Special Area Assignments) should aid in tracking specific land allocations by alternative. Table III-10 (Descriptive Indices by Planning Basin) covers the Planning Basin acreages and percentages; references to prior harvest by decades are taken from this source.

Further, to partially mitigate potential significant cumulative impacts within a given basin, various levels of timber harvest constraints have been applied to selected alternatives. These constraints apply to the tentatively suitable lands within the basin over the decade. Where alternative constraints are not specified in the following analysis, the Management Requirement of 20 percent is used The constraints only apply to Siskiyou National Forest System lands; the analysis of basin impacts on the fish and water resource,

however, include the probable management activity of private and other land ownerships in these Planning Basin assessments

Basin 01 - Elk/Sixes

In addition to salmonid habitat capability, the following includes estimated risk to domestic water supplies and fishing in terms of potential increase in accelerated sediment and turbidity

Estimated risk from increased sediment and turbidity.

Alternatives NC, A, A-Departure, and C are **negligible**
Alternatives B, D, D1, K, and S are **negligible (minor improvement).**
Alternatives E, G, and M are **negligible (moderate improvement)**

Estimated risk from increased temperature·

Alternatives NC, A, A-Departure, and C are **negligible** (Prescription B)
All other Alternatives are **negligible (moderate improvement)**(Prescription C or M).

The Elk/Sixes Planning Basin is shared between two separate coastal rivers, the Elk and the Sixes The basin is characterized by it's high-value anadromous fisheries, including the Oregon Department of Fish and Wildlife's Elk River Hatchery. The north side of the Elk River, plus the Dry Creek basin on the Sixes, is in the Grassy Knob Wilderness. Two-thirds of the basin under National Forest management is tentatively suitable for the production of timber. Of this, 18 percent was harvested from 1950-70, and 20 percent from 1970-80 Management activity in the 1980's on the Siskiyou National Forest lands has continued at about the same level

As a result of past timber harvest and roading activities on both Forest and private lands, this basin is presently in a recovery mode The rate of recovery varies greatly by small watershed In several instances, the type and extent of older activity has created some adverse, long-term impacts to tributary drainages Other watersheds have either been more resilient or did not experience the level of poor practices or heavy, *cumulative impacts within a relatively short period This past activity has been accounted for in the above* ratings.

While the Elk and Sixes Rivers are contiguous and contain high-valued anadromous fisheries, this is where much of their similarity ends. The Elk River is a very steep, rugged drainage largely within the Siskiyou National Forest Private land within and outside this watershed has been harvested in the past, road systems are complete and the lands are revegetated. Very little harvesting on private land occurred during the 1980's, little is expected in the 1990's

The Sixes River, different in geology, responses to activity, and history of development, presents another scenario. However, the trend in water quality is again expected to improve over the next few decades Most of the watershed is in private ownership. The Forest's portion has access and much of it was harvested within the last 20 years Harvesting of the private land was heaviest in the 1950's and 1960's. Harvesting since has been scattered and limited The road system is in place Activity levels for private lands in the entire drainage are low and expected to remain so for a few decades until the new stands reach merchantable size. Impacts of past activities still remain, but much reduced from the likely levels that occurred in 1950's and 1960's.

Under Alternatives E, G, and M, management activities and resulting sediment would be concentrated in the headwaters of South Fork Sixes River and the south side of Elk River. All other alternatives would distribute activities and associated sediment outputs to the South Fork Sixes River and throughout the Elk River watershed. Improvement of existing conditions under Alternatives E, G, K, M, and S will be due

primarily to allocations of Management Areas 1-9 in selected portions of these two watersheds. Complementing these allocations, the Elk River was designated Wild and Scenic for nearly 20 miles upstream from the Forest boundary as a result of the Oregon Omnibus Wild and Scenic River Act of 1988

Alternatives B, D, D1, E, G, K, and M have a 10 percent per-decade basin timber harvest dispersion constraint Alternative S applies a 12 percent basin harvest constraint.

For all alternatives, there is an estimated negligible potential risk for timber management/road-related cumulative effects, both on- and off-Forest, considering anticipated levels of new activity on both National Forest and other lands for at least the next two decades. The risk of cumulative effects is further reduced in alternatives with either basin harvest constraints. Water quality is expected to be maintained or improved for rivers and streams, including the Wild and Scenic Elk River No cumulative effects in the Wild and Scenic Elk River are anticipated

Basin 02 - South Fork Coquille

In addition to salmonid habitat capability, the following includes the estimated risk to the Powers municipal water supply (low-flow period), domestic water supplies, and fishing in terms of potential increase in accelerated sediment and turbidity.

Potential risk from sediment and turbidity increases.

Alternative NC, A, A-Departure, B, C, D, and D1 are **negligible.**
Alternatives E, G, K, and S are **negligible (minor improvement).**
Alternative M is negligible (**moderate improvement**).

Estimated risk from increased temperature:

All alternatives other than E, G, and M are **negligible** (Prescription B).
Alternatives E, G, and M are **negligible (minor improvement)**(Prescription C or M).

Salmonid habitat and water quality in the South Fork Coquille Basin is a reflection of both Forest and private management, past and present. Early timber harvest operations on private lands in the Coquille River watershed involved use of large steam yarders and railroads. These operations, plus extensive burning of logging slash on oversteepened slopes and riparian areas, resulted in many water quality problems in the 1920's through the 1950's.

By the early 1980's, much of the mature timber on private lands in the South Fork Coquille River watershed had been harvested, leaving about 18 percent of the private lands in the basin available for harvest Ninety percent of the basin under National Forest management is tentatively suitable for the production of timber Of this, 16 percent was harvested from 1950-69, and 20 percent from 1970-79. Timber harvest activity on Siskiyou National Forest lands in the 1980's has continued at about the same level. While some harvest on private lands occurred during the 1980's, streamside and upslope areas are generally in a recovery phase Stands of 10-30 foot high Douglas-fir dominate much of both private and National Forest lands today.

The summer water withdrawal from the South Fork Coquille River for the Powers municipal use is largely unaffected by sediment and turbidity due to the water quality conditions at this time of year. During winter and high-flow periods, the water source is switched to a small watershed (Bingham Creek) outside the National Forest boundary.

All alternatives have selected Management Area 1-9 allocations coupled with visual management objectives and Riparian areas which provide added benefits above the Standards and Guidelines to the

mainstem river corridor. Alternatives G and M, however, have Supplemental Resource areas of one-eighth mile corridors along Coal, Johnson, Sucker, and Rock Creeks, and along the upper mainstem of the South Fork Coquille. An extensive road system already exists, so few additional roads will be needed.

Alternatives E, G, K, and M have a 11 percent per-decade basin timber harvest dispersion constraint Alternative S applies a 12 percent constraint

For all alternatives, there is an estimated negligible potential risk for timber management/road-related cumulative effects This considers both existing conditions and anticipated levels of activity on both National Forest and other lands for at least the next two decades. The risk of cumulative effects is further reduced in alternatives with either basin timber harvest constraint Water quality is expected to be maintained or improved

Basin 03 - Lobster.

In addition to salmonid habitat capability, the following includes the estimated risk to the public water supply and fishing in terms of potential increase in accelerated sediment and turbidity

Estimated risk from increased sediment and turbidity.

Alternatives D1 is **minor adverse**
Alternatives NC, A, A-Departure, C, and D are **negligible.**
Alternatives B, E, G, K, and S are **negligible (minor improvement).**
Alternative M is **negligible (moderate improvement).**

Estimated risk from increased temperature.

Alternatives other than E, G, M, and S are **negligible** (Prescription B).
Alternatives E, G, M and S are **negligible (minor improvement)** (Prescription C or M)

National Forest lands, located in the upper watershed area of Lobster Creek, comprise approximately 44 percent of the Planning Basin. The majority of the private lands in the lower watershed were harvested and burned between 1960 and 1980, leaving about five percent of the private lands to be harvested This harvest activity and associated practices in the lower watershed lead to both temperature and sediment cumulative impacts on the fishery habitat downstream from National Forest lands. Of land within the basin under National Forest management, 93 percent is tentatively suitable for the production of timber Of this, eight percent was harvested from 1950-70, and 18 percent from 1970-80 Some additional harvest of the remaining commercial-sized stands on private land and moderate harvest levels (similar to the prior decade) on the Siskiyou National Forest has occurred through the 1980's, however at a much reduced rate for the basin. As a result, the Lobster Creek watershed is currently in a recovery period.

Portions of the Euchre Creek watershed are located in the Lobster Creek Planning Basin Removal of timber from private lands within the basin occurred over a relatively short time period during the 1960's and 1970's The type and extent of these harvest practices, coupled with even older livestock grazing in the lower reach, resulted in extensive damage to the low-gradient stream system in the form of aggraded channels and bank instability. Timber harvesting and associated roading on National Forest lands has been moderate and mostly within the last two decades The Euchre Creek watershed is currently slowly recovering, but poor salmonid fish habitat characteristics are expected to remain for at least the next two decades.

Alternatives E, G, K, and M have a 11 percent per-decade basin timber harvest dispersion constraint; Alternative S applies a 12 percent constraint These alternatives also allocate Lobster Creek and South Fork Lobster Creek to Supplemental Resource Management Areas.

For all alternatives except D1, there is an estimated negligible potential risk for timber management/road-related cumulative effects. This considers both existing conditions and anticipated levels of activity on National Forest, BLM, and other lands for at least the next three decades. The risk of cumulative effects is further reduced in alternatives with the basin timber harvest constraints. For alternatives other than Alternative D1, water quality is expected to be maintained or improved No cumulative effects downstream in either the Rogue River or the estuary are anticipated.

Basin 04 - Upper Rogue

In addition to salmonid habitat capability, the following includes the estimated risk to public and domestic water supplies, fishing, boating, and visual quality in terms of a potential increase in accelerated sediment and turbidity.

Estimated risk from increased sediment and turbidity:

Alternative C is **minor adverse**
Alternatives NC, A, A-Departure, B, D, D1, K, and S are **negligible.**
Alternatives E and G are **negligible (minor improvement)**
Alternative M is **negligible (moderate improvement).**

Estimated risk from increased temperature·

Alternatives NC, A, A-Departure, C, K, and S are **negligible** (Prescription B).
Alternatives B, D, D1, E, G, and M are **negligible (minor improvement)**(Prescription C or M)

The Upper Rogue Planning Basin contains the designated Wild Rogue Wilderness and the Wild and Scenic Rogue River. Nearly all (97 percent) of the basin is National Forest Much of the basin lies within the Wild Rogue Wilderness. Shasta Costa and Foster Creek are major fish-producing tributaries Approximately 60 percent of the total basin is tentatively suitable for timber production Of this, six percent was harvested from 1950-70, and six percent from 1970-80 Timber harvest activity on National Forest lands in the 1980's has continued at about the same level

The basin has been heavily harvested on the west and essentially undeveloped on the east (Shasta Costa and Stair Creeks, and the Wild Rogue Wilderness). In the upper reach of the Rogue River in this basin, summer water quality and fish habitat conditions have improved since the completion of Lost Creek Reservoir in 1977 and Applegate Reservoir in 1980.

Under Alternatives E and M, management activities and associated sediment output would be concentrated in the headwaters of Stair Creek and to the west side of the Rogue River. All other alternatives would distribute the accelerated sediment levels throughout the non-Wilderness portion of the basin. All Alternatives except C include the Shasta Costa Supplemental Resource Management Area(s). Within the Rogue River corridor, visual management constraints are applied in Alternatives E, G, K, M, and S which further reduce potential impacts. A 12 percent basin timber harvest dispersion constraint applies to Alternatives B, D, D1, E, G, K, and M, a 16 percent constraint applies to Alternative S

For all alternatives except Alternative C, there is an estimated negligible potential risk for timber management/road-related cumulative effects This considers both existing conditions and anticipated levels of activity on predominately National Forest lands Alternative C is anticipated to result in a minor adverse potential risk for cumulative effects from timber management and road-related sedimentation. The risk of cumulative effects is further reduced in alternatives with basin timber harvest constraints of either 12 or 16 percent For other than Alternative C, water quality is expected to be maintained or improved in rivers and streams, including the Wild and Scenic Rogue River. No cumulative effects downstream in either the Rogue River or estuary are anticipated

Basin 05 - Lower Rogue

In addition to salmonid habitat capability, the following includes the estimated risk to public and domestic water supplies, fishing, boating, navigation, and visual quality in terms of a potential increase in accelerated sediment and turbidity.

Estimated risk from increased sediment and turbidity:

Alternatives NC, A, A-Departure, B, C, D, D1, K, and S are **negligible.**
Alternatives E and G are **negligible (minor improvement)**
Alternative M is **negligible (moderate improvement)**

Estimated risk from increased temperature:

Alternatives NC, A, A-Departure, C, and K are **negligible** (Prescription B).
Alternatives B, D, D1, E, G, M, and S are **negligible (moderate improvement)** (Prescription C or M)

The Rogue River watershed is one of the top salmonid fish producers in the United Stated in terms of species diversity, angler success, and opportunity. Salmonid habitat capability of the Lower Rogue Planning Basin is strongly influenced by the designated Wild and Scenic Rogue River and other complementary land allocations within the river corridor High concern for the fisheries also centers on the quality of tributary streams such as Quosatana Creek

Nearly 90 percent of the National Forest portion of the basin is tentatively suitable for timber production. Six percent of this was harvested from 1950-70, and 12 percent from 1970-80. A moderate level of harvest has continued through the 1980's on the Siskiyou National Forest About six percent of the private land is still available for harvest.

Alternatives E and M would spatially distribute sediment impacts to the south and western portions of the basin; the east side of Quosatana Creek would not be developed. All other alternatives would distribute higher sediment levels throughout the basin. Alternatives B, D, D1, E, G, K, and M have a 12 percent per-decade basin timber harvest dispersion constraint; a harvest constraint of 15 percent applies to Alternative S. Alternatives E, G, K, M, and S have a high level of visual management applied along the Rogue River and Quosatana Creek allocated to Supplemental Resource areas

For all alternatives, there is an estimated negligible potential risk for timber management/road-related cumulative effects This considers both existing conditions and anticipated levels of activity on both National Forest and other lands. The risk of cumulative effects is further reduced in alternatives with basin timber harvest constraints of either 12 or 15 percent. Water quality is expected to be maintained or improved in rivers and streams, including the Wild and Scenic Rogue River. No cumulative effects downstream in either the Rogue River or estuary are anticipated.

Basin 06 - Indigo

In addition to salmonid habitat capability, the following includes the estimated risk to fishing and wildlife in terms of a potential increase in accelerated sediment and turbidity

Estimated risk from increased sediment and turbidity:

Alternatives B, C, D, and D1 are **moderate adverse.**
Alternatives NC, A, A-Departure, K, and S are **minor adverse.**
Alternatives E and G are **negligible.**
Alternative M is **negligible (moderate improvement).**

Estimated risk from increased temperature

All Alternatives except E, G, M, and S are **negligible** (Prescription B).
Alternatives E, G, M, and S are **negligible (moderate improvement)** (Prescription C or M)

By providing cool water to the Illinois River during the time of low summer flows, this Planning Basin strongly influences salmonid habitat off-site All of the basin is National Forest lands Much of the headwaters of Indigo Creek have been roaded Most of the south side of Indigo Creek, though, remains unroaded.

Nearly 80 percent of the basin under National Forest management is tentatively available for the production of timber. Of this, three percent was harvested from 1950-70, and five percent from 1970-80 Timber harvest activity on National Forest lands in the 1980's has continued at about the same limited rate.

Under Alternatives E and M, potential sediment production would occur on lands in the northwest and extreme eastern (headwaters) portions of the basin All other alternatives with higher sediment yields would distribute the effects throughout the basin.

Alternatives E, G, M, and S have allocated both Indigo Creek and the East and West Forks of Indigo Creek to Supplemental Resource areas, all alternatives except C allocate Indigo Creek. For these alternatives and Alternative K, a basin timber harvest dispersion constraint of 11 percent per decade applies For further analysis of potential cumulative effects, refer to Silver Fire Recovery Project FEIS (USDA 1988d).

For all alternatives other than E, G, and M, there is either an estimated minor or moderate adverse risk for wildfire and timber management/road-related cumulative effects This analysis considers both existing conditions, including 1987 fire impacts, and anticipated levels of activity on National Forest lands Alternatives B, C, D, and D1 are anticipated to result in a moderate adverse risk for cumulative effects from wildfire, timber management, and road-related sedimentation. Alternatives NC, A, A-Departure, K, and A are anticipated to result in a minor adverse risk for cumulative effects The risk of cumulative effects is reduced in alternatives with a basin timber harvest constraint For other than Alternatives B, C, D, and D1, water quality is expected to be maintained or improved. No cumulative effects downstream in either the Wild and Scenic Illinois or Rogue River are anticipated.

Basin 07 - Silver.

In addition to salmonid habitat capability, the following includes the estimated risk to fishing and wildlife in terms of a potential increase in accelerated sediment and turbidity.

Estimated risk from increased sediment and turbidity

Alternative C is **moderate adverse**
Alternatives NC, A, A-Departure, B, D, D1, K, and S are **minor adverse.**
Alternatives E and G are **negligible.**
Alternative M is **negligible (moderate improvement).**

Estimated risk from increased temperature

Alternatives NC, A, A-Departure, C, and K are **negligible** (Prescription B)
All other alternatives are **negligible (minor improvement)** (Prescription C or M).

Silver Creek continues to be an important source of cooler water for the Illinois River, and is an important influence on fish habitats both on- and off-site

The headwaters of Silver Creek were harvested in localized areas by the Forest Service and BLM in the 1960's and early 1970's. Most (one percent of the tentatively suitable land) of the past National Forest harvesting occurred in the headwaters of Silver and South Fork Silver Creeks in the 1960's The Bureau of Land Management harvests are located in the North Fork Silver Creek headwaters from the 1960's to date. Less than one percent of the suitable Siskiyou National Forest lands were harvested in the decade of 1970-80. Approximately 60 percent of the basin under National Forest management is tentatively suitable for the production of timber

With the exception of the Silver Fire Recovery Project, little harvest activity has occurred in the 1980's. Salvage logging using helicopter and long-span skyline systems in the Silver Fire area is presently underway. Very few miles of new road construction accompanied the fire salvage activities. Whereas the area covered by harvest is relatively large, the associated impacts are minor due to the type of logging systems utilized, the limited roading, and other mitigation measures applied. For further discussion of potential effects, including the cumulative effects analysis, refer to Silver Fire Recovery Project FEIS (USDA 1988d).

Some recovery is still occurring within riparian areas as a result of the older harvest practices. However, the residual impact today is not significant on the downstream fishery resources.

Alternatives E, G, M, and S would hold the minor sediment impacts to predominately the eastern fringes of the basin. All other alternatives would distribute higher sediment levels throughout the basin. Most activity, however, would occur away from the inner gorge areas due to allocations to Supplemental Resource and other Management Areas with no programmed harvest, and the prevalence of unsuitable land in the lower slope areas

A nine percent per-decade basin timber harvest constraint would apply to Alternatives B, D, D1, E, G, K, and M. A seven percent constraint is applied to Alternative S to mitigate some of the Silver Fire Recovery Project impacts. In addition, Alternatives E, G, M, and S have very limited harvest within the Silver Planning Basin as a result of the large area allocated to Backcountry Recreation.

For all alternatives other than E, G, and M, there is either an estimated minor or moderate adverse risk for wildfire and timber management/road-related cumulative effects. This analysis considers both existing conditions and anticipated levels of activity on predominately National Forest and BLM lands. Alternatives NC, A, A-Departure, B, D, D1, K, and S are anticipated to result in a minor adverse potential risk for cumulative effects from wildfire, timber management, and road-related sedimentation, while Alternative C would result in a moderate adverse potential risk. The risk of cumulative effects is reduced in alternatives with basin harvest constraints. For other than Alternative C, water quality is expected to be maintained or improved. No cumulative effects downstream in either the Wild and Scenic Illinois or Rogue River are anticipated

Basin 08 - Galice/Slate.

In addition to salmonid habitat capability, the following includes the estimated risk to domestic water supplies and irrigation in terms of potential increase in accelerated sediment and turbidity.

Estimated risk from increased sediment and turbidity.

Alternatives B, C, D, and D1 are **minor adverse.**
Alternatives NC, A, A-Departure, E, G, K, and S are **negligible.**
Alternative M is **negligible (moderate improvement).**

Estimated risk from increased temperature:

All Alternatives except E, G, and M are **negligible** (Prescription B)
Alternatives E, G, and M are **negligible (minor improvement)** (Prescription C or M).

The Planning Basin contains tributaries of both the Rogue and Applegate Rivers. This basin contains some of the prime summer steelhead spawning and rearing habitat on the Forest. Salmonid production in the basin is affected by naturally low flows and water withdrawals for irrigation and domestic uses mostly below the Forest boundary.

About one half of the basin is National Forest land. Of this, three-quarters is tentatively suitable for the production of timber. While only four percent of the suitable National Forest lands were harvested between 1950-70 and two percent between 1970-80, private lands were heavily logged in the 1960's. This resulted in localized impacts on water quality. The watershed condition as a result of this past harvesting, along with that of older mining and present activities, were considered in making the above estimates of effects. Harvest activity in the 1980's has largely been on National Forest lands, the extent of activity has varied by stream tributary from light to moderate.

Mining within riparian areas, road erosion, water withdrawal, and localized landslides triggered (in part) by timber harvest activities, have all contributed to the present salmonid habitat conditions in the basin. Coupled with these, a major fish habitat problem occurs because of water withdrawals on private land in the lower eight miles of Slate Creek and it's tributaries. Poor ground water conditions and a relatively high demand for domestic water will continue to impact salmonid habitat throughout the this drainage.

Alternatives E, G, K, and M have a 12 percent per-decade basin harvest constraint, Alternative S has a 14 percent constraint. These five alternatives have Management Areas with either no programmed harvest or constrained harvest along Taylor, Galice, and Slate Creeks.

For all alternatives except B, C, D, and D1, there is an estimated negligible risk for wildfire and timber management/road-related cumulative effects. This analysis considers both existing conditions, including the Galice Fire of 1987, and anticipated levels of activity on National Forest, BLM, and other lands. Alternatives B, C, D, and D1 are anticipated to result in a minor adverse potential risk for cumulative effects from wildfire, timber management, and road-related sedimentation. The risk of cumulative effects is further reduced in alternatives with a basin harvest constraints. For other than Alternatives B, C, D, and D1, water quality is expected to be maintained or improved. No cumulative effects downstream in either the Wild and Scenic Rogue River or Applegate River are anticipated.

Basin 09 - Lower Illinois

In addition to salmonid habitat capability, the following includes the estimated risk to the fishing, boating, and visual quality in terms of a potential increase in accelerated sediment and turbidity.

Estimated risk from increased sediment and turbidity:

Alternatives B, C, D, and D1 are **minor adverse.**
Alternatives NC, A, A-Departure, K, and S are **negligible**
Alternatives E and G are **negligible (minor improvement).**
Alternatives M is **negligible (moderate improvement).**

Estimated risk from increased temperature

All alternatives except E, G, and M are **negligible** (Prescription B).
Alternatives E, G, and M are **negligible (minor improvement)**(Prescription C or M).

The Lower Illinois Planning Basin is considered to be of primary importance to rearing adult and juvenile salmon and steelhead. Habitat capability is heavily influenced by off-Forest consumptive water uses in the Illinois Valley and Deer Creek. This influence presently reduces salmonid habitat capability of the mainstem Illinois River Tributary streams managed by the Forest are extremely important for maintaining viability of salmonid populations in the Lower Illinois Planning Basin Inner gorge areas along the two principal tributaries, Lawson and Collier Creeks, are extremely unstable and have been classed as unsuitable for the production of timber.

Nearly all of the basin is National Forest land. Stability problems have contributed to the reduction of tentatively suitable land to about one half of the total basin area. The 1950-1970 harvest of five percent of the suitable land was followed by eight percent for the 1970-1980 period. Most activity in the 1980's has been concentrated on the north and west portions of the Lawson Creek watershed; the extent of activity has been limited for the Planning Basin.

In Alternatives E, G, M, and S, considerable portions of Lawson Creek watershed are allocated to Backcountry Recreation. Alternatives E and M shift development activities to the western boundaries of Lawson Creek; activities under Alternatives G and S occur west of Lawson Creek and Game Lake. In alternatives without Lawson Creek allocated to the Backcountry Recreation, sediment impacts would be distributed throughout the suitable land base. Activity acres would occur to the west and north of the Kalmiopsis Wilderness, and outside the large block of unsuitable land within Lawson Creek.

All alternatives include the Wild and Scenic Illinois River corridor. The Collier Creek drainage is largely within the Kalmiopsis Wilderness. All alternatives, except C, include Lawson Creek Supplemental Resource Management Area Alternatives E, G, K, M, and S also include Horse Sign and Collier Creek Supplemental Resource areas Alternatives E, G, K, and M set basin harvest constraints at 11 percent per decade; *Alternative S has a 14 percent harvest constraint.*

For all alternatives except B, C, D, and D1, there is an estimated negligible potential risk for timber management/road-related cumulative effects This considers both existing conditions and anticipated levels of activity on mostly National Forest land Alternatives B, C, D, and D1 are anticipated to result in a minor adverse potential risk for cumulative effects from timber management and road-related sedimentation. The risk of cumulative effects is further reduced in alternatives with a basin harvest constraint of either 11 or 14 percent. For other than Alternatives B, C, D, and D1, water quality is expected to be maintained or improved. This evaluation also considers the cumulative influence of the Upper Illinois, Silver, and Briggs Planning Basins on the Lower Illinois River. No cumulative effects downstream in either the Wild and Scenic Illinois or Rogue River are anticipated.

Basin 10 - Upper Illinois.

In addition to salmonid habitat capability, the following includes the estimated risk to fishing, boating, water contact recreation, and visual quality in terms of a potential increase in accelerated sediment and turbidity

Estimated risk from increased sediment and turbidity

Alternatives NC, A, A-Departure, B, C, D, D1, K, and S are **negligible**
Alternatives E, G, and M are **negligible (minor improvement)**

Estimated risk from increased temperature.

All alternatives are **negligible.**

Salmonid habitat capability of the Upper Illinois Planning Basin is highly related to water supply. Geology and low elevations are prime reasons for natural low flows in the Upper Illinois River drainage A cumulative effect to fish habitat condition and water quality exists because of water withdrawals outside the Forest. Salmonid habitat located on Forest Service administered tributary streams are in the best condition for the basin. One-half of the basin within the Siskiyou National Forest boundary is in the Kalmiopsis Wilderness. Outside the Wilderness, the mainstem of the Illinois River is designated Wild and Scenic River.

Private timber lands in the Upper Illinois Planning Basin were almost entirely harvested on first entry by 1980. The majority of private timber lands are now in a recovery and regrowth state, timber harvest on these lands will not occur for at least two decades Forest timber harvest activity per decade has remained relatively low at two to three percent of the suitable land since 1950 Most National Forest harvest has occurred in area north of the Illinois River and east of Briggs Creek basin.

Significant opportunities exist for improving tributary stream habitat capability through capital investments on selected Forest streams having favorable habitat opportunity. For the mainstem Illinois River, unless supplemental water supplies are developed to meet off-Forest irrigation and domestic needs and assure adequate releases for minimum flows downstream, there is little doubt that the increasing demand for water will further exasperate the existing fish habitat problems on the Forest.

Potential sediment producing activities for Alternatives E and M, and to a lesser degree G, are concentrated in localized areas along the south side and to a limited area north of the Illinois River. For all other alternatives, sediment impacts occur over the half of the basin which is outside the Wilderness.

Alternatives E, G, K, M, and S have significant areas set aside in Management Areas with no programmed harvest or with visual constraints. Alternatives E, G, K, and M have a 12 percent per-decade basin harvest constraint; Alternative S has a 17 percent harvest constraint.

For all alternatives, there is an estimated negligible potential risk for timber management/road-related cumulative effects. This considers both existing conditions and anticipated levels of activity on National Forest, BLM, and other lands The risk of cumulative effects is further reduced in alternatives with a basin harvest constraint of either 12 or 17 percent Water quality is expected to be maintained or improved. No cumulative effects downstream in either the Wild and Scenic Illinois or Rogue River are anticipated.

Basin 11 - Briggs

In addition to salmonid habitat capability, the following includes the estimated risk to fishing and wildlife in terms of a potential increase in accelerated sediment and turbidity.

Estimated risk from increased sediment and turbidity.

Alternatives NC, A, A-Departure, B, C, D, and D1 are **minor adverse.**
Alternatives E, G, K, and S are **negligible**
Alternative M is **negligible (minor improvement)**

Estimated risk from increased temperature

All Alternatives except E, G, and M are **negligible** (Prescription B)
Alternatives E, G, and M are **negligible (minor improvement)** (Prescription C or M).

The Briggs Creek Planning Basin is considered to be more manageable for timber because of gentler slopes adjacent to riparian areas and greater slope stability Seventy-eight percent of the basin is tentatively suitable for timber production. Approximately five percent of the basin is in private ownership

From 1950 to date, less than 20 percent of the suitable National Forest land was harvested. Private lands in the upper Briggs Creek drainage received extensive harvest activity of mature pine timber in the 1920's through the 1960's. Road development in the watershed is nearly complete on both National Forest and private lands. New access development will be concentrated on upgrading existing systems and short local roads to harvest units.

Alternatives NC, A, E, G, and M have Briggs Creek allocated to Supplemental Resource Alternatives E and M place the majority of the Briggs Creek drainage under roadless management. Alternatives E, G, K, and M have a 12 percent per-decade basin timber harvest dispersion constraint; Alternative S applies a 16 percent basin harvest constraint.

For all alternatives except NC, A, A-Departure, B, C, D, and D1, there is an estimated negligible potential risk for timber management/road-related cumulative effects. This considers both existing conditions and anticipated levels of activity on mostly National Forest land and limited private ownerships Alternatives NC, A, A-Departure, B, C, D, and D1 are anticipated to result in a minor adverse potential risk for cumulative effects from timber management and road-related sedimentation. The risk of cumulative effects is further reduced in alternatives with a basin harvest constraint of either 12 or 16 percent. For other than Alternatives NC, A, A-Departure, B, C, D, and D1, water quality is expected to be maintained or improved. No cumulative effects downstream in either the Wild and Scenic Illinois or Rogue River are anticipated.

Basin 12 - Pistol.

In addition to salmonid habitat capability, the following includes the estimated risk to domestic water supplies and fishing in terms of a potential increase in accelerated sediment and turbidity

Estimated risk from increased sediment and turbidity:

Alternatives D and D1 are **minor adverse.**
Alternatives NC, A, A-Departure, B, and C are **negligible.**
Alternatives E, G, K, and S are **negligible (minor improvement).**
Alternative M is **negligible (moderate improvement).**

Estimated risk from increased temperature:

Alternatives NC, A, A-Departure, B, C, D, D1, and K are **negligible** (Prescription B).
Alternatives E, G, M, and S are **negligible (minor improvement)** (Prescription C or M)

Forest administration in this basin is interspersed with private lands. Quality of fish habitat is a combined result of both private and Forest influences. In general, the upper half of the basin is National Forest

Over 85 percent of the basin under National Forest management is tentatively suitable for the production of timber While approximately 20 percent of the suitable National Forest lands were harvested since 1950, harvesting on private lands in the 1960's and early 1970's was extensive in the western half of the basin. The type and extent of harvest and roading contributed significantly to off-Forest direct and cumulative

effects This past activity and current recovery trend, particularly sediment rates, was considered in making the above assessments

Road development within the Pistol Planning Basin is currently extensive On National Forest lands, upgrading and developing short, local roads to access harvest units is expected to be the prime engineering activity. Most of the road system is also in place on private lands. The commercial timber volume has been nearly depleted, harvest in the next few decades is expected to be very light

Due to the private land ownership being distributed along the much of the mainstem of Pistol River, benefits potentially attributable to Supplemental Resource areas is limited. Alternatives E and M provide some protection to the East Fork Pistol River by allocation to Backcountry Recreation, the other alternatives provide lesser amounts of area with no programmed harvest. Alternatives E, G, K, M, and S have a 12 percent basin harvest constraint per decade

For all alternatives except D and D1, there is an estimated negligible potential risk for timber management/road-related cumulative effects. This considers both existing conditions and anticipated levels of activity on both National Forest and other lands. Alternatives D and D1 are anticipated to result in a minor adverse potential risk for cumulative effects from timber management and road-related sedimentation. The risk of cumulative effects is further reduced in alternatives with a basin harvest constraint. For other than Alternatives D and D1, water quality is expected to be maintained or improved.

Basin 13 - Lower Chetco

In addition to salmonid habitat capability, the following includes the estimated risk to public and domestic water supplies, wildlife, fishing, boating, water contact recreation, visual quality, and navigation in terms of a potential increase in accelerated sediment and turbidity.

Estimated risk from increased sediment and turbidity.

Alternatives NC, A, A-Departure, B, C, D, D1, K, and S are **negligible.**
Alternatives E and G are **negligible (minor improvement)**
Alternative M is **negligible (moderate improvement)**

Estimated risk from increased temperature.

Alternatives NC, A, A-Departure, C, and K are **negligible** (Prescription B).
Alternatives B, D, D1, E, G, and S are **negligible (minor improvement)**(Prescription C or M).

Salmonid capability of this basin is strongly influenced by the Upper Chetco Planning Basin, which is in the Kalmiopsis Wilderness. Even though close to the ocean, low summer flows are an inherent problem in the basin (due primarily to the geology in the upper reaches). Steep, highly erodible slopes also affect the recovery of fish habitats in the basin from past activities.

About 61 percent of the Lower Chetco Planning Basin is National Forest System lands. Nearly three-quarters of the basin under National Forest management is tentatively suitable for the production of timber

The majority of private timber in the lower Chetco River drainage was logged during the latter 1950's through the early 1970's Over 30 percent of the suitable land within the National Forest has also been harvested between 1950 and 1980. The level of harvest activity in the 1980's has continued at about the same rate. Erodible soils, heavy rainfall, and older timber harvest and roading practices resulted in extensive erosion and loss of riparian vegetation on much of the private and Forest lands during the latter 1950's and 1960's Vegetative recovery since that time has resulted in mixed stands of young alder (20-40

ft high), tanoak, and second growth conifers on the majority of cut-over lands. On smaller tributary streams, many of the second-growth riparian stands are sufficient to offer good stream shade cover on both National Forest and private lands

Forest transportation systems within the Chetco watershed are extensive. Future transportation work will be limited to short roads to harvest units and upgrading of the existing system.

Seventy-four percent of the basin is tentatively suitable for timber harvest Potential sediment impacts are fairly well distributed throughout the basin in all alternatives However, Alternatives E and M reduce the spatial impacts to the suitable lands outside of the four Backcountry Recreation Management Areas.

All Alternatives include the Emily Creek Supplemental Resource Management Area. Alternatives E, G, K, M, and S have allocated the Mislatnah and South Fork Chetco Supplemental Resource areas And, as a result of the Oregon Omnibus Wild and Scenic River Act of 1988, the entire mainstem of the Chetco River within the National Forest boundary is now designated Wild and Scenic. Alternatives B, D, D1, E, G, K, M, and S have applied a basin timber harvest constraint of 10 percent per decade or less, to both disperse activity over time and space, and to allow for some recovery from prior decade activities.

For all alternatives, there is an estimated negligible potential risk for timber management/road-related cumulative effects. This considers both existing conditions and anticipated levels of activity on National Forest, BLM, and other lands. The risk of cumulative effects is further reduced in alternatives with the basin harvest constraint Water quality is expected to be maintained or improved.

Basin 14 - Upper Chetco

Essentially unchanged under all alternatives, this Planning Basin offers few opportunities for enhancement of fish habitat beyond current conditions As it is entirely within the Kalmiopsis Wilderness, risks (cumulative or otherwise) to beneficial uses of anadromous fishery, wildlife, fishing, and visual quality in terms of potential increases in sediment, turbidity, or temperature under all alternatives is negligible.

Basin 15 - Rough/Josephine.

In addition to salmonid habitat capability, the following includes the estimated risk to fishing and water contact recreation in terms of potential increase in accelerated sediment and turbidity

Estimated risk from increased sediment and turbidity.

Alternatives NC, B, C, D, and D1 are **minor adverse.**
Alternatives A, A-Departure, K, and S are **negligible.**
Alternatives E, G, and M are **negligible (minor improvement).**

Potential risk from increased temperature.

All alternatives are **negligible**

The Rough/Josephine Planning Basin has very low potential for cumulative effects and other impacts from timber harvest since very few acres (10 percent) are tentatively suitable for timber production As a result, the potential for sediment outputs is also very low Nearly three-fourths of the basin is National Forest Far less than 10 percent of the suitable National Forest lands have been harvested from 1950 to date. This basin is characterized by very sparse riparian vegetation and poor soil conditions for conifer tree growth over much of the area. There are few opportunities for improvement of riparian areas Much of the basin is in an unroaded condition

Mineral exploration and development activity for both gold and chromium ore has resulted in past heavy sediment loads to tributary streams. Similarly, the riparian vegetation along many streams was removed during these operations This situation persisted up to the 1960's

The potential sediment impacts are generally along the Babyfoot Lake access corridor, or are very localized in areas suitable for the production of timber. In Alternatives E, G, M, and S, activities are almost exclusively concentrated along the Babyfoot Lake access corridor.

Opportunities for effective Supplemental Resource Management Areas are limited Alternatives E, G, K, and M have an 11 percent per-decade basin timber harvest constraint, while Alternative S has a 17 percent harvest constraint.

For all alternatives except NC, B, C, D, and D1, there is an estimated negligible potential risk for timber management/road-related cumulative effects. This considers both existing conditions and anticipated levels of activity on mostly National Forest land and to a limited extent lands of others. Alternatives NC, B, C, D, and D1 are anticipated to result in a minor adverse potential risk for cumulative effects from timber management and road-related sedimentation. The risk of cumulative effects is further reduced in alternatives with a basin harvest constraint of either 11 or 17 percent. For other than Alternatives NC, B, C, D, and D1, water quality is expected to be maintained or improved.

Basin 16 - Winchuck

In addition to salmonid habitat capability, the following includes the estimated risk to domestic water supplies, wildlife, fishing, boating, water contact recreation, and visual quality in terms of an increase in potential sediment

Estimated risk from increased sediment and turbidity·

Alternatives NC and C are **minor adverse.**
Alternatives A, A-Departure, B, and S are **negligible.**
Alternatives D, D1, G, and K are **negligible (minor improvement)**
Alternatives E and M are **negligible (moderate improvement).**

Estimated risk from increased temperature:

Alternatives NC, A, A-Departure, C, K, and S are **negligible** (Prescription B).
Alternatives B, D, D1, E, G, and M are **negligible (minor improvement)**(Prescription C and M).

This Planning Basin has high fish and timber production capabilities Nearly 90 percent of the basin is National Forest Ninety-two percent of the total land base is classified as tentatively suitable for timber production.

About 15 percent of the suitable National Forest lands were harvested in the decade of 1970-80 A similar level of activity has continued since 1980 Extensive timber harvest occurred on privately owned portions of the lower Winchuck watershed during the 1950's and 1960's Transportation systems in the Winchuck Planning Basin are extensive Future road development is anticipated to be limited to short roads to access harvest units, plus improvement of the existing system Although the trend should be favorable for recovery, the riparian areas have not reforested sufficiently from previous timber harvest activities to measurably improve conditions over the past impacts

Many of the private timber lands and farms in the lower river reach have since been divided into home sites With continued development of off-Forest home sites, the demand for domestic water and irrigation has

greatly increased in recent years. This trend is expected to continue to the detriment of fish life in the lower Winchuck River.

All alternatives, except C, contain the Winchuck River Supplemental Resource Management Area Alternatives B, D, D1, E, G, and M have a 12 percent per-decade harvest constraint; Alternative S includes a 15 percent basin timber harvest constraint.

For all alternatives except NC and C, there is an estimated negligible potential risk for timber management/road-related cumulative effects This considers both existing conditions and anticipated levels of activity on largely National Forest lands and limited other ownerships; however, this analysis does not consider any cumulative effects associated with the South Fork Winchuck Alternatives NC and C are anticipated to result in a minor adverse potential risk for cumulative effects from timber management and road-related sedimentation The risk of cumulative effects is further reduced in alternatives with a basin harvest constraint of either 12 or 15 percent. For other than Alternatives NC and C, water quality is expected to be maintained or improved

Basin 17 - North Fork Smith River.

In addition to salmonid habitat capability, the following includes the estimated risk to fishing and visual quality in terms of an increase in potential sediment.

Estimated risk from increased sediment

All alternatives except E, G, and M are **negligible**
Alternatives E, G, and M are **negligible (minor improvement)**

Estimated risk from increased temperatures.

All Alternatives are **negligible.**

The entire North Fork Smith Planning Basin is administered by the National Forest. From 1950 to date, less than one-quarter of the National Forest lands suitable for the production of timber have been harvested This basin is characterized by rough, rugged terrain with sparse timber resources. Mineral development is a major potential activity in this area. Twenty-two percent of the land is tentatively suitable for timber production. Considerable area is within the Kalmiopsis Wilderness Only the extreme western edge of the basin (west of North Fork Smith River) is currently affected by accelerated sediment from management activities. Thirteen miles of the North Fork Smith River was included in the Omnibus Oregon Wild and Scenic Rivers Act of 1988.

Alternatives E, G, M, and S concentrate activities to the northwest, but their low sediment yield has little impact on water quality due to the limited activity area However, due to the large percentage of unsuitable land within the areas allocated to Management Areas 1-9, the difference between these alternatives and others is insignificant Alternatives except E, G, K, and M have applied an 12 percent per-decade basin timber harvest constraint Alternative S has a 17 percent harvest constraint.

For all alternatives, there is an estimated negligible potential risk for timber management/road-related cumulative effects. This considers both existing conditions and anticipated levels of activity on National Forest lands. The risk of cumulative effects is further reduced in alternatives with a basin harvest constraint of either 12 or 17 percent. Water quality is expected to be maintained or improved. No cumulative effects downstream in the Wild and Scenic North Fork Smith River are anticipated.

Basin 19 - East and West Forks Illinois River.

In addition to salmonid habitat capability, the following includes the estimated risk to public and domestic water supplies, fishing, water contact recreation, and visual quality in terms of a potential increase in accelerated sediment and turbidity

Estimated risk from increased sediment and turbidity.

Alternatives B, C, D, and D1 are **minor adverse**
Alternatives NC, A, A-Departure, K, and S are **negligible.**
Alternatives E, G, and M are **negligible (minor improvement).**

Estimated risk from increased temperature:

All Alternatives except E, G, and M are **negligible** (Prescription B)
Alternatives E, G, and M are **negligible (minor improvement)**(Prescription C or M)

The East and West Forks of the Illinois River and many of the tributaries are critical to on-site salmonid production and immediate off-Forest domestic and salmonid water needs. Elk Creek, a tributary of the West Fork Illinois River, contains one of the few remaining native coho populations in California

National Forest System lands made up less than 60 percent of this Planning Basin. Sixty percent of the National Forest portion is tentatively suitable for the production of timber Of this, 14 percent was harvested from 1950-70, and 10 percent from 1970-80. Timber harvest activity on National Forest lands in the 1980's has continued at about the same level. Some harvest on private and BLM lands also occurred during the 1980's, but was rather limited For a more indepth evaluation of cumulative effects in this Planning Basin, refer to the Planning Records (Forest Service document titled, "Cumulative Effects Analysis for the East Fork Illinois River basin"; September 15, 1986).

The largest single activity in the basin, much being timber salvage on prior managed lands, occurred as a result of the Longwood Fire in 1987 Several Environmental Assessments or Revisions were prepared for the salvage of the fire-killed trees; these documents are in the Planning Records of the Illinois Valley Ranger District and the Supervisor's Office. Impacts on the fish, soil, and water resources were analyzed, along with the cumulative effects, of the fire salvage projects.

Extensive timber harvest activity, with little regard for fish habitat or water quality, occurred on private lands of the Elk Creek and East Fork Illinois River drainages during the 1950's and 1960's. Compounding this, the demand for the limited water supply during the late summer results in lower Elk Creek and the East Fork having no surface flow in many areas. This dewatering also affects salmonid fish capability of the National Forest portion of this watershed since many juvenile fish produced on the Forest attempt to rear in the lower portions of the watershed The demand for good quality water has had a cumulative effect on the other beneficial uses of water within the basin

Due to the relative stability of adjacent slopes of many riparian in this basin that are also suitable for timber management, the potentially significant impact on water quality and fish habitat is directed to adequacy of streamside shade. Therefore, Riparian prescriptions are highly oriented to shade maintenance; use of more restrictive land allocations provide little additional reduction in risk Alternatives E, G, K, M, and S have a 12 percent per-decade basin harvest constraint

For all alternatives except B, C, D, and D1, there is an estimated negligible potential risk for wildfire and timber management/road-related cumulative effects. This analysis considers both existing conditions, including the Longwood Fire of 1987, and anticipated levels of activity on National Forest, BLM, and other lands. Alternatives B, C, D, and D1 are anticipated to result in a minor adverse potential risk for cumulative

effects from wildfire, timber management, and road-related sedimentation The risk of cumulative effects is reduced in alternatives with the basin harvest constraint For other than Alternatives B, C, D, and D1, water quality is expected to be maintained or improved

Basin 20 - Sucker.

In addition to salmonid habitat capability, the following includes the estimated risk to public and domestic water supplies, irrigation, fishing, and visual quality in terms of potential accelerated sediment and turbidity

Estimated risk from increased sediment and turbidity·

All alternatives except E, G, and M are **negligible**
Alternatives E and G are ***negligible (minor improvement)***
Alternative M is **negligible (moderate improvement)**

Estimated risk from increased temperature

All Alternatives except E, G, and M are **negligible** (Prescription B).
Alternatives E, G, and M are **negligible (minor improvement)**(Prescription C and M).

This basin has had extensive past and current mining and timber harvest activities. Seventy-one percent of total basin acreage is tentatively suitable for timber production. Landforms and effects of management activities are very similar to the East and West Fork Illinois Planning Basin

Sixty percent of the basin in National Forest System land. Of this, about 70 percent is tentatively suitable for the production of timber. Between 1950-1970, 11 percent of the National Forest timber lands were harvested; 11 percent was also harvested for the decade 1970-1980. About the same level of activity has continued through the 1980's.

Currently, irrigation and domestic demands for water in off-Forest portions of Sucker Creek essentially dry up the stream by late summer. The effects of water withdrawal in these private land reaches of Sucker Creek and for miles downstream in the Illinois River system is significant relative to both the instream habitat for fisheries, and recreational and esthetic values along the Wild and Scenic River

As with the East and West Fork Illinois Planning Basin, Riparian prescriptions are aligned to maintenance of stream canopy shade The use of Supplemental Resource areas provide little extra in reducing sediment or stream temperature risks Alternative E, G, K, and M have a 13 percent per-decade basin timber harvest constraint; Alternative S provides a 17 percent constraint. This assessment of effects also considered the cumulative effects of past mining activities

For all alternatives, there is an estimated negligible potential risk for timber management/road-related cumulative effects. This considers both existing conditions and anticipated levels of activity on National Forest, BLM, and other lands The risk of cumulative effects is further reduced in alternatives with a basin harvest constraint of either 13 or 17 percent. Water quality is expected to be maintained or improved

SUMMARY OF FOREST-WIDE EFFECTS ON FISH HABITAT BY ALTERNATIVE

The following discussion summarizes the analysis of each alternative for effects on fish habitat from the composite of the 19 Planning Basins. The currently most important basins in terms of opportunities for instream fish habitat improvements are the· East and West Forks Illinois, Lower Chetco, Galice/Slate, Winchuck, Briggs, and Lower Rogue. Capital investments are not included in this evaluation

Alternatives NC, A, and A-Departure

These alternatives would be expected to result in an estimated potential risk to salmonid fish habitat capability ranging from negligible to minor adverse. The Indigo, Silver, Briggs, Rough/Josephine, and Winchuck Planning Basins, if managed under Alternative NC, would have a minor adverse risk to salmonid habitat from timber management/road-related sedimentation Briggs, Indigo, and Silver Planning Basins, if managed under Alternatives A or A-Departure, would have a minor adverse risk to salmonid habitat from timber management/road-related sedimentation. The potential increase in risks from either sediment or temperature is negligible in all other basins

Alternative B

Alternative B would be expected to result in an estimated risk to salmonid fish habitat capability ranging from negligible (minor improvement) to moderate adverse. A potential risk of minor adverse impacts to salmonid habitat from timber management/road-related sedimentation is predicted in the Galice/Slate, Lower Illinois, Briggs, Silver, Rough/Josephine, and East and West Forks Illinois Planning Basins A potential risk of moderate adverse impacts is predicted for Indigo Planning Basin A potential for minor improvement in salmonid habitat is predicted for the Elk/Sixes and Lobster Planning Basins. All other basins would have negligible increases in risk from sediment or temperature changes.

Alternative C

Alternative C would be expected to result in an estimated risk to salmonid fish habitat capability ranging from negligible to moderate adverse A potential risk of minor adverse impacts to salmonid habitat is predicted in the Upper Rogue, Galice/Slate, Lower Illinois, Briggs, Rough/Josephine, Winchuck, and East and West Forks Illinois Planning Basins from timber management/road-related sedimentation, and a potential risk of moderate adverse impacts for the Indigo and Silver Planning Basins. All other basins would have negligible predicted increases in risk from sediment or temperature changes

Alternatives D and D1

Alternatives D and D1 would be expected to result in an estimated risk to salmonid fish habitat capability ranging from negligible (minor improvement) to moderate adverse. A potential risk of minor adverse impacts to salmonid habitat is predicted in the Lobster (Alternative D1 only), Galice/Slate, Lower Illinois, Briggs, Pistol, Silver, Rough/Josephine, and East and West Forks Illinois Planning Basins from timber management/road-related sedimentation A potential risk of moderate adverse impacts is predicted for Indigo Planning Basin. A potential for minor improvement in salmonid habitat is predicted for the Elk/Sixes and Winchuck Planning Basins All other basins would have negligible increases in predicted risk from sediment or temperature changes.

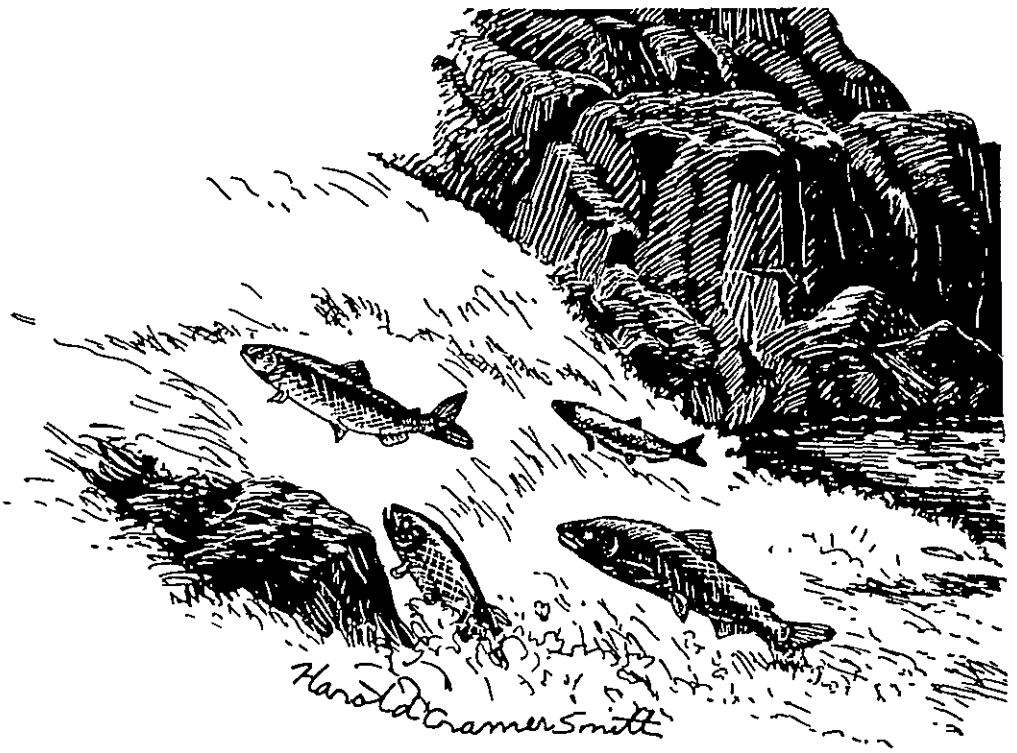
Alternatives E and G

Alternatives E and G would be expected to result in an estimated risk to salmonid fish habitat capability ranging from negligible to negligible (moderate improvement). For the Galice/Slate, Briggs, Indigo, and Silver Planning Basins, the risk to salmonid habitat is negligible. For the Elk/Sixes and Winchuck (Alternative E only) Planning Basins, there is the potential for moderate improvement in salmonid habitat For all remaining basins there is the potential for minor improvement in salmonid habitat capability.

Alternative K

Alternative K would be expected to result in either an estimated negligible to minor adverse risks to salmonid fish habitat capability, or minor improvement in current salmonid habitat conditions For the Elk/Sixes, Winchuck, South Fork Coquille, Lobster, and Pistol Planning Basins, there is the potential for

minor improvement in salmonid habitat. A potential risk of minor adverse impacts is predicted for Silver and Indigo Planning Basins All other basins would have negligible increases in predicted risk from sediment or temperature changes.



Alternative M

Alternative M would be expected to result in an estimated moderate improvement in salmonid fish habitat capability in all but five of the basins analyzed Current salmonid habitat conditions have potential for only minor improvement in the East and West Fork Illinois, Upper Illinois, Briggs, Rough/Josephine, and the North Fork Smith Planning Basins

Alternative S

Alternative S would be expected to result in either an estimated negligible to minor adverse risk to salmonid fish habitat capability, or minor improvement in current salmonid habitat conditions. For the Elk/Sixes, South Fork Coquille, Lobster, and Pistol Planning Basins, there is the potential for minor improvement in salmonid habitat. All other basins would have negligible increases in predicted risk from sediment or temperature changes.

Minor improvements of salmonid fish habitat are also predicted for all priority basins for instream fish habitat improvements due to the application of Riparian Prescription C, or the inclusion of selected land allocations in Management Areas 1-9.

WILDLIFE

SIGNIFICANT INTERACTIONS

Recreation does not generally have a major adverse effect on wildlife resources However, site-specific impacts, due to developed recreation sites, trail construction, or dispersed activities, such as ORV use or hunting, will have adverse effects on localized wildlife communities Many wildlife species benefit from small, dispersed openings which are characteristic of areas managed to achieve the VQO's of Retention and Partial Retention

Timber management activities generally improve the quantity of food resources for black-tail deer, Roosevelt elk, and many other game and nongame species Early successional stages resulting from timber harvest provide cover for a variety of wildlife Timber management activities can generally improve food resources for mountain quail, most other game birds, and a variety of nongame species Timber management activities may also limit many animals which frequent mature or old-growth forest, including such birds as the goshawk, saw-whet owl, and Hammond's flycatcher.

Snag levels in unmanaged forest support 100 percent population levels of all woodpecker species. In managed timber stands, Wildlife Tree Guidelines are employed to ensure that affected species will be maintained at either 20 or 60 percent of their maximum population potential The percent level depends on which Forest Plan alternative is employed; current Forest policy is 60 percent. The 20 percent level is the MR and the 60 percent level provides a highly viable population (Thomas 1979).

Roads needed for access to timber harvest areas allow the public greater access to wildlife habitat. Although roads provide travelways for many species, roads which remain open may result in increased road mortality Road building results in a direct loss of wildlife habitat. Increased vehicle access results in increased vulnerability of animals to both legal and illegal harvest.

Wildlife habitat is disturbed by new road construction This activity displaces one population segment into the territory of another, resulting in increased competition for space and forage (Brown 1985). Increased access has a short-term detrimental effect on species that adjust to road traffic (such as songbirds and squirrels), but will negatively affect other species which avoid the activities of humans (such as elk, bear, and cougar).

The suitability of vegetative cover for wildlife is modified by the amount of roads open to the public. The effectiveness of wildlife hiding cover is reduced by an increase in roads Often it is the use of roads, rather than the roads themselves, that negatively affect local wildlife. Specific roads can be closed to protect wildlife travel corridors or hiding cover. Closed roads can be seeded to provide additional forage. Seeded cut and fill slopes provide some forage for wildlife Deer and elk use of otherwise suitable feeding and resting areas is reduced adjacent to open primary and secondary roads (Brown 1985:241)

Mining activities may adversely affect wildlife needs Wildlife habitats may be modified and species distribution influenced Wildlife may be exposed to toxic substances used or uncovered during mining activities Vehicle use and other mining activities produce noise, which may affect calving, feeding, migration, and other activities of wildlife. Reclamation may create additional forage areas and wildlife sighting opportunities

Direct interactions between fire and wildlife populations vary widely While some evidence of vertebrate mortality has been reported, the most commonly held opinion is that vertebrates are rarely killed in fires, instances of mortality are usually negligible. Interactions with invertebrate populations may be short-term or long-lasting Population levels may decrease because the individuals or their eggs are killed, or their food supply or shelter are diminished. In some instances, populations of some species which are attracted to heat, smoke, or damaged trees may increase during and after the fire.

The immediate post-fire environment presents all terrestrial wildlife with a sudden and drastic modification of habitat structure and local microclimates This may have positive or negative influences depending on the species involved Long-term influence of post-fire vegetation succession on wildlife populations cannot be generalized Vegetation growth and change provide the driving force for a dynamic system in which some species are favored, while others are not (Lyon and others 1978).

Land allocations affect wildlife populations. Designated Wildlife Habitat and Special Wildlife Site Management Areas maintain animal populations dependent on habitats which are scarce or diminishing as more of the Forest is brought into a managed rotation The description and size of each wildlife management area is included in the description of alternatives (Chapter II). Permitted activities and mitigation measures for each Management Area are included in Standards and Guidelines (Forest Plan, Chapter IV).

RESPONSE TO THE PLANNING PROBLEMS

In the following discussions on environmental effects of the alternatives, Planning Problem #7, is addressed in depth This Planning Problem asks, "How should wildlife habitats on the Forest be managed?" Two other Planning Problems are addressed indirectly: #1, "How much timber should the Forest produce?"; #2, "How much old-growth forest should be preserved?"

ENVIRONMENTAL EFFECTS AND MITIGATION

The management objective for wildlife resources is to provide habitat capable of indefinitely supporting all native and desirable nonnative wildlife species All alternatives are designed to meet this objective in at least a minimally adequate fashion. Alternatives that allocate relatively large amounts of land for preservation of specific wildlife resources result in the best long-term protection Alternatives that allocate the most land to categories other than General Forest, especially Backcountry Recreation, also result *(de facto)* in the best level of protection for species requiring older forest successional stages Alternatives with lower timber harvests also have fewer roads; this generally means less potential disturbance to wildlife in general, and especially big game.

All alternatives except NC provide a mix of habitats capable of sustaining all species at viable population levels or higher over the long term Refer to the **WILDLIFE** section of Chapter II for discussion of Management Requirements (MR's) for spotted owls. MR's for wildlife ensure that viable populations of all species will be well-distributed throughout the Siskiyou. All alternatives except NC are bound by MR's. The major difference between other alternatives and NC relates to management of habitat for species dependent on mature or old-growth forest This alternative makes no provisions for habitat enclaves devoted to pileated woodpeckers, pine marten, and the species they represent.

Some alternatives provide for significantly more old-growth habitat; this habitat type will gradually diminish and by the fifth decade will be greatly reduced in commodity-oriented alternatives. Various alternatives provide for woodpecker populations at the 60 percent level, other alternatives provide snags for 20 percent of the woodpecker population (MR level)

Various alternatives provide significantly more foraging habitat for deer and elk (although less thermal cover) Eagle and osprey habitat is protected in all alternatives

All alternatives contain land allocations for special wildlife habitats not represented by indicator species. Table II-3 describes these habitats. More riparian habitat, hardwood stands, meadows, and other special sites are allocated in some alternatives than in others

All alternatives provide for capital investment in wildlife habitat improvement projects through implementation of all or part of the Forest's Comprehensive Fish and Wildlife Plan (Sikes Act--Public Law

93-452), plus K-V (Knutson-Vandenberg) projects. If funding is made available to implement wildlife habitat improvement projects identified in Appendix B of the Forest Plan, total habitat capability would increase for many species (especially deer and elk)

In alternatives where a decrease in "hunting" WFUD's is associated with a decline in habitat capability for deer and elk (see **WILDLIFE** section of Chapter II), the falldown may not actually be as great as predicted. Hunters may accept lower success rates, in fact, hunter success has decreased markedly on the Siskiyou in the last 25 years, but hunter-days have increased substantially (see **WILDLIFE** section [Consumptive Use] of Chapter III)

There are two methods of managing wildlife resources protection and standards Protection involves designation of specific sites as Designated Wildlife Habitat, Special Wildlife Sites, and Supplemental Resource Management Areas In other areas, such as General Forest, Forest-wide Standards and Guidelines for wildlife resources will guide timber management, road building, mining, and livestock grazing.

MITIGATION. Standards and Guidelines provide the necessary provisions to ameliorate major adverse consequences of the alternatives. However, some habitat changes can only be partially mitigated The amount of mature and old-growth habitat will be reduced substantially under most alternatives. Habitat for cavity nesters will decline, as will optimal thermal cover.

The Forest can protect spotted owl nest and roost sites found outside of designated SOHA's (in areas managed for timber) Chapter IV (Forest-wide Standards and Guidelines) of the Forest Plan provides specific details. Designated SOHA's, as well as habitat in Wilderness and other reserved areas, can be monitored to determine pair occupancy and reproductive status within sites allocated for spotted owls. General population trends for spotted owls can be determined through random samples of suitable habitat Chapter V of the Forest Plan provides more detail on monitoring For at least the next decade, the Forest has the flexibility to modify the SOHA network to accommodate changes caused by fire or other catastrophic events For at least the next five to ten years, the Forest would also be able to expand the size of most SOHA's, if current research shows a need to do so

Alternative NC

DIRECT EFFECTS. Alternative NC continues the management regime responsible for the Forest's existing condition. This is the only alternative which will not provide for the long-term viability of populations of wildlife species that are dependent on mature or old-growth Forest; NFMA MR's are not incorporated Alternative NC would not supply enough mature or old-growth habitat within General Forest land, both in terms of block size (acres), and dispersion. The eastern portion of the Illinois Valley Ranger District would be particularly lacking in this habitat Populations of some species would ultimately be reduced to below-minimum levels

Pileated woodpeckers, pine martens, and spotted owls represent all wildlife species on the Forest that are dependent on mature or old-growth habitat No provisions for habitat for pileated woodpecker, pine marten, and the species they represent are made in this alternative. In addition, spotted owl enclaves are limited to 300 acres of old growth per pair, are not well dispersed, and provide for only 32 owl pairs Management Requirements are not met for this species

In the short term (first decade), some options are maintained to allocate specific habitat sites for wildlife Over the long term (by the third decade), some species may disappear from the Siskiyou because of Forest Service actions, and opportunities to allocate specific habitat sites for wildlife would diminish quickly as options are foregone.

A significant adverse effect results from the 20 percent basin constraint (up to 20 percent of the land tentatively suitable for timber production in an individual basin can be programmed for harvest per decade). Because the average harvest rotation on the Forest is 100 years, up to twice as much land could be harvested per decade in a given basin as could be sustained over the long term This could cause a maldistribution of successional stages over time which would have a detrimental effect on habitat diversity.

In Alternative NC, a small number of Special Wildlife Sites are allocated directly for wildlife, plus one of the four Supplemental Resource areas most important to wildlife (Windy Valley) Eighteen Supplemental Resource Management Areas are designated, providing significant habitat diversity for wildlife. Other new land allocations which would contribute to overall habitat diversity, such as Botanical or Unique Interest areas, are not selected in this alternative. Standards and Guidelines are used to govern management of specific wildlife resources

Just over 58,000 acres of prime habitat for bald eagle and osprey have been identified on the Forest; nearly 55,000 acres are safeguarded. Additional secondary habitat is available in the short term, but will eventually be altered by timber harvest.

At the beginning of the second decade, 113, 602, and 2,730 habitat areas will be available for spotted owls, pileated woodpeckers, and pine marten, respectively By the fifth decade the numbers will decrease to 32, 335, and 1,370. Habitat capability for woodpeckers will be sustained at 60 percent in areas managed for timber

Fifty-three percent of the Forest (576,000 acres) is managed for timber harvest and, consequently, a sustained supply of forage for deer and elk will be provided During the first five decades, habitat capability for deer and elk will average nine percent over current levels, for an average herd size of 30,800 animals (down from 28,300 at present).

Riparian areas are managed through the application of Standards and Guidelines; 81,300 acres of riparian habitat are managed, in part, for timber under Prescription B Twelve major stream corridors are allocated to Supplemental Resource, and five of eleven types of wildlife sites are protected, including meadows and wildlife areas. Meadow edges receive no special protection

INDIRECT EFFECTS Wildlife will continue to supply significant recreation to the public. The first five decades average 85,300 WFUD's annually, a five percent increase from the present situation No capital investments are made for habitat improvement projects

Habitat allocations for Wildlife Special Sites and Designated Habitat will result in a slight reduction in the amount of land available for timber management; 6,450 acres fall in this category, although many sites contain overlapping land allocations installed to meet other resource objectives.

CUMULATIVE EFFECTS. The average 100-year rotation applied to areas managed for timber will provide a continual rotating supply of habitat to those wildlife species dependent on early successional stages. However, habitat for species dependent on old-growth forest will undergo a 53 percent reduction during the next 50 years (73 percent by the tenth decade). Open roads reduce habitat capability for some species of wildlife, especially elk. By the fifth decade, the Forest road system will total 3,884 miles, with 749 miles closed to vehicular traffic. First decade figures are 2,875 and 347, respectively

Alternative A

DIRECT EFFECTS. Alternative A continues the management regime responsible for the Forest's existing condition. In the short term (first decade), this alternative does a reasonable job of maintaining a diversity of wildlife habitats. Over the long term (by the fifth decade), no species would disappear from the Siskiyou

because of Forest Service actions, but opportunities to allocate specific habitat sites for wildlife would diminish significantly as options are foregone.

A significant adverse effect results from the 20 percent basin constraint (up to 20 percent of the land tentatively suitable for timber production in an individual basin can be programmed for harvest per decade). Because the average harvest rotation on the Forest is 100 years, up to twice as much land could be harvested each decade in a given basin as could be sustained over the long term. This could cause a maldistribution of successional stages over time which would have a detrimental effect on habitat diversity.

In Alternative A, a small number of Special Wildlife Sites are allocated directly for wildlife, plus one of the four Supplemental Resource areas most important to wildlife (Windy Valley). Eighteen Supplemental Resource Management Areas are designated, providing significant habitat diversity for wildlife. Designated Wildlife Habitat areas are allocated at MR levels. Other new land allocations which would contribute to overall habitat diversity, such as Botanical or Unique Interest areas, are not selected in this alternative. Standards and Guidelines are used to govern management of specific wildlife resources. Capital investments for wildlife habitat improvements will result in increased habitat carrying capacity for many wildlife species in specific local areas, $56,000 per year is programmed

Just over 58,000 acres of prime habitat for bald eagle and osprey has been identified on the Forest, nearly 55,000 acres are safeguarded Additional secondary habitat is available in the short term, but will eventually be altered by timber harvest.

At the beginning of the second decade, 137, 607, and 2,387 habitat areas will be available for spotted owl, pileated woodpecker, and pine marten, respectively By the fifth decade the numbers will decrease to 90, 357, and 1,450. Habitat capability for woodpeckers will be sustained at 60 percent in areas managed for timber

Fifty-one percent of the Forest (557,000 acres) is managed for timber harvest and, consequently, a sustained supply of forage for deer and elk will be provided. During the first five decades, habitat capability for deer and elk will average eight percent above current levels for an average herd size of 30,500 animals (up from 28,300 at present)

Riparian areas are managed through the application of Standards and Guidelines; 84,600 acres of riparian habitat are managed, in part, for timber under Prescription B Twelve major stream corridors are allocated to Supplemental Resource areas, and five of 11 types of wildlife sites are protected, including meadows and wildlife areas. Meadow edges receive no special protection

INDIRECT EFFECTS. Wildlife will continue to supply significant recreation to the public. The first five decades average 91,700 WFUD's annually, a 13 percent increase from the current situation; 7,400 WFUD's are derived from habitat improvement projects. If improvement projects are not funded, total WFUD's would be reduced to 84,300 annually, still an increase of four percent over the present situation

Habitat allocations for Wildlife Special Sites and Designated Habitat will result in a reduction in the amount of land available for timber management, 31,824 acres fall in this category, although many sites contain overlapping land allocations installed to meet other resource objectives

CUMULATIVE EFFECTS. The average 100-year rotation applied to areas managed for timber will provide a continual rotating supply of habitat to those wildlife species dependent on early successional stages. However, habitat for species dependent on old-growth forest will undergo a 51 percent reduction during the next 50 years (68 percent by the tenth decade) Open roads reduce habitat capability for some species of wildlife, especially elk. By the fifth decade, the Forest road system will total 3,884 miles, with 749 miles closed to vehicular traffic. First decade figures are 2,875 and 347, respectively.

Alternative A-Departure

The following effects are the same as Alternative A, except for the following differences due to increased timber harvest in the first two decades.

DIRECT EFFECTS. At the beginning of the second decade, 137, 605, and 2,381 habitat areas will be available for spotted owl, pileated woodpecker, and pine marten, respectively. By the fifth decade the numbers will decrease to 90, 357, and 1,450. During the first five decades habitat capability for deer and elk will average nine percent above current levels, for an average herd size of 30,800 animals (up from 28,300 at present).

INDIRECT EFFECTS. The first five decades average 92,100 WFUD's annually, a 14 percent increase from the existing situation, but include 7,400 WFUD's attributed to habitat improvement projects If improvement projects are not funded, total WFUD's would be 84,700 annually, or a five percent increase from present.

CUMULATIVE EFFECTS. Habitat for species dependent on old-growth forest will undergo a 51 percent reduction during the next 50 years (68 percent by the tenth decade). Because the annual timber harvest will be based on a departure schedule in this alternative, the reduction in old-growth habitat will be more pronounced during the first two decades. Open roads reduce habitat capability for some species of wildlife, especially elk. By the fifth decade the Forest road system will total 3,889 miles, with 752 miles closed to vehicular traffic (first decade figures are 2,876 and 348).

Alternative B

DIRECT EFFECTS In the short term (first decade) this alternative does a reasonable job of maintaining a diversity of wildlife habitats Over the long term (by the fifth decade), no species would disappear from the Siskiyou because of Forest Service actions, but opportunities to allocate specific habitat sites for wildlife would diminish significantly as options are relinquished. Because timber harvest is accelerated in the first two decades, options for reallocations would diminish with relative quickness.

A pair of 20 percent constraints are significant detriments of this alternative. First, habitat capability for woodpeckers will be sustained at 20 percent in areas managed for timber; this will maintain a minimally viable population which has little influence on its habitat. Second, a 20 percent basin constraint is applied to 12 of the Forest's 19 planning basins (in these basins up to 20 percent of the land tentatively suitable for timber production can be programmed for harvest per decade). Because the average harvest rotation on the Forest is 100 years, up to twice as much land could be harvested each decade in a given basin as could be sustained over the long term This could cause a maldistribution of successional stages over time and have a detrimental effect on habitat diversity. Another seven basins are constrained at 9-13 percent per decade; in these areas, successional stage distribution over time would be satisfactory The last basin is contained within the Kalmiopsis Wilderness and harvest constraints do not apply

None of the four Supplemental Resource Management Areas with high priority for wildlife are allocated, although 15 other designated Supplemental Resource areas provide habitat diversity for wildlife Designated Habitat areas are allocated at MR levels A few other new land allocations which contribute to overall habitat diversity, such as Botanical or Unique Interest areas, are selected, but the land sites represented are mostly serpentine areas and other relatively open vegetative types. Standards and Guidelines are used to govern management of specific wildlife resources

Capital investments for wildlife habitat improvements will result in increased habitat carrying capacity for many wildlife species in specific local areas, $109,800 per year is programmed to meet RPA targets of 4,549 acres of habitat improvement. This is nearly a seven-fold increase in improvements over the projects listed in the Forest's Fish and Wildlife Comprehensive Plan These additional projects would be accomplished, for example, by seeding edges of clearcuts.

Just over 58,000 acres of prime habitat for bald eagle and osprey have been identified on the Forest; slightly less than 49,000 acres are safeguarded Additional secondary habitat is available in the short-term, but will eventually be altered by timber harvest.

At the end of the first decade, 135, 583, and 2,300 Habitat areas will be available for spotted owl, pileated woodpecker, and pine marten, respectively By the fifth decade the numbers will decrease to 81, 327, and 1,337. Fifty-one percent of the Forest (558,000 acres) is managed for timber harvest and consequently will provide a sustained supply of forage for deer and elk During the first five decades habitat capability for deer and elk will average 11 percent above current levels, for an average herd size of 31,300 animals (up from 28,300 at present)

Riparian areas are managed through the application of Standards and Guidelines; 84,300 acres of riparian habitat are managed, in part, for timber. Twelve basins are managed under Prescription B and six under Prescription C; the latter prescription provides less risk of adverse impacts to wildlife Thirteen major stream corridors are classed as Supplemental Resource areas, and five of 11 types of wildlife sites are protected, including all water-related sites and meadows (with their buffers).

INDIRECT EFFECTS. Wildlife will continue to supply significant recreation to the public. The first five decades average 99,900 WFUD's annually. This is a twenty-three percent increase from the current situation, and includes 14,500 WFUD's attributed to habitat improvement projects If improvement projects are not funded, total WFUD's would be reduced to 85,400 annually, or a six percent increase from the existing situation.

Habitat allocations for Special Wildlife Sites and Designated Wildlife Habitat will result in a reduction in the amount of land available for timber management; 34,507 acres falls in this category, although many sites contain overlapping land allocations installed to meet other resource objectives

CUMULATIVE EFFECTS. The average 100-year rotation applied to areas managed for timber will provide a continual rotating supply of habitat to those wildlife species dependent on early successional stages However, habitat for species dependent on old-growth forest will undergo a 56 percent reduction during the next 50 years (69 percent by the tenth decade) Because the annual timber harvest on the Siskiyou will be based on a departure schedule in this alternative, the reduction in old-growth habitat will be more pronounced during the first two decades. Open roads reduce habitat capability for some species of wildlife, especially elk. By the fifth decade the Forest road system will total 3,960 miles, with 783 miles closed to vehicular traffic (first decade figures are 2,922 and 368).

Alternative C

DIRECT EFFECTS. Same as Alternative B, except for the following differences. Land allocations which provide for a diversity of wildlife habitats are at a minimum. The Forest is managed to produce a nondeclining flow of timber throughout the next 150 years, rather than the accelerated harvest prescribed in Alternative B during the first two decades, thus options for reallocations would not diminish as quickly. The 20 percent per decade harvest constraint is applied to all basins

Only three Supplemental Resource Management Areas are designated, none of the four areas with high priority for wildlife are included At the beginning of the second decade, 136, 623, and 2,450 habitat areas will be available for spotted owl, pileated woodpecker, and pine marten, respectively. By the fifth decade the numbers will decrease to 86, 343, and 1,400 Fifty-two percent of the Forest (566,000 acres) is managed for timber harvest and consequently will provide a sustained supply of forage for deer and elk. During the first five decades the deer herd will average 17 percent above current levels (28,300), for an average herd size of 33,000 animals.

Riparian areas are managed through the application of Standards and Guidelines; 86,000 acres of riparian habitat are managed, in part, for timber. Only one major stream corridor is classed as Supplemental Resource areas, and 5 of 11 types of wildlife sites are protected, including all water-related sites and meadows (with buffers).

INDIRECT EFFECTS. Same as Alternative B, except for the following differences. Wildlife will continue to supply significant recreation to the public The first five decades average 95,100 WFUD's annually This is an 18 percent increase from the existing situation, and includes 7,400 WFUD's attributed to habitat improvement projects. If improvement projects are not funded, total WFUD's would be reduced to 87,700 annually, still an eight percent increase over the present situation.

CUMULATIVE EFFECTS. The average 100-year rotation applied to areas managed for timber will provide a continual rotating supply of habitat to those wildlife species dependent on early successional stages. However, habitat for species dependent on old-growth forest will undergo a 53 percent reduction during the next 50 years (70 percent by the tenth decade). Open roads reduce habitat capability for some species of wildlife, especially elk By the fifth decade the Forest road system will total 4,072 miles, with 825 miles closed to vehicular traffic (first decade figures are 2,953 and 377).

Alternative D

DIRECT EFFECTS. Same as Alternative B, except for the following differences. Land allocations which provide for a diversity of wildlife habitats are at a minimum The Forest is managed to produce a nondeclining flow of timber throughout the next 150 years, rather than the accelerated harvest prescribed in Alternative B; thus options for reallocations would not diminish as quickly

Capital investments for wildlife habitat improvements are programmed at $28,000 per year

At the beginning of the second decade 137, 615, and 2,200 habitat areas will be available for spotted owl, pileated woodpecker, and pine marten, respectively. By the fifth decade the numbers will decrease to 89, 355, and 1,444.

The 51 percent (558,000 acres) of the Forest managed for timber harvest will provide a sustained supply of forage for deer and elk. During the first five decades habitat capability for deer and elk will average 11 percent above current levels, for an average herd size of 31,400 animals (up from 28,300 at present).

INDIRECT EFFECTS. Same as Alternative B, except for the following differences. The first five decades average 89,500 WFUD's annually. This is an 11 percent increase from Alternative A, and includes 3,700 WFUD's attributed to habitat improvement projects. If improvement projects are not funded, total WFUD's would be reduced to 85,800 annually, or a six percent increase from the present situation.

CUMULATIVE EFFECTS. The average 100-year rotation applied to areas managed for timber will provide a continual rotating supply of habitat to those wildlife species dependent on early successional stages However, habitat for species dependent on old-growth forest will undergo a 51 percent reduction during the next 50 years (69 percent by the tenth decade). Open roads reduce habitat capability for some species of wildlife, especially elk. By the fifth decade the Forest road system will total 3,933 miles, with 768 miles closed to vehicular traffic (first decade figures are 2,916 and 362).

Alternative D1

DIRECT EFFECTS. Same as Alternative B, except for the following differences At the beginning of the second decade 135, 592, and 2,331 habitat areas will be available for spotted owl, pileated woodpecker, and pine marten, respectively. By the fifth decade the numbers will decrease to 80, 323, and 1325 Fifty-one percent of the Forest (558,000 acres) is managed for timber harvest and consequently will provide a

sustained supply of forage for deer and elk During the first five decades habitat capability for deer and elk will average 12 percent above current levels, for an average herd size of 31,700 animals (up from 28,300 at present). Rotation lengths are two decades shorter in Alternative D1; this means that a relatively high proportion of the area managed for timber will consist of forage habitat (25 percent versus 20 percent) However, this supplement is partially offset by the smaller land base devoted to timber management in this alternative Riparian areas are managed through the application of Standards and Guidelines, 77,400 acres of riparian habitat are managed, in part, for timber

INDIRECT EFFECTS. Same as Alternative B, except for the following differences. The first five decades average 93,900 WFUD's annually This is a 16 percent increase from the existing situation, and includes 7,400 WFUD's attributed to habitat improvement projects. If improvement projects are not funded, total WFUD's would be reduced to 86,500 annually, or a seven percent increase from the present situation

CUMULATIVE EFFECTS. The average 80-year rotation applied to areas managed for timber will provide a continual rotating supply of habitat to those wildlife species dependent on early successional stages However, habitat for species dependent on old-growth forest will undergo a 56 percent reduction during the next 50 years (69 percent by the tenth decade). Open roads reduce habitat capability for some species of wildlife, especially elk. By the fifth decade the Forest road system will total 3,936 miles, with 770 miles closed to vehicular traffic (first decade figures are 2,915 and 362).

Alternative E

DIRECT EFFECTS. This alternative does a reasonably good job of providing a variety of habitats for Siskiyou wildlife In the short term (first decade) this alternative does well in maintaining a diversity of wildlife habitats. Over the long term (by the fifth decade), all species would be maintained above minimum viable levels, and most opportunities to allocate specific habitat sites for wildlife would still be available. All planning basins are constrained at 9-13 percent per decade, which results in a reasonable distribution of successional stages over time.

Overall, this alternative provides significant habitat diversity for wildlife Among the important land allocations are all Special Wildlife Sites, plus 48 Supplemental Resource areas, including the four with the highest priority for wildlife (Fishhook Peak, Morris Rodgers, Pebble Hill, and Windy Valley).
Designated Wildlife Habitat areas are allocated at 14,561 acres above MR levels This includes 18,086 acres of habitat (mostly small blocks of mature or old-growth forest unsuitable for timber management) incorporated into the MR network as "stepping stones" between some individual Designated Wildlife habitat areas. A variety of new land allocations which contribute to overall habitat diversity, such as Botanical, RNA, or Unique Interest areas, are selected, representing a variety of habitat types.

All roadless areas are designated Backcountry Recreation; this results in a relatively small proportion of the Forest managed for timber, and young successional stages Species needing early successional stages are provided with a less than optimum amount of habitat. Standards and Guidelines are used to govern management of specific wildlife resources. Capital investments for wildlife habitat improvements will result in increased habitat carrying capacity for many wildlife species in specific local areas; $56,000 per year is programmed.

Just over 58,000 acres of prime habitat for bald eagle and osprey have been identified on the Forest, all are safeguarded in this alternative. Additional secondary habitat is available in the short-term, but some will eventually be altered by timber harvest.

At the end of the first decade, 147, 643, and 2,525 habitat areas will be available for spotted owl, pileated woodpecker, and pine marten, respectively By the fifth decade the numbers will decrease to 129, 528, and 2,094. Habitat capability for woodpeckers will be sustained at 60 percent in areas managed for timber; this level provides for a highly viable population

Twenty-six percent of the Forest (287,000 acres) is managed for timber harvest and consequently will provide a sustained supply of forage for deer and elk. During the first five decades habitat capability for deer and elk will average 24 percent below current levels, for an average herd size of 21,600 animals (considerably down from 28,300 at present).

Riparian areas are managed through the application of Standards and Guidelines. All basins are managed at Minimum Level (no timber harvest), this prescription results in slightly improved cover for wildlife over Prescription C. All types of wildlife sites are protected, including general wildlife areas, all water-related sites, and meadows with their buffers.

INDIRECT EFFECTS. Wildlife will continue to supply significant recreation to the public. The first five decades average 79,800 WFUD's annually. This is a one percent decrease from the current situation, and includes 7,400 WFUD's attributed to habitat improvement projects. If improvement projects are not funded, total WFUD's would be reduced to 72,400 annually, or an 11 percent reduction from the present situation. Habitat allocations for Special Wildlife Sites, Designated Wildlife Habitat, and Supplemental Resource areas (the areas most important for wildlife) will result in a reduction in the amount of land available for timber management; 58,670 acres fall in this category, although many sites contain overlapping land allocations installed to meet other resource objectives.

CUMULATIVE EFFECTS. The average 100-year rotation applied to areas managed for timber will provide a continual rotating supply of habitat to those wildlife species dependent on early successional stages. Habitat for species dependent on old-growth forest will undergo a 25 percent reduction during the next 50 years (29 percent by the tenth decade). Open roads reduce habitat capability for some species of wildlife, especially elk. By the fifth decade the Forest road system will total 3,153 miles, with 992 miles closed to vehicular traffic (first decade figures are 2,755 and 733).

Alternative G

DIRECT EFFECTS. In both the short term (first decade) and long term (by the fifth decade), this alternative does very well in maintaining a diversity of wildlife habitats. Over the long-term, all species would be maintained above minimum viable levels, and opportunities to allocate additional specific habitat sites for wildlife would still be available. All planning basins are constrained at 9-13 percent per decade, which results in a reasonable distribution of successional stages over time.

Overall, this alternative provides significant habitat diversity for wildlife. Among the important land allocations are all Special Wildlife Sites, plus 49 Supplemental Resource areas, including the four with the highest priority for wildlife (Fishhook Peak, Morris Rodgers, Pebble Hill, and Windy Valley). Designated Wildlife Habitat areas are allocated at the highest level, 37,574 acres above MR levels. This includes 18,086 acres of habitat (mostly small blocks of mature or old-growth forest unsuitable for timber management) incorporated into the MR network as "stepping stones" between some individual Designated Wildlife Habitat areas. A variety of land allocations which contribute to overall habitat diversity, such as Botanical, RNA, or Unique Interest areas, are allocated, representing a variety of habitat types.

Selected unroaded areas are designated Backcountry Recreation; this results in a reasonably good distribution of large blocks of land not managed for timber, which will benefit wildlife species needing mature and old-growth forest. Species needing early successional stages are provided with somewhat more than an optimum amount of habitat. Standards and Guidelines are used to govern management of specific wildlife resources. Capital investments for wildlife habitat improvements will result in increased habitat carrying capacity for many wildlife species in specific local areas; $56,000 per year is programmed.

Just over 58,000 acres of prime habitat for bald eagle and osprey have been identified on the Forest; all are safeguarded in this alternative. Additional secondary habitat is available in the short-term, but some will eventually be altered by timber harvest.

At the end of the first decade, 142, 632, and 2,481 habitat areas will be available for spotted owl, pileated woodpecker, and pine marten, respectively By the fifth decade the numbers will decrease to 107, 450, and 2,362. Habitat capability for woodpeckers will be sustained at 60 percent in areas managed for timber; this level provides for a highly viable population.

Thirty-seven percent of the Forest (406,000 acres) is managed for timber harvest and consequently will provide a sustained supply of forage for deer and elk During the first five decades habitat capability for deer and elk will average 13 percent below current levels, for an average herd size of 24,500 animals (down from 28,300 at present)

Riparian areas are managed through the application of Standards and Guidelines; 46,400 acres of riparian habitat are managed in part for timber. All basins are managed under Prescription C, which provides less risk of adverse impact to wildlife than Prescription B. All types of wildlife sites are protected, including general wildlife areas, all water-related sites, and meadows with their buffers.

INDIRECT EFFECTS. Wildlife will continue to supply significant recreation to the public. The first five decades average 83,600 WFUD's annually. This is a three percent increase from the present situation, and includes 7,400 WFUD's attributed to habitat improvement projects. If improvement projects are not funded, total WFUD's would be reduced to 76,200 annually, or a six percent reduction from the present situation.

Habitat allocations for Special Wildlife Sites, Designated Habitat, and Supplemental Resource areas (four sites) will result in a reduction in the amount of land available for timber management; 80,355 acres fall in this category, although many sites contain overlapping land allocations installed to meet other resource objectives

CUMULATIVE EFFECTS. The average 100-year rotation applied to areas managed for timber will provide a continual rotating supply of habitat to those wildlife species dependent on early successional stages. Habitat for species dependent on old-growth forest will undergo a 37 percent reduction during the next 50 years (46 percent by the tenth decade). Open roads reduce habitat capability for some species of wildlife, especially elk. By the fifth decade the Forest road system will total 3,333 miles, with 812 miles closed to vehicular traffic (first decade figures are 2,787 and 483).

Alternative K

DIRECT EFFECTS. This alternative does a reasonably good job of providing a variety of well-dispersed habitats for Siskiyou wildlife. In the short term (first decade) this alternative does well in maintaining a diversity of wildlife habitats. Over the long term (by the fifth decade), all species would be maintained at or above minimum viable levels, and some opportunities to allocate specific habitat sites for wildlife would still be available. All planning basins are constrained at 9-13 percent per decade, which results in a reasonable distribution of successional stages over time

Overall, significant habitat diversity for wildlife is provided Among the important land allocations are all Special Wildlife Sites, plus 31 Supplemental Resource areas, including three of the four with the highest priority for wildlife (Fishhook Peak, Morris Rodgers, and Windy Valley) Designated Wildlife Habitat areas are allocated at MR levels Additionally, 18,086 acres of habitat (mostly small blocks of mature or old-growth forest unsuitable for timber management) are incorporated into the MR network as "stepping stones" between some individual Designated Wildlife Habitat areas. A variety of new land allocations which contribute to overall habitat diversity, such as Botanical, RNA, or Unique Interest areas, are selected, representing a variety of habitat types. Standards and Guidelines are used to govern management of specific wildlife resources Capital investments for wildlife habitat improvements will result in increased habitat carrying capacity for many wildlife species in specific local areas; $56,000 per year is programmed

Just over 58,000 acres of prime habitat for bald eagle and osprey has been identified on the Forest; just over 52,000 acres are safeguarded in this alternative Additional secondary habitat is available in the short-term, but will eventually be altered by timber harvest

At the end of the first decade, 138, 607, and 2,387 habitat areas will be available for spotted owl, pileated woodpecker, and pine marten, respectively. By the fifth decade, the numbers will decrease to 93, 368, and 1,494 Habitat capability for woodpeckers will be sustained at 60 percent in areas managed for timber, this level provides for a highly viable population.

Forty-eight percent of the Forest (529,000 acres) is managed for timber harvest and consequently will provide a sustained supply of forage for deer and elk During the first five decades habitat capability for deer and elk will average one percent below current levels, for an average herd size of 28,000 animals (down slightly from 28,300 at present).

Riparian areas are managed through the application of Standards and Guidelines, 76,900 acres of riparian habitat are managed in part for timber. Seventeen basins are managed under Prescription B and one under Prescription C; the latter prescription provides less risk of adverse impacts to wildlife. Nineteen major stream corridors are classified as Supplemental Resource areas, and all types of wildlife sites are protected, including general wildlife areas, all water-related sites, and meadows with their buffers.

INDIRECT EFFECTS. Wildlife will continue to supply significant recreation to the public. The first five decades average 88,300 WFUD's annually. This is a nine percent increase over the present situation, and includes 7,400 WFUD's attributed to habitat improvement projects. If improvement projects are not funded, total WFUD's would be reduced to 80,900 annually, or equal to the present situation.

Habitat allocations for Wildlife Special Sites, Designated Habitat, and Supplemental Resource areas (three of the four most important wildlife sites) will result in a reduction in the amount of land available for timber management; 42,919 acres fall in this category, although many sites contain overlapping land allocations installed to meet other resource objectives.

CUMULATIVE EFFECTS. The average 100-year rotation applied to areas managed for timber will provide a continual rotating supply of habitat to those wildlife species dependent on early successional stages. However, habitat for species dependent on old-growth forest will undergo a 49 percent reduction during the next 50 years (64 percent by the tenth decade). Open roads reduce habitat capability for some species of wildlife, especially elk; by the fifth decade the Forest road system will total 3,652 miles, with 1,128 miles closed to vehicular traffic (first decade figures are 2,851 and 649).

Alternative M

DIRECT EFFECTS. In the short term (first decade) this alternative does a reasonable job of maintaining a diversity of wildlife habitats. Over the long term (by the fifth decade), all species would be maintained above minimum viable levels, but populations of wildlife species dependent on early successional stages would be considerably reduced from present levels.

Alternative M favors wildlife species dependent on mature and old-growth forest Among the significant land allocations are all Special Wildlife Sites, and 51 Supplemental Resource areas, including those four with the highest priority for wildlife. Designated Wildlife Habitat areas are allocated at the highest level, 37,574 acres above MR levels. This includes 18,086 acres of habitat (mostly small blocks of mature or old-growth forest unsuitable for timber management) incorporated into the MR network as "stepping stones" between some individual Designated Wildlife Habitat areas.

A variety of new land allocations which contribute to overall habitat diversity, such as Botanical, RNA, or Unique Interest areas, are selected, representing a variety of habitat types. All roadless areas are

designated Backcountry Recreation, and all land tentatively suitable for timber production is managed on a 250-year rotation; this results in a relatively small proportion of the Forest managed for timber, and young successional stages Species needing early successional stages are provided with considerably less than an optimum amount of habitat. Standards and Guidelines are used to govern management of specific wildlife resources Capital investments for wildlife habitat improvements will result in increased habitat carrying capacity for many wildlife species in specific local areas; $56,000 per year is programmed.

Just over 58,000 acres of prime habitat for bald eagle and osprey have been identified on the Forest; all are safeguarded in this alternative. Additional secondary habitat is present, most of which will always be available for these species' use. At the beginning of the second decade, 150, 678, and 2,656 habitat areas will be available for spotted owl, pileated woodpecker,and pine marten, respectively By the fifth decade the numbers will decrease to 140, 628, and 2,469 Habitat capability for woodpeckers will be sustained at 60 percent in areas managed for timber; this level provides for a highly viable population Nineteen percent of the Forest (207,000 acres) is managed for timber harvest and consequently will provide a sustained (although limited) supply of forage for deer and elk During the first five decades habitat capability for deer and elk will average 41 percent below current levels, for an average herd size of 16,700 animals (down from 28,300 at present). This major reduction is due to both the small amount of area managed for timber harvest and the long rotation length (250 years)

Riparian areas are managed through the application of Standards and Guidelines. Riparian areas in all planning basins are managed at Minimum Level (no timber harvest); this prescription results in excellent cover for wildlife. In this alternative, all types of wildlife sites are protected, including general wildlife areas, all water-related sites, and meadows with their buffers.

INDIRECT EFFECTS. Wildlife will continue to supply recreation to the public, although use levels would be lower than at present. The first five decades average 71,500 WFUD's annually This is a 12 percent decrease from the present situation, and includes 7,400 WFUD's attributed to habitat improvement projects If improvement projects are not funded, total WFUD's would be reduced to 64,100 annually, or a 21 percent reduction from the present situation

Habitat allocations for Special Wildlife Sites, Designated Habitat, and Supplemental Resource areas (four sites) will result in a reduction in the amount of land available for timber management; 80,355 acres fall in this category, although many sites contain overlapping land allocations installed to meet other resource objectives.

CUMULATIVE EFFECTS. The average 250-year rotation applied to areas managed for timber will provide a continual, albeit small, rotating supply of habitat to those wildlife species dependent on early successional stages Habitat for species dependent on old-growth forest will undergo only a nine percent reduction during the next 50 years (13 percent by the tenth decade). By the fifteenth decade old-growth habitat will actually increase 40 percent over present levels because of the 250-year rotation schedule for timber harvest Open roads reduce habitat capability for some species of wildlife, especially elk Wildlife are least affected by this alternative because the Forest road system stays constant at 2,645 miles, with 529 miles closed

Alternative S

DIRECT EFFECTS. This alternative does a reasonably good job of providing a variety of well-dispersed habitats for Siskiyou wildlife In the short term (first decade) this alternative does well in maintaining a diversity of wildlife habitats Over the long term (by the fifth decade), all species would be maintained above viable levels, and some opportunities to allocate specific habitat sites for wildlife would still be available. All planning basins are constrained at 7-17 percent per decade, which results in a reasonable distribution of successional stages over time

Overall, significant habitat diversity for wildlife is provided Among the important land allocations are all Special Wildlife Sites, plus 22 Supplemental Resource areas The Special Wildlife Sites encompass 41,753 acres, including over 15,000 acres of dispersed old growth (scattered small patches of timber not suitable for timber management). Important wildlife sites protected include Fishhook Peak, Morris Rodgers, Windy Valley, Pebble Hill, Horse Creek, and Adams Prairie. Designated Wildlife Habitat areas are allocated at MR levels A variety of new land allocations which contribute to overall habitat diversity, such as Botanical, RNA, or Unique Interest areas, are selected, representing a variety of habitat types. Standards and Guidelines are used to govern management of specific wildlife resources. Capital investments for wildlife habitat improvements will result in increased habitat carrying capacity for many wildlife species in specific local areas, well over $100,000 per year is programmed.

Just over 58,000 acres of prime habitat for bald eagle and osprey has been identified on the Forest, just over 52,000 acres are safeguarded in this alternative. Additional secondary habitat is available in the short-term, but will eventually be altered by timber harvest

At the end of the first decade, 139, 604, and 2,380 habitat areas will be available for spotted owl, pileated woodpecker, and pine marten, respectively. By the fifth decade, the numbers will decrease to 97, 384, and 1,552 Habitat capability for woodpeckers will be sustained at 60 percent in areas managed for timber; this level provides for a highly viable population

Forty-six percent of the Forest (505,000 acres) is managed for timber harvest and consequently will provide a sustained supply of forage for deer and elk During the first five decades habitat capability for deer and elk will average one above below current levels, for an average herd size of 28,500 animals (slightly up from 28,300 at present)

Riparian areas are managed through the application of Standards and Guidelines; 66,396 acres of riparian habitat are managed in part for timber Eleven basins are managed under Prescription B and seven under Prescription C; the latter prescription provides less risk of adverse impacts to wildlife. Thirteen major stream corridors are classed as Supplemental Resource areas, and wildlife sites protected include general wildlife areas, all water-related sites, and meadows with their buffers.

INDIRECT EFFECTS. Wildlife will continue to supply significant recreation to the public. The first five decades average 102,300 WFUD's annually This is a 26 percent increase over the present situation, and includes 21,400 WFUD's attributed to habitat improvement projects If improvement projects are not funded, total WFUD's would be reduced to 80,900 annually, or equal to the present situation. Without investment in habitat improvement projects, there would be a significant Forest-wide reduction in average deer habitat capability during the first five decades.

Habitat allocations for Wildlife Special Sites, Designated Habitat, and Supplemental Resource areas will result in a reduction in the amount of land available for timber management; 66,745 acres fall in this category. However, many sites contain overlapping allocations installed to meet other resource objectives.

CUMULATIVE EFFECTS. The average 100-year rotation applied to areas managed for timber will provide a continual rotating supply of habitat to those wildlife species dependent on early successional stages. However, habitat for species dependent on old-growth forest will undergo a 47 percent reduction during the next 50 years (61 percent by the tenth decade). Open roads reduce habitat capability for some species of wildlife, especially elk; by the fifth decade the Forest road system will total 3,711 miles, with 1,163 miles closed to vehicular traffic (first decade figures are 2,873 and 662).

BIOLOGICAL DIVERSITY

The effects on biological diversity should not vary substantially by alternative. The National Forest Management Act (NFMA) requires forest diversity to be maintained or enhanced within a planning area The Forest strategy is to deal with diversity by allocating some lands to management areas with no programmed harvest, by applying Standards and Guidelines to areas under active management, and by carefully monitoring species and habitat throughout the Forest. This should either assure maintenance of "natural" diversity, or indicate need for direction change.

A definition acceptable to a variety of value systems would help to simplify evaluation of the effects of management alternatives on diversity. The law requires that the "natural forest" be used as the basis for evaluating the maintenance of diversity Yet, existing conditions have been so thoroughly influenced by man that "natural" references are difficult to find and apply

Ecosystems are resilient and adjust to impacts such as fire, flood, and other agents of change. Actively managed lands (Management Areas 10-14) are usually invaded by a rich mixture of early seral plant species, and frequented by animals that require open-structured habitat and shrub/forb dominated systems. Lands affected primarily by natural processes (Management Areas 1-9) can be species rich or poor depending on their successional history and age It is generally agreed, however, that biological diversity is at risk when a high percentage of the land base is actively managed for consumptive purposes such as timber management Indeed, many ownerships surrounding the Forest, particularly those to the north and west, are dominated by consumptive uses. As such, Forest lands allocated to non-consumptive uses act as refuges for those species that require later seral stages, such as spotted owl or western hemlock

It is debatable as to whether the more consumptive alternatives or the less consumptive alternatives provide the "best" diversity In most instances, lands allocated to non-consumptive uses are dominated by natural processes that shape forest composition and structure. Natural processes, when undisrupted by human activity, are generally good for diversity Furthermore, actively managed lands are not at risk of losing diversity as long as detrimental activities are curbed by effective Standards and Guidelines. Admittedly, some Standards and Guidelines are as yet untried and thereby carry a degree of uncertainty as to their effectiveness. Consequently, there is a greater *risk* to the maintenance of biological diversity in the more consumptive alternatives.

Selected suitable acreage ranges from 207,000 acres for Alternative M to 576,000 acres for Alternative NC. In other words, consumptive use ranges from 19 to 53 percent of the Forest acreage. Regardless of the allocation scheme, in every alternative all plant and animal species are managed at viable levels, and management indicator species are monitored. Monitoring is expected to point up any shortcomings in the Standards and Guidelines so that changes can be made. There is more to learn before we can conclusively and appropriately monitor and manage for biological diversity. But based on available information, we have set in motion our best effort. In summary, we do not expect the differences in land allocation between alternatives to significantly affect biological diversity.

VISUAL RESOURCE

SIGNIFICANT INTERACTIONS

Impacts to the visual resource will vary through the range of alternatives (see Figure III-20, Visual Quality Objective Map). Site-disturbing activities associated with Management Areas 10-14 will have the most significant effect on the visual resource. Management activities within any of the alternatives that would affect the resource are primarily those associated with timber harvest, related road construction, and other facility construction. Management activities that are designed to be in compliance with the inventoried Visual Quality Objective (VQO's) for a particular area are designed to blend with the character of the landscape so that the effects are within acceptable limits. Management activities that are evident to Forest visitors can affect the quality of recreation experiences (Clark and others 1984)

Alternative land allocations whose management activities are not designed to meet inventoried VQO's will have a noticeable impact on the character of the Forest landscape, and will be noticeable to the casual Forest visitor. The effects of the alternatives on the resource are summarized by Table IV-9 which displays the Expected Future Condition of the Forest's 44 viewsheds. The "Expected Future Condition" is a prediction of the effects of the management alternatives on the visual resource relative to the existing visual condition of the Forest. Alternative A depicts the existing condition. "Natural appearing" and "natural/near-natural" viewsheds are the 17 most sensitive viewsheds. The 13 "near-natural/modified" viewsheds are secondary viewsheds; the 14 "modified" viewsheds are those not visible from primary or secondary travel routes (see Figure III-20, Visual Quality Objective Map).

Table IV-9. Expected Future Viewshed Condition

	No of Viewsheds by Alternative								
Viewshed Condition	NC/A/A-Dep	B	C	D/D1	E	G	K	M	S
Natural Appearing	*6*	*5*	*5*	*5*	*11*	*10*	*5*	*11*	*6*
Natural/Near-natural	11	0	0	2	15	13	5	17	12
Near-natural/Modified	13	12	11	9	11	11	11	10	10
Modified	14	27	28	28	7	10	23	6	16

RESPONSE TO THE PLANNING PROBLEMS

This discussion is pertinent to Planning Problem #4, "How, and to what extent, should lands in and adjacent to river corridors be managed to protect, preserve, and enhance Wild and Scenic River attributes?" and Planning Problem #6, "How, and to what degree, should Forest scenic values be protected through visual resource management?" Response to these questions will primarily be tracked through changes in viewsheds from the inventoried VQO's For a full discussion of Planning Problem #4, please refer to the section on **WILD AND SCENIC RIVERS.**

ENVIRONMENTAL EFFECTS AND MITIGATION

Alternatives NC, A, and A-Departure meet the inventoried VQO's in all viewsheds. Alternatives B, C, D, D1, K, and S emphasize the production of goods and services requiring site disturbance, as well as varying degrees of protection to the visual resource. The VQO's will not be fully achieved in these alternatives Alternatives E and G emphasize the production of goods and services which generally value and maintain the current VQO's in those viewsheds located in the motorized portions of the Forest. Visual objectives would be upgraded to Preservation in areas allocated to unroaded uses. Alternative M would improve, in effect, the current VQO's by requiring timber to be managed under a 250-year harvest rotation which is analogous to the requirements for management under the Retention objective.

DIRECT EFFECTS of management activities associated with these alternatives include the construction of roads, developed recreation sites, and trails The *INDIRECT EFFECTS* of management activities associated with the alternatives include timber harvest and related activities, recreation users, and mineral development For the purposes of this document, these effects are combined and addressed in common during the discussion of effects of the various alternatives

NOTE: The percentages shown in the land allocations by VQO's represent the percent increase or decrease relative to the current inventory (shown in Alternative A).

NOTE: "Modification" is the term used to describe the amount of land managed to achieve the Modification/Maximum Modification VQO's

Alternative NC

The Forest would achieve the full range of inventoried VQO's under this alternative. There would be an increase in the acreage allocated to Retention and Partial Retention relative to current condition represented by Alternatives A The increase can be attributed to the decrease in area allocated to Designated Wildlife Habitat. Land Allocations by VQO are.

Visual Quality Objective	Acres	Percent
Preservation	318,625	- 11
Retention	72,323	+ 10
Partial Retention	258,622	+ 5
Modification	442,732	+ 4

Forest visitors may see some noticeable changes in the natural character of the Forest on a site-specific basis. In general, however, Forest visitors can expect to see a forest setting similar to that described for Alternatves A and A-Departure

Alternatives A and A-Departure

The Forest would achieve the full range of inventoried VQO's under these alternatives. Land allocations by VQO are

Visual Quality Objective	Acres	Percent
Preservation	356,603	0
Retention	65,536	0
Partial Retention	246,281	0
Modification	423,882	0

Forest visitors can expect to see an undisturbed Forest setting exhibiting mature and old-growth character in Wildernesses. Foreground views with managed stands of conifers and hardwoods exhibiting old-growth characteristics will be offered in the heavily used viewsheds and along major travel routes. Middle and background vistas feature younger managed stands of conifers and hardwoods with some noticeable interruptions in the vegetative character that vary in size and distribution, depending on the distance zone and applicable visual objective.

Alternatives B, D, and D1

The Forest would not achieve the full range of the visual inventory under these alternatives. Land allocations by VQO are:

Visual Quality Objective	Acres	Percent
Preservation	349,707	- 2
Retention	18,168	- 72
Partial Retention	106,123	- 57
Modification	618,304	+ 46

Natural/near-natural Forest settings will be maintained within five viewsheds (Rogue-Illinois, Upper Illinois, Chetco, Coquille, and Oregon Caves), and would offer vistas in the fore, middle, and background distance zones similar to those described in Alternative A above.

Areas currently inventoried for Retention in four viewsheds (Upper Illinois, Rogue-Illinois, Coquille, and Chetco) would be managed to achieve Partial Retention which would have some effect on the quality of the recreation settings within these viewsheds. Forest visitors can expect views in the foreground and middleground distance zones featuring managed young stands of conifers and hardwoods with some noticeable interruptions in the vegetative character that would resemble vegetative patterns occurring naturally in the landscape. Background vistas would feature obvious interruptions in the vegetative character that are larger in size and would resemble patterns occurring naturally.

In three viewsheds (Bob's Garden, Chetco, and Winchuck River), the Forest would not achieve the inventoried VQO's. Areas inventoried as Retention would be managed to achieve Partial Retention, and areas inventoried for Partial Retention would be managed to achieve Modification objectives. These reductions in the visual inventory may be appropriate for the Bob's Garden viewshed where the vistas offered consist of secondary middle and background views that are seen for only short periods of time. The situation differs in the lower river portions of the Chetco and Winchuck River viewsheds which receive consistently moderate to high levels of recreation use, indicating a greater level of viewer sensitivity than allocations made in this alternative

Alternative C

The Forest would not achieve the full range of VQO's under this alternative Land allocations by Visual Quality Objective are.

Visual Quality Objective	Acres	Percent
Preservation	342,016	- 4
Retention	9,526	- 85
Partial Retention	97,551	- 60
Modification	643,209	+ 52

Forest visitors can expect views in all distance zones that feature young managed stands consisting primarily of conifers with interruptions to the vegetative character that are obvious and occur frequently

Four viewsheds (Oregon Caves, Upper Illinois, Rogue-Illinois, and Chetco) would allocate areas inventoried for Retention to Partial Retention and would have an effect on the recreation setting within these viewsheds. Management activities would be evident in the near foreground and the middleground in areas previously managed to achieve the Retention objective.

In three viewsheds (Bob's Garden, Chetco, and Winchuck River), the same discussion of effects as described in Alternatives B, D, and D1 apply.

Alternative E

The Forest would achieve and exceed the inventoried VQO's in those viewsheds allocated to management. Land allocation by VQO are:

Visual Quality Objective	Acres	Percent
Preservation	704,686	+ 98
Retention	25,814	- 61
Partial Retention	116,281	- 53
Modification	245,521	- 42

Reductions (relative to the visual inventory) in allocations to Retention, Partial Retention, and Modification are created by increasing acres in Preservation as a result of the Management Area allocations to Backcountry Recreation. The Forest would maintain its current overall appearance.

Forest visitors can expect vistas similar to those described in Alternative A in those viewsheds allocated to management. Undisturbed vistas featuring uninterrupted vegetative patterns would be available throughout the remainder of the Forest

Alternative G

The Forest would achieve and exceed the inventoried VQO's in those viewsheds allocated to management. Land allocations by VQO are:

Visual Quality Objective	Acres	Percent
Preservation	584,952	+ 64
Retention	31,309	- 52
Partial Retention	164,680	- 33
Modification	311,361	- 27

Reductions (relative to the inventoried VQO's) in allocations to Retention, Partial Retention, and Modification are created by increasing acres in Preservation as a result of the Management Area allocations to Backcountry Recreation The Forest would maintain its current overall appearance.

The net effect of implementing this alternative would be the maintenance of the natural character of the Forest in areas allocated to roadless management objectives, and the maintenance of a natural/near-natural character in all of the Forests most sensitive viewsheds Forest visitors can expect foreground views exhibiting a managed old-growth character featuring a vegetative mix of conifer and deciduous tree species. Middle and background distance zones will offer views toward a managed vegetative mosaic of varying size, age class, and distribution. Disturbances to the uninterrupted character of the landscape will vary in size and distribution, depending on distance zone and the requirements of the applicable VQO's. Vistas from some Forest roads (such as Burnt Ridge) will offer views towards undisturbed areas of the Forest that will be maintained in an unaltered condition

Alternative K

The Forest would not achieve the full range of inventoried VQO's. Land allocations by VQO are

Visual Quality Objective	Acres	Percent
Preservation	402,268	+ 13
Retention	15,118	- 77
Partial Retention	145,436	- 41
Modification	529,480	+ 25

Forest visitors can expect undisturbed vistas toward unmanaged stands of conifers, mixed-conifer/deciduous species, deciduous tree species, and shrub stands from the trails and water routes within the Wildernesses and and in the viewshed adjacent to the last six miles of the Wild section of the Illinois River. Foreground views featuring managed stands of conifers and deciduous tree species will be offered in three other of the Forest's most sensitive viewsheds (Oregon Caves, Upper Illinois, and Rogue-Illinois). These same viewsheds will offer views toward middle and background distance zones featuring a managed vegetative mosaic of varying size, age class, and distribution similar to that described in Alternative G above.

In addition to the visual allocations, the inventoried foreground Retention (9,943 acres) within the Rogue-Illinois viewshed would not have programmed timber harvest in order to maintain the old-growth character of the foreground landscape.

Areas currently inventoried for Retention in eight viewsheds (Bolan Lake, Crazy Peak, Babyfoot Lake, Bear Camp, Coquille River, Elk River, Game Lake, and Quail Mountain) would be managed to achieve Partial Retention. These are secondary recreation travel routes (except for Bear Camp, which is primary); the maintenance of near-natural Forest settings is important in that they reflect levels of recreation use and associated viewer concern. Forest visitors can expect views toward fore, middle, and background distance zones featuring young managed stands consisting primarily of conifers Noticeable interruptions would exist in the vegetative character that vary in size and distribution depending on the distance zone and applicable VQO's.

In three viewsheds (Bob's Garden, Chetco, and Winchuck River), the same discussion of effects as described in Alternatives B, D, and D1 apply.

The current inventory in the Brigg's Valley/Shan Creek viewshed would be adjusted toward Modification objectives to more accurately reflect levels of recreation use and the level of viewer concern The Partial Retention objective would be applied to selected areas in Brigg's Valley.

Alternative M

The Forest would achieve and exceed the full range of VQO's in those viewsheds allocated to management. Land allocations by VQO are.

Visual Quality Objective	Acres	Percent
Preservation	726,256	+ 104
Retention	23,329	- 64
Partial Retention	109,448	- 56
Modification	233,269	- 45

Reductions (relative to the inventory) in allocations to Retention, Partial Retention, and Modification are created by increasing acres in Preservation as a result of the Management Area allocations to Backcountry Recreation. The Forest would maintain its current overall appearance as it now exists.

Another significant factor is the extended rotation of 250 years (approximately the same as Retention) for areas already roaded. The net effect of this management scheme would be the restoration of a more natural appearance in all areas of the Forest by approximately the fifth decade Forest visitors can expect an eventual return to a managed old-growth character in those areas allocated to management The remainder of the Forest would exhibit an undisturbed Forest setting.

Alternative S

The Forest would not achieve the full range of inventoried VQO's. Land allocations by VQO are.

Visual Quality Objective	Acres	Percent
Preservation	486,970	+ 37
Retention	21,266	- 68
Partial Retention	148,539	- 40
Modification	435,527	+ 3

Forest visitors can expect undisturbed vistas toward unmanaged stands of conifers, mixed-conifer/deciduous species, deciduous tree species, and shrub stands from the trails and water routes within Wildernesses, Backcountry Recreation areas, and in the viewshed adjacent to the last six miles of the Wild section of the Illinois River. Foreground views featuring managed stands of conifers and deciduous tree species will be offered in six of the Forests most sensitive viewsheds (Oregon Caves, Upper Illinois, Rogue-Illinois, Bolan Lake, Game Lake, and Highway 199) In addition, the inventory of VQO's would be achieved in the Chetco and Winchuck River drainages These same viewsheds will offer views toward middle and background distance zones featuring a managed vegetative mosaic of varying size, age class, and distribution similar to that described in Alternative G above

In addition to the visual allocations, the inventoried foreground Retention (9,943 acres) within the Rogue-Illinois viewshed would not have programmed timber harvest in order to maintain the old-growth character of the foreground landscape

Areas currently inventoried for Retention in six viewsheds (Crazy Peak, Babyfoot Lake, a portion of Bear Camp, Coquille River, Elk River, and Quail Mountain) would be managed to achieve the Partial Retention visual objective. These are secondary recreation travel routes (except for Bear Camp, which is primary); maintenance of near-natural Forest settings is important in that they reflect levels of recreation use and associated viewer concern. Forest visitors can expect views toward fore, middle, and background distance zones featuring young managed stands consisting primarily of conifers. Noticeable interruptions would exist in the vegetative character that vary in size and distribution depending on the distance zone and applicable VQO's.

The current inventory in the Brigg's Valley/Shan Creek and Bobs Garden viewsheds would be adjusted toward Modification objectives to more accurately reflect levels of recreation use and the level of viewer concern. The Partial Retention objective would be applied to selected areas in both viewsheds.

RECREATION SETTINGS

SIGNIFICANT INTERACTIONS

Impacts to the recreation resource will vary through the range of alternatives. Impacts are the result of management activities (direct or indirect) that affect the quality of the recreation setting. Alternatives will also affect the availability of recreation opportunities and the Forest's ability to provide them. These effects are demonstrated through the fluctuations in recreation capacities (refer to Table IV-10 for a display of the various recreation capacities by alternative, and to Table II-57, ROS Acreages by Alternative). Management activities affecting the resource are primarily those associated with timber harvest, related road construction, and other facility construction. Management Area allocations that have the greatest effect on the Recreation resource are General Forest, Wild and Scenic/Recreation Rivers, Retention Visual, Partial Retention Visual, and Backcountry Recreation. Refer to Figure III-21, Recreation Opportunity Spectrum Map, for location of opportunities.

RESPONSE TO PLANNING PROBLEMS

Planning Problem #8, "How will management direction affect recreation opportunities in the wilderness and unroaded areas?" is addressed, in part, here. The allocations are evaluated in the section entitled **WILDERNESS AND ROADLESS AREAS.** The quality of recreation opportunities is analyzed for each alternative, along with recreational development aspects. For a discussion of effects of the management alternatives on the recreation settings of river corridors and adjacent viewsheds of Wild River and Scenic/Recreation River Management Area allocations, refer to the section on **WILD AND SCENIC RIVERS.**

ENVIRONMENT EFFECTS AND MITIGATION

Current land allocations and management policies will remain fixed over the course of the planning period in Alternatives NC, A, and A-Departure. Alternatives B, C, D, and D1 will affect both the recreation settings (reduced visual allocations), and recreation capacities for Primitive and Semi-Primitive recreation opportunities. Alternatives K and S will maintain a natural/near-natural landscape within the areas of the Forest where recreation use is concentrated. Recreation capacities for Primitive and Semi-primitive recreation opportunities will be reduced, but retained in Backcountry Recreation areas and Wilderness. Alternatives E and G will retain the natural/near-natural character throughout much of the Forest, as well as maintain the availability of Primitive and Semi-primitive opportunities in areas outside of the Wildernesses Alternative M is essentially a maintenance alternative which would emphasize the maintenance or improvement of the Forest's existing condition. Timber harvest rotations will be extended to 250 years resulting eventually in a largely natural appearing Forest character.

DIRECT EFFECTS The direct effects include land allocations, construction of developed sites and trails, levels of protection afforded the landscape within and adjacent to Wild and Scenic Rivers, and the construction of trails in the Wildernesses. The range of effects on the recreation resource is expected to vary only in the degree of impact.

INDIRECT EFFECTS. The indirect effects of implementing these alternatives include: recreation use (the effects of people, stock, vehicles, and ORV's), timber harvest and related activities, and mineral exploration and development. The range of indirect effects on the recreation resource is expected to vary only in the degree of impact

CUMULATIVE EFFECTS. Timber harvest is identified as having a cumulative effect on the visual resource and has a bearing on the quality of the recreation setting throughout the Forest (USDA 1974). Impacts of recreation users, particularly in heavily used areas, is a cumulative effect to the recreation resource (USDA 1986a) These effects are monitored in all areas of the Forest, including General Forest as well as

designated areas such as Wilderness. The range of cumulative effects on the recreation resource is expected to vary only in the degree of impact.

Alternatives NC, A, and A-Departure

Current land allocations and management policies will remain unchanged over the course of the planning period for these alternatives Existing developed sites will be maintained or improved in order to increase the Forest's Developed Recreation carrying capacity. Management of the existing sites would be limited to routine maintenance and vegetative management to eliminate potential hazards and offset the impacts of recreation use over time. Recreation settings adjacent to these sites would be maintained in a natural/near-natural condition over the course of the plan

Moderate levels of trail construction (102 miles) will occur in General Forest and the Kalmiopsis Wilderness which increase the recreation carrying capacities Wilderness character and recreation settings are not expected to be significantly affected. Limited trail construction would occur in the Scenic section of the Illinois Wild and Scenic River and some construction in General Forest. Recreation settings will vary between natural/near-natural appearing to modified depending on the location of the trail system. Some trails in General Forest are likely to be displaced by road construction under these alternatives. However, a net increase in non-motorized recreation capacities will occur as a result of trail construction.

Motorized recreation opportunities will be increased as timber-related road construction is completed. The quality of recreation experience may be reduced for some users, though, due to the close proximity of harvest activities in General Forest. Road construction and harvest activities appear consistent and acceptable to many people presently using dispersed, roaded areas. Recreation settings in these areas will vary between near-natural appearing in those areas managed for Visual Quality Objectives to Modification in those areas managed for General Forest objectives Motorized recreation capacities will be increased.

Currently inventoried roadless areas will be entered for timber harvest, resulting in the loss of Primitive opportunities on approximately 14,000 acres outside of Wilderness by the end of the second decade. Land capable of providing Semi-primitive Non-motorized opportunities will be reduced from approximately 99,000 acres to 29,000 acres over time. The undeveloped character (i e , Wilderness potential) would be lost as the areas are scheduled for entry and development through the General Forest allocation. The reduction in the land capable of providing Semi-primitive Non-motorized opportunities would not sustain projected levels of demand over the course of the planning period. The Forest has the capacity to satisfy projected levels of demand for similar opportunities within the existing Wilderness system until the fifth decade of the planning period.

Alternatives B, D, and D-1

Under these alternatives, developed sites would be maintained in a condition in which capacities would be consistent with current patterns of use Developed recreation capacity would be reduced by the closure of seven developed sites As demand for developed sites increases over the first four decades, seven new sites would be constructed in areas where concentrations of recreation use are expected to occur. Developed recreation capacities would consequently be increased from 162 M RVD's to 194 M RVD's. Recreation settings immediately adjacent to these sites would be maintained in a natural condition; however, some effects of timber harvest would be apparent in the middle and background vistas due to reduced land allocations to visual resources

There would be limited trail construction in General Forest under these alternatives It is likely that some trails in General Forest would be displaced by road construction. Most existing trails would be maintained Recreation settings adjacent to existing trail systems will vary between natural and modified depending on the location of the trail and the scheme of visual quality applicable to the area

Trail construction within the Wildernesses will increase the capacity for Primitive opportunities from 11 M RVD's to 19 M RVD's by the fourth decade. Semi-primitive recreation capacities would be increased from 29 M RVD's to 42 M RVD's by the same time The amount of Pristine recreation opportunities will be reduced in the Kalmiopsis Wilderness. The natural appearance and Wilderness character of these areas are not expected to be degraded as a result of trail construction.

Recreation capacities for motorized recreation opportunities will increase by approximately 501 M RVD's. Motorized access to remote areas of the Forest will increase as new roads are built The undeveloped character and opportunities for Primitive recreation available in the North Kalmiopsis Roadless Area (Silver Creek drainage) will be lost and Semi-primitive capacities reduced to a point that will not sustain projected levels of demand by the end of the second decade. The effects of activities on the lands adjacent to Wildernesses would be most apparent under these alternatives.

Alternative C

There would be no new developed sites constructed under this alternative. Existing sites would be improved and capacity expanded by 10 M RVD's. Recreation settings around these sites would be maintained in a natural/near-natural condition, although some activities would be evident in the the middle and background distance zones due to reduced allocations to visual management.

Trail construction and reconstruction under this alternative totals 124 miles and is concentrated in the Kalmiopsis and Wild Rogue Wildernesses. Trail construction in General Forest limited to that required to access Wilderness trail systems No others would be programmed Some of the existing trail system is expected to be displaced by roads. Recreation settings will vary between natural and modified depending on the location of the trail. The quality of recreation experiences on General Forest trail systems may be affected by management activities.

Wilderness capacities for Primitive recreation opportunities would be increased by 8 M RVD's, and Semi-primitive opportunities by 16 M RVD's Wilderness character and the quality of recreation experiences are not expected to be degraded as a result of the proposed trail construction.

Motorized recreation opportunities will be increased by 660 M RVD's and access to remote areas improved as a result of proposed road construction. Recreation settings in General Forest are expected to be in a modified condition due to the close proximity of management activities to roads in General Forest areas. Within two decades, the undeveloped character and opportunities for Primitive recreation will be lost in the Silver Creek drainage As a result, capacities for Semi-primitive Non-motorized opportunities would be reduced to approximately 6 M RVD's which would not sustain projected levels of demand by the second decade. The effects of activities on the lands adjacent to Wildernesses will be apparent to Wilderness users and may affect the quality of their recreation experiences.

Alternative E

This alternative would maintain the Forest in essentially its present condition There would be eight new developed sites constructed under this alternative which would expand the Forest capacity for developed recreation 19 M RVD's by the fifth decade Recreation settings adjacent to all developed recreation sites would be maintained in a natural or near-natural condition.

Trail construction (60 miles) would be limited to General Forest or Backcountry Recreation areas. Existing trail systems in the General Forest would be maintained, although some in areas already entered for harvest would be displaced by road construction. The effect is not expected to be extensive due to the amount of land allocated to Backcountry Recreation.

Motorized recreation capacities would be increased moderately (by 476 M RVD's), but would largely be limited to areas currently harvested Recreation settings in these areas are expected to vary between near-natural and modified

Opportunities for Primitive recreation experiences will be maintained due to the allocation of all of the Forest's roadless areas to Backcountry Recreation Capacities for Semi-primitive opportunities will be reduced slightly due to continued harvest in areas allocated to General Forest. Recreation settings in these areas would be maintained in a natural condition

Alternative G

The effects of implementing Alternative G would be similar to those identified in Alternative E, but vary enough to warrant discussion. Eighteen new developed sites would be constructed, and existing sites maintained. Developed recreation capacity would be expanded by 83 M RVD's by the fifth decade. Recreation settings in areas adjacent to these sites would be maintained in a natural/near-natural condition

Wilderness trail construction (50 miles) would increase recreation capacities by 7 M RVD's. Wilderness character and the quality of recreation experiences are not expected to be significantly affected as a result of trail construction.

Motorized recreation capacities would expand by 415 M RVD's due to road construction and a reduced level of land allocated to Backcountry Recreation. Recreation settings in General Forest lands are expected to vary between near-natural and modified

Primitive opportunities available in the Silver Creek drainage would be maintained due to allocations to Backcountry Recreation Opportunities for Semi-Primitive Non-motorized recreation would be reduced, although the reduction would be partially offset by closing the Hobson Horn/Silver Peak Trail to motorized use Recreation settings in lands allocated to Backcountry Recreation are expected to remain in a natural appearing condition

Alternative K

This alternative will alter the existing condition of the Forest due to reduced allocations to visual management. Four existing developed recreation sites would be closed. Ten new developed sites would be programmed for construction over the first five decades. Developed recreation capacity would be increased by 10 M RVD's by the fifth decade Recreation settings would be maintained in a natural/near-natural condition.

There would be a total of 147 miles of trail programmed for construction and reconstruction. Construction would be split between the General Forest and the Kalmiopsis and Wild Rogue Wildernesses Some existing trail systems are expected to be interrupted or displaced by roads in General Forest. Recreation settings will vary between natural/near-natural and modified depending on the location of the trail.

A moderate amount of trail is proposed for construction in the Kalmiopsis and Wild Rogue Wildernesses (50 miles). Recreation capacities will be increased by 7 M RVD's Wilderness character and the quality of recreation experiences are not expected to be significantly affected as a result of trail construction.

Opportunities for motorized recreation experiences will be improved due to road construction, although the quality may change as a result of activities with lower VQO's. Motorized recreation capacities would be increased by 470 M RVD's. Much of the area allocated to General Forest will exhibit a modified character due to the close proximity of management activities to road systems. Viewsheds adjacent to roads with access to major recreation areas receiving high levels of use such as Bear Camp, Highway 199, Coquille

River, and others will be maintained in a near-natural condition due to allocations to visual resource management. Major Wilderness access routes would exhibit a near-natural foreground character due to allocations to visual management

Within two decades, the opportunity for Primitive and Semi-primitive Non-motorized recreation opportunities are either permanently foregone (Silver Creek drainage) or significantly reduced due to allocations of unroaded areas to General Forest.

Alternative M

Alternative M is essentially a maintenance alternative which would emphasize the maintenance or improvement of the Forest's existing condition Eighteen new developed recreation sites are programmed for construction By the fifth decade, developed recreation capacities would increase by 10 M RVD's Existing sites would be maintained. Recreation settings adjacent to these and all of the potential sites would remain in a natural/near-natural condition.

Opportunities for motorized recreation activities would remain essentially unchanged. Recreation settings in General Forest areas are expected to gradually improve over time to a near-natural condition due to the extended harvest rotations required under this alternative

All of the Forest's unroaded areas would be allocated to Backcountry Recreation which would protect their undeveloped character and maintain capacities for Primitive and Semi-primitive Non-motorized recreation opportunities. Recreation settings are expected to remain in a natural condition in these areas

Alternative S

Existing conditions will be altered on lands allocated to Management Areas 10-14 The character of the lands allocated to Management Areas 1-9 would retain their existing character.

Under this alternative, four existing developed recreation sites would be dropped from maintenance scheduling and closed Nine new developed sites would be programmed for construction over the first two decades, including the Agness Visitor Center. A moderate amount of rehabilitation would be scheduled for the remaining developed sites. Developed recreation would be increased by approximately 10 M RVD's by the second decade. Recreation settings within and adjacent to these sites would be maintained in a natural/near-natural condition.

There would be a total of 193 miles of trail programmed for construction and reconstruction. Construction would occur in Wilderness, Backcountry Recreation, and General Forest areas Some existing trail systems are expected to be interrupted or displaced by roads in General Forest Most of the existing trail system is expected to be retained under this alternative. Recreation settings adjacent to trails will vary between natural, near-natural or modified depending on the location of the trail.

A higher level of trail construction is proposed for the Kalmiopsis, Wild Rogue, and Grassy Knob Wildernesses (78 miles). Recreation capacities will be increased by approximately 18 M RVD's. Wilderness character and the quality of recreation experiences are not expected to be significantly affected.

Opportunities for motorized recreation experiences will be improved due to road construction and availability of a portion of the Backcountry Recreation areas for motorized uses (generally off-road vehicles) The quality of the recreation settings on some areas of the Forest may change as a result of activities with lower Visual Quality Objectives. Motorized recreation capacities would be increased by 475 M RVD's. Much of the General Forest will exhibit a modified character due to the proximity of management activities to road systems. Viewsheds adjacent to roads with access to recreation areas receiving high levels of use such as Highway 199, Oregon Caves, Bear Camp, and along the river corridors will be

maintained in a near-natural condition due to visual management allocations Major Wilderness access routes would exhibit a natural/near-natural character in fore and middleground distance zones due to the visual management allocations.

Within two to three decades, the undeveloped character and opportunity for Primitive and Semi-primitive Non-motorized recreation are either permanently foregone or reduced due to the allocation of previously unroaded areas to General Forest. For the balance of areas allocated to Backcountry Recreation, the Forest will retain capacity for approximately 15 M RVD's of Primitive and Semi-primitive Non-motorized recreation opportunities outside of Wildernesses.

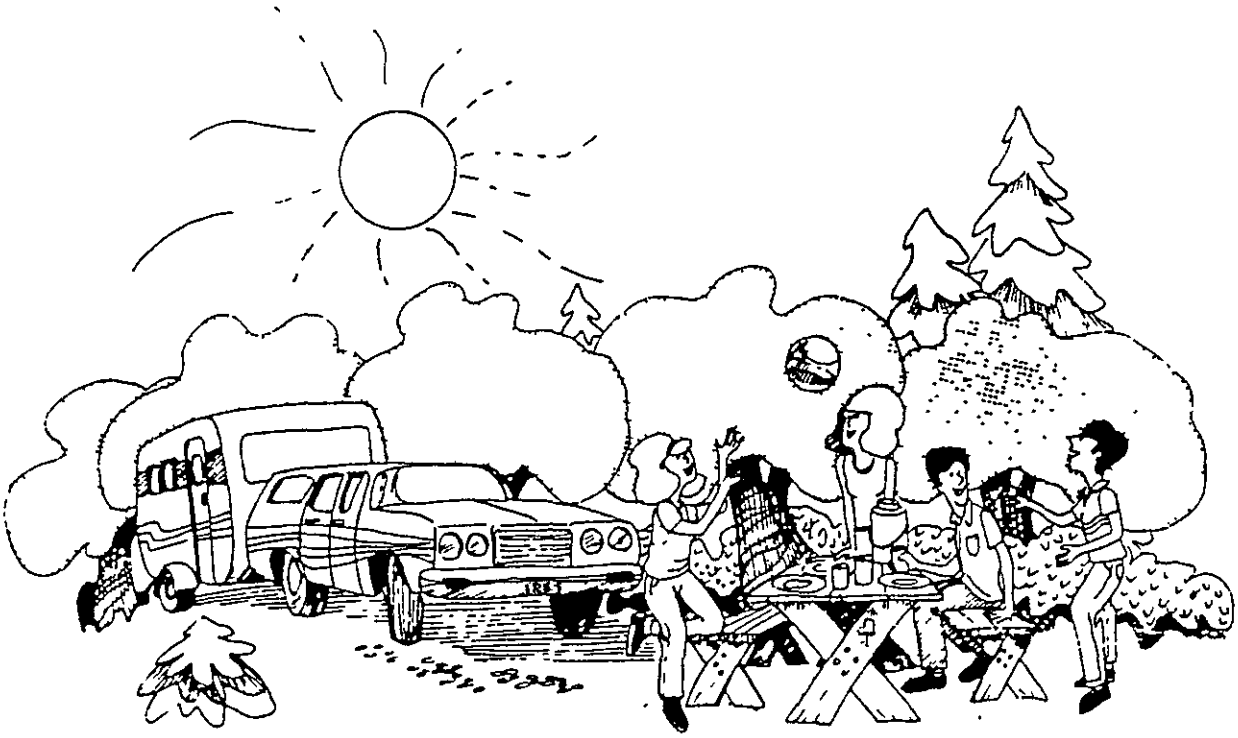


Table IV-10. Recreation Carrying Capacities (M RVD's Fifth Decade) by Alternative

	Exist.	No Change	A	A-Dep	B	C	D	D1	E	G	K	M	S

ECONOMIC AND SOCIAL

SIGNIFICANT INTERACTIONS

Land allocations and program budgets are used by the Forest Service to generate forest products consumed by the public. The level and mix of goods and services available for public consumption varies by alternative, which creates impacts on the social and economic environment.

The social and economic consequences associated with alternatives are presented in this section. The consequences of each alternative are characterized as direct, indirect, and cumulative economic and social effects *DIRECT EFFECTS* of each alternative are the estimated government expenditures for each alternative As a result of these expenditures, the public consumes forest products (goods and services) which produce *INDIRECT EFFECTS* including benefits, revenue, jobs, and incomes. *CUMULATIVE EFFECTS* on the social and economic environment reflect the net effect of Forest Service programs on the entire array of user groups. Examples of these effects include the economic viability of Forest programs, the total predicted changes in jobs and income, opportunity costs, and resulting impacts on lifestyles, attitudes, and community cohesion.

DIRECT EFFECTS As was shown in Table II-58, total costs vary considerably by alternative· from $330 million for Alternative M to $817 million for Alternative C. Table IV-11 displays the direct effects of the alternatives in response to the Planning Problems. The major variable costs are associated with the timber program and road construction. For example, Alternative M with a total cost of $330 million has low road costs (present value of $16 million) and a small timber program budget (discounted costs of $90 million). Conversely, Alternative C, with total discounted costs of $817 million, has high road costs (discounted costs of $187 million) to support a large timber program budget (discounted costs of $428 million). Undiscounted annual costs are lower in Alternatives E, G, and M during the first decade than the current Forest budget. The remaining alternatives are higher than the current Forest budget.

The amount of selected suitable land for timber production varies across the alternatives. Alternatives NC, A, A-Departure, B, C, D, D1, K, and S have a large selected suitable area (greater than 500,000 acres) while Alternatives E, G, and M have a smaller land base for timber production (less than 410,000 acres).

Significant differences also exist between alternatives on the amount of Oregon and California (O&C) land managed for timber production. The range varies from Alternative M which only manages 29,000 O&C acres for timber production to Alternative C which manages 89,000 acres. Alternatives NC and C have the most O&C land managed for timber production; Alternatives A, A-Departure, B, D, D1, K, and S not far behind. Alternatives E, G, and M have significant reductions in the amount of O&C land managed for timber harvest.

The capital investment program for fisheries varies from $227,000 (Alternative A) to $350,000 (Alternatives B, K and S) and are coordinated with Riparian prescriptions. Watershed capital investments vary from $18,000 in Alternative M to $195,000 in Alternative C, varying primarily with needs for soil and water resource mitigation. The wildlife habitat capital investment programs are constant across all alternatives ($56,000), with the exceptions of Alternatives B, D, and S. In Alternative B, capital investments increase to $110,000 per year; Alternative D, the program is reduced to $28,000 per year; and, for Alternative S, it is increased to $123,000 per year.

The recreation budget, including capital investments, is relatively stable across the range of alternatives due to the excess capacity for most recreational demands on the Forest.

Table IV-11. Direct Effects

	ALTERNATIVE												
	Max. PNV	No Change	A	A Departure	B	C	D	D1	E	G	K	M	S
TIMBER

1/ Alternative M includes 97,661 acres in general forest which were not selected as suitable for timber management.

INDIRECT EFFECTS Estimated returns to the U.S. Treasury and other benefits are displayed in Table IV-12. Timber receipts comprise the largest share of total revenue However, recreation, fisheries, and wildlife values are also significant from the economic and social perspective.

Alternatives A-Departure and B have harvest schedules which depart from nondeclining flow. Allowable harvest starts above the base level for the first decade and then declines in future decades before increasing to the long-term sustained yield. These fluctuations, measured as the percentage change from timber harvest levels for the previous decade, are graphically depicted for the two departure alternatives in Figure IV-13 Harvest levels decrease in the third decade for both Alternatives. Harvest schedules increase over time in the remaining alternatives which are constrained by the nondeclining yield policy

Mills in Coos, Curry, Jackson, and Josephine Counties are expected to face a fluctuating timber supply over the next 30 years Projections indicate that the supply of non-National Forest stumpage will increase from the harvest level in the early 1980's for the next 10 years A significant decrease in supply is then forecast for the following 10 to 20 years, with insufficient raw material to satisfy potential consumption needs (as postulated in Chapter III). Therefore, alternatives containing National Forest harvest flows that counterbalance changes in non-National Forest supply could have the beneficial effect of stabilizing the total timber supply over time. Different alternatives then have different levels of projected supply within the four-county area. Table IV-13 displays the historical and projected timber supply by decade for each alternative. Data for the historical period, 1980-84, was extrapolated to provide values representing a decade.

Table IV-13. Total Projected Four County Timber Supply and Needs, by Alternative

	MMCF/Years			
	Historical	Projected Supply		
Alternative	1980-84	1989-98	1999-2008	2009-18
Supply Other Than Siskiyou National Forest	1,447	1,966	1,352	1,939
Total Supply by Alternative, All Sources, All Ownerships, Including Siskiyou National Forest				
NC	1,606	2,276	1,662	2,249
A	1,606	2,267	1,653	2,240
A-Departure	1,606	2,278	1,664	2,242
B	1,606	2,334	1,720	2,269

K	1,606	2,244	1,630	2,217
M	1,606	2,027	1,413	2,000
S	1,606	2,250	1,636	2,223
Estimated Consumption Needs, All Ownerships'				
High Projection	-	2,282	2,506	2,506
Low Projection	-	2,056	2,282	2,282

In the first decade, Alternatives B, C, and D1 meet or exceed anticipated log consumption needs using the high end of the range for consumption as discussed in Chapter III. Alternatives NC, A, A-Departure, and D exceed the lower end of projected consumption while Alternatives K and S fall just below the projected consumption. Alternatives E, G, and M fall way short of the projected log needs

In the second decade, no alternative meets or exceeds anticipated log consumption needs for the local area of influence at the lowest level of projected demand. Alternative B comes the closest to meeting the projected needs with a total supply of 1,720 MMCF per decade.

In the third decade, the pattern of the second decade is repeated. No alternative meets the low projection of wood consumption needs Alternatives NC, A, A-Departure, B, C, D, D1, K, and S provide levels of harvests which approach the lower limit of projected raw material needs; Alternatives E, G, and M do not meet the low limit of projected consumption. As discussed earlier, the departure alternatives (Alternative A-Departure and B) then have decreases in timber production while the other alternatives maintain or increase their timber outputs

Payments to counties (Table IV-12) in which Siskiyou National Forest land is located constitute the largest direct economic impact made by the Forest on its surrounding area Alternative B has the most O&C and National Forest Fund (NFF) payments for the first decade due to the highest first decade sell quantity. Alternatives NC, A, A-Departure, C, D, D1, K, and S are not far behind Alternatives E, G, and M have significant reductions in the amount of O&C receipts for the first decade.

From the above discussion, it would appear that the level of timber harvest determines the magnitude of payments to counties. While this is true, it is only partly so. Other very important factors are the price of the timber sold and the timing of harvest. The estimates presented here are based on assumptions that sold volume will be harvested, and that the selling price is equal to the average price used in the planning analysis. What will happen in future years may be influenced more by national economic conditions and their ramifications on the timber market than on the Forest's management alternatives.

Alternatives B, C, D, and D1 are projected to have the largest number of sales where the immediate cash flow is negative (sales below cost). These alternatives would harvest large amounts of hardwood stands. Due to the costs of road development and low values of hardwood products, these alternatives have a high potential for some individual sales to have costs exceed revenues. However, the timber program benefits are higher than the program costs for all alternatives.

CUMULATIVE EFFECTS. The present net worth and costs of each alternative by program are displayed in Table IV-14. At first glance it would appear that the high timber harvest alternatives are the most efficient. It should be noted, however, that returns to the Treasury are based to a large extent on timber. If the price remains low, as it has in the recent past, and costs continue to rise, a different relationship will be evidenced in the short run. The long run should follow the predicted trend used for the timber prices.

The total change in jobs varies from an increase of 1,200 jobs to a decrease of 1,600 jobs from the current situation. It is again emphasized that these estimates are derived from planning assumptions which are approximations, only to be used for comparisons between alternatives. Reference should be made to Appendix B for more information on assumptions used in the analysis.

The magnitude of difference for changes in employment between alternatives appears high (Table IV-14). However, taken in context of the four-county labor force, the greatest difference only predicts a three percent change in total employment.

The sectors which show the largest direct changes in employment are lumber and wood products, and pulp and paper which are directly responsive to timber output changed. Auto dealers, gas stations, eating and drinking establishments, services, and retail trade are mostly responsive to recreation visitor use changes, but also benefit from indirect and induced transactions due to changes in the wood products industry. When indirect (second round, inter-industry purchasing effects) and induced impacts (consumer purchasing effects) are added, the economic sectors which exhibit the greatest sensitivity are lumber and wood products, services, transportation, communications, and utilities. The types of jobs which account for approximately 80 percent of the employment change are equipment operators (25 percent); laborers (20 percent); service workers (16 percent); and craft, foremen and mechanical, and clerical (11 percent each). Professional, technical, managerial, and administrative positions comprise about 10 percent of the total employment change by alternative. The proportions of employment change by sector, and the geographic distribution of the employment and income impacts remain relatively constant among alternatives.

The total change in income ranges from an increase of $29 million to a projected decrease of $39 million. Though these numbers appear large and may be significant to individual businesses or communities, the maximum change represents only four percent of the total income in the area of influence.

Caution should be exercised when interpreting the results of the input/output model (IMPLAN) used to make predictions The model uses a 1972 data base, updated to 1977, to determine linkages between industries. No substitutes for any products are assumed to exist and complete consumption of all available products is assumed. The area's economic health is greatly influenced by national forces Inflation, interest rates, conditions in the housing market, and individual preferences for recreational opportunities and living environment have more of an influence on local jobs and incomes than does the Siskiyou National Forest. However, the projected outcomes are useful for evaluating relative differences between alternatives

Three social parameters are used to assess the cumulative impacts of the planning alternatives (1) lifestyles, social organization, and employment of affected communities, (2) attitudes of people within those communities, i e , how people feel about the responsiveness of the National Forest to their interests, and (3) community cohesion, or the degree of unity and cooperation evident in a community as it defines and resolves problems

Four community types with distinct lifestyles, employment, and social organization were identified in Chapter III. Grants Pass, Coos Bay, and Medford represent metropolitan **Urban** areas. Communities, such as Powers and Selma, represent **Rural** communities that are dependent on wood products and agriculture. **Westside** communities, such as Bandon and Brookings, have more diversified economies with tourism and fisheries. Takilma and Ruch are more self-contained and are **Alternate Lifestyle** communities with cottage industries as the main economic enterprise. While these are largely generalizations and do not explicitly reflect a given community structure, they can be used for representing broad value types. As discussed in Appendix B, the trend of changing values for the overall population under existing conditions is predicted to lead toward increased polarization and potential conflict, especially in Urban areas.

Each alternative was assessed with respect to demands, wants, and desires commonly associated with quality of life for major interests within each of the four community types The results are displayed in Table IV-15a. A minus (-) indicates a decrease in activity, lifestyle, or potential disruption in social organization relative to trends predicted for the existing condition (Alternative A). Such a decrease, compared to the existing condition, leads to a negative attitude (-), or lack of responsiveness to that particular issue: people feel they have not been heard. Depending upon the degree of impact, this may accelerate potential internal conflict within a community, especially if other activities have increased at the expense of fewer outputs.

Conversely, a plus (+) signifies an increase in activity, higher standard of living, or potential disruption in social organization due to growth; again relative to predicted trends for the existing condition (Alternative A). This increase then leads to people feeling their needs have been heard on any one issue with resulting positive attitudes (+). If these gains do not detract from other interests within the community, then potential internal community conflict is predicted to decelerate relative to the current trend. A zero (0) signifies circumstances where a given alternative does not vary significantly with respect to the existing condition

Social impacts for all alternatives, as a whole, are then summarized by each community type (Table IV-15b). Any significant change from existing condition is predicted to decrease cohesion (-) in the Urban areas where diverse, and often polarized, interests are represented Due to the existing cohesion in the Alternate Lifestyle communities, any tradeoff of amenity or preservation values is predicted to increase cohesion (+) due to the perception of confronting common adversity The Rural communities are predicted to experience increased internal cohesion when they feel threatened by tradeoffs of timber, motorized recreation, and wildlife (mainly hunting) outputs. These outputs generally increase or decrease hand-in-hand. The Westside communities are predicted to experience increased internal conflict where motorized recreation, scenic characteristics, fisheries, and timber outputs are relatively unbalanced.

0 = No change from current perceptions and attitudes.
- = Leads to negative attitudes, perception of needs not being heard.

Table IV-15b. Cumulative Effects on Community Cohesion

Socioeconomic Indicators	ALTERNATIVE 1/											
	No Change	A	A-Dep	B	C	D	D1	E	G	K	M	S
URBAN AREAS	-	0	-	-	-	0	-	-	-	0	-	0
RURAL	0	0	0	*	*	0	*	+	+	+	+	+
WESTSIDE	0	0	-	+	-	0	-	+	+	0	+	*
ALTERNATIVE LIFESTYLE	0	0	0	+	+	0	+	*	*	0	*	0
COMPOSITE	-	0	-	-	-	0	-	-	-	0	-	0

1/ + = Community cohesion accelerates. (Community unites against common threat.)
0 = No change in existing condition. (Internal conflict continues to grow.)
- = Community cohesion decreases. (Internal conflict accelerates.)
* = Community cohesion stabilizes. (Forest related internal conflicts decrease.)

However, since these communities tend to appreciate the diverse needs of their economies, alternatives that grossly unbalance resource outputs could lead to cohesion due to a feeling of common threat in all factions of the community. Several alternatives do a good job of meeting the wants, needs, and desires of the Rural, Westside, or Alternate Lifestyle communities. Under these circumstances, internal conflict due to Forest-related issues decreases and community cohesion is predicted to stabilize (denoted by an *). Attitudes toward the Forest improve as people feel their wants, needs, and desires are being heard.

Please note that the parameter that indicates community cohesion does not indicate how a community might receive an alternative Rather than indicating whether a community would consider an alternative desirable or not desirable, this parameter indicates whether potential internal conflict would change relative to predicted trends for that community.

ENVIRONMENTAL EFFECTS AND MITIGATION

For each alternative, the direct, indirect, and cumulative effects are discussed below. For cumulative effects, the total present net value of each alternative reflects deductions for certain items that have negative present net values, including overhead, law enforcement, wildfire activities, and natural fuels management. Consequently, the sum of present net values (shown in parenthesis) for timber, recreation, fisheries, and wildlife will exceed the total present net value for each alternative.

For indirect effects, all alternatives except NC, D, and S have been analyzed using older data which were not corrected for the nongame wildlife component of WFUD's. While there are differences compared to revised data in Table II-5, the effects to economic indicators are negligible and do not affect relative differences among the alternatives. Tables IV-16 to IV-27 display the economic and social implications of each alternative.

Alternative NC

DIRECT EFFECTS. The direct effects of the Alternative NC (Table IV-16) are $732 MM total government expenditures for the 150-year period discounted at four percent. The discounted costs of the timber program are $358 MM with additional discounted costs of $165 MM for road construction ($151 MM for purchaser credits and $14 MM for appropriated dollars). The next highest cost is for the recreation program which has discounted costs of $12.3 MM. Fisheries ($6.8 MM) and wildlife programs ($2.5 MM) are the other major costs. First decade average annual costs are $21.0 MM.

INDIRECT EFFECTS. These effects are average yearly consumption of 31.0 MMCF of timber harvest, 67,000 WFUD's due to fisheries, 741,000 RVD's for recreation, and 77,000 WFUD's for wildlife for the first decade. Total benefits (discounted at four percent for a 150-year period) equal $1,614 MM for timber, $185 MM for recreation, $90 MM for fisheries, and $53 MM for wildlife Payments to counties would average $13.8 MM each year

CUMULATIVE EFFECTS. The cumulative impacts on economic and social aspects of the environment are a present net value of $1,214 MM (timber, $1,104 MM; recreation, $173 MM; fisheries, $84 MM; and wildlife, $50 MM). Total opportunity costs compared to the maximum PNV benchmark is $64 MM which is mainly lost revenue due to lower timber production. An additional 660 jobs and $15.7 MM of income are generated by this alternative when compared to the average number of jobs and income realized in the last 10 years.

Community cohesion will probably decrease faster than predicted trends. The accelerated decrease in community cohesion is primarily due to conflicts in Urban areas concerning the Management Requirements for old-growth-dependent wildlife species As old-growth habitat is reduced beyond the minimum needed for viable populations, internal tensions would rise sharply. The other three community types would be unchanged; predicted trends would continue with decreasing cohesion and increasing internal conflict.

Alternative A

DIRECT EFFECTS. The direct effects of Alternative A (Table IV-17) are government expenditures of $736 MM for the 150-year period discounted at four percent. The discounted costs of the timber program are $366 MM with additional discounted costs of $162 MM for road construction ($148 MM for purchaser credits and $14 MM for appropriated dollars). The next highest cost is for the recreation program which has discounted costs of $12.3 MM. Fisheries ($6 8 MM) and wildlife programs ($2.5 MM) are the other major costs. First decade average annual costs are $21.1 MM.

INDIRECT EFFECTS. These effects are average yearly consumption of 30.1 MMCF of timber harvest, 67,000 WFUD'S due to fisheries, 741,000 RVD'S for recreation, and 77,000 WFUD'S for wildlife for the first decade. Total benefits (discounted at four percent for a 150-year period) equal $1,554 MM for timber, $185 MM for recreation, $90 MM for fisheries, and $52 MM for wildlife. Payments to counties would average $13.4 MM each year.

CUMULATIVE EFFECTS. The cumulative impacts on economic and social aspects of the environment are a present net value of $1,150 MM (timber, $1,041 MM; recreation, $173 MM; fisheries, $84 MM; and wildlife, $49 MM). Total opportunity costs compared to the maximum PNV benchmark is $128 MM which is mainly lost revenue due to lower timber production. An additional 580 jobs and $13.8 MM of income is generated by this alternative when compared to the average number of jobs and income realized in the last 10 years.

No change in community cohesion is expected. Internal conflicts will continue to increase. Conflicts concerning the Forest will not disappear.

Table IV-17. Alternative A - Social and Economic Effects.

MINERALS	268,000 Acres Withdrawn From Mineral Entry		
TOTAL CUMULATIVE EFFECTS	No changes in community cohesion are predicted as existing trends will continue. Conflicts concerning the Forest will not disappear.		$+13.8 MM Annual Income/+580 Jobs $1,150 MM PNV $ 128 MM Opportunity Costs

Alternative A-Departure

DIRECT EFFECTS. The direct effects of Alternative A-Departure (Table IV-18) are $743 MM total government expenditures for the 150-year period discounted at four percent. The discounted costs of the timber program are $373 MM with additional discounted costs of $162 MM for road construction ($148 MM for purchaser credits and $14 MM for appropriated dollars). The next highest cost is for the recreation program which has discounted costs of $12.3 MM Fisheries ($6.8 MM) and wildlife programs ($2 5 MM) are the other major costs. First decade average annual costs are $21.6 MM.

INDIRECT EFFECTS These effects are average yearly consumption of 31.2 MMCF of timber harvest, 67,000 WFUD's due to fisheries, 741,000 RVD'S for recreation, and 78,000 WFUD'S for wildlife for the first decade. Total benefits (discounted at four percent for a 150 year period) equal $1,571 MM for timber, $185 MM for recreation, $90 MM for fisheries, and $53 MM for wildlife Payments to counties would average $13.9 MM each year.

CUMULATIVE EFFECTS. The cumulative impacts on economic and social aspects of the environment are a present net value of $1,160 MM (timber, $1,050 MM; recreation, $173 MM; fisheries, $84 MM; and wildlife, $50 MM). Total opportunity costs compared to the maximum PNV benchmark is $118 MM which is mainly lost revenue due to lower timber production. An additional 680 jobs and $16.1 MM of income is generated by this alternative when compared to average of the last 10 years.

Community cohesion is predicted to decrease faster than predicted trends in the Urban and Westside areas. This is due to the perception by some factions in the community that timber harvests are being increased at the expense of unroaded areas, visual quality, and old-growth habitat. Rural communities may benefit from increased consumption of timber and increased opportunities for big game and motorized recreation in the first decade. However, these increases would not be sufficient to effect community cohesion. Alternate Lifestyle communities would have little change in existing cohesion, trends toward conflict concerning the Forest will probably continue.

Table IV-18. Alternative A-Departure - Social and Economic Effects.

PLANNING PROBLEM	DIRECT EFFECT	INDIRECT EFFECT	CUMULATIVE EFFECT
TIMBER PRODUCTION	$373 MM Program Costs $ 2 MM Fixed Costs $371 MM Variable Costs $148 MM Purchaser Credits 87 M Acres O&C Land 558 M Acres Selected Suitable	31.2 MMCF 1st Decade $1,571 MM Benefits PV +680 Jobs +$16.1 MM Annual Income $13.9 MM Annual Payments to Counties Moderate Potential for Below Cost Sales	$1,050 MM PNV $ 14.8/Cubic Foot-average Discounted Costs $ 89 MM Opportunity Costs Compared to PNV Timber

TOTAL CUMULATIVE EFFECTS	Community cohesion is expected to decrease more rapidly than existing trends due to controversy over increasing timber harvests at the expense of other resources.		$+16.1 MM Annual Income/+680 Jobs $1,160 MM PNV $ 118 MM Opportunity Costs

Alternative B

DIRECT EFFECTS. The direct effects of Alternative B (Table IV-19) are $799 MM total government expenditures for the 150-year period discounted at four percent The discounted costs of the timber program are $415 MM with additional discounted costs of $181 MM for road construction ($158 MM for purchaser credits and $23 MM for appropriated dollars) The next highest cost is for the recreation program which has discounted costs of $13.5 MM Fisheries ($9 9 MM) and wildlife programs ($3 8 MM) are the other major costs First decade average annual costs are $24.9 MM

INDIRECT EFFECTS. These effects are average yearly consumption of 36.8 MMCF of timber harvest, 72,000 WFUD'S due to fisheries, 741,000 RVD'S for recreation, and 89,000 WFUD'S for wildlife for the first decade. Total benefits (discounted at four percent for a 150-year period) equal $1,691 MM for timber, $185 MM for recreation, $104 MM for fisheries, and $58 MM for wildlife. Payments to counties would average $16.4 MM each year.

CUMULATIVE IMPACTS. The cumulative impacts on economic and social aspects of the environment are a present net value of $1,241 MM [timber, $1,119 MM; recreation, $172 MM; fisheries, $94 MM; and wildlife, $54 MM)] Total opportunity costs compared to the maximum PNV benchmark is $37 MM which is mainly lost revenue due to lower timber production. An additional 1,230 jobs and $28 7 MM of income is generated by this alternative when compared to the average of the last 10 years.

Decreases in community cohesion are predicted to accelerate in Urban areas as timber harvests are increased at the expense of unroaded areas, visual quality, and old-growth habitat. Rural communities would benefit from increased consumption of timber and increased opportunities for big game and motorized recreation in the first decade This stabilizes community cohesion; as people feel their needs are being met, attitudes toward the Forest become positive. Westside communities gain cohesion as the vast majority of the population, including most timber interests, collectively feel threatened by the gross imbalance of resource outputs and management. As negative attitudes toward external interests intensify due to increased commodity outputs at the expense of amenity values, community cohesion accelerates in Alternate Lifestyle communities

Alternative C

DIRECT EFFECTS. The direct effects of Alternative C (Table IV-20) are $817 MM total government expenditures for the 150-year period discounted at four percent. The discounted costs of the timber program are $428 MM with additional discounted costs of $187 MM for road construction ($164 MM for purchaser credits and $23 MM for appropriated dollars). The next highest cost is for the recreation program which has discounted costs of $13 6 MM. Fisheries ($7.6 MM) and wildlife programs ($2.5 MM) are the other major costs. First decade average annual costs are $26.3 MM.

INDIRECT EFFECTS. These effects are average yearly consumption of 31.8 MMCF of timber harvest, 68,000 WFUD'S due to fisheries, 718,000 RVD'S for recreation, and 96,000 WFUD's for wildlife Total benefits equal $1,674 MM for timber, $185 MM for recreation, $92 MM for fisheries, and $59 MM for wildlife programs Payments to counties would average $14 2 MM each year

CUMULATIVE EFFECTS. The cumulative impacts on economic and social aspects of the environment are a present net value of $1,197 MM (timber, $1,082 MM, recreation, $172 MM; fisheries, $84 MM; and wildlife, $56 MM).

Total opportunity costs compared to the maximum PNV benchmark is $81 MM which is mainly lost revenue due to lower timber production An additional 830 jobs and $18 2 MM of income is generated by this program mainly due to increased timber outputs relative to past timber harvest

Decreases in community cohesion are predicted to accelerate in Urban areas as timber harvests are increased at the expense of unroaded areas, visual quality, and old-growth habitat. Rural communities would benefit from increased consumption of timber and increased opportunities for big game and motorized recreation in the first decade. This would stabilize community cohesion, as people feel their needs are being met, attitudes toward the Forest become positive. Westside communities suffer decreased cohesion as the perception that fisheries and recreation values are being sacrificed for timber interests polarizes the community There is disagreement over "balanced" resource management and this leads to accelerated internal conflict. Community cohesion is accelerated in Alternate Lifestyle communities, as negative attitudes toward external forces intensify due to increased commodity outputs at the expense of amenity values

WILDLIFE HABITAT	$ 2.5 MM Program Costs $ 1.1 MM Fixed Costs $ 1.4 MM Variable Costs $56.2 M Annual Capital Investment Program	$59 MM Benefits PV 95.8 M WFUDs + 42 Jobs +$720.0 M Annual Income	$ 56 MM PNV $28.9/WFUD Average Disc.Cost $ 0 MM Opportunity Costs Compared to PNV Wildlife
MINERALS	265,000 Acres Withdrawn From Mineral Entry		
TOTAL CUMULATIVE EFFECTS	Community cohesion is predicted to increase due to contoversy over increased outputs at expense of unroaded areas, old-growth habitat, and visual quality.		$+18.2 MM Annual Income/+830 Jobs $1,197 MM PNV $ 81 MM Opportunity Costs

Alternative D

DIRECT EFFECTS. The direct effects of Alternative D (Table IV-21) are $780 MM total government expenditures for the 150-year period discounted at four percent The discounted costs of the timber program are $405 MM; with additional discounted costs of $172 MM for road construction ($152 MM for purchaser credits and $20 MM for appropriated dollars). The next highest cost is for the recreation program which has discounted costs of $13.5 MM Fisheries ($7.4 MM) and wildlife programs ($1 8 MM) are the other major costs First decade average annual costs are $24 2 MM

INDIRECT EFFECTS. These effects are average yearly consumption of 30 4 MMCF of timber harvest, 69,000 WFUD'S due to fisheries, 718,000 RVD'S for recreation, and 87,000 WFUD'S for wildlife for the first decade Total benefits equal $1,601 MM for timber, $185 MM for recreation, $96 MM for fisheries, and $54 MM for wildlife programs (discounted values for a 150-year period at four percent interest) Payments to counties would average $13.5 MM each year

CUMULATIVE EFFECTS. The cumulative impacts on economic and social aspects of the environment are a present net value of $1,160 MM (timber, $1,044 MM; recreation, $174 MM; fisheries, $89 MM; and wildlife, $52 MM). Total opportunity costs compared to the maximum PNV benchmark is $118 MM which is mainly lost revenue due to lower timber production. An additional 640 jobs and $15 0 MM of income is generated by this program mainly due to increased timber outputs relative to past timber harvest.

No change in expected trends for community cohesion is expected Internal conflicts will continue to increase. Conflicts concerning the Forest will not disappear

Table IV-21. Alternative D - Social and Economic Effects.

Alternative D1

DIRECT EFFECTS The direct effects of Alternative D1 (Table IV-22) are $792 MM total government expenditures for the 150-year period discounted at four percent. The discounted costs of the timber program are $404 MM with additional discounted costs of $181 MM for road construction ($164 MM for purchaser credits and $17 MM for appropriated dollars). The next highest cost is for the recreation program which has discounted costs of $13.5 MM Fisheries ($7.4 MM) and wildlife programs ($2 5 MM) are the other major costs. First decade average annual costs are $23 1 MM.

INDIRECT EFFECTS These effects are average yearly consumption of 33 2 MMCF of timber harvest, 69,000 WFUD'S due to fisheries, 718,000 RVD'S for recreation, and 81,000 WFUD'S for wildlife for the first decade. Total benefits equal $1,666 MM for timber, $185 MM for recreation, $96 MM for fisheries, and $55 MM for wildlife programs (discounted values for a 150-year period at four percent interest) Payments to counties would average $14.8 MM each year.

CUMULATIVE EFFECTS. The cumulative impacts on economic and social aspects of the environment are a present net value of $1,214 MM (timber, $1,098 MM; recreation, $172 MM; fisheries, $89 MM, and wildlife, $53 MM). Total opportunity costs compared to the maximum PNV benchmark is $64 MM which is mainly lost revenue due to lower timber production. An additional 880 jobs and $20 7 MM of income is generated by this program mainly due to increased timber outputs relative to past timber harvest.

Decreases in community cohesion are predicted to accelerate in Urban areas as timber harvests are increased at the expense of unroaded areas, visual quality, and old-growth habitat. Rural communities would benefit from increased consumption of timber and increased opportunities for big game and motorized recreation in the first decade. This would stabilize community cohesion; as people feel their needs are being met, attitudes toward the Forest become positive Westside communities suffer decreased cohesion as the perception that fisheries and recreation values are being sacrificed for timber interests polarizes the community. There is disagreement over "balanced" resource management and this leads to accelerated internal conflict. Community cohesion is accelerated in Alternate Lifestyle communities, as negative attitudes toward external forces intensify due to increased commodity outputs at the expense of amenity values.

Table IV-22. Alternative D1 - Social and Economic Effects.

PLANNING PROBLEM	DIRECT EFFECT	INDIRECT EFFECT	CUMULATIVE EFFECT
TIMBER PRODUCTION	$404 MM Program Costs $ 2 MM Fixed Costs $402 MM Variable Costs $164 MM Purchaser Credits 86 M Acres O&C Land 550 M Acres Selected Suitable	33.2 MMCF 1st Decade $1,666 MM Benefits PV + 861 Jobs +$20.4 MM Annual Income $14.8 MM Annual Payments to Counties High Potential for Below Cost Sales	$1,098 MM PNV $ 15.1/Cubic Foot-average Discounted Costs $ 41 MM Opportunity Costs Compared to PNV Timber

MINERALS	266,000 Acres Withdrawn From Mineral Entry		
TOTAL CUMULATIVE EFFECTS	Decrease in community cohesion is predicted to proceed more rapidly than under existing conditions due to concerns over increases in timber outputs at the expense of old growth species.		$+20.7 MM Annual Income/+880 Jobs $1,214 MM PNV $ 64 MM Opportunity Costs

Alternative E

DIRECT EFFECTS. The direct effects of Alternative E (Table IV-23) are $517 MM total costs for the 150-year period discounted at four percent The discounted costs of the timber program are $211 MM with additional discounted costs of $88 MM for road construction ($83 MM for purchaser credits and $5 MM for appropriated dollars) The next highest cost is for the recreation program which has discounted costs of $12.9 MM Fisheries ($7 4 MM) and wildlife programs ($2 5 MM) are the other major costs. First decade average annual costs are $16 7 MM.

INDIRECT EFFECTS. These effects are average yearly consumption of 16.2 MMCF of timber harvest, 69,000 WFUD'S due to fisheries, 718,000 RVD'S for recreation, and 60,000 WFUD'S for wildlife for the first decade. Total benefits equal $871 MM for timber, $185 MM for recreation, $97 MM for fisheries, and $39 MM for wildlife programs (discounted values for a 150-year period at four percent interest) Payments to counties would average $6.8 MM each year.

CUMULATIVE EFFECTS. The cumulative impacts on economic and social aspects of the environment are a present net value of $679 MM (timber, $578 MM; recreation, $172 MM, fisheries, $90 MM; and wildlife, $36 MM) Total opportunity costs compared to the maximum PNV benchmark are $599 MM which is mainly lost revenue due to lower timber production A loss of 700 jobs and $15.3 MM of income is mainly due to decreased timber outputs relative to past timber harvest

A reduction in community cohesion is predicted for Urban areas as unroaded areas and old growth are preserved at the expense of timber harvest Community cohesion accelerates rapidly in Rural areas due to the collective perception that jobs and livelihood are being sacrificed to protect unroaded areas and old growth. Similarly, community cohesion increases in Westside areas since resource use is perceived to be out of balance; the community as a whole feels threatened by adverse impacts on the timber industry. Community cohesion will tend to stabilize in the Alternate Lifestyle communities, since their wants, needs, and desires have been heard Their attitude toward the Forest improves and Forest-related external conflicts decline.

Alternative G

DIRECT EFFECTS The direct effects of Alternative G (Table IV-24) are $577 MM total costs for the 150-year period discounted at four percent. The discounted costs of the timber program are $251 MM with additional discounted costs of $107 MM for road construction ($102 MM for purchaser credits and $5 MM for appropriated dollars). The next highest cost is for the recreation program which has discounted costs of $14 0 MM. Fisheries ($7.6 MM) and wildlife programs ($2.5 MM) are the other major costs First decade average annual costs are $17 8 MM

INDIRECT EFFECTS. These effects are average yearly consumption of 20.5 MMCF of timber harvest, 69,000 WFUD'S due to fisheries, 718,000 RVD'S for recreation, and 66,000 WFUD'S for wildlife for the first decade. Total benefits equal $1,092 MM for timber, $185 MM for recreation, $98 MM for fisheries, and $43 MM for wildlife programs (discounted values for a 150-year period at four percent interest). The potential for below cost timber sales is low due to limited road construction and no hardwood conversion program Payments to counties would average $8.8 MM each year

CUMULATIVE EFFECTS The cumulative impacts on economic and social aspects of the environment are a present net value of $844 MM (timber, $739 MM; recreation, $171 MM, fisheries, $90 MM, and wildlife, $41 MM). Total opportunity costs compared to the maximum PNV benchmark are $434 MM which is mainly lost revenue due to lower timber production. A loss of 300 jobs and $6.4 MM of income is mainly due to decreased timber outputs relative to past timber harvest

A reduction in community cohesion is predicted for Urban areas as unroaded areas and old growth are preserved at the expense of timber harvest Community cohesion accelerates rapidly in Rural areas due to the collective perception that jobs and livelihood are being sacrificed to protect unroaded areas and old growth Similarly, community cohesion increases in Westside areas since resource use is perceived to be out of balance, the community as a whole feels threatened by adverse impacts on the timber industry. Community cohesion will tend to stabilize in the Alternate Lifestyle communities, since their wants, needs and desires have been heard Their attitude toward the Forest improves and Forest-related external conflicts decline.

TOTAL CUMULATIVE EFFECTS	Accelerated decrease in community cohesion is predicted due to increases in roadless areas, preserved old growth and visual quality at the expense of timber Production.		$- 6.4 MM Annual Income/-300 Jobs $ 844 MM PNV $ 434 MM Opportunity Costs

Alternative K

DIRECT EFFECTS The direct effects of Alternative K (Table IV-25) are $713 MM total costs for the 150-year period discounted at four percent. The discounted costs of the timber program are $345 MM with additional discounted costs of $153 MM for road construction ($139 MM for purchaser credits and $14 MM for appropriated dollars). The next highest cost is for the recreation program which has discounted costs of $13.5 MM Fisheries ($9.9 MM) and wildlife programs ($2 5 MM) are the other major costs First decade average annual costs are $21 4 MM

INDIRECT EFFECTS These effects are average yearly consumption of 27 8 MMCF of timber harvest, 71,000 WFUD'S due to fisheries, 718,000 RVD'S for recreation, and 75,000 WFUD'S for wildlife for the first decade. Total benefits equal $1,454 MM for timber, $185 MM for recreation, $101 MM for fisheries, and $50 MM for wildlife programs (discounted values for a 150-year period at four percent interest). The potential for below cost timber sales is moderate due to limited road construction, entry into previously unroaded areas, and limited hardwood conversion program. Payments to counties would average $12 4 MM each year.

CUMULATIVE EFFECTS. The cumulative impacts on economic and social aspects of the environment are a present net value of $1,083 MM (timber, $970 MM, recreation, $172 MM, fisheries, $91 MM; and wildlife, $47 MM). Total opportunity costs compared to the maximum PNV benchmark are $195 MM which is mainly lost revenue due to lower timber production. A gain of 380 jobs and $9 0 MM of income is mainly due to increased timber outputs relative to past timber harvest.

A slight increase in community cohesion is predicted in Rural areas as unroaded areas and old growth are perceived to be preserved at the expense of timber harvest, and common adversity is confronted. The other three community types would be unchanged, predicted trends would continue with decreasing cohesion and increasing internal conflict.

Table IV-25. Alternative K - Social and Economic Effects.

PLANNING PROBLEM	DIRECT EFFECT	INDIRECT EFFECT	CUMULATIVE EFFECT
TIMBER PRODUCTION	$345 MM Program Costs $ 2 MM Fixed Costs $343 MM Variable Costs $139 MM Purchaser Credits 80 M Acres O&C Land 529 M Acres Selected Suitable	27.8 MMCF 1st Decade $1,454 MM Benefits PV + 371 Jobs +$ 8.8 MM Annual Income $12.4 MM Annual Payments to Counties Moderate Potential for Below Cost Sales	$ 970 MM PNV $ 14.4/Cubic Foot-average Discounted Costs $ 169 MM Opportunity Costs Compared to PNV Timber

Alternative M

DIRECT EFFECTS. The direct effects of Alternative M (Table IV-26) are $330 MM total costs for the 150-year period discounted at four percent. The discounted costs of the timber program are $90 MM with additional discounted costs of $16 MM for road construction ($15 MM for purchaser credits and $1 MM for appropriated dollars). The next highest cost is for the recreation program which has discounted costs of $14 0 MM. Fisheries ($7.6 MM) and wildlife programs ($2.5 MM) are the other major costs. First decade average annual costs are $12.2 MM.

INDIRECT EFFECTS. These effects are average yearly consumption of 6.1 MMCF of timber harvest, 69,000 WFUD'S due to fisheries, 718,000 RVD'S for recreation, and 45,000 WFUD'S for wildlife for the first decade. Total benefits equal $286 MM for timber, $185 MM for recreation, $98 MM for fisheries, and $29 MM for wildlife programs (discounted values for a 150-year period at four percent interest). The potential for below cost timber sales is low due to limited road construction, no entry into previously unroaded areas, and limited hardwood conversion program. Payments to counties would average $2.7 MM each year for the first decade.

CUMULATIVE EFFECTS. The cumulative impacts on economic and social aspects of the environment are a present net value of $272 MM (timber, $181 MM; recreation, $171 MM; fisheries, $90 MM, and wildlife, $26 MM). Total opportunity costs compared to the maximum PNV benchmark are $1,006 MM which is mainly lost revenue due to lower timber production. A loss of 1,650 jobs and $38.8 MM of income in the first decade is mainly due to decreased timber outputs relative to past timber harvest

A reduction in community cohesion is predicted for Urban areas as unroaded areas and old growth are preserved at the expense of timber harvest. Community cohesion accelerates rapidly in Rural areas due to the collective perception that jobs and livelihood are being sacrificed to protect unroaded areas and old growth. Similarly, community cohesion increases rapidly in Westside areas since resource use is perceived to be way out of balance, the community as a whole feels threatened by severely adverse impacts on the timber industry. Community cohesion will tend to stabilize in the Alternate Lifestyle communities, since their wants, needs, and desires have been heard. Their attitude toward the Forest improves significantly and Forest-related external conflicts decline.

Alternative S

DIRECT EFFECTS. The direct effects of Alternative S (Table IV-27) are $712 MM total costs for the 150-year period discounted at four percent. The discounted costs of the timber program are $336 MM with additional discounted costs of $156 MM for road construction ($142 MM for purchaser credits and $14 MM for appropriated dollars). The next highest cost is for the recreation program which has discounted costs of $17.2 MM. Fisheries ($12.4 MM) and wildlife programs ($6.6 MM) are the other major costs First decade average annual costs are $21.7 MM

INDIRECT EFFECTS. These effects are average yearly consumption of 29.0 MMCF of timber harvest, 79,000 WFUD'S due to fisheries, 718,000 RVD'S for recreation, and 97,000 WFUD'S for wildlife for the first decade Total benefits equal $1,486 MM for timber, $185 MM for recreation, $103 MM for fisheries, and $67 MM for wildlife programs (discounted values for a 150-year period at four percent interest). The potential for below cost timber sales is low due to limited road construction, limited entry into previously unroaded areas, and a limited hardwood conversion program. Payments to counties would average $12.9 MM each year for the first decade.

CUMULATIVE EFFECTS. The cumulative impacts on economic and social aspects of the environment are a present net value of $1,131 MM (timber, $1,008 MM; recreation, $169 MM; fisheries, $90 MM; and wildlife, $60 MM). Total opportunity costs compared to the maximum PNV benchmark are $147 MM which is mainly lost revenue due to lower timber production. A gain of 560 jobs and $13 MM of income in the first decade is mainly due to increased timber outputs relative to past timber harvest.

A slight increase in community cohesion is predicted in Rural areas as unroaded areas and old growth are perceived to be preserved at the expense of timber harvest; and common adversity is confronted Urban areas and Alternate Lifestyle communities would be unchanged, predicted trends would continue with decreasing cohesion and increasing internal conflict in these areas. Internal conflicts in Westside communities would decrease as the management of Forest resources are perceived to be balanced. Community cohesion stabilizes and attitudes toward the Forest become positive as wants, needs, and desires are felt to be heard.

1987 FIRES

The Siskiyou was impacted by several large fires in 1987. The effects of those fires and subsequent timber salvage projects, and the changes in the environmental components relevant to this Forest Plan analysis are described in the section **1987 FIRES** of Chapter III Numerous changes have occurred which have only limited implication for the Forest Plan analysis; while they affect the Forest potential to produce a particular output or condition, the changes are small fractions of the Forest totals Additionally, the fire effects, having already taken place and a decision made relative to the Silver Fire Recovery Project, will be the same for all alternatives in this analysis regardless of the one selected. For Forest Planning purposes, none of the alternatives or environmental components are significantly affected when viewed on a Forest-wide scale. Only those elements which have implications for changed outputs or environmental conditions are discussed here.

WILDERNESS AND ROADLESS AREAS

The character of parts of the Kalmiopsis and Siskiyou Wildernesses have been altered by the affects of the fires on the vegetation. These changes are part of the natural ecological processes that have occurred repeatedly in these areas for centuries and do not affect their quality as Wilderness. For some of the unroaded areas, Wilderness potential (i e , presence of Wilderness characteristics or attributes) has been affected by the road construction and timber salvage in the Silver Fire area. The changes in Recreation Opportunity Spectrum (ROS) Class are described in Chapter III, **1987 FIRES**, and the changes in the former North Kalmiopsis Roadless Area are described in Appendix C. Alternatives that would allocate areas involved in the roading and timber salvage to Backcountry Recreation (Alternatives E, G, and M) would require restoration of the affected areas to accelerate their return to more natural conditions

SOIL AND WATER

Impacts to soil and water are described in detail in the environmental documents prepared for the individual timber salvage and recovery projects referenced in Chapter III. The more important effects of water temperature increases and sediment production are also summarized in Chapter III. Sediment production will be higher in the immediate future in the burned drainages than displayed earlier in this Chapter. These effects will occur regardless of the actions taken with this Forest Plan analysis, and irrespective of the alternative selected. The consideration here is for cumulative effects that could result from implementation of a Forest Plan alternative

The most critical area of consideration is associated with the Silver Fire area. The Record of Decision for the Silver Fire Recovery Project (1988d) precludes additional timber harvest in the fire area until project monitoring indicates that watershed recovery is sufficient to allow activities to proceed without significant adverse cumulative impacts (probably about 10 years) Any alternative selected for the Forest Plan would need to honor this additional mitigation, Forest-wide outputs would not be affected. An additional mitigation for the Silver Fire and associated timber salvage project activity can be made through adjusting the basin harvest dispersion constraints for the unburned portions of Silver and Indigo Planning Basins Such an adjustment has been applied in Alternative S. See discussions in **SOIL AND WATER** and **FISH** sections of this chapter for the effects of these dispersion constraints.

VEGETATION (including TIMBER)

Fire is a natural process, affects on sensitive plants and other vegetation resources are generally not adverse. However, the loss of timber volume from the inventory has implications for some alternatives, particularly those that project high levels of timber harvest The volumes salvaged in place of sales that would normally have been scheduled offset part of the potential loss Since most of the available volume in the Galice and Longwood Fire areas will be salvaged, the only losses of any importance occur in the

Silver Fire area. Alternatives that would allocate part or all of the burned areas to uses with programmed timber outputs would be affected, others would not

The Silver Fire Recovery Project analysis also identified some additional lands that are unsuitable due to reforestation difficulty or potential for irreversible soil damage. The Record of Decision for the project indicated that the final Forest Plan would account for these inventory changes along with the changes from the fires themselves Table II-63 displays the ASQ projected for each alternative of this FEIS, and the ASQ that would be projected with the changes from the 1987 fires and revised land suitability status in the Silver Fire area. Any alternative selected would be modified to be consistent with these resource potentials prior to development of the Forest Plan for implementation. Departure Alternatives A-Departure and B could remain the same for the first decade, but would have slightly more reduction in future decades than projected.

FISH

The discussion in Chapter III explains the scope of the impacts to the fisheries resource (the primary beneficial use of water for the areas impacted). The total impact to fish production is projected to be less than one percent when viewed in the Forest-wide context. This impact has already been incurred and will not be affected by the alternatives considered in this analysis The only consideration here is the need to allow the burned areas to recover before additional timber harvest is scheduled within the perimeter of the Silver Fire area Harvest scheduling for any alternative selected for implementation could be modified to provide additional mitigation in these areas until recovery has progressed to a stage allowing further harvest activities without significant adverse cumulative impacts. Additional mitigation could be in the form of precluding timber harvest within the fire perimeter during a period to allow recovery as described under SOIL AND WATER above. It could also include delaying or modifying harvests in riparian areas in the affected watersheds.

WILDLIFE

Impacts to many species of wildlife are positive as greater diversity and distribution of seral stages has been created by the fires. Habitat for species favoring mature and old-growth forest has been reduced, though not significantly when viewed on the Forest-wide scale Impacts to the habitat networks for species dependent on mature and old growth habitat are described in Chapter III. Although mature and old-growth forests are now approximately 25,000 acres less than displayed from the planning inventory (443,000 acres), Forest-wide there is no serious impact as a result of the fires on the habitat network proposed to maintain minimum viable populations of wildlife species dependent on mature and old-growth forest

RECREATION SETTING

The character of the recreational setting is changed in the burned areas as a result of changes in the vegetation caused by the fires. The more important change relative to this analysis is the modification of the unroaded character and the ROS inventory resulting from the roading associated with the Silver Fire Recovery Project as described under WILDERNESS AND ROADLESS AREAS above. Alternatives which would allocate areas with new roads to the Backcountry Recreation Management Area would need restoration for these areas to return them to a more natural, undeveloped condition over time Alternatives that would be affected are E, G, and M

POTENTIAL CONFLICTS WITH PLANS AND POLICIES OF OTHER JURISDICTIONS

The following statements are provided to help define areas of potential differences between the proponent of the action (USDA Forest Service) and the policies, management, and enforcement responsibilities of other agencies

CULTURAL RESOURCES

The Oregon State Historic Preservation Office is presently preparing a State-wide Preservation Plan for cultural resources. Since it is in the preliminary stages, potential conflicts between the management alternatives and the objectives of the Plan cannot be determined However, the laws and policies that govern cultural resource work on Federal lands are coordinated and consistent with those of the State

Potential conflicts are not anticipated with the plans and policies of Native American tribes located adjacent to the Forest However, should issues arise, the Forest will work with those groups to seek resolution.

MINERAL DEPOSITS

Mining and minerals are important to county, state, and national plans at all levels of the economy. The effects of implementing any alternative may conflict with their objectives and Federal mining laws. The U.S. Mining Laws Act of 1872 predates all other laws that govern Forest Service activity Because of this, frequent conflicts arise between administration of mining and other resources such as visuals, water, sensitive plants, and recreation.

SOIL AND WATER

Cumulative Effects

Essentially all private land adjacent to the Forest have been cut at one time or another Little timber harvest or associated road construction (most road systems are in place) is expected in the next 10 to 15 years on private lands in the watersheds of multiple ownership (National Forest, BLM, State, and private land). The potential for cumulative effects by specific basins from harvest and associated roading is discussed in the Planning Basin analyses under the **FISH** section of this chapter. Nevertheless, conflicts may exist between State administration and enforcement of Best Management Practices (BMP's) on private timber harvest activities versus those practices implemented through the Forest's policies, Standards and Guidelines, and BMP's.

Water Supply

During the summer months the demand for water often exceeds supply, especially on the east side of the Forest. In the main stem and several tributaries of the Illinois River, water withdrawal by private landowners may interfere with the Forest meeting its goal of maintaining instream flows for recreation, aesthetics, ecosystem maintenance, and fishery values associated with the designated Wild and Scenic Illinois River. The Federal requirements and authorities for maintenance and protection of the resources may conflict with the State's administration of water rights

Water Quality

Appendix F of the Forest Plan describes the process for determining appropriate BMP's and ensuring their implementation at both the Forest Plan and Project level. Potential for conflicts exist over jurisdictional responsibilities, problem identification, interpretation of potential management activity impacts on water quality, and the selection, effectiveness, and appropriate monitoring level for BMP's

Implementation of the State Water Quality Management Plan on lands administered by the USDA Forest Service is described in Memoranda of Understanding between:

(a) The Oregon Department of Environmental Quality (DEQ) and USDA Forest Service (2/12/79 and 12/7/82), and "Attachments A and B" referred to in this MOU (Implementation Plan for Water Quality Planning on National Forest lands in the Pacific Northwest 12/78 and BMP's for Range and Grazing Activities on Federal lands, respectively).

(b) The State Water Resources Control Board (SWRCB), State of California, and USDA Forest Service, Pacific Southwest Region, 1981

These Memoranda of Understanding and plans provide the basis for the interagency agreement whereby the Governor of the State designates the Forest Service as the implementing agency for nonpoint source pollution control for lands under its jurisdiction. The agreement provides for annual meetings between the Pacific Northwest Region of the Forest Service and DEQ to evaluate the program and progress being made, and provides the basis for recertification by the Governor. Available monitoring information is reviewed, revisions or additions to the BMP's are addressed, progress on problem identification and treatment is provided, and reports are written and resubmitted by the State to the U.S. Environmental Protection Agency (EPA).

There is essentially little difference in the EPA, State of California, and Forest Service process interrelationships than described for Oregon However, the development and implementation of BMP's appears to be more structured.

Compliance with State requirements for protection of waters of the State of Oregon (Oregon Administrative Rules, Chapter 340-41), and the State of California (Porter-Cologne Water Quality Control Act, Division 7) will be achieved through planning, application, and monitoring of BMP's, in conformance with the Clean Water Act, regulations, and Federal guidance issued thereto.

The key beneficial uses of water which BMP's are designed to protect are fishery and domestic uses. The Standards and Guidelines and Appendix F require consistency with the BMP's contained in:

California

"Water Quality Management For National Forest System Lands in California - BMP's," Chapter 10, **Draft** Soil and Water Conservation Handbook, Pacific Southwest Region, San Francisco (1988).

Oregon

"General Water Quality BMP's," Pacific Northwest Region (1988).

"Siskiyou National Forest Best Management Practices," Forest Planning Records (1988).

The Forest lies partially within two Oregon Regional Water Quality Basins, the Rogue Basin and South Coast Basin, and one California Regional Water Quality Basin, the North Coast Region Intermingled basins (i.e., differing levels of water quality standards within the same watershed), such as the East and West Fork Illinois, North Fork Smith, and Winchuck Rivers, could pose some problems relative to whose standards apply to what part, when. Any conflicts that arise, however, will likely be worked out through communication between the affected agencies.

FIRE

Only minor impacts are expected in the areas of fire prevention and detection. These conflicts will be resolved through modification of existing Cooperative Agreements and Operating Plans

The Forest's use of appropriate suppression response is expected to cause minor conflicts with the agencies that are responsible for wildland fire protection on lands adjacent to the National Forest. These conflicts will be resolved as the other agencies gain a better understanding of the Forest's suppression response concept and have an opportunity to view its application.

AIR QUALITY

All prescribed burning operations on the Oregon portions of the Forest would be conducted in accordance with the Oregon Smoke Management Plan (OAR 629-43-043). The actual burning operations would be further regulated by Oregon State Forestry Directive 1-4-1-601, Operational Details for the Oregon Smoke Management Plan Prescribed burning operations in California would comply with the appropriate regulations.

Potential conflicts exist between Federal land managers and the agencies of each state (Oregon State Department of Environmental Quality, the Oregon Department of Forestry, and the California Air Resources Board) responsible for the regulation of forestry and wildland burning operations. This conflict would revolve around the state agency's commitment to clean air and the Forest's goal of meeting management goals and objectives.

Another area of potential conflict exists between adjoining National Forests, other State and Federal land management agencies, and corporate and private land owners. The conflict here will be a question of burning priorities, i.e., who gets to burn which units on days when only limited burning is allowed.

A third area of potential conflict involves the Class I areas managed by other Federal land managers Smoke from prescribed fire activities on the Forest could intrude into these Class I areas, creating interdepartmental as well as political dissatisfaction. The reverse is also true for smoke that could intrude in the Class I area managed by the Forest from activities off the Forest.

The potential for conflict also exists between local governments, Oregon Department of Environmental Quality, and the Forest over the amounts of readily available firewood which could contribute to the air quality problems in the Rogue Valley during the winter months.

WILDLIFE

The mission of the State wildlife agencies differs from the mission of the Siskiyou National Forest. The Forest manages the habitat, the Department manages the animals. Therefore, plans for the management of the wildlife occupying Forest land may conflict, special efforts to address differences will be necessary

The Oregon Department of Fish and Wildlife (ODFW) has offered goals for deer and elk populations on National Forests Alternatives E, G, and M, with lower levels of timber harvest, will never meet these objectives Alternatives K and S come close to the current situation in most decades. During the next five decades, habitat capability is significantly higher than at present in Alternatives NC, A, A-Departure, B, C, D, and D1. The ODFW goals are probably achievable for Alternatives E and G (but not M) with special management direction to invest in forage enhancement projects, manage cover and access, and cooperate in restocking elk in their historical range.

PROBABLE ADVERSE ENVIRONMENTAL EFFECTS THAT CANNOT BE AVOIDED

Implementation of any of the alternatives would inevitably result in some adverse environmental effects. The severity of the effects can be minimized by adhering to the direction in the management prescriptions and Standards and Guidelines in Chapter IV of the Forest Plan. Some impacts, however, generally cannot be avoided if management activities are implemented.

CULTURAL RESOURCES

Current methodology cannot insure that all sites will be located. Some significant sites may be inadvertently destroyed or damaged. Pending advances in inventory techniques, such impacts are unavoidable.

Mitigation of adverse effects at significant sites will release affected acres for project activity. Elsewhere, continued avoidance of sites will prevent or minimize the activities within the affected acres.

IMPROVEMENTS

The construction of new roads will have a long-lasting impact by changing the line, color, texture, and vegetative growth along the road as viewed by the Forest user. As an access for recreation, timber, and administration activities, use causes wear on roads and trails. The wear effects can be mitigated by maintenance or reconstruction activities

Developed recreation sites are susceptible to use and vandalism effects Some impacts can be mitigated through maintenance, reconstruction, and various preventative or enforcement methods applied to vandalism problems.

WILDERNESS AND ROADLESS AREAS

The primitive (undeveloped and trailless) character of the Kalmiopsis Wilderness will be degraded to a limited extent due to trail construction.

The existing Wilderness potential in any of the inventoried roadless areas would be foregone under alternatives where these areas are allocated to some form of development.

Mineral exploration and development will be prohibited or restrained in designated Wildernesses.

SOIL AND WATER

Although the Forest Standards and Guidelines, BMP's, and Monitoring and Evaluation Plan have been designed to prevent significant adverse effects to soil and water, the potential for their occurrence does exist. Sediment production will exceed natural rates as long as roads are built, timber is harvested, and other activities take place which disturb the vegetation and soil. Sediment will be produced by surface erosion, channel erosion, and landslides.

State and Federal water quality standards for turbidity may not be met temporarily, nor in some specific locations, because of the difficulty in preventing all soil erosion from newly disturbed sites. A greater rate of landsliding will occur in clearcut units and along roads than in unmanaged or existing stable areas. However, BMP's currently being implemented, coupled with the Standards and Guidelines and monitoring, will prevent or mitigate any major or highly adverse soil and water impact to the established beneficial uses In addition, the Forest will coordinate with the State water quality agencies and the EPA in regard to BMP's

implementation Current practices will be continually updated when new information or improved methods are developed that are both technically correct and practical in application

Sediment and turbidity originating from areas being managed for timber production have the greatest potential to adversely impact fish habitat Stream water temperatures will increase in certain stream reaches if riparian vegetation is inadvertently removed (such as blowdown), but should remain unchanged or be reduced under normal conditions over time.

Drinking water may be contaminated by human use, especially when such use is concentrated along streams. Domestic water supply, if diverted directly from Forest streams, could be adversely affected during or shortly after road construction or other activities, and for short periods during more intense winter storms However, the degree of impact will be both short in duration and limited due to site-specific planning requirements and mitigations provided through the Standards and Guidelines Existing or potential conditions that are or have a good probability of adversely impacting the soil or water resource will be treated through watershed restoration or rehabilitation improvement projects.

FIRE

Impacts to the total array of Forest resources from wildfire cannot be totally avoided; wildfires will continue to occur Their occurrence will be random in both time and space, but areas with the highest probabilities for an ignition can be identified. The severity of the impact will be dependent on the intensity of the fire, and this will be determined by site-specific parameters such as fuel loading, weather conditions, and topography

Short-term loss of soil that is due to the construction of firelines and the loss of vegetation will occur, despite preventive measures The buildup of fuels will continue in areas protected by a fire exclusion philosophy. Soil erosion and the use of aerially delivered fire retardants may result in short-term water quality degradation. Recreational opportunities may be interrupted or limited in fire areas for short periods of time The aftermath of the fire will remain visible for a short time, and the location of a major fire will remain visible through the vegetation for decades. Smoke will be produced.

Adverse impacts will also occur to some resources, such as soil and air quality, from the use of prescribed fire in the treatment of activity and natural fuels, and from wildlife habitat maintenance The severity of these impacts will be dependent on the intensity and duration of the prescribed fire Normally the prescription will be designed so that the activity is implemented to achieve an acceptable level of impact to the target and nontarget resource values.

VEGETATION

Implementation of Standards and Guidelines in the proposed action allows protection of sensitive plant sites. This can affect the amount of timber, minerals, and grazing resources available for consumption.

AIR QUALITY

Impacts to air quality cannot be avoided in the range of alternatives, however, all of the impacts will be temporary. Wildfires will continue to occur, and generally at times and under conditions that produce more TSP than a prescribed fire of equal size In addition, these will usually occur under meteorological conditions that are not conducive to good smoke dispersal

Prescribed fire is a necessary, integral part of resource management on the Siskiyou National Forest When prescribed fire is utilized, there is smoke.

Road construction, silviculture practices such as the aerial application of herbicides, and motorized recreation will all contribute in one degree or another to the temporary degradation of air quality on the Forest

WILDLIFE

Acres of mature and old-growth forest will be significantly reduced. Populations of wildlife species which depend on these habitat types will be smaller. Hardwood habitat will also be reduced.

Wildlife will be temporarily displaced (permanent in limited cases) when habitat is disturbed by timber management activities, facility development, or recreation use.

Decreases in snag habitat for cavity dependent wildlife will occur due to timber harvesting, firewood cutting, and salvage programs.

VISUAL RESOURCE

Standards and Guidelines for visual resource management under the VQO of "Modification" require that harvest units, road construction, and related activities blend with the patterns exhibited by the characteristic landscape and appear as a natural occurrence when "viewed in the background " Due to the steep topography typical of the Forest, the majority of the roads constructed in General Forest are on ridgetops or in mid-slope locations that expose recreation users to a modified forest in the near foreground (adjacent to roads), middle ground, and background This situation cannot be avoided if additional roading is permitted by the selected alternative

RECREATION SETTINGS

The Primitive and Semi-primitive Non-motorized character and recreation opportunities of all or parts of the inventoried unroaded areas allocated to Management Areas 10-14 will be significantly altered or entirely foregone

Developed sites are responsible for the suppression or loss of vegetation and a resultant change in natural setting. Wildlife habitat would be concurrently degraded.

RELATIONSHIP BETWEEN SHORT-TERM USE AND LONG-TERM PRODUCTIVITY

The relationship between short-term uses of man's environment and the maintenance and/or enhancement of long-term productivity is complex Short-term uses are those that generally occur on an annual basis on some area of the Forest Long-term productivity refers to the land's capability to produce a continuous supply of resources and values for future generations For purposes of this analysis, the period is either beyond the first decade or the planning horizon (150 years), depending on the specific resource. Under all alternatives, the long-term productivity of the Forest is protected from unacceptable degradation by specific Standards and Guidelines. Below are those environmental components that relate today's uses, allocations, and activities to tomorrow's productivity

MINERAL DEPOSITS

Management prescriptions which call for increasing accessibility restrictions on mineral entry have a short-term effect on mineral availability The effect, however, can be long-term if minerals are withdrawn from entry.

IMPROVEMENTS

Structural improvements contribute towards the opportunity to utilize the potential productivity of Forest resources. Producing the goods and services associated with forest environments require functional improvements which enhance economic values. Roads and trails provide the necessary access. Roads are considered to be long-term improvements which provide for continued use over time.

Wildlife use the created openings resulting from the presence of roadways. When people use vehicles on these roads, wildlife are at risk to "road kill," hunting, and harassment during their life cycle. These actions may modify future population levels, with a greater effect on nongame species and selected species types as game species have regulated population levels.

Where a road is temporarily closed between periods of use, the ability to use the road for other purposes is foregone. Revegetation of these closed roadways will have to be removed before reuse to permit travel. Compaction of the roadbed reduces the ability of some vegetation (especially commercial tree species) to grow on many closed roads; however, this is irrelevant to long-term site productivity as the area encompassing the road has been removed from the land base suitable for the production of timber.

WILDERNESS AND ROADLESS AREAS

The designation of Wilderness has some effect on long-term productivity Opportunities to increase productivity or capture sustainable outputs through management of timber and wildlife habitat are foregone. The maintenance of Primitive recreation opportunities is maximized, however other recreation opportunities are not. Maximum protection is afforded water quality and the related fishery, old-growth trees, and associated wildlife species However, any enhancement or restoration opportunities are severely constrained. Threatened and endangered plant and animal species are protected, but little can be done to improve their habitats Natural-appearing landscapes are preserved, although buildup of natural fuels may increase risks of catastrophic wildfire. Prescribed fire may be used to mitigate this impact.

WILD AND SCENIC RIVERS

The designation of the inventoried Wild and Scenic Rivers has some effect on long-term productivity Harvest levels are reduced in the Recreation and Scenic sections No harvest is programmed in the Wild sections, opportunities to increase productivity through management of timber are thereby foregone. Mineral outputs may be severely constrained or lands withdrawn.

SOIL AND WATER

Preserving long-term soil productivity is essential for allowing the sustained yield of timber and other renewable resources from the Forest. Recognized are the potentials for adverse direct, indirect, and cumulative impacts due to management activities on the soil resource. Conclusive evidence relative to short-term impacts of timber harvest and prescribed fire adversely effecting long-term site productivity does not exist. Considerable research suggests, however, that nitrogen reserves, organic residues, and soil physical properties are critical elements of the ecosystem that must be carefully managed to ensure long-term productivity (Little and Klock 1985; Sachs and Sollens 1986; Harvey and others 1987, Powers and Weatherspoon 1984, and Amaranthus and Perry 1987). These researchers suggest that the various components of the site should be maintained to ensure that potential losses of nutrients and changes in soil physical and biological properties do not occur.

Based on current literature, peer review in associated sciences, and field observations, soil protection measures proposed in the Standards and Guidelines will maintain long-term soil productivity. While these newer practices may reasonably assure a good degree of protection to the soil resource, new information provided through research and Forest Plan monitoring efforts will lead to changes (improvements) in the Standards and Guidelines.

No long-term effects to the water resource and beneficial uses are known to occur or are expected from the proposed Forest management activities under any alternative. However, stream channel morphology may be temporarily or permanently altered as a consequence of short-term direct or indirect effects of management, i e., road crossings, erosion, and deposition of sediments, etc.

FIRE

Effective fire prevention and suppression action will minimize damage to existing timber stands and other resources. The long-term change in vegetative composition and density may reduce timber productivity. Site productivity may also be reduced by a catastrophic wildfire resulting from excessive fuel buildups

Slash disposal, if done through a proper prescription, will have little effect on long-term productivity. However, productivity may be adversely affected if slash is not treated or is inadequately treated. Burning at the wrong time and allowing for a high intensity, long duration fire (i.e., too hot too long) will result in loss of soil fertility. Most other effects of slash disposal are short-term and have little effect on productivity.

VEGETATION

Short-term use of timber, mining, and grazing resources can result in long-term loss of productivity within sensitive plant habitats, especially in potential Botanical areas not allocated in the proposed action.

Management of the timber resource today will have effects upon long-term productivity depending on the intensity of management selected. All alternatives would increase projected per acre productivity over time

AIR QUALITY

The temporary impacts of smoke from prescribed fire will have minor effects on the short-term use of Forest resources such as recreation sites, visual resources, and Wilderness. A fire exclusion policy that is developed for the purpose of maintaining air quality would have significant effects on long-term productivity of the Forest as well as set the stage for significant impacts to air quality and other forest resources from wildfires at a later date.

Fire has been of great ecological significance in the development and perpetuation of Douglas-fir and other valuable tree species The future of these species depends to a considerable extent on the skillful

application of fire as a management tool (Weaver 1974) Wright and Bailey (1982) concluded, however, that there is not a straightforward "yes" or "no" answer to the question· Does slash burning after logging benefit Douglas-fir regeneration?

The use of prescribed fire to reduce the flammability of activity fuels affects long-term forest productivity by reducing the risks and consequences of a major wildfire. The long-term benefits of prescribed fire in natural fuels more than outweigh the short-term impact to air quality. Unnatural fuel accumulations have developed as a result of fire exclusion This is particularly true in Wildernesses, where there have been no offsetting resource management actions to provide diversity and discontinuity in the fuels complex

Only one factor in the fire environment is within the control of land managers. Fuels (Countryman 1972). The other elements, weather and topography, are beyond control. Topography is usually considered static since it changes slowly with time. Air mass characteristics are highly variable, and little can be done to control or modify them.

Prescribed fire can be utilized both effectively and efficiently to reduce fuel loadings and otherwise manipulate the various fuels complexes found on the Forest This will greatly reduce the consequences of a wildfire in the manipulated fuels complexes and in adjacent complexes It will also enhance the long-term productivity of wildlife habitat, increase stream flows, provide more visual diversity, and provide the disturbance necessary for the perpetuation of important plant species, such as *Kalmiopsis leachiana*.

WILDLIFE

All wildlife species residing on the Siskiyou National Forest will be assured of long-term population viability; however, changes will occur in species populations Long-term reductions will occur in populations of species utilizing mature/old-growth forest, hardwood stands, and snag habitat. An enduring decline in deer numbers would occur in Alternatives E, G, and M, and is not confined to a specific segment of the planning period.

BIOLOGICAL DIVERSITY

In the long-term, biological diversity is directly related to forest health, productivity, and the Forest's ability to respond to change. Tree species diversity, for example, slows insect epidemics and provides habitat for animals that prey on insects. Habitat diversity provides homes for rodents that reinfect the forest with beneficial mycorrhiza after a fire.

VISUAL RESOURCE

The commitment of land currently inventoried for Retention and Partial Retention to management under Modification visual objectives would constitute a long-term commitment of the scenic values in those areas Restoring these areas to their current condition would be a costly, time-consuming process that is not likely to occur The management of the Forest's viewsheds to achieve the Retention and the Partial Retention visual objectives will constrain the Forest's ability to produce more timber due to extended harvest rotations.

Management of large areas of the Forest under the Modification visual objective would not produce a noticeable effect on the natural appearance of these areas over the short-term (first decade), but will result in the modification of the natural appearance over the long-term (the second decade and beyond).

RECREATION SETTINGS

The management of developed sites will have an adverse effect on the long-term productivity of the land and mineral production The vegetation and soils on much of each site will remain impacted by the

presence of compacted, graveled, or paved roads, paths, and camp spots These impacts will be increased on some sites as they are redesigned or reconstructed to conform to modern standards The vegetation and soils on much of the remainder will be affected by the concentration of users. These effects would remain evident for a long time even if the sites are abandoned Efforts to restore sites to previous productivity levels would be costly, however, many mitigation measures are designed into developments to reduce the overall impact to existing vegetation.

The short-term use (construction and maintenance) of trails, trailheads, toilets, or other facilities to enhance the dispersed recreation experience will have long-term effects on productivity similar to those described for developed recreation sites. Most are very insignificant in extent (area).

IRREVERSIBLE AND IRRETRIEVABLE COMMITMENT OF RESOURCES

An irreversible commitment of resources results from a decision to use or modify resources that are renewable only over a long period of time Nonrenewable resources, e g., rock resources, minerals, etc., are an irreversible commitment once used An irretrievable commitment of resources refers to resource production or the use of a renewable resource that is lost because of land allocation and/or scheduling decisions. In other words, opportunities are foregone for the period of time that the resource cannot be used The Forest Plan and the alternatives examined are all based on the principles of multiple use and long-term productivity for all resources Measures to protect natural resources that could be irreversibly affected by management practices are incorporated into the Standards and Guidelines of the Forest Plan.

CULTURAL RESOURCES

Data recovery efforts represent, in essence, the scientific and controlled destruction of a cultural resource site Once undertaken, the effects of data recovery are irreversible; this mitigation measure represents an irretrievable commitment to the resource At a minimum, conventional archaeological techniques and methods will be employed for data recovery projects This commitment to high quality field and laboratory work will ensure the consistency and usefulness of the data.

The combination of impacts from past and proposed future landscape modification, private developments, natural deterioration, and vandalism will significantly reduce the existing cultural resource data base Information on past ways of life within southwestern Oregon, beyond our current understanding, may eventually be unavailable

An incremental decrease of the cultural resource data base will occur wherever sites are lost due to ground-disturbing activities of other ownerships adjacent to the Siskiyou National Forest. For example, private logging and road building in the Pistol River basin are disturbing cultural evidence which would be valuable for comparative studies underway in that same drainage on Forest Service lands. In other cases, nonprofessional excavation of sites on private lands, such as at the Indian sites near Agness, Oregon, further reduce the cultural resource data base as well as our opportunity to understand the heritage of southwestern Oregon. Such actions have irreversible and cumulative effects on this resource.

For each alternative, mitigation measures are developed whenever a Class I cultural resource is affected by projects, vandalism, or natural deterioration These measures include· site avoidance, data recovery, photo documentation, restoration, and analysis. The Standards and Guidelines outline the mitigation measures, as necessary, and the Monitoring Plan insures compliance. Mitigation measures will improve in the future Techniques used for data recovery and other professional analyses will be refined.

Any cultural resource lost, either overlooked or unmitigated, will be unavailable either for future analysis or interpretative opportunities Current management practices will continue for those sites previously treated; newly discovered sites will be managed as prescribed by any revised direction, including any forthcoming changes in the scope of standards for survey, analysis, reporting, and mitigation.

Sites which are known to exist outside of proposed project boundaries are difficult to manage. Inventory, as a rule, occurs within areas selected for timber harvest, road building, or other ground-disturbing activities Therefore, sites may be lost which are: (1) never identified or recorded, and (2) identified, yet are located outside of proposed project areas

ENERGY

The use of fossil fuels in the administration of the National Forest is an irreversible resource commitment. Alternatives only vary by the amount; none abstain from use.

IMPROVEMENTS

Because the majority of the roads constructed on the Forest traverse steep ground slopes, they become permanent features on the landscape. Many roads which are scheduled for reclamation do not return the land to the prior productive state For these and all other roads on the transportation system, there is a definite long-term loss of either some or all of site productivity within the excavated road prism.

Although rock used for surfacing can be found in many places, once it is ground to dust by traffic on the road or broken up by weathering agents, it can no longer retain the desired characteristics

WILDERNESS AND ROADLESS AREAS

Wilderness potential (characteristics) in those roadless areas allocated to management where development may occur is irretrievably lost. This irretrievable loss, though, will only occur upon project implementation and not as a direct effect of the Forest Plan allocation. However, this is more a preference than real as evidenced by existing developments when specific areas were designated as Wilderness on this Forest and elsewhere.

WILD AND SCENIC RIVER

Designation of the inventoried Wild and Scenic Rivers would permanently reduce or prohibit timber harvest. Mineral exploration and development is also restricted or prohibited. Opportunities for the construction of dams, diversions, and hydropower development are prohibited.

SOIL AND WATER

There is an inherent risk of accelerating landslides, erosion, and other changes in the soil physical and biological properties when harvesting timber and building roads in the steep, rugged terrain on the Forest. Debris avalanches, when they occur, often scour to bedrock Surface and channel erosion, severe soil compaction and displacement, damage to proper functioning of soil biological processes, etc , could lead to either a limited or total loss of site productivity. Productivity, once lost, requires a long time for natural processes to restore. The soil and water protection measures identified in the Standards and Guidelines are designed to avoid or minimize the potential for irreversible losses from the proposed management practices.

FIRE

There is no irreversible commitment of resources associated with the fire prevention, suppression, or fuels programs as they could be curtailed at any time. There will be a minor irreversible commitment of fossil fuels involved with various fire management activities.

VEGETATION

Grazing allotments may be restricted to protect sensitive plant species. This would constitute an irretrievable loss to the permittees

Old-growth forests, once harvested, are considered an irretrievable loss. Once harvested, the stand begins anew To again develop old-growth forest characteristics will require approximately 200 years Insects, disease, and fire can also contribute to this loss. If left unmanaged, stand decadence may alter the old growth sufficiently to set the vegetative structure back to an early successional stage. The result would be a natural change, or loss, of old growth.

AIR QUALITY

There is no irreversible or irretrievable commitment of resources associated with the temporary impacts to air quality over the range of alternatives Mitigating measures such as YUM, PUM, chipping, and burying will, however, require the irretrievable commitment of fossil fuels.

WILDLIFE

Old-growth wildlife habitat, once harvested, cannot be replaced through regrowth over the planning horizon (150 years) It is possible that the number, size, and dispersal of mature and old-growth blocks allocated to spotted owl, pileated woodpecker, and pine martin (and the species they represent) may not be sufficient to maintain viable populations over time. If land allocations were not corrected in subsequent planning cycles, species could be lost.

There will be a reduction in some types of hunting opportunities because of changes in habitat Some wildlife species will be reduced and others will increase, depending on the kind of habitat available.

Forage reserved for wildlife within grazing allotments constitutes an irretrievable loss to the permittees, unless reallocated to permittees

BIOLOGICAL DIVERSITY

Species extinction is irreversible It is essential that habitat for sensitive species be maintained or enhanced, although the risk of extinction is very low

VISUAL RESOURCE

The commitment of Forest land to development of such facilities as roads or rock pits constitute an irreversible and irretrievable commitment of the natural appearance of the landscape.

RECREATION SETTINGS

The Forest's established developed sites are programmed for a full level of maintenance and so become an irreversible, long-term commitment of a resource. Wood fiber or forage which would have been produced on the sites is irretrievably lost

The commitment of the Forest's unroaded areas to timber production constitutes an irretrievable loss of the primitive character required to maintain the physical and psychological settings necessary for Primitive and Semi-primitive Non-motorized recreation experiences

ENVIRONMENTAL EFFECTS UNCHANGED BY ALTERNATIVES

Some of the resources on the Forest are not affected by implementation of any of the alternatives More often, the activity-induced impacts are either similar or conditions of the environment remain unaffected

LAND ALLOCATIONS

The relationships of National Forest planning to statewide planning programs, along with Oregon's Coastal Management Program, is briefly discussed herein. In Oregon, the Land Conservation and Development Commission (LCDC) sets overall rules for planning decisions, cities and counties adopt plans which meet the statewide requirements. Statewide Planning Goals are Oregon's standards for comprehensive planning. Of the 19 Goals, a number are strongly interrelated with management of the Siskiyou National Forest, a few are indirectly related, and several others have little or no bearing on or from the Forests uses, activities, or outputs.

In summary, the alternatives either complement, meet, or exceed the Statewide Planning Goals and the intent of the Coastal Management Program (Federal Coastal Zone Management Act of 1972). Proposed activities that would be implemented under the alternatives comply with the Goals, are compatible with county comprehensive plans and land use regulations, and conform with various State agency statutory authorities. Input and coordination on a wide array of planning topics has been ongoing between the Forest and adjacent counties and State agencies. Planned activities will continue to be conducted consistent with the state management programs.

Activities which produce offsite effects on the coastal zone have been analyzed in this chapter under numerous section headings. Portions of the coast in Curry, Coos, and Del Norte Counties were evaluated for potential indirect and cumulative effects The effects predicted for all alternatives have been compared to the county plans and are consistent at this programmatic level.

ENERGY

Utility corridors do not vary by alternative They will continue basically as they exist today, with normal *maintenance as needed There are no proposed corridors, future proposals will be analyzed on a* project-specific basis

Small hydroelectric projects do not vary by alternative. They, too, will be dealt with on a case by case basis as proposals are administered through established Federal Energy Regulatory Commission procedures and Agency analysis

MINERAL DEPOSITS

Roads developed for minerals access and development can add to dispersed motorized recreation opportunities.

Mined-area rehabilitation has the potential to improve fish and wildlife habitat, and restore old erosion and water pollution sources.

IMPROVEMENTS

There will continue to be a road system to serve the needs of Forest users and for Forest management and protection. Each alternative has a transportation system; the only change occurs in extent and management objectives. All alternatives provide for some degree of accessibility for various resources, such as timber management, fire prevention and suppression, recreation, and special uses

Although it could be increased or decreased in size, the basic arterial road system will remain unchanged Trails will continue to be present, and will help in the use and protection of the Forest New road construction will be subject to the project prescription and Standards and Guidelines in meeting the specific management objectives of the area served

All existing developed recreation sites in use will remain in service, whereas some of the existing minimum developed recreation sites may be closed as a result of different alternatives The number and location of administrative sites and water developments are not based directly on the alternatives, but are based on physical and economic considerations common to all alternatives. Other improvements unchanged by the alternatives include utility and transportation corridors, the solid waste collection site, communication facilities, and fire lookout structures.

A variety of users will travel on roads and trails they find to be suitable or need upgrading for their needs. All alternatives recognize there will be use at developed recreation sites There will be continued use of the existing utility and transportation corridors There will be very little or no change in established use of the existing miscellaneous improvements.

Use of roads during wet ground or freezing conditions can cause excessive damage to the road bed. Limitations in road use permits or suspension of commercial use offers some control of the problem; however, it is recognized that control of public use even with area closures is difficult. With the addition of new roads, all alternatives except M, account for the cumulative increase in maintenance and reconstruction, along with the accompanying effects.

WILDERNESS AND ROADLESS AREAS

The character of the designated Wildernesses on the Siskiyou National Forest is not expected to change as a result of programmed management activities under any of the alternatives.

Recreation use can have a cumulative effect on the character of the Wilderness However, the impacts of recreation users are monitored within each Wilderness in order to insure that they do not exceed a point detrimental to the area The Limits of Acceptable Change concept (Stankey and others 1985) will be applied, along with the Standards and Guidelines, to all Wildernesses over the course of the planning period, and will be the primary "tools" used to prevent resource degradation associated with recreation use.

WILD AND SCENIC RIVERS

The "outstandingly remarkable" attributes of the designated Wild and Scenic Rivers are not expected to significantly change as a result of management activities programmed within any of the alternatives

Both timber harvest and recreation use can have a cumulative effect on the Wild and Scenic River resource. Management (both past and planned) seeks to tailor the degree of management to meet specific objectives designed to protect the character of the Wild and Scenic River corridors regardless of the alternative. Cumulative effects are common to all alternatives and are not expected to vary.

SOIL AND WATER

Naturally occurring landslides, those not related to management activities, will continue to occur under all alternatives.

Annual water yield for the Forest will remain essentially unchanged except for small increases in some watersheds. The additional water produced by the removal of forest vegetation during timber harvest and other management practices represents less than one percent of the total Forest water yield

With few exceptions, research has shown that timber harvest increases water yield from 5 to 20 years The magnitude of increase depends on the amount of cutting, vegetation type, soils, geology, and climatic factors. Water yield will decline with time as harvested areas reforest. When the extra water contributed from newly harvested areas is added to the vast areas yielding water at the background level, the increase in water yield becomes insignificant. Harr (1979) succinctly puts the issue of water yield increases into perspective

> "Certain characteristics of water yield increases combine to make such increases in headwaters of basins of little consequence downstream First, increases tend to diminish over time, so that only a fraction of a watershed managed for sustained production of timber products will be in a condition to yield appreciably more water. The remainder will yield normal or nearly normal flows which tend to mask increased flows from freshly logged upland areas.
>
> Examples used by Rothacher (1970), Bethlahmy (1974), and Harr and others (1979) show that forest cutting in large watersheds--about 100 kilometers squared--probably would be only about four to six *percent, an amount well within the normal accuracy of streamflow measurement for the large* watershed. Management under nonsustained yield of timber products, however, could result in somewhat greater water yields for a large watershed.
>
> A second characteristic of water yield increases that bears on the value or utility of increases downstream is their timing. Substantial increases during the fall-winter rainy season will do little to satisfy summer demand for water. This timing, coupled with the fact that water yield increases tend to occur during wet years, further limits the real benefits commonly attributed to increased water yield after timber cutting. To use these increases would require storage facilities; and if storage facilities were present, storage of yield increases would be of miniscule importance compared with storage of normal winter runoff for release during the summer dry period."

For the departure alternatives, more water will be available in the short-term by departing from base harvest schedules, but sizable long-term increases in water yield will not occur Even if sizable increases in water yield were expected, it would be difficult to attribute significant adverse environmental consequences to them. Within the transient snow zone, the possibility exists that harvest clearcuts for reforestation may increase peak discharges within large basins; however, the research to date is inconclusive. Even if large increases in peak discharge result from clearcutting in the drainage basins, the adverse effects and their significance remain to be established. In many alternatives, mitigation of this potential impact is provided through the basin timber harvest dispersion constraints; the Management Requirement of 20 percent is provided in all alternatives

A positive result of harvest clearcuts and water yield is the increase in streamflow during the critical summer low-flow months. As discussed above, substantial increases in water yield occur per acre harvested, but most of the extra water yield occurs in the large base flow of the winter high-flow months. Whereas the increased flow in the summer period is small, the greatest increase percentage-wise occurs during the summer. Also, current research suggests that the duration of increase for summer low-flows is shorter, perhaps only five years, even though the increase in total annual yield may persist for up to 25 years.

As discussed above, water yield is almost always increased by timber harvest. One exception, however, may occur in areas of frequent fog (Harr 1982). The Siskiyou has a fog zone that is confined to a narrow strip and river valleys along the coast Decreases in water yield will likely be of the same magnitude, or less, as the fog increases. Research is not as clear on long-term water yield changes resulting from timber harvest, and particularly if 20- to 100-year old trees transpire more water than slower growing trees. All changes in water yield are expected to be minimal and vary little between alternatives.

FIRE

The microclimate of the Forest will be modified by management activities such as timber harvest, resulting in an environment more suitable for an unplanned ignition.

Fuel accumulations will continue to increase in areas, such as Grassy Knob Wilderness, that are subjected to a fire exclusion policy Fuel treatment activities in timber harvest units will reduce material by amounts prescribed through the Standards and Guidelines

SENSITIVE PLANTS

Serpentine and rocky habitats will be maintained at current levels for sensitive plant species in areas withdrawn from mineral entry.

AIR QUALITY

Wildfire smoke will affect air quality and air quality-related values throughout the array of alternatives Since the occurrence of wildfires is a random event in both time and space, the severity of the air quality impact will vary depending upon fire intensity, fuel type and conditions, size of the fire, and meteorological conditions Wildfires, and lightning fires in Wilderness that are managed as prescribed fires, are not considered in TSP production estimates.

Forest protection efforts would occasionally be hampered by smoky conditions. The visibility from fixed detection points (lookout towers) would be reduced and aerial detection capabilities restricted, increasing the probability of a wildfire being undetected for a short period of time. This could lead to more costly wildfires through increased fire suppression costs and resource damage. Wildfire smoke would add to already existing smoky conditions, compounding the visibility impact.

Management efforts to meet air quality standards and direction, and not exceed the TSP baseline value of 7,300 tons annually, will compound resource management complexities and raise the overall Forest management costs. Day-to-day burning restrictions could limit the actual fuel reduction accomplishments, thereby extending the amount of time and increasing the effort required to complete the necessary prescribed burning. Reforestation efforts, for example, in some harvested units could be slowed or delayed because of inadequately treated or unburned logging slash due to the limited availability of suitable burning days, from a smoke management standpoint Planting costs could be higher due to additional "scalping" requirements and slower production rates associated with untreated or marginally treated units.

From a forest protection standpoint, the risk of wildfire could increase because of the insufficient treatment of timber harvest slash and other fuels due to smoke management and short-term economic considerations. The ability of the Forest to provide visually acceptable harvest areas could also be hampered by accumulations of marginally-treated slash.

FISH

The following cumulative effects are considered common to all alternatives in terms of low water flow and fish habitat capability interrelationships:

Natural

This effect is inherent to Siskiyou National Forest streams. Low elevations and physiography, coupled with long, hot and dry summers contribute to the naturally low stream flows experienced across the Forest. This situation reduces the capability to rear anadromous salmonids to the smolt stage primarily because of shallow pool depths during summer months

Human Caused

Off-Forest water withdrawal presents a serious problem to water quality and survival of juvenile and adult salmonids on several basins within the Forest (OWRD 1984b). This problem is expected to continue and expand in magnitude as population and accompanying demand for water increase. Current State water appropriation laws do not prevent this serious threat to salmonid survival.

Harvest of salmonids is in direct relationship to available supply as projected by State agencies, National Marine Fisheries Service, and International agreement.

Off-Site Habitat Conditions

The life cycle of anadromous salmonids places them in a vulnerable position to any weak links in the cycle from the small stream to ocean environment Obstructions to adult or juvenile passage, such as poorly placed road crossings, open-ditch water diversions, and dams, along with off-shore food source availability, water temperature problems, sedimentation, and diseases all combine in the life cycle to create habitat problems for wild stock

Competition from Hatchery Stock

A serious threat to wild (nonhatchery) stock can occur when these fish are intermixed with larger populations of hatchery salmonids available to the sport and commercial fishery. Direct competition for food and space is very apparent between hatchery and wild stock salmonids Hatchery stock are usually larger and more aggressive than wild stock juvenile salmonid steelhead. Often wild stock salmonids are forced out of their native environment to rear elsewhere or perish from lack of space or food.

Interspecies Competition

Competition between salmonids and nongame fish is generally a direct reflection of water quality and quantity. Competition between various fish species for food and space is a problem in the Illinois River and upper basins, and is limiting capability in other basins such as the Winchuck and Coquille. Without increased flows from water storage it is doubtful that this situation will be reversed.

WILDLIFE

Serpentine and cliffs/talus habitats will be maintained at current levels.

VISUAL RESOURCE

The visual character of the designated Wildernesses is not expected to change significantly as a result of programmed management activities designed to achieve the Preservation visual objective

Timber harvest has a cumulative effect on the visual resource within a viewshed. Harvest activities are modeled in Retention and Partial Retention areas based on acre per decade coefficients for each objective (DeWerff and others 1981). Harvest levels will be monitored so that agency activities meet the Standard and Guidelines for visual management objectives within each viewshed. Monitoring and evaluation will also take into consideration the incremental impacts of other ownerships within the Forest boundary as well. These effects are the same regardless of the alternative.

RECREATION SETTINGS

At least 30,000 acres of unroaded area capable of providing Semi-primitive Non-motorized recreation opportunities is not expected to change as a result of programmed management activities. The largest tract of this occurs in the South Kalmiopsis.

SPECIFICALLY REQUIRED DISCLOSURES

EFFECTS OF ALTERNATIVES ON THREATENED AND ENDANGERED SPECIES, AND CRITICAL HABITAT

Regardless of the alternative, protection of listed species will take precedence over other land management direction. The bald eagle and the peregrine falcon are the only threatened/endangered species identified as present by the USDI Fish and Wildlife Service (bald eagle is threatened in Oregon and endangered in California, but only known from the Oregon portion of the Forest; peregrine falcon is endangered). None of the alternatives would have an impact on threatened or endangered species.

The Forest will comply with all appropriate threatened and endangered species recovery plans. Provision is made in the plan to pursue informal or formal consultation as necessary during project design and analysis. The Siskiyou National Forest contains no listed critical habitat areas (as defined by the Endangered Species Act).

EFFECTS OF ALTERNATIVES ON PRIME FARM LAND, RANGELAND, AND FOREST LAND

All alternatives are in keeping with the intent of Secretary of Agriculture Memorandum 1827 for prime rangeland, farm land, and forest land. Regardless of alternative, Forest Service lands will be managed with a sensitivity to the effects which their management will have on adjacent private and public lands.

The Forest does not contain prime farm lands or rangelands. "Prime" forest land is a term used only for non-Federal land and does not apply to lands within the National Forest System.

ENERGY REQUIREMENTS OF ALTERNATIVES

There are direct and indirect effects upon the energy requirements necessary to carry out the proposed alternatives. The approximate energy requirements for each alternative are listed in Table IV-28.

Table IV-28. Annual MM BTU's for First Decade by Alternative

Alternative	MM BTU
NC	4,384,122
A	4,293,102
A-Departure	4,433,679
B	5,171,022
C	4,583,388
D	4,352,947
D1	4,720,065
E	2,394,452
G	2,987,814
K	3,962,206
M	1,011,175
S	4,067,865

EFFECTS OF ALTERNATIVES ON THE HUMAN ENVIRONMENT

Local consumers will be affected by the supplies of various commodities documented previously in Chapter IV.

The civil rights of any American citizen are not differentially affected by implementation of any alternative.

EFFECTS ON WETLANDS AND FLOODPLAINS

No significant adverse effects within areas of wetlands and floodplains are anticipated. This is largely due to the very small size of upslope wetlands, i.e , tiny bogs and small ponds, and the position of the limited floodplains in the stream and river areas. Siskiyou National Forest landform is steep and most drainages are tightly confined to a narrow strip and rapidly drained due to stream slope. However, where narrow floodplains do exist, they correspond to the Riparian Management Area and other land allocations which restrict or prohibit management activities and development. Other than existing developments such as roads and campgrounds, human habitation in the riverine areas on National Forest lands is extremely limited.

Protection is afforded to these areas through BMP's incorporated in the Standards and Guidelines, NEPA analyses, and accompanying management requirements, Executive Orders 11988 (floodplains) and 11990 (wetlands). Collectively, these provide excellent direction to ensure that road construction, campground development, structural placements, and other facilities will not have unacceptable adverse impacts on the wetlands and floodplains. Except along the major river areas, avoidance or measures to protect the high values of these sensitive sites are the normal prescription Many sites are associated not only with high wildlife values, but often are indicators of major areas of old or recent mass instability.

The riparian ecosystems contiguous to several thousand miles of streams across the Forest are protected and managed through the prescriptions and Standards and Guidelines applied to the Riparian Management Area and other Management Areas that have little or no development activity, and Regional and Forest policy. Considerable discussion, management direction, and evaluation of impacts are provided in all chapters of this document under the sections titled LAND ALLOCATIONS, WILD AND SCENIC RIVER, SOIL AND WATER, and FISH.

LIST OF PREPARERS

LIST OF PREPARERS

The following is a list of Forest Interdisciplinary Team (IDT) members and/or the Forest Planning core team (CORE) personnel. Provided are their qualifications (position, education, and experience) and responsibilities in preparation of the Final Environmental Impact Statement and Forest Plan, including significant methodology and/or analysis as indicated. Numerous other Forest Service employees contributed to the completion of the document through assignments to the Forest Supervisor's Office, by providing needed information, or by assuming the duties of co-workers who were deeply involved in the planning effort.

AMARANTHUS, Michael P. — Eastside Soil Scientist

Education: B.S., Soil Resource Management; M.S., Ecosystem Management, PhD, Forest Ecology
Experience: Forest Service - 11 yrs; soils and watershed management (California and Oregon). University - 1 yr; soils instructor.
Function: IDT (4 yrs). Soil, geology, and water temperature modeling input.

ARNESON, Kerry A. — Writer-Editor

Experience: US Army Corps of Engineers - 2 yrs, public information. Forest Service - 6 yrs; public information and planning (Washington and Oregon).
Function: CORE (1 yr). Coordinated analysis of public response; assisted in edit and review of documents.

ATZET, Thomas — Area Ecologist

Education: B.S., Forest Science; M.S., Physiological Ecology; PhD, Plant Ecology
Experience: Forest Service - 20 yrs; forest management and ecology (California, Colorado, Washington, and Oregon).
Function: IDT (1 yr). Vegetative input and analysis.

CONKLIN, William F. — Lands and Recreation Staff

Education: B.S., Forestry
Experience: Forest Service - 30 yrs; forest management, lands, minerals, fish and wildlife, range, and recreation (Colorado, Pacific Northwest Region, Oregon).
Function: IDT (7 yrs). Minerals input and analysis.

COX, Gregory L. — Forest Planner; Planning Team Leader (Transferred 9/87)

Education: B.S , Forest Management; M.S., Natural Resource Economics
Experience: Private industry - 1 yr; forestry (Texas).
Forest Service - 9 yrs; forest economics and planning (Oregon).
Function: IDT (3 yrs); CORE. Administered Forest planning process.

CRAIG, David W. — Silviculturist, Resource Analyst

Experience: Forest Service - 18 yrs; forest management (Oregon).
Function: IDT (5 yrs); CORE. Developed timber yield tables. Formulated and ran FORPLAN model, analyzed data. Timber input and analysis.

ETTNER, Robert F. — Planning and Watershed Management Staff

Education: B.S., Forest Management; Graduate level - Watershed Management/Water Resources
Experience: Forest Service - 22 yrs; watershed and forest management, hydrology, environmental coordination, and planning (California, Pacific Southwest Region, Colorado, and Oregon).
Function: CORE (4 yr). Forest Management Team and Forest Plan Steering Committee member (8 yrs). Provides direction and coordination for the Forest planning effort. Responsible for unroaded area analyses; NEPA sufficiency.

GRIPP, Russell A. — Assistant Aviation and Fire Management Staff

Education: B.S , Forest Management; M.S., Natural Resources
Experience: Dept. of Army and Bureau of Land Management - 3 yrs; forest management, aviation and fire management (Kansas and Alaska). Forest Service - 15 yrs; aviation, fire and fuels management, air quality (Oregon, Idaho and California).
Function: IDT (8 yrs). Input and analyses for air quality, fire and fuels management.

HALSHAW-PROWELL, Sharon A. — Data Manager

Experience: Dept. of Defense - 3 yrs; Veterans Admin. - 6 yrs (California)
Forest Service - 11 yrs; computer mapping and data management (Oregon).
Function: CORE (5 yrs). Responsible for inventory and other data bases.

JOYER, Janet E. — Forest Archeologist

Education: B.A., Anthropology
Experience: University - 4 yrs; archaeological research (Missouri, Washington, and Colorado)
Forest Service - 7 yrs; cultural resource management (Oregon)
Function: IDT (2 yrs). Cultural and historic resources input and analyses, assisted in edit and review of documents.

KING, Don N. — Forest Fisheries Biologist

Education: B.S., Fish and Wildlife Management
Experience: State Dept. of Fish and Wildlife - 7 yrs; fishery biology (Oregon). Bureau of Land Management - 8 yrs; fishery biology (Oregon). Forest Service - 11 yrs; fisheries management (Oregon).
Function: IDT (10 yrs). Fisheries input and analysis.

KING, Joel — Forest Economist (Transferred 8/88)

Education: B.S., Forest Management; M S., Soil Science; Minor, Resource Economics
Experience: Private industry - 1 yr; forest management (Oklahoma).
Forest Service - 9 yrs; forest management; soil science, planning and economics (Oregon and Washington).
Function: IDT (2 yrs); CORE. Conducted social and economic analyses.

LYKE, Donald J. — Computer Specialist (Transferred 3/88)

Education: B.S., Computer Science/Business Administration
Experience: Private industry - 3 yrs; computer programming. Forest Service - 12 yrs; computer programming and systems mgmt.
Function. CORE (3 yrs). Provided computer analysis and programming support.

MENDENHALL, Roger L. — Forest Environmental Coordinator

Education: B S., Forestry
Experience: Forest Service - 24 yrs; forest management and appeals/environmental coordination (Montana, Oregon and Washington).
Function: IDT (4 yrs). Energy input and analysis.

O'LEARY, Robert E. — Assistant Forest Engineer, Operations & Maintenance

Education: B.S., Forest Management; B.S., Forest Engineering
Experience: Forest Service - 31 yrs, forest management and engineering (Oregon).
Function: IDT (3 yrs). Transportation system input and analysis.

PUGH, Ronald L. — Forest Landscape Architect

Education: B.S., Landscape Architect
Experience. Private industry - 1 yr; landscape architecture. Forest Service - 12 yrs; landscape architecture and recreation planning (Idaho, Utah and Oregon).
Function: IDT (9 yrs). Input and analyses for recreation, wilderness, visual, and wild and scenic river resources.

ROLLE, Susan E. — Forest Planner; Planning Team Leader

Education: B.S., Soil Resource Management
Experience: Soil Conservation Service - 1 yr; soil scientist. Forest Service - 11 yrs; soil resource management; watershed, recreation, range, wildlife, timber management.
Function: IDT (1 yr); CORE. Administers Forest planning process.

SCHUSTER, Barbara A. — Writer-Editor

Education: B S., Forestry
Experience: Peace Corps - 2 yrs; agroforestry. Forest Service - 6 yrs; silviculture, timber.
Function: IDT (1 yr). Prepared Record of Decision.

STEINBLUMS, Ivars J. — Forest Hydrologist

Education: B.S , Forest Management; M.S., Wildland Hydrology
Experience: Local Government - 1 yr; timber appraisal (California) Forest Service - 11 yrs; lands, watershed management (California, Pacific Southwest Region, Oregon).
Function: IDT (3 yrs). Soil, water, and geology resource analyses.

TUSO, Thomas D. — Civil Engineering Technician

Experience: Forest Service - 27 yrs; engineering and planning.
Function: IDT (10 yrs). Assisted with computer mapping data base, transportation planning, and minerals assessments.

WEBB, Lee O. — Forest Wildlife Biologist

Education: B.S., Wildlife Biology; M S., Wildlife Management
Experience: Forest Service - 14 yrs; wildlife biology and botany.
Function: IDT (10 yrs). Input and analyses for wildlife, sensitive plant resources, and threatened and endangered species.

Many other people contributed time and energy to completion of these documents. Their help is greatly appreciated.

LIST OF

AGENCIES, ORGANIZATIONS, AND PERSONS TO WHOM COPIES OF STATEMENT WERE SENT

FEDERAL AGENCIES AND OFFICIALS

ADVISORY COUNCIL ON HISTORIC PRESERVATION (ACHP)
- Office of Architectural and Environmental Preservation

AGRICULTURE, U.S. DEPARTMENT OF
- Agriculture Stabilization and Conservation Service
- Animal and Plant Health
- Equal Opportunity Office
- Secretaries Office
- Forest Service
  - Chief's Office
  - Regional Offices
    - Region 1
    - Region 2
    - Region 3
    - Region 4
    - Region 5
    - Region 6
    - Region 8
    - Region 9
    - Region 10
  - National Forests
    - Colville
    - Deschutes
    - Fremont
    - Gifford Pinchot
    - Klamath
    - Malheur
    - Mt. Baker-Snoqualmie
    - Mt Hood
    - Ochoco
    - Okanogan
    - Olympic
    - Rogue River
    - Siuslaw
    - Six Rivers
    - Umatilla
    - Umpqua
    - Wallowa-Whitman
    - Wenatchee
    - Willamette
    - Winema
  - Ranger Districts
    - Applegate
    - Gasquet
    - Happy Camp
  - Forest and Range Experiment Stations
    - Pacific Northwest
      - Assistant State Director
      - Research Planning and Applications
      - R O. Woodfin
      - Sarah Greene
    - Pacific Southwest
      - Redwood Sciences Laboratory
    - Rocky Mountain - Tony Baltic
    - WESTFORNET/South - Pacific Southwest Library
    - WESTFORNET/North - Forest Resources Library

- Soil Conservation Service
  - Coos-Curry County
  - Environmental Coordinator - Washington, D.C.
  - Illinois Valley Soil and Water Conservation District
  - Josephine County
  - State Resource Conservationist (Oregon)

COMMERCE, U.S. DEPARTMENT OF
- National Marine Fisheries Service
  - Habitat Conservation Division - Portland, Oregon
- National Oceanic and Atmospheric Administration
  - Ecology and Conservation Division - Washington, D.C

DEFENSE, U.S DEPARTMENT OF
- Air Force
  - Environment and Safety - Washington, D C.
- Army Corps of Engineers
  - Washington, D C.
  - Portland, Oregon
- Coast Guard
  - Environmental Impact Branch - Washington, D.C.
- Deputy Assistant Secretary
- Explosives Safety Board
- Navy
  - Chief of Operations - Washington, D.C.

ENERGY, U S. DEPARTMENT OF
- Bonneville Power Administration
  - Portland, Oregon - Anthony Morrell
- Federal Energy Regulatory Commission
  - Environmental Quality - Washington, D.C.
- Office of Environmental Compliance

ENVIRONMENTAL PROTECTION AGENCY
- Office of Environmental Review
- Regional Offices
  - San Francisco, California
  - Seattle, Washington - Robert Burd

EQUAL EMPLOYMENT OPPORTUNITY OFFICE

FEDERAL AVIATION ADMINISTRATION
- Regional Directors
  - Hawthorne, California
  - Seattle, Washington

FEDERAL CONGRESSIONAL DELEGATION
- U S Representative
  - Honorable Les Aucoin - Oregon
  - Honorable Pete DeFazio - Oregon
  - Honorable Wally Herger - California
  - Honorable Bob Smith - Oregon
- U S Senators
  - Honorable Alan Cranston - California
  - Honorable Mark Hatfield - Oregon
  - Honorable Robert W. Packwood - Oregon
  - Honorable Pete Wilson - California

FEDERAL HIGHWAY ADMINISTRATION
- Regions
  - Region 9
  - Region 10

FEDERAL RAILROAD ADMINISTRATION
- Policy and Plans

GENERAL SERVICES ADMINISTRATION
- Environmental Staff

HEALTH AND HUMAN SERVICES, U.S. DEPARTMENT OF
- Department of Environmental Review
  - Washington, D.C.
  - San Francisco, California

HOUSING AND URBAN DEVELOPMENT, U.S DEPARTMENT OF
- Energy and Environmental Review
- Environmental Officer
  - San Francisco, California
  - Seattle, Washington

INTERIOR, U.S. DEPARTMENT OF
- Bureau of Mines - Spokane, Washington
- Bureau of Land Management
  - Division of Forestry - Washington, D.C
  - State Office - Portland, Oregon
  - District Offices
    - Coos Bay, Oregon
    - Medford, Oregon
- Bureau of Reclamation - Salem, Oregon
- Delaware River Basin Commission
  - Head Environmental Unit - West Trenton, NJ
- Environmental Review
- National Park Service
  - Oregon Caves National Monument

INTERSTATE COMMERCE COMMISSION
- Energy and Environment

JAPAN CONSOLATE GENERAL - Seattle, Washington

LABOR, U.S. DEPARTMENT OF
- Occupational Safety and Health Administration
  - Evaluation - Washington, D.C.

NATIONAL MARINE FISHERIES SERVICE
- Habitat Conservation Division - Portland, Oregon

NATIONAL ENDOWMENT FOR ARTS

RURAL ELECTRIC ADMINISTRATION
- Assistant Administrator for Management
- Environmental Policy Office

TRANSPORTATION, U.S DEPARTMENT OF
- Policy and International Affairs

STATE AGENCIES AND OFFICIALS

CALIFORNIA
- Assembly - Stan Stathum
- Clearing House
- Department of Fish and Game - Redding
- Senate - John Doolittle
- Water Quality Control Board - William Winchester - Santa Rosa

OREGON
- Executive Department
  - Clearing House Coordinator
- Department of Environmental Quality
  - Southwest Region Branch Office - Roseburg
- Joint Legislative Committee
  - Trade and Economic Development

- State Information Center
- Klamath Falls
- Department of Fish and Wildlife
  - Environmental Management - Portland
  - Southwest Regional Office - Roseburg
  - Environmental Management - Salem
  - District Offices
    - Gold Beach
    - Charleston
    - Grants Pass
- House of Representatives
  - Honorable Bill Markham
  - Honorable Bob Repine
  - Honorable Eldon Johnson
  - Honorable Walt Schroeder
- Office of the Governor
- Oregon State Forestry Department
  - Forest Resource Study Program - Salem
  - Southern Oregon Area Director - Roseburg
  - District Forester
    - Central Point
    - Coos Bay
- Senate
  - Honorable Bill Bradbury
  - Honorable George Trahern
  - Honorable John Kitzhaber
  - Honorable Ron Grensky
  - Senate Majority Office
- State Geology Department - Grants Pass
- State Lands Office - Pam Wiley

COUNTY/CITY AGENCIES AND OFFICIALS

ASSOCIATION OF O&C COUNTIES

CITIES
- Brookings - Roy Rainey
- Cave Junction - Irvin Whiting
- Glendale - David Malinoff
- Gold Beach - Sam Wilson
- Grants Pass
  - Chamber of Commerce
  - City Manager
  - Jane Reyneke
  - Planning Commission
  - Planning Department
- Medford
  - Mayor's Office
  - Jerry Lausmann
- Myrtle Point - Edward Cook
- North Bend - Joseph Mulloy
- Port Orford - Gary Cully
- Powers

COOS COUNTY
- Board of County Commissioners - Jack Beebe
- Chairman, Board of County Commissioners
- Planning Department

COOS-CURRY COUNCIL OF GOVERNMENTS

CURRY COUNTY
- Board of County Commissioners
- Planning Department
- Rocky McVay
- T.V. Skinner

DEL NORTE COUNTY
- Board of Supervisors
- Planning Department

DOUGLAS COUNTY
- Board of County Commissioners
- Planning Department

JACKSON COUNTY
- Board of County Commissioners
- Planning Department

JOSEPHINE COUNTY
- Commissioners
- Forestry Department
- Parks Department
- Planning Director
- William Ford

LINN COUNTY
- Board of County Commissioners
- Planning Department

SISKIYOU COUNTY
- Board of Supervisors
- Planning Department

PORTS
- Bandon - Bandon, Oregon
- Brookings/Harbor - Brookings, Oregon
- Gold Beach - Gold Beach, Oregon
- Port Orford - Port Orford, Oregon
- Crescent City - Crescent City, California

ROGUE VALLEY COUNCIL OF GOVERNMENTS

COLLEGES, SCHOOLS, AND UNIVERSITIES (Also, see LIBRARIES)

Agness School District (Sue Hunt)
Antioch College - Yellow Springs, Ohio
Bandon School District (David Hamilton)
Brookings/Harbor School District (John Rapraeger)
Coos County School District (Ward Colerick)
Coquille School District (Jim Harris)
Glendale School District (Donald Currey)
Gold Beach High School (Jay Johnson)
Gold Beach/Riley Creek School District (Reed Ringer)
Lewis and Clark College - Portland, Oregon
Ophir Elementary School (James Shockley)
Oregon State University (NCASI, George Ice; Environmental Center)
Pistol River School Board (Neil Walker)
Reed College - Portland, Oregon
Siskiyou County Board of Education (Frank Tallerico)
Southern Oregon State College (Biology Department, Frank Lang and Steve Cross)
Southwestern Oregon Community College (Bob Cooper)
University of California (Jurisprudence and Social Policy, Ruth Lawrence)

University of Colorado - Colorado Springs
University of Illinois - Champaign, Chicago, Evanston, Urbana
University of Oregon (Survival Center, Lands Coordinator; Law Center, Environmental Research Group, Sharon Raymond)
University of Texas - Austin, Houston
University of Wisconsin-Madison, Milwaukee
University of Wyoming (Department of Economics, David S. Brookshire)
Willamette University (Environmental Science Program, Gilbert Lafreniere)

LIBRARIES

Agness Public Library
Bandon Public Library
Chetco Community Library
Colorado State University Library

Oregon Daily Emerald (Environmental Editor)

ORGANIZATIONS AND BUSINESSES

American Fisheries Society (Steve Smith)
American Mining Congress (Keith R Knoblock)
American Rivers (Kevin Coyle)
American Wilderness Alliance
Association of Oregon Archaeologists (Paul Jenkins)
Association of Oregon Loggers (Steven Kadas, Greg Miller)
Audubon Society (Frederick Allen, M. Draper, Arthur Farley, Felice Pace, Orley Ringering, Jim Rogers, Chuck Sisco, Dave Werschkul, Glenn Vancise)
Bain Insurance Agency (Joseph Bain)
Bandon Rotary Club (Joseph Bain)
Bay Area Chamber of Commerce (Crystal Shoji)
Beaver State Sand and Gravel (Don Barnes)
Boise Cascade Corporation (Kirk Ewart, Russ McKinley)
Brauner Trucking
Breitenbush Retreat Center (Mark Ottenad)
Brookings/Harbor Chamber of Commerce (Terry Connolly)
Broyles Lumber Company
Campground Management
Cardinal Trading Limited (Jim Schlauch)
Cascade Holistic Economic Consultants (Randal O'Toole)
Caveman 4-Wheelers (Dennis Sellards)
CCD Business Development Corporation
C&D Lumber Company (Ricki Barnes)
Citizen's Task Force Timber Review (Joseph Spivack)
Coastal Mining Company
Coquille Chamber of Commerce (Eloise Freauff)
Courts Whitewater Trips (Court Boice)
Del Norte Taxpayers League (Bill Ambrose)
Douglas Timber Operators (Troy Reinhart, Ralph Saperstein)
Douglas Pacific Lumber Company (Kim McLaughlin)
Earth First! (Biodiversity Project, Robert Brothers, Peter Bralver, Don Morris)
Ellingson Lumber Company (Peter Ellingson)
Eugene Burrill Lumber Company (Michael Burrill)
Forest Manager
Friends of the Earth Northwest (David Ortman)
Gebhardt's
Georgia Pacific (Carl Ehlen, Blair Holman, Norm Smith)
Gold Beach Plywood (Frank St. Clair)
Grants Pass - Josephine County Chamber of Commerce (Robert Repine)
Grayback Forestry Contractors (Michael Wheelock)
Gregory Forest Products (T.H. Mehl)
Hambro Forest Products (Lee Wetzel)
Headwaters (Julie Norman)
Health Future Enterprises (Dennis Olson)
Hi-Ridge Lumber (Gerhart Bendix)
H.H. Ketcham Timber Company (Victor Tarr)
Illinois Valley Chamber of Commerce (Leonard Frick)
Illinois Valley Grange (William Lytle)
Independent Troll Fisherman of Oregon (Harold Dixon)
Industrial Lumber Company (R.W. Edwards)
Izaak Walton League (Glenn Welden)

Josephine Forest Farm Association (Jerry Schaeffer)
Kauffmans Streamborn Fly Shop (Randall Kauffman)
Key Log Limited (Greg Keylock)
Klamath Alliance Res. and Environment (William Overman)
League of Conservation Voters (J. Martineau)
Leonard Charles and Associates Environmental Consultants
Mail Boat Hydro-Jets (Ed Kramer)
Marquart-Wolfe Lumber Company (Jonathan Wolfe)
Mason, Bruce, and Girard, Inc. (Carl Newports)
Mazamas (Oran Abbott, Gregory Parsons, Bob Powne)
M C Lininger and Sons (Dale Lininger)
Medford/Jackson County Chamber of Commerce (Nick King)
Medford Corporation (Bruno Meyer)
Menasha Corporation (William Lansing)
Motorcycle Riders Association (Will Hislebeard)
Mountain Lumber Company (C C Lloyd)
National Forest Products Association (Beth Norcross)
National Wildlife Federation (Andy Stahl)
National Organization for River Sports (Eric Leaper)
Native Plant Society of Oregon (Clara Fairfield, Warren Pavlat, Wayne Rolle)
Native Plant Society of Washington (Mark Egger, Arthur Kruckeberg)
Natural Resources Conservation Association (Jean Patterson)
Natural Resources Defense Council (David Edelson)
Northcoast Environmental Center (Tim McKay)
Northwest Center For A Future (Larry Svart)
Northwest Forest Resource Council (Gerry Hamilton)
Northwest Forestry Association (Charles Shotts)
Northwest Mining Association (Karl Mote)
Northwest Rivers Council (Douglas North)
Northwest Steelheaders Association (Glen Welden)
Northwest Timber Association (Gregory Miller)
Obsidians (Douglas Long)
Oregon Coastal Zone Management Association
Oregon Council of Rock and Mineral Clubs (Ronald Stockhoff)
Oregon Environmental Council (Jean Meddaugh)
Oregon Mr. Longears Club (Robert Clarke)
Oregon Natural Resources Council (Andy Kerr, Marc Prevost)
Oregon Rare and Endangered Plant Species Task Force
Oregon Trout (William Bakke)
Pacific Marine Technology (M B Wagner)
Pacific Fisheries Enhancement Corporation (Jan Obrien)
Pacific Lumber and Shipping Company (Marla Marvin)
Pacific Power and Light Company (Faye Albertson, Scott Hannigan)
Pacific Southeast Forest Products (Donald Crane)
Prairie Wood Products (Ronald Yockim)
Redwood Lions Club (Wayne Ray)
Reservation Ranch (Bob Brown)
Roseburg Chamber of Commerce (Richard Eisenhauer)
Roseburg Forest Products Company (Allyn Ford)
Roseburg Lumber Company (Jim Churchill)
Roseburg Paving Company (Jeff Braun)
Rough and Ready Lumber Company (Lew Krauss)
Save the Redwoods League (John Dewitt)

Scenic Shoreline Preservation Conference (Fred Eissler)
Sierra Club (Bill Arthur, Alan Carlton, Candace Cloud, Vicky Hoover, Daniel Kellog, Joe Knotts)
Sierra Forest Products (Glen Duysen)
Siskiyou Mountains Resources Council (Chris Jenican)
Siskiyou Regional Education Project
Society of American Foresters (Mike Meredith)
SONCAP (Marie Reeder)
Sorenson and Atkin (David Atkin)
South Coast Lumber Company (Mack Brown, James Murphy)
Southern Oregon Citizens Against Toxic Sprays (Phyllis Cribby)
Southern Oregon Timber Industry Association (Greg Miller)
Southern Oregon Regional Economic Development (Art Jackson)
Southern Oregon Resource Reliance (Anne Basker)
Southwest Forest Industries (Leonard Smith)
Southwestern Forest Industries (E.A. Kupillas)
Sunstar
Tahana Whitecrow Foundation (Melanie Smith)
Takilma Community Association (Romain Cooper)
Teeco Corporation (Jean Loosley)
The Friends of Del Norte County (Martin C. Kelly)
The Nature Conservancy (Dick Vander Schaaf)
The Oregon Extension (Dave and Kate Willis)
The Oregon Rivers Council (Bob Doppelt)
The Wilderness Society (Jean Durning, Peter Kirby)
Tidewater Veneer (Les Hoffer)
Timber and Wood Products Group (Russell McKinley)
Tri-City Ready Mix (Steve Loosley)
Trinity Resource Action Council (Judy Bendix)
Tri-State Building Materials (David Paul)
Trout Unlimited of Oregon (Eric Schulz)
Tualatin Dam Park Citizens League (Pete Paul)
Wallowas Alliance (Kifar Yosemite)
Washington Native Plant Society (Mark Egger)
West Coast Alliance for Resources and Environment (David Dillon)
Western Forest Industry Association (Ralph Saperstein)
Western Wood Products Association (R.M. Fredsall)
Weyerhaeuser Company (Richard Pierson, James Romback)
Wilderness Society (Northwest and Washington, D C Representatives)
Wildlife Management Institute (Kieth Harmon)
Wildwater Whitewater Trips
Women's Oregon Trail Riders (Merrianne Metzger)
Virginia 4-Wheel Drive Association (David Hook)

ACRONYMS AND GLOSSARY

ACRONYMS AND GLOSSARY

The definitions and abbreviations included herein are most common to Forest Service management and planning terminology. Meanings may differ when used in context other than these documents. The sources of the definitions vary, but the majority were taken from the Regional Guide for the Pacific Northwest, FSM, FSH, the Wildland Planning Glossary, NFMA Regulations (36 CFR 219), and CEQ Regulations (40 CFR 1500-1508). Some definitions have been shortened, paraphrased, or adapted to match usage implied within this document

GLOSSARY

A

Acre-foot.
A unit of measurement equal to the volume which would cover one acre to a depth of one foot (i.e., 43,560 cubic feet).

Activity
The work processes or management practices that are conducted to produce, enhance, or maintain outputs or achieve administrative and environmental quality objectives An activity can generate multiple outputs

Activity Fuels.
Burnable debris created by various management activities

Affected Environment
The natural, physical, and human-related environment that is sensitive to changes due to proposed actions.

Age Class.
One of the intervals into which the age range of trees is divided for classification or use.

Airshed.
A geographical area that, because of topography, meteorology, and climate, shares the same air

Allowable Cut Effect
An increase in today's permissible timber harvest level that is made by intensive timber management practices applied now or in the future.

Allowable Sale Quantity
The quantity of timber that may be sold from the area of suitable land covered by the Forest Plan Both the time period and utilization standards are specified by the Plan. This is usually expressed on an annual basis as the "average annual allowable sale quantity."

Allocated Funds.
Those funds transferred to the Forest from other agencies (including those from the Land and Water Conservation Fund, the Department of Labor, and the Soil Conservation Service) or provided from the K-V, Brush Disposal, Co-op Road Maintenance, or Purchaser Road Credits accounts

Allocation.
The assignment of management prescriptions to specific land areas to achieve the goals and objectives of an alternative

Alternative
A mix of management prescriptions and land allocations applied to specific land areas to achieve a set of goals and objectives The resulting alternative provides the management direction of the Forest.

Amenity.
Resources or experiences enjoyed on the Forest that do not have established market values, e.g , scenic views, recreational activities, etc.

Anadromous Fish.
Species of fish which mature in the ocean and migrate into streams to spawn, use herein refers to *salmon and steelhead*

Analysis Area
A delineated area of land subject to analysis of (1) responses to proposed management practices in the production, enhancement, or maintenance of Forest outputs and environmental quality objectives, and (2) economic and social impacts.

Animal Community.
Any assemblage of animals which interact and occur in a common area

Animal Unit Month (AUM)
The quantity of forage required by one mature cow and calf, or equivalent, for one month.

Annual Sale Quantity.
See Allowable Sale Quantity

Appropriated Funds.
Monies authorized by Congress which permit Federal agencies to incur obligations and to make payments for specific purposes

Appropriate Suppression Response.
The kind, amount, and timing of suppression action on a wildfire which most efficiently meets fire management direction under current and expected burning conditions.

Area of Influence.
Local area where most of the goods and services produced from the Forest are processed or used, and where the employment, income, and other social impact of Forest policies are felt

Arterial Road.
A major transportation route that accesses and services a large land area; usually connects with public highways or other arterial routes.

Association.
(Plant Ecology) A kind of plant community with a definite species composition and structure, and relatively uniform environment.

Available Land.
Capable land which has not been administratively or legislatively withdrawn from timber production on a permanent basis by the Chief or higher authority.

B

Basal Area
The cross-sectional area, in square feet, of a tree measured at breast height (4 5 feet).

Base Sale Schedule.
A timber sale schedule formulated on the basis that the quantity of timber planned for sale and harvest for any future decade is equal to or greater than the planned sale and harvest for the preceding decade, and that this planned sale and harvest for any decade is not greater than the long-term sustained-yield capacity. This definition expresses the principle of nondeclining flow.

Benchmark.
An analysis reference point of the maximum physical/biological capability to produce a resource output from Forest lands while maintaining minimum legal requirements for production of other resources and maintenance of soil and water productivity. Benchmarks define the area (i e , provide the bounds) within which alternatives can be formulated.

Benefit-Cost Ratio.
Measure of economic efficiency computed by dividing total discounted *primary benefits* by total discounted *economic costs.*

Best Management Practice (BMP)
The method, measure or practice selected by an agency to meet its nonpoint source pollution control needs BMPs include, but are not limited to, structural controls, operations, and maintenance procedures. BMPs can be applied before, during, and after pollution-producing activities to reduce or eliminate the introduction of pollutants into receiving waters

Big Game.
Those species of large mammals normally managed for sport hunting Herein, generally refers to Roosevelt elk, black-tail deer, or black bear

Biological Diversity.
The distribution and abundance of different plant and animal communities and species over time and space

Biological Growth Potential
The average net growth attainable in a fully stocked natural forest stand.

Biotic Community.
Any interacting assemblage of animal and plant communities living in a prescribed area or physical habitat.

Board Foot (BF).
A *unit of measurement equal to an unfinished board one foot square by one inch thick.*

Botanical Area.
An area which has been designated by the Forest Service as containing specimens or groups of plants, and plant communities which are significant because of form, color, occurrences, habitat, location, life history, arrangement, ecology, environment, rarity and/or other features (FSM 2360)

C

Calibration.
The process of adjusting modeled fire sizes by fire intensity levels for each Fire Management Analysis Zone against historical occurrence and burn acreage to accurately reflect the "real world " Adjustments are based on modeling the current organization (1978) against historical occurrence (1970-1979) using the same dispatch philosophy and suppression strategies

Canopy.
The uppermost spreading, branchy layer of a forest

Canopy Closure.
The progressive reduction in space between tree crowns as they spread laterally (Ford-Robertson 1971); a measure of the percent of potential open space occupied by the collective tree crowns in a stand

Capability
The potential of an area of land to produce resources, supply goods and services, and allow resource uses under an assumed set of management practices at a given level of management intensity. Capability depends upon current conditions and site conditions such as climate, slope, landform, and geology, as well as the application of management practices, such as silviculture or protection from fire, insects and disease

Capability Area
A delineated area with a logical combination of biological potential and physical characteristics which are used to estimate responsiveness to various management practices, resource values, output coefficients, and multi-resource or joint production.

Capital Investment
Money spent to provide a facility or product that will be used in the future.

Carrying Capacity
The maximum number of organisms that a particular habitat can support without causing deterioration of the ecosystem

Cavity Nester.
Wildlife species that excavate and/or occupy cavities in trees and snags

Chargeable Volume
All timber volume included in the growth and yield projections for the selected management prescriptions used to arrive at the allowable sale quantity, based on regional utilization standards

Clearcutting.
The harvesting of an entire stand of trees in one cutting operation, leading to the establishment of an even-aged stand.

Climax.
The culminating stage in plant succession for a given site where the vegetation has reached a highly stable condition.

Code of Federal Regulations (CFR)
The listing of various regulations pertaining to management and administration of the National Forests

Collector Road.
A road which collects traffic from Forest local roads or other collector roads. These roads serve smaller land areas than arterial roads and are usually connected to a National Forest arterial or public highway.

Commercial Forest Land (CFL).
See Tentatively Suitable Forest Land.

Commercial Thinning.
Timber sales which call for selective harvest in immature stands designed to improve the quality and growth of the *remaining trees*

Commodity.
A resource product with commercial value; all resource products which are articles of commerce (transportable)

Community Cohesion
The degree of unity and cooperation evident in a community as it defines problems and attempts to resolve them

Community Stability.
A community's capacity to handle change without major hardships or disruptions to component groups or institutions.

Concern.
See Issues, Concerns, and Opportunities

Confine Wildfire Strategy.
To restrict fire within determined boundaries

Constraint.
A limit placed in the FORPLAN model designed to control the functioning of the model to meet specified goals, legal or feasibility requirements

Consumptive Use
Those uses of a resource that reduce its supply

Contain Wildfire Strategy
To surround a fire with control line to check the fire's spread.

Control Wildfire Strategy.
To complete and hold the control line around a fire.

Conversion (Management)
A change from one silvicultural system to another (e.g from hardwood to conifer forest) or from one tree species to another

Cord
A wood stack equivalent to 128 cubic feet (4 x 4 x 8 feet).

Cost Effective.
Achieving specified outputs or objectives under given conditions for the least cost.

Cover
Vegetation used by wildlife for protection from predators, or to ameliorate conditions of weather, or in which to reproduce.

Cover/Forage Ratio.
The ratio, in percent, of the amount of area in forage conditions to that in cover conditions.

Created Opening.
An opening in the forest created as the result of even-aged silviculture through clearcutting, group selection, or shelterwood regeneration timber harvest systems.

Critical Habitat.
That habitat designated by the Secretary, USDI, as critical to the continued survival of threatened or endangered species.

Critical Minerals.
Minerals vital to the National defense, securing these minerals is less serious than those classified as strategic minerals.

Cubic Feet Per Second (cfs).
A unit of measure applied to fluid flow. A rate of discharge

Cubic Foot
A measure of volume equivalent to 1 foot by 1 foot by 1 foot.

Culmination of Mean Annual Increment (CMAI).
The age at which the average annual growth is greatest for a stand of trees Mean annual increment is expressed in cubic feet measure and is based on expected growth according to the management intensities and utilization standards assumed in accordance with 36 CFR 219.16(a)(2)(i) and (ii) Culmination of mean annual increment (CMAI) includes regeneration harvest yields and any additional yields from planned intermediate harvests.

Cultural Resources
Buildings, sites, areas, architecture, memorials, and objects having scientific, prehistoric, historic, or social values

Cumulative Effect
The impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency or person undertakes such other actions Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time.

Current Direction.
The combination of activities dictated by laws, regulations, the Forest Service Manual, and existing unit plans.

D

Departure.
A schedule which deviates from the principle of nondeclining flow by exhibiting a planned decrease in the sale schedule at any time during the planning horizon. A departure is characterized by a temporary increase, usually in the beginning decade(s) of the planning horizon, over the base sale schedule originally established. This increase does not impair the future attainment of the long-term sustained yield capacity.

Designated Habitat Area.
A mature of old-growth habitat area that has been located on a map or in the field, or both. For this document, specific areas identified for spotted owls, pine marten, and pileated woodpeckers

Desired Residue Profile.
The desired level of both living and dead vegetative material that is desired by the land manager for a specific site or prescription. Residue includes slash materials, litter on the forest floor, living brush, tree and standing dead trees and snags.

Developed Recreation.
Outdoor recreation requiring significant capital investment in facilities to handle a concentration of visitors on a relatively small area Examples are ski areas, resorts and campgrounds.

Diameter at Breast Height (DBH)
The diameter of a standing tree measured at a point four feet-six inches from ground level on the uphill side

Direct Attack
A method of fire suppression that treats the fire at its burning edge.

Discounting
The process of estimating the present worth of an anticipated item of income or expenditure by determining the amount of money which, if presently invested and allowed to accumulate at compound interest, will exactly equal the expected item of income or expenditure at the time when it becomes due.

Dispersed Recreation
Outdoor recreation in which visitors are diffused over relatively large areas Where facilities or developments are provided, they are more for access and protection of the environment than for the comfort or convenience of the people

Diversity.
The distribution and abundance of different plant and animal communities and species within an area.

Downward Sloping Demand
A price-quantity demand schedule based on the assumption that the quantity offered inversely affects the price received.

E

Ecosystem.
The complete system formed by the interaction of a group of organisms and their environment

Ecosystem Function.
The manner in which organisms interact with each other and their environments.

Edaphic.
Pertaining to the soil.

Edge.
Where plant communities meet or where successional stages of vegetative conditions within plant communities come together, e.g , field and woodland, forest and meadow.

Edge Effect.
The increased richness of flora and fauna resulting from the mixing of two communities where they join, as at the edge of a meadow

Effects (or Impacts).
Environmental consequences (the scientific and analytical basis for comparison of alternatives) as a result of a proposed action Effects may be either *direct*, which are caused by the action and occur at the same time and place, *indirect*, which are caused by the action and are later in time or farther removed in distance, but are still reasonably foreseeable, or *cumulative* (See definition above).

Empirical Yield Table.
A table showing, for one or more given species on a given site, the progressive development of a timber stand at periodic intervals covering the greater part of its useful life This table is prepared for existing stands on the basis of actual average stand conditions.

Endangered Species.
Any plant or animal species which is in danger of extinction throughout all or a significant portion of its range. (Endangered Species Act of 1973)

Endemic Species.
A species whose natural occurrence is confined to a certain region and whose distribution is relatively limited

Environment.
The aggregate of physical, biological, economic, and social factors affecting organisms in an area

Environmental Analysis.
An analysis of alternative actions and their predictable environmental effects, including physical, biological, economic, and social consequences and their interactions, short- and long-term effects, direct, indirect, and cumulative effects

Environmental Assessment (EA)
A concise public document which serves to. (a) Briefly provide sufficient evidence and analysis for determining whether to prepare an EIS or a Finding of No Significant Impact, (b) Aid an agency's compliance with NEPA when no EIS is necessary; (c) Facilitate preparation of an EIS when necessary.

Environmental Impact Statement (EIS)
A detailed statement prepared by the responsible official in which a major Federal action which significantly affects the quality of the human environment is described, alternatives to the proposed action provided, and effects analyzed.

Erosion
Detachment or movement of soil or rock fragments by water, wind, ice, or gravity Accelerated erosion is much more rapid than normal, natural, or geologic erosion, primarily as a result of the influence of activities of man, animals, or natural catastrophies.

Escaped Fire Situation Analysis.
A study of the factors influencing the suppression of a fire not controlled during initial attack, conducted for the purpose of deciding which suppression strategy will be used.

Even-aged Management.
The application of a combination of actions that results in the creation of stands in which trees of essentially the same age grow together. Managed even-aged forests are characterized by a distribution of stands of varying ages (and therefore tree sizes) throughout the forest area. The difference in age between trees forming the main canopy level of a stand usually does not exceed 20 percent of the age of the stand at harvest rotation age. Regeneration in a particular stand is obtained during a short period at or near the time that the stand has reached the desired age or size for regeneration and is harvested. Clearcut, shelterwood, or seed tree cutting methods produce even-aged stands.

Expected Burned Acreage.
The expected annual number of acres burned by fire size class and intensity level for a given program option or budget level, and which must equal or be less than the resource protection objective to be a valid option.

F

Fire Intensity Level (FIL).
A relative measure of fire severity based on flame height, higher flames indicating a more intense fire

Fire Management Analysis Zone (FMAZ).
The geographically delineated areas into which the planning unit is divided for the purpose of analysis based upon common fire-behavior characteristics.

Fire Management Efficiency Index (FMEI).
An index based on the protection costs (less proposed fuels investment), expected annual fire-fighting costs, and expected annual net value change for the next planning period.

FIREPLAN.
The title for a computer system consisting of eight programs which perform data retrieval and processing for the fire management analysis

Fire Program Option
A given program mix funded at a given program level developed in response to specific fire management direction established for the Forest Plan

Fixed Program Management.
The cost of managing Forest programs which is independent of output levels.

Floodplain
The lowland and relatively flat areas adjoining inland and coastal waters, including, at a minimum, that area subject to a one percent or greater chance of flooding in any given year.

Forage
Vegetation used for food by wildlife, particularly ungulate wildlife and domestic livestock

Forb.
Any herbaceous plant species other than those in the Gramineae (grasses), Cyperaceae (sedges), and Juncaceae (rushes) families; fleshy-leaved plants

Forage Areas.
Vegetated areas with less than 60 percent combined canopy closure of tree and tall shrub (greater than seven feet in height). This includes the grass-forb, shrub and open sapling-pole stand conditions and may include some older stands that have been thinned In a managed forest the primary forage areas are those that have had all or most of the forest canopy removed, i e. clearcut or shelterwood units

Forest Fragmentation.
The creation of habitat islands through land development or through natural causes, such as fire.

Forest Land.
Land at least 10 percent occupied by forest trees or formerly having had such tree cover and not currently developed for nonforest use. Lands developed for nonforest use include areas for crops, improved pasture, residential, or administrative areas, improved roads of any width, and adjoining road clearing and powerline clearing of any width.

FORPLAN
A linear programming model used for development and analysis of Forest Plan alternatives, and to display long and short-term resource interactions in forest management

Fry.
The life stage of salmonid fish species that refers to the juvenile fish which have either not emerged from the gravel or have recently emerged.

Fuelbreak.
A natural or constructed barrier utilized to stop or control the spread of fire.

Fuel Treatment.
The process of removing and/or modifying natural or human created fuels to reduce fire hazard and achieve other resource objectives

Fuelwood.
Wood that is round, split, or sawn and/or otherwise generally refuse material cut into short lengths or chipped for burning

Full Log Suspension.
The system of transporting logs from the cutting site to the landing without touching the ground.

G

Game Species.
Any species of wildlife or fish for which hunting seasons and bag limits have been established, and which are normally harvested by hunters and fishermen

Goal
A concise statement that describes a desired condition to be achieved sometime in the future Normally expressed in broad, general terms, it is timeless in that it has no specific date by which it is to be completed Goal statements form the basis from which objectives are developed

Gross National Product (GNP).
The sum of final products, such as consumption of goods and gross investment, produced in the Nation in a given year. It is reported in dollars, as a measure of the economic performance of the entire economy.

Guideline.
An indication or outline of policy or conduct.

H

Habitat.
The natural environment of a plant or animal

Habitat Capability Index
An indirect measure of the quality and quantity of habitat for a specific species, or group of species. The index is usually a range that is based on the predicted number of animals that could theoretically occupy the habitat available given a certain set of management prescriptions.

Habitat Diversity.
Distribution and abundance of plant and wildlife habitats.

Habitat Island.
The occurrance of a habitat, such as an old-growth forest, that is physically separated from the next closest habitat of the same type by vegetation that is markedly different in composition and structure

Hard Snag.
A snag composed primarily of sound wood, particularly sound sapwood; generally merchantable

Hardwood
A conventional term for the wood of broadleaf trees. Hardwood areas reference herein are usually the result of past forest fires, and once supported conifer trees in the past See Tentatively Suitable Forest Land.

Hardwood Conversion
The replacement of broadleaf trees or brush with conifer trees

Hazard Reduction.
Any treatment of forest fuels that reduces the threat, ignition, or spread of wildfire.

Hiding Cover
Vegetation capable of hiding 90 percent of a standing adult deer or elk at 200 feet or less. Includes some shrub stands and all forested stand conditions with adequate tree stem density or shrub layer to hide animals. In some cases, topographic features also can provide hiding cover

I

Immature-Poles.
See Tentatively Suitable Forest Land.

Immature-Small Timber
See Tentatively Suitable Forest Land

Impacts.
See Effects

Indicator Species.
Species of fish, wildlife, or plants which reflect ecological changes caused by land management activities See Management Indicator Species

Indirect Attack.
A method of fire suppression in which the control line takes advantage of natural fire breaks, topography, and fuel between the line and the fire

Individual Tree Selection
The selection of trees for harvest based on individual tree characteristics.

Instream Flow
Streamflow required to support instream uses, the flow required varying widely by type of channel, water quality, and time of distribution

Integrated Pest Management.
A process for selecting strategies to regulate forest pests in which all aspects of a pest-host system are studied and weighed. The information considered in selecting appropriate strategies includes the impact of the unregulated pest population on various resources values, alternative regulatory tactics and strategies, and benefit and cost estimates for these alternative strategies. Regulatory strategies are based on sound silvicultural practices and ecology of the pest-host system and consist of a combination of tactics such as timber stand improvement plus selective use of pesticides. A basic principle in the choice of strategy is that it be ecologically compatible or acceptable

Integrated Prescription
A planning prescription in which the Forest ID team identifies and quantifies outputs, effects, benefits, and costs of all forest resources to the extent practical The management emphasis may be single or multiple use

Intensive Management.
A high investment level of timber management that includes precommercial and commercial thinnings, planting with genetically improved stock, control of competing vegetation, and other practices which increase tree growth.

Irretrievable
Applies to losses of production, harvest, or use of renewable natural resources For example, where production is lost, the action is irretrievable, but not irreversible.

Irreversible.
Applies primarily to the use of nonrenewable resources, such as minerals or cultural resources, or to those factors, such as soil productivity, that are renewable only over long time periods; also includes loss of future options.

Irreversible Soils.
See Unsuitable Forest Lands.

Issue.
See Issues, Concerns, and Opportunities.

Issues, Concerns, and Opportunities (ICO).
A public issue is a subject or question of widespread public interest relating to management of the National Forest resources, as identified through public participation and addressed through the planning process. A management concern is an issue, problem, or condition which constrains the range of management practices identified by the Forest Service in the planning process. Opportunities are those resource uses and development possibilities suggested by both the public and the Forest Service

K

K-V Funds.
Funds collected from timber purchasers for reforestation under the Knutson-Vandenburg (K-V) Act of 1930. National Forest Management Act expanded collection authority to include other resource protection and improvement on the sale area

Knutson-Vandenburg Act of 1930, as amended.
A law which provides for a special fund, derived from the sale of timber, which may be used to fund reforestation and the protection and improvement of the Forest renewable resources on the sale area

L

Land Allocation.
The assignment of a management emphasis to particular land areas with the purpose of achieving the goals and objectives of the alternative.

Land Class.
The topographic relief of a unit of land Land classes are separated by slope, which coincides with the timber inventory process

Land Exchange
The conveyance of non-Federal land or interests to the United States in exchange for National Forest Land or interests

Land Inventory Mapping (LIM)
A grid mapping system with overlay and computational capability to input, store, edit, manipulate, overlay, and display resource information layers in a geographical quadrangle format

Landscape Ecology.
The science of describing and understanding how plant and animal species and communities interact across watershed- and regional-scale areas.

Land Stratification.
Inventory of land according to a set of specific land characteristics, such as the ability to grow timber or the ability to resist erosion

Leasable Minerals
Mineral deposits specifically excepted from the General Mining Law by Congress (principally through the Mineral Lands Leasing Act of 1920, the Mineral Leasing Act of Acquired Lands of 1947, the President's Reorganization Plan No 3 of 1946), and the Geothermal Act of 1970

Linear Programming.
A mathematical process that provides numerical solutions to problems of meeting a certain objective, within given boundaries and constraints Information is expressed in linear, mathematical format.

Local Road.
A road constructed to provide access to specific resource areas. As such, these roads connect terminal facilities with Forest collector or arterial roads or public highways.

Locatable Minerals.
Mineral deposits open to exploration, location, development, and purchase under the General Mining Law of 1972, as amended and interpreted Minerals in sufficient quality and quantity to be a "valuable deposit" (FSM 2810)

Long-term Productivity.
The redistribution of resources within the ecosystem into products used by humans.

Long-term Sustained Yield (LTSY)
The estimated timber harvest that can be maintained indefinitely over time, once all stands have been converted to a managed state under a specific management intensity consistent with multiple use objectives.

M

Management Area.
An area composed of aggregate pieces of land (generally several to many analysis areas) to which a given management objective and prescriptions are applied.

Management Concern.
See Issues, Concerns, and Opportunities

Management Direction
A statement of multiple use and other goals and objectives, along with the associated management prescriptions and standards and guidelines to direct resource management

Management Indicator Species.
Management indicator species are animals or plants selected for special attention in the Forest Plan for one or more of three reasons They may be·

(1) *Emphasis species* - species to be managed as key resources on the basis of identified issues, e.g , threatened, endangered, rare, sensitive, harvest, or special interest species;

(2) *Indicate special habitat conditions* - species that require special habitat such as snags, riparian, old-growth forest stands, etc , and/or

(3) *Indicate cumulative forest ecosystem change* - generally species having large home ranges and requiring a diversity of habitats.

Management Intensity.
A management practices or combination of management practices and associated costs designed to obtain different levels of goods and services

Management Practice.
A specific action, measure, course of action, or treatment

Management Prescription
Management practices and intensity designed to attain multiple use benefits and other goals and objectives when applied to a specific land area at a particular point in time

Management Requirements (MR).
Requirements designed to assure compliance with the applicable laws and regulations, specifically 36 CFR 219 27 for resource protection

Mass Failure (also Wasting)
All geologic processes in which earth materials move downslope, either slowly or quickly, by gravitational forces.

Mature.
See Tentatively Suitable Forest Land.

Mean Annual Increment.
The average annual growth of a stand, calculated by dividing the total growth accrued over its life by its age in years at the time of measurement.

Mean Basin Variation (Coefficient of Variation).
The coefficient of variation is a statistical tool used to compare the amount of variation in populations having different means In this case, to compare the variation in accelerated sediment production in a Planning Basin over the first five decades. Lower values indicate a more even distribution of the sediment production, therefore less risk of watershed degradation that might result from concentrations of peak outputs.

Mitigation.
Actions to avoid, minimize, reduce, eliminate, compensate, or rectify the impact of a management practice

Monitoring and Evaluation.
The evaluation, on a sample basis, of Forest Plan management practices to determine how well objectives are being met, as well as the effects of those management practices on the land and environment.

Multiple Use.
Management of all the various renewable surface resources of the National Forest so that they are utilized in the combination that will best meet the needs of the American people The concept also includes making the most judicious use of the land for some or all of these resources or related services over areas large enough to provide sufficient latitude for periodic adjustments in use to conform to changing needs and conditions. Some of the land will be used for less than all of the resources There should be harmonious and coordinated management of the various resources, each with the other, without impairment of the productivity of the land. Consideration is given to the relative values of the various resources, and not necessarily to the combination of uses that will give the greatest dollar return or the greatest unit output.

N

Native species.
A plant or animal species that occurs indigenously in an area.

Natural Opening
A break in the forest canopy A naturally-occurring area of bare soil, grasses, forbs, or shrubs located in a large area dominated by trees Also included are created openings no longer suitable for timber production.

Naturalized Species.
A non-native species established as if it were a native species.

NEPA Process
An interdisciplinary process, mandated by the NEPA, which concentrates decisionmaking around issues, concerns, alternatives and the effects of alternatives on the environment

Net Public Benefit (NPB).
The total benefits minus costs of all priced and non-priced resource outputs and effects. It is an expression used to signify the overall long-term value to the nation of all outputs and positive effects (benefits) less all associated inputs and negative effects (costs) whether they can be quantitatively valued or not. Maximization of NPB's to be derived from management of units of the National Forest system is consistent with the principles of multiple-use and sustained yield

Nonchargeable Timber.
Timber volumes that are not included in calculations of a regulated sale schedule and therefore cannot be included when determining achievement of that timber sale schedule

Nondeclining Flow and **Nondeclining Yield**
See base sale schedule

Nonforest Land
Lands that never have had or that are incapable of having 10 percent or more of the area occupied by forest trees; or lands previously having such cover and currently developed for nonforest use '

Nonvegetative.
Rock and rock outcrops

O

O&C (Oregon and California) **Funds.**
A fund administrated by the Bureau of Land Management accummulated from payments made by timber purchasers when timber is harvested on O&C lands. O&C lands are those which were repossessed by the U S Government from the Oregon and California Railroad Company in 1916 Payments are made to counties by BLM in lieu of taxes from these funds, and a portion of the fund is used for resource mitigation and enhancement projects on those lands

Objective.
Specific statement of measurable planned results to be achieved within a stated time period Reflects alternative mixes of all outputs or achievement which can be attained at a given budget level.

Objective Function
The item to be maximized or minimized, for example, timber or present net value in the solution of a linear programming model

Off-Road Vehicle (ORV)
A vehicle capable of cross-country travel or travel on low-standard roads and trails, e g , motorbikes, ATV's, 4-wheel drive vehicles, snowmobiles

Old Growth.
Any stand of trees 10 acres or greater generally containing the following characteristics: (1) stands contain mature and overmature trees in the overstory and are well into the mature growth stage, (2) stands will usually contain a multi-layered canopy with trees of several age classes, (3) standing dead trees and down material are present, and (4) evidence of human activities may be present, but do not significantly alter the other characteristics and are a subordinate factor in the stand description

Opportunity.
See Issues, Concerns, and Opportunities

Opportunity Cost
The dollar-quantifiable net loss resulting from selecting a less efficient course of action.

Optimal Thermal Cover
A forest stand with: (1) four layers (overstory canopy, sub-canopy, shrub layer, and herbaceous layer), and (2) an overstory canopy which can intercept and hold a substantial amount of snow yet has dispersed, small (less than one-eighth acre) openings. These criteria are generally achieved when the dominant trees average 21 inches Diameter at Breast Height (DBH) or greater crown closure, and are in the large sawtimber or old-growth stand condition

Outputs
The goods, services, and products which are measurable and capable of being used to determine the effectiveness of programs and activities in meeting objectives. Also goods, end products, or services that are purchased, consumed or utilized directly by people

Overstory.
The portion of trees in a forest which forms the uppermost layer of foliage

P

PARS.
The burned acreage and fire occurrence guidelines which represent the annual average long-term loss; PARS are expressed by forest size classes and intensity levels.

Peak Flow.
The highest value of stream stage or flow attained during a flood

Perennial Streams.
Streams which normally flow throughout the year.

Peridotite.
Plutonic rocks containing olivine, amphibole, pyroxenes, and micas. See Ultramafic.

Permittee.
A holder of a permit to use public land or resources for a specific purpose

Persons At One Time (PAOT).
A recreation capacity measurement indicating the number of people who can use a facility or area at one time.

Pioneer Species.
A plant capable of invading bare sites (newly exposed soil surface) and persisting there, i e , "colonizing" them, until supplanted.

Planning Basins.
Geographical locator areas that approximate major drainages on the Forest Designated for planning purposes.

Planning Horizon.
In the planning process, the overall time period that spans all activities covered in the analysis or plan and all future conditions and effects of proposed actions that would influence the planning decisions, in this case, 150 years

Planning Period
The length of time that a Plan is intended to be in effect, in this case, 10 to 15 years

Plant Community.
Any assemblage of plants which occur in the same area and that form a distinct ecological unit.

Pool/Riffle Ratio
The ratio of pools to riffles, expressed as a percentage, used to describe fish habitat rearing quality.

Population.
All interbreeding individuals of a given species living in a particular area.

Population Viability.
The degree to which a population can maintain itself over time; population viability analysis is the process by which this is estimated See also Viable Population.

Precommerical Thinning.
The selective felling or removal of trees in a young stand, conducted to accelerate diameter growth on remaining trees, maintain a specific stocking density, and improve vigor and quality of remaining trees; conducted at an age before the trees are commercially merchantable.

Prescribed Fire
Intentional application of fire, of either planned or unplanned ignitions, to accomplish certain planned objectives.

Prescription.
Management practices selected and scheduled for application on a specific area to attain goals and objectives.

Present Net Value (PNV)
The difference between discounted benefits and discounted costs

Presuppression.
Activities conducted in advance of fire occurrence to insure effective suppression.

Primitive Recreation Opportunities.
See Recreation Opportunity Spectrum

Programmed Harvest.
Timber scheduled for harvest for a specific time period

Public Issue.
See Issues, Concerns, and Opportunities

Purchaser Road Credit
Dollar credits earned by a timber purchaser for constructing or reconstructing roads needed for removal of timber included in a timber sale contract Credits are applied toward the purchase price of the timber

R

Ranger District (R.D.).
Administrative subdivision of the Forest, supervised by a District Ranger who reports to the Forest Supervisor

Rare
Plant or animal species which are uncommon in a specific area. All endangered, threatened, and sensitive species can be considered rare, but the converse is not true.

Rearing Habitat
The river or stream areas where juvenile salmonids must find food and shelter to survive for a period of time

Reconstruction.
Activities performed on an existing road or other facility to restore it to a specified standard.

Recreation Capacity.
The number of peple that can take advantage of the supply of a recreation opportunity during an established use period without substantially diminishing the quality of the recreation experience or the resources.

Recreation Inventory Management (RIM)
The Forest Service system for recording the condition of recreation facilities and use

Recreation Opportunity Spectrum (ROS)
Land delineations that identify possible combinations of recreation activities, settings, and experience opportunities, from Primitive to Urban, arranged along a continuum Classes used herein are:

Primitive - Area is characterized by essentially unmodified natural environment of a size or location that provides the opportunity for isolation from sights and sounds of people. Motorized use within the area is normally not permitted.

Semi-primitive Non-motorized - Area is characterized by predominantly unmodified natural environment of a size or location that provides a good-to-moderate opportunity for isolation from sights and sounds of people. Motorized use is not normally permitted.

Semi-primitive Motorized - Area is characterized by predominantly unmodified natural environment of a size or location that provides a good-to-moderate opportunity for isolation from sights and sounds of people except for facilities essential for the use of motorized equipment Motorized use is permitted Limited primitive road construction to enhance recreation opportunity is permissible

Roaded Natural - Area is characterized by predominantly natural appearing environments with moderate evidences of the sights and sounds of people Conventional motorized use is provided for in construction standards and design of facilities.

Rural - Area is characterized by substantially modified natural environment. Facilities for intensified motorized use are available.

Recreation Visitor Day (RVD).
A unit for measuring recreation activities. One unit equals 12 visitor hours and may consist of one person for 12 hours, or 12 persons for one hour, or any equivalent combination

Recreation River
See Wild, Scenic and Recreation Rivers.

Redd
Nest in gravel of stream bottom where fish deposit eggs; herein, refers to salmon spawning redds

Reforestation.
The natural or artificial restocking of an area with forest trees; includes measures to obtain natural regeneration, as well as tree planting and seeding The work is done on National Forests to produce timber and other forest products, protect watershed functioning, prevent erosion, and improve other social and economic values of the forests, such as wildlife, recreation, and natural beauty

Regeneration.
The renewal of a tree crop, whether by natural or artificial means Also the young tree crop (seedlings and saplings) itself

Release
All work done to free desirable trees from competition with other less desirable vegetation

Research Natural Area (RNA)
An area representing the major natural timber types or other plant communities in unmodified condition (FSM 4060). A natural plant community established for research and study of ecosystem and their changes.

Residue (Timber)
The portions of trees left in the forest during timber harvest, i.e., tops, limbs, chunks and other material not usable for manufacturing into timber products.

Resource Allocation.
Designation of specific parcels of land for the production of certain resources; the resources derived may be commodities, amenities, or a combination of each. See Land Allocation

Riparian Areas.
Terrestrial areas where the vegetation and microclimate are influenced by perennial and/or intermittent water, associated high water tables and soils which exhibit some wetness characteristics; this habitat is transitional between true bottom land wetlands and upland terrestrial habitats and, while associated with water courses, may extend inland for considerable distance.

Riparian Ecosystems
See Riparian Areas.

Riparian Habitat.
See Riparian Areas.

Riparian Prescription.
As used in this document, a method to provide flexibility for retaining shade, large organic debris, and other inherent features in the riparian areas for long-term input to stream systems Three options are identified (B, C, and M Prescriptions) for management of the riparian vegetation in areas suitable for timber management; they differ in the amount of vegetation that must be retained after management activities

Risk
Different possible outcomes, where a probability can be assigned to each outcome with a degree of accuracy

River Corridor.
A strip of land, ridge top-to-ridge top, which is seen or potentially seen from a river

Road Corridor.
A strip of land between two points used by a road, or some future road whose exact location remains to be determined; usually with an indefinite width

Roadless Area Review and Evaluation II (RARE II)
A comprehensive process (the second) instituted in 1977 to identify roadless and undeveloped land areas containing 5,000 acres or more in the National Forest System for the purpose of determining which of the inventoried areas should be recommended to Congress for inclusion in the National Wilderness Preservation System, which areas should be managed for nonwilderness uses, and which areas required further planning before a reasonable decision on them could be made. This assessment was documented through an FEIS.

Roaded Natural
See Recreation Opportunity Spectrum

Rotation
The planned number of years required to establish (including the regeneration period) and grow timber crops to a specified condition or maturity for regeneration harvest. Selected management prescriptions in the Forest Plan provide the basis for the rotation age

S

Salable Minerals.
Mineral deposits outside the scope of the General Mining Law because of widespread occurrence and "common" nature (disposal under the Materials Act of 1947, as amended)

Salmonid.
Member of the fish family *salmonidae*; includes salmon and trout

Sale Schedule
The quantity of timber planned for sale by time period from the area of suitable land covered by a Forest Plan The first period, usually a decade, of the selected sale schedule provides the allowable sale quantity. Future periods are shown to establish that long-term sustained yield will be achieved and maintained.

Salvage
Removal of recently-dead or dying trees to minimize the loss of wood products.

Sawtimber.
Trees that are nine inch Diameter at Breast Height (DBH) or larger and can be made into timber

Scenic Easement
An interest in the land which allows the holder specified uses or rights without ownership of the land In this case, control of the use of land adjacent to public highways, parks, and rivers. It may provide something attractive to look at within the easement area, an open area to look through to see something attractive beyond the easement itself, or a screen to block out an unsightly view beyond the easement area.

Scenic River
See Wild, Scenic and Recreation Rivers

Scoping
The procedures by which the Forest Service determines the extent of analysis necessary for a proposed action, i e , the range of actions, alternatives, and impacts to be addressed, identification of significant issues related to a proposed action, and establishing the depth of environmental analysis, data, and task assignments needed.

Second Growth (Young Growth)
Timber stands established after natural or human-caused removal of the original stand or previous forest growth

Seed Tree.
A tree selected, and often reserved for seed collection

Seed Tree Cutting.
Similar to clearcutting, except that a few of the better trees of the desired species are left scattered over the area to provide seed for regeneration.

Seedlings and Saplings
See Tentatively Suitable Forest Land.

Selection Cutting
The annual or periodic removal of trees, individually or in small groups, from an uneven-aged forest in order to realize yield and establish a new stand of irregular constitution.

Semi-primitive Motorized.
See Recreation Opportunity Spectrum.

Semi-primitive Non-motorized.
See Recreation Opportunity Spectrum

Sensitive Species
Those plant and animal species identified by the Regional Forester for which population viability is a concern as evidenced by significant current or predicted downward trends in (a) population numbers or density, or (b) habitat capability that would reduce a species' existing distribution

Separate Suitability Component (SSC).
See Tentatively Suitable Forest Land

Seral Stage
A transitory or developmental stage of a biotic community in an ecological succession (does not include climax successional stage)

Serpentine.
A mineral or rock (serpentinite) consisting essentially of a hydrous magnesium silicate usually having a dull green color and often a mottled appearance Term sometimes used with soil, to indicate environmental conditions found on soils derived from serpentinite or peridotite See Ultramafic

Shelterwood Cutting.
A regeneration method under an even-aged silvicultural system. A portion of the mature stand is retained as a source of seed and/or protection during the period of regeneration. The mature stand is removed in two or more cuttings

Significant.
As used in NEPA, requires consideration of both context and intensity. Context means that the significance of an action must be analyzed in several contexts such as society as a whole, and the affected region, interests, and locality. Intensity refers to the severity of impacts (40 CFR 1508 27)

Silviculture
The art and science of growing and tending forest vegetation, i.e., controlling the establishment, composition, and growth of forests, for specific management goals

Silvicultural System.
A management process whereby forests are tended, harvested, and replaced, resulting in a forest of distinctive form. Systems are classified according to the method of carrying out the fellings that remove the mature crop and provide for regeneration, and according to the type of forest thereby produced

Site Preparation
Removal of unwanted vegetation, slash, roots, and stones from a site before reforestation

Slash.
Woody material left after logging, pruning, thinning, brush cutting, or other management activities and/or accumulating there as a result of storm, fire, or other damage

Smolt.
Juvenile salmon or steelhead which are ready to leave freshwater for the ocean. They mature in the ocean before returning as adults to rivers and streams to spawn.

Smolt Habitat Capability Index.
An indicator of the quality of rearing habitat for young salmon or steelhead (smolt). It assumes that spawning gravels are adequate to provide sufficient spawning areas to fully seed the existing rearing habitat and that sufficient numbers of adults will escape past fishermen, dams, or natural mortality to return and fully seed the spawning gravels. It is expressed as the number of smolt which could be produced, estimating potential rather than actual production.

Snag.
A standing dead tree.

Spatial.
Referring to the distance, interval, or area between or within things.

Special Use Permit.
A permit issued to an individual, organization, or company for use of National Forest Land for some specified purpose

Species.
Organisms that successfully reproduce among themselves and cannot reproduce successfully with other organisms.

Species Diversity
The distribution and abundance of different plant and animal communities and species

Spotted Owl Habitat Area (SOHA).
A habitat area designated to support one owl pair

Spotted Owl Management Area (SOMA).
A habitat area designated to support more than one owl pair. An outdated phrase, see Spotted Owl Habitat Area.

Stand.
A community of trees or other vegetation sufficiently uniform in composition, constitution, age, spatial arrangement, or condition to be distinguishable from adjacent communities and so form a silvicultural or management entity

Standard.
A principle requiring a specific level of attainment; a rule to measure against

Steelhead
A large-sized, silvery anadromous rainbow trout

Stocking.
The degree to which trees occupy the land, measured by basal area and/or number of trees by size and spacing, compared with a stocking standard; that is, the basal area and/or number of trees required to fully utilize the land's growth potential

Strategic Minerals.
Any mineral neither found or produced in the United States in sufficient quantities to sustain the Nation during a period in which the security and/or economy of the country is threatened by a foreign power.

Stream Class
The classification of streams according to their beneficial uses. Whole streams or parts of streams can be classified. One stream may be divided into several classes.

Class I. Perennial or intermittent streams have one or more of the following characteristics. (1) Is the direct source of water for domestic use (cities, recreation sites, etc.); (2) Are used by large numbers of fish for spawning, rearing, or migration; (3) Flow enough water to have a major influence on water quality of a Class I stream.

Class II. Perennial or intermittent streams have one or both of the following characteristics: (1) Are used by moderate though significant numbers of fish for spawning, rearing, or migration; (2) Flow enough water to have a moderate influence on downstream quality of a Class I or II stream.

Class III All other perennial streams not meeting Class I or Class II definitions.

Class IV. All other intermittent streams not meeting Class I, II, or III definitions.

Streamside Management Unit (SMU).
The stream and an adjacent area of varying width where practices that might affect water quality, fish, and other resources are modified, as necessary, to meet management goals for each class of stream.

Stumpage.
Standing timber or its value.

Successional Stage
A stage or recognizable condition of a plant community which occurs during its development from bare ground to climax

Suitable Forest Land
Land to be managed for timber production on a regulated basis Also, see Tentatively Suitable Forest Land.

Suppression Strategy.
The broad application of plans and tactics to a specific fire situation; basic strategies include confine, contain, and control.

Sustained Yield
The achievement and maintenance in perpetuity of a high-level annual or regular periodic output of the various renewable resources of the National Forest System, without impairment of the productivity of the land.

T

Talus
The loose accumulation of fragmented rock material on slopes, especially at the base of a cliff.

Temporal.
Referring to time.

Tentatively Suitable Forest Land.
Forest land that is producing or is capable of producing crops of industrial wood and: (a) has not been withdrawn by Congress, the Secretary, or the Chief; (b) existing technology and knowledge is available to ensure timber production without irreversible damage to soils productivity, or watershed conditions; (c) existing technology and knowledge, as reflected in current research and experience, provides reasonable assurance that it is possible to restock adequately within 5 years after final harvest; and (d) adequate information is available to project responses to timber management activities

Mature - In the context of timber -- trees or stands that have reached rotation age, generally around 100 years. In the context of wildlife -- Mature forest habitat with characteristics needed to provide habitat for species such as pine marten and pileated woodpecker (generally occurs around age 100) With regard to land type -- Lands with 100-year-old, or older, timber stands available for harvest cutting.

Immature-Small Timber - With regard to land type -- Lands with well stocked timber stands less than rotation age that are suitable for commercial thinning in the next two decades.

Immature-Poles - With regard to land type -- Lands with timber stands less than rotation age that do not have excess stocking available for commercial thinning

Seedlings and Saplings - With regard to land type -- Lands with non-commercial-size young stands, generally plantations.

Hardwoods - With regard to land type -- Lands occupied by hardwood stands with less than 10 MBF per acre stocking of conifer timber.

Separate Suitability Component (SSC) - Lands with timber production potential less than 20 cubic feet per acre per year. The vegetation on these lands was not inventoried in the 1979 timber inventory (they were arbitrarily considered noncommercial at that time).

Terrestrial.
Living on land. distinguished from aquatic (living in water)

Thermal Cover.
Vegetation used by animals to modify the adverse effects of weather. A forest stand that is at least 40 feet in height with tree canopy cover of at least 70 percent These stand conditions are achieved in closed sapling-pole stands and by all older stands unless the canopy cover is reduced below 70 percent. Deciduous stands may serve as thermal cover in summer, but not in winter.

Threatened Species
Any species of plant or animal which is likely to become endangered within the foreseeable future throughout all or a significant portion of its range

Timber Site Index
A measure of site productivity based on the maximum rate of tree height growth It is normally expressed as the height in feet reached by a tree at a given or base age (the site index)

Timber Stand Improvement (TSI).
Measures such as thinning, pruning, release cutting, prescribed fire, girdling, weeding, etc , of unwanted trees with the objective of improving growing conditions of the remaining trees

Tolerance
The forestry term for expressing the relative capacity of a tree to compete under low light and high root competition·

Tolerant Trees - Trees which reproduce and form understories beneath canopies of less tolerant trees or even beneath shade of their own species

Intolerant Trees - Trees which reproduce successfully only in the open or where the canopy is greatly broken.

Total Resource Information (TRI) System
A natural resource data base used on National Forests in the Pacific Northwest Region This multimedia information system was established to provide storage and retrieval of large volumes of in-place resource data

Transportation Corridor
As used in this document, a strip of land of variable width designated to accommodate the clearing and access control of a State or Federal Highway.

Tradeoff.
Foregoing certain options in the decision process to take advantage of others

Travel Corridor.
A road, trail, or waterway used by people; or a strip of land used by wildlife

TRI Compartment.
An area identified on an orthophoto map for indexing and storing data locations Each compartment has a unique name and number.

Turbidity.
The optical property of water as affected by suspension of material such as sediment, i.e , the muddy or cloudy state of water.

U

Ultramafic
Intrusive rocks composed chiefly of mafic minerals such as olivine, pyroxene, and serpentine Also called ultrabasic. See Peridotite and Serpentine

Unavailable Forest Land
Lands which have been legislatively or administratively withdrawn from timber production by law, the Secretary of Agriculture, or the Chief of the Forest Service.

Understory
Vegetation (trees or shrubs) growing under the canopy formed by taller trees

Uneven-age Management.
The application of a combination of actions needed to simultaneously maintain continuous high-forest cover, recurring regeneration of desirable species, and orderly growth and development

of trees through a range of diameter or age classes to provide a sustained yield of forest products Cutting is usually regulated by specifying the number or proportion of trees of particular sizes to retain within each area, thereby maintaining a planned distribution of size classes Cutting methods that develop and maintain uneven-aged stands are single-tree and group selection

Unsuitable Land
Forest land withdrawn from timber utilization by statute or administrative regulation, or identified as not appropriate for timber production in the Forest planning process, i e , irreversible soil loss and nonreforestable within five years.

V

Viability.
Capable of living, growing, and developing

Viable Population.
A *population of plants or animals large enough and distributed in such a way as to ensure their* continued existence over a specified period of time, usually on the order of decades to centuries

Viewshed.
A total landscape seen or potentially seen from specific points on a logical part of a travel route or water body.

Visual Corridor.
A series of viewsheds identified for special attention under visual quality management

Visual Resource.
The composite of basic physiographic features and patterns, and land use effects that typify a land unit and influence the visual appeal the unit may have for visitors

Visual Quality Objective (VQO)
Measurable standards for visual resource management based on the acceptable degree of alteration of the characteristic landscape The VQO's and their definitions are·

Preservation. Provides for ecological changes only.

Retention Activities are not evident to the casual forest visitor

Partial Retention Activities may be evident but must remain subordinate to the characteristic landscape.

Modification. Activities may dominate, but must utilize naturally-established form, color, and texture. These areas should appear natural when viewed in foreground or middleground situations

Maximum Modification Activities may dominate, but should appear as a natural occurrence in background situations

W

Watershed.
The land area drained by a river system.

Wetlands.
Areas that are inundated by surface or ground water with a frequency sufficient to support, and that, under normal circumstances, do or would support, a prevalence of vegetative or aquatic life that requires saturated or seasonally saturated soil conditions for growth and reproduction Wetlands

generally include swamps, marshes, bogs, wet meadows, river overflows, mud flats and natural ponds

Wild, Scenic, and Recreation Rivers.
Rivers or river segments which have been designated as part of the National Wild and Scenic Rivers System (Public Law 90-542, 1968) Criteria for classification are as follows:

Wild Rivers - Those rivers or sections of rivers that are free of impoundments and generally inaccessible except by trail, with watersheds or shorelines essentially primitive and waters unpolluted. These represent vestiges of primitive America

Scenic Rivers - Those rivers or sections of rivers that are free of impoundments, with shorelines or watersheds still largely primitive and shorelines largely undeveloped, but accessible in places by roads.

Recreation Rivers - Those rivers or sections of rivers that are readily accessible by road or railroad, that may have some development along their shorelines, and that may have undergone some impoundment or diversion in the past

Wilderness.
All lands included in the National Wilderness Preservation System by public law; generally defined as undeveloped Federal land retaining its primeval character and influence without permanent improvements or human habitation

Wilderness Recreation Spectrum (WRS).
A further refinement of the *primitive* portion of the Recreation Opportunity Spectrum The following terms deal only with officially designated wilderness

Pristine - The most remote; generally the core area which is least accessible. The area is characterized by no trails. A *most outstanding* opportunity exists for isolation and solitude free from evidence of past human activity.

Primitive - The sights, sounds, and smells relating to human activities outside the wilderness are essentially nonexistent. The area is generally accessible by trail An *extremely high opportunity* exists for exploring and experiencing considerable isolation, tranquility and self-reliance

Semi-primitive - The least remote; generally areas nearest trailheads and major access points or the wilderness periphery. Opportunities for a wilderness-related experience are only *moderate*.

Wildlife Tree.
A snag or a live tree designated for wildlife habitat.

Wild River.
See Wild, Scenic, and Recreation Rivers.

Winter Range.
An area used by deer and elk during the winter months; usually at lower elevation and/or south and west exposures

Withdrawn
Land areas where certain uses are excluded

Y

Yield Table
A table of timber volumes expected to be produced under a specified set of conditions.

INTRODUCTION

This appendix discusses the. (1) process used to identify the issues, concerns, and opportunities (ICO's); (2) list of ICO's identified; (3) development of the Planning Problems addressed in the Draft Environmental Impact Statement (DEIS) which are carried forward into the Final Environmental Impact Statement (FEIS); (4) Forest's ability to resolve the Planning Problems including the indicators used to measure resolution, and (5) the consultation with other agencies, groups, and individuals

The different preferences of individuals and groups, and the physical, biological, and legal limits of Forest management are present in the **issues** and **concerns** which guide the Forest planning process. Resource use and development **opportunities** are the basis of many of the issues and concerns identified. The opportunities to preserve or use the resources of the National Forest are the focus of many of the Agency's programs, and are the principal focus of the management alternatives presented in the FEIS.

The ICO's have been further analyzed and grouped or restated in the Planning Problems, posed as questions relating to resource outputs or conditions that can be used to guide the development and evaluation of alternatives The Forest's ability to resolve the Planning Problems depends on the relationships of the outputs and conditions and responses to various management options Measurable outputs or conditions have been identified for use as key indicators of the Forest's potential, and of the degree of problem resolution under each alternative.

Appendix A reviews the development of ICO's and Planning Problems up to the time the DEIS was released (August, 1987). Any changes to the aspects of certain ICO's or Planning Problems as a result of the public response to the DEIS, Congressional Acts, or other reasons are discussed in Chapter I of the FEIS

IDENTIFICATION PROCESS

The information needed to identify the ICO's was collected and refined throughout the entire planning effort. The process started in the spring of 1979 when a list of potential ICO's was developed from previous public comments on Forest management problems. Several meetings with Forest Service employees and the public contributed to the further development of these ICO's. These meetings took place in various Oregon communities On January 15, 1980, the ICO's were published as a Forest Plan Report and sent to a wide variety of interested citizens and groups; and state, county, and Federal agencies in Oregon and California.

Following the distribution of this list of ICO's, additional meetings were held and contacts made to allow for review and discussion Using all of the information gathered, the ICO's were modified and semi-finalized in June 1980. Starting with this tentative list, all of the potential ICO's and modifications were screened to determine their appropriateness during the Forest planning process The following criteria was used in this screening:

1 Is the potential ICO within the authority of the Forest Service to resolve, or does it belong to another agency?

2. Is the potential ICO covered by laws and regulations which block Forest Service action?

3. Is the potential ICO of such a nature that changing Forest Service Management Direction will affect it?

4. Is the potential ICO of a nature that it should be addressed in a separate Environmental Impact Statement (EIS) or Environmental Assessment (EA)?

5 Is the potential ICO of a short-term nature that will be resolved through normal management and, therefore, does not need to be addressed in the Forest planning process?

On December 1, 1980, a slightly modified list of ICO's was adopted for Forest planning purposes and released to the public

The ICO's have changed somewhat with time. As new events occurred and local, regional, and National goals and policies changed, the ICO's were modified accordingly This confirmation was essential in order to keep the lengthy planning process updated and the analysis tracking with current conditions and views.

Following the pause in Forest planning, the ICO's were reanalyzed in October 1983 Two new issues were subsequently added One is the issue concerning Wilderness and the management of unroaded areas which resurfaced following the Court decision that the RARE II analysis was inadequate. The other deals with the conversion of hardwood stands to conifers which received more attention due to the energy shortage and recognition of the potential to utilize the hardwood volume under future markets and technology. Only minor revision and editing has occurred since that time.

The ICO's for Forest planning were ratified again through extensive public comment received after publication of the DEIS and proposed Forest plan. The Forest received a total of 16,983 responses (with 17,277 signatures) during the 150-day review period The normal 90-day public review period was extended twice, the first time was related to the impacts of the fires on the Forest's ability to meet with all the public The second extension came in response to local officials' requests.

Several issues or aspects of ICO's received fresh emphasis after the issuance of the DEIS in 1987 as described in Chapter I of the FEIS Numerous meetings with interested agency officials, groups and individuals since that point have continued to clarify ICO's Appendix K describes the public involvement process between the DEIS and FEIS; it also displays public comments received and responses to the comments

ISSUES, CONCERNS, AND OPPORTUNITIES

PUBLIC ISSUES

TIMBER MANAGEMENT

The **issues** of widespread public interest related to management of the Siskiyou National Forest include the following:

1. How should the Forest manage its timber lands? Should current management practices be intensified, relaxed, or maintained?

Many individuals and several interest groups feel that the Forest has an obligation to sustain regional and local economies by.

1. maintaining or increasing annual Forest timber harvests;

2. conserving the forest land base suitable for the production of timber, and

3. using intensive timber management practices to maximize timber yields.

Conversely, there are concerns about the potential effects of intensive timber management on other resources and the ability of the Forest to maintain plant and animal species diversity, reforest harvested areas, and reach predicted timber harvest levels in the future. To benefit wildlife and recreation, many feel

that the Forest should reduce the amount of timber harvested each year and thereby reduce the rate of forest change

Associated concerns are (1) that lands with relatively low productivity should not be included in the land base suitable for the production of timber, and (2) that economic criteria and analysis should be incorporated in the evaluation of timber harvest and other management options.

The economic feasibility of using optimum silvicultural methods and requiring superior logging systems has also been questioned.

USE OF HERBICIDES ON FOREST LANDS

2. Should herbicides continue to be used on the Siskiyou National Forest?

Some people are concerned about the entry of herbicides into the forest environment and potential effects on human health. There is demand for consideration of alternative methods of vegetation management There are also potential social and economic impacts to consider that would result from possible reductions in yields in the absence of herbicide use. The debate includes numerous other variables which are addressed in Regional and Forest vegetation management program documents

OLD-GROWTH FOREST

3. How much old-growth acreage should be preserved?

Controversy over harvesting old-growth trees has risen sharply over the last few years. The reduction in old-growth acreage affects the suitable habitat for old-growth-dependent wildlife and plant species, opportunities for recreational enjoyment, and the ecological diversity associated with old-growth stands.

Protecting old-growth would reduce the volume available for timber harvest. There is also concern that potential volume production is lost due to slow growth or decay and mortality in the mature or old-growth stands. Some people suggest that these stands should be regenerated at an even faster rate to avoid these losses

RESIDUE MANAGEMENT

4. What are the acceptable limits of residue abatement? What are the methods of disposal of timber harvest residues to meet these limits economically, without damaging other resources or exceeding air and water quality constraints?

The large amount of residue remaining after timber harvest has many potential uses. Many people prefer to more fully utilize this material through providing firewood or other products. Disposal of these harvest residues can impact other resources and affect land productivity.

Some people feel that the hazard of a catastrophic fire may be greatly increased if forest managers do not sufficiently treat residues because of difficulties in complying with economic and environmental guidelines. Others believe that the risks associated with the activity fuels do not pose as serious a risk in many instances as has been suggested.

DEPARTURE FROM NONDECLINING FLOW

5. Should the Siskiyou National Forest depart from a nondeclining flow harvest schedule? If so, how much, and what would be the effects of such a departure on Forest resources and on local communities now and in the future?

State and local industry projections indicate approximately a two decade period when harvestable timber volume available on private forest lands will be at a low level. Departure on Federal land has been suggested as a means to fill this void. Secondly, departure could be used to maintain historic Forest harvest levels for the next two decades, even though additions to the Wilderness System within the last ten years have reduced the land base available for timber management (departure could be used similarly for alternatives that allocate additional land to other uses). There is also the opportunity to increase the level of timber production by regenerating the mature stands at a faster rate

Departing from nondeclining flow would set up an inevitable decline in harvest levels in the future. Many feel that the Forest should not be managed to provide present benefits at the expense of the future. There is also concern that second growth stands will not be available for harvest as early as projected and the falldown in the future could be greater than expected. Some also feel that accelerating the harvest schedule by departure would increase the risk of adverse environmental impacts

WILDLIFE HABITAT

6. The issue of management of wildlife habitat on the Siskiyou National Forest is two-fold: (1) How to preserve and manage a diversity of wildlife habitats to maintain self-sustaining populations of all native animal species (endangered, threatened, or sensitive species being especially important); and, (2) How to manage big-game habitat to provide quality experiences for an increasing number of big-game hunters.

There is particular concern for species, such as the spotted owl, which are dependent on specific seral stages Management of lands for timber production has the potential to reduce some seral stages or create an imbalance of habitats that would be detrimental to some species. There is also concern for species with specific habitat requirements such as snags, meadows, and rock cliffs or talus

There is also interest in providing habitat for big game species to support populations capable of supplying the demand for hunting opportunities. Considerations are for maintaining a balance of forage and cover habitats through time as various management activities are carried out.

SOILS

7. What are the potential impacts of management activities on Forest soils?

The soils on the Siskiyou National Forest are developed from complex geologic material of the Klamath Mountain and Coast Range Provinces Many highly unstable geologic formations and steep, rugged topography typifies this mountainous area. Management activities can affect soils through compaction, displacement, disruption of nutrient cycles, movement of unstable or high rock fragment soils, reduction of organic matter, and increased erosion and sedimentation

A considerable portion of the timber land base has been classified as unsuitable due to extremes of the above conditions. Intensive inventory and evaluation by specialists in project activity and application of numerous Best Management Practices (BMP's), accompanied by various constraints in planning, layout, and design, have added to the cost of managing these sensitive lands.

WILD AND SCENIC RIVERS

8. How can conflicts between users on the Rogue and Illinois Wild and Scenic Rivers be minimized? Should the inventoried Chetco and North Fork Smith rivers be recommended for additions to the National Wild and Scenic River System?

The Wild and Scenic Rivers Act sets management direction and may limit some previously unregulated uses. Concerns of users include (1) the levels of recreation use; (2) the allocations of use; (3) power boats

in the "Wild" segment, (4) need for use regulations on other segments, (5) allocation of viewsheds outside the corridor to meet Visual Quality Objectives; and (6) management of the tributary watersheds to meet water quality standards.

The second part of this issue deals with the two inventoried rivers in the extreme southwestern part of Oregon. The North Fork Smith River is a Wild and Scenic River in California; but upriver, the Siskiyou National Forest segment of this river has not been designated The Chetco River is also included in the Nationwide River Inventory Both rivers require a suitability evaluation to determine whether they should be recommended for addition to the National Wild and Scenic River System.

SENSITIVE PLANTS

9. How can the habitat of sensitive plants be protected from damage or loss resulting from management activities, such as timber harvest and road building?

The unique geologic and climatic history of the Siskiyou Mountains of southwest Oregon and northwest California has resulted in the evolution of a number of unusual plants, either not found elsewhere or occurring here at the limits of their range. Many sensitive plants occur within the Siskiyou National Forest boundary. The range of some of these plants lies almost entirely within the Forest. Many of these plants occupy fragile ecosystems which may not be restorable once altered by Forest activities.

FISHERIES

10. How can the Forest prevent or minimize fish habitat degradation resulting from management activities and maintain or improve current fish production levels?

Fish habitat on the Siskiyou supports one of the most economically valuable fisheries in the United States. Segments of the public, including sport and commercial fishermen, are worried that spawning, rearing, and migration habitat is being adversely affected by timber harvest and road building, and fear that fish production from the Forest will decline as a result of these activities.

VISUAL RESOURCES

11. How should Forest scenic values be protected, and to what degree? What costs and impacts to other Forest management activities are acceptable to protect these values?

As timber harvest and road construction activities enter new areas, changes in the scenic resource become more apparent. The visual resource management issue revolves around the degree of protection scenic values should be given and the costs and impacts of visual resource management on other Forest activities, in particular, reductions in the annual timber harvest and associated costs of implementing visual management activities.

ROADS

12. There is little public understanding and support of road management objectives of the Forest road system, the economic rationale behind Forest road construction, and the diversity of road standards and the purposes of each.

The array of road management objectives may be confusing to the public. Some users see all roads leading to, or within, the Forest as "forest roads" available for their use at their convenience. The differences in standards of width, surfacing, grades, safety, and comfort are confusing. Road closures may protect one resource, while conflicting with or restricting use of another. Logging traffic may create hazards for recreation traffic, and vice versa. The economics of road construction often appear unreasonable. Some

road users see the standards of the roads as either too high or not sophisticated enough for their particular purposes

As management of the road system is intensified and some roads are closed to meet specific objectives or reduce maintenance costs, public concern will increase.

MINERALS

13. How should Forest lands with mineral potential be allocated? How should the environmental impacts of mining on other Forest resources be mitigated?

Utilization of mineral resources is increasing in importance. The issue raised by the mining industry is the allocation of lands with mineral potential to uses which prohibit or severely limit mining They also fear environmental constraints imposed by work and restoration plans.

To other segments of the public, the environmental impact associated with mineral extraction, processing, and reclamation is the issue. Some groups are apprehensive about the potential social change in communities as the mining industry grows, and of the potential for degradation of air and water quality.

RECREATION

14. How should the Forest provide a wide spectrum of recreation opportunities ranging from developed facilities to primitive experiences?

The public is concerned about the impacts of other management activities on recreational opportunities. There is particular interest in maintaining, restoring, and expanding the trail system; this includes both day-loop trails close to population centers, and trails with more primitive settings in the Wilderness or unroaded areas.

Availability of land contributing to the primitive spectrum of recreation experience is limited in Oregon While the Forest has a sizeable block of land offering a very primitive experience, some of this area is subject to change from timber harvest and roading activity Concern has been expressed as to the uniqueness of this type of remote experience and the essentially irreversible nature of the decision once development has occurred.

WATER

15. How should the Forest maintain a sufficient quantity of clean, cool water for domestic use and fish needs?

The development, management, and use of other resources may degrade water quality through increased siltation, water temperature, and potential for other pollutants Activities with site disturbance have the potential to adversely affect water quality.

Forest management practices can also affect the quantity and timing of water leaving the Forest through alterations in vegetative cover and subsequent changes in ground water recharge and release. Some people dependent on water supply or residing within floodplains affected by upslope activities are concerned about both flow being diminished during critical low flow periods and the potential for increased flooding during winter storms.

WILDERNESS AND UNROADED AREAS

16. How much Wilderness should be preserved on the Siskiyou? What should be the degree of development (such as trails and campsites), and how should wilderness values be protected? How

should the presently unroaded areas outside of the Wildernesses be managed; how much and which parts of these areas should be developed for timber or mineral production?

Some people feel that additions should be made to the existing Wilderness System Even though the Oregon and California Wilderness Acts of 1984 preclude designation of additional Wilderness during this planning period, the issue still remains as to the appropriate management direction for the unroaded areas. Many people feel that all or part of the areas should be allocated to uses that would preclude development, thus preserving their primitive nature Others are concerned with the effects that such designations might have on the Forest's ability to provide other resources and sustain timber harvest levels.

The public also wants the Forest Plan to address management of the existing Wildernesses. There is concern for the management of recreation opportunities through trail construction and reconstruction. Concerns over the role of fire in these protected ecosystems has also been expressed.

HARDWOOD CONVERSION

17. Should the Forest convert areas suitable for the production of timber that are currently occupied by hardwoods (primarily tanoak) to conifer production?

This issue has surfaced because many people are concerned with the amount of hardwood volume that is lost in the conversion process. They feel that this material could provide a useful product in the future, and that it is wasteful to convert the acres to conifer production Others disagree, feeling that the current and future economic benefits resulting from increased commercial conifer production are important enough to warrant conversion of these stands, even though much of the hardwood material may not be utilized

Many people are also concerned about the role of hardwoods in the ecosystem through providing vegetation diversity, wildlife habitat, and aesthetic variety. The value of these areas for wildlife has received increasingly more attention. There is also concern about soil and watershed impacts resulting from disposing of the heavy fuels created by the conversion projects.

MANAGEMENT CONCERNS

The identified management **concerns** are as follows·

1. Provide goods and services efficiently.

2 Produce a sustained timber and wood fiber output.

3. Manage and utilize range resources and improve range grazing.

4. Manage fire to improve and protect resources.

5. Protect resources from disease, pests, and similar threats. Of special concern is *Phytophthora lateralis* root rot in Port-Orford-cedar.

6. Enhance water quality and quantity, soil productivity, and restore watershed conditions where degradation has occurred

7 Adjust land ownership as needed to support resource management goals.

8. Provide a variety of recreation opportunities

9. Maintain or improve fish and wildlife habitat

10. Maintain or improve critical and essential habitats of endangered, threatened, or sensitive plant and animal species

11. Assess probabilities of mineral exploration and development for immediate and future needs, and consider nonrenewable resources in the management of renewable natural resources.

12. Construct, operate, and maintain transportation facilities in a cost effective way while minimizing impacts on other resources.

13 Identify, maintain, and enhance visual quality.

14 Require corridors, to the extent practicable, to minimize adverse impacts caused by the proliferation of separate rights-of-way.

15 Discover, manage, protect, and interpret cultural sites that are in, or may qualify for inclusion in, the National Register of Historic Places.

16. Identify typical examples of important botanical, aquatic, and geologic types; and protect them through establishment of special area designations or through management prescriptions, accompanied by standards and guidelines.

17. Provide for various Wilderness management options.

OPPORTUNITIES

The following resource use and development **opportunities** have also been identified.

1. The Forest has the ability to increase tree growth and harvest levels through intensive management and timber harvest scheduling

   Through intensive timber management, the Forest has the opportunity to improve visual quality in specific areas and improve habitat and distribution of some kinds of wildlife.

   Integrated pest management methods could be used to minimize the impact of dwarf mistletoe, root rot, and other diseases on trees, and thereby extend the available timber supply

2. Through the use of herbicides, the Forest could maintain and increase tree growth and harvest levels at least cost.

   Through development and use of other than chemical treatments in vegetation management, the Forest may be able to reduce herbicide use and create more employment where costs and effectiveness are comparable

3 Forest managers have the opportunity to maintain adequate habitat for old-growth-dependent wildlife and for recreational enjoyment of old-growth stands Opportunities exist for preservation of old-growth stands near roads for public enjoyment.

4. Forest residues which remain after harvesting and hardwood conversion projects may provide an energy source for either private or commercial use. Increasing firewood demands should improve utilization while reducing dependency on fossil fuel sources

   The use of advanced logging techniques, such as directional felling and lining of trees, is an opportunity to improve the utilization of the standing timber. Reductions in the amount of residue created and better utilization of that residue could result in less need to dispose of residues by burning, and consequently reduce air quality impacts

5. Increased timber harvests might simultaneously help supply the Nation and world market needs while increasing annual growth through conversions to managed stand conditions Increased timber harvest might increase local employment and improve local economic stability at a time when the timber supply from private lands is declining.

6. The opportunity exists to work more closely with the Oregon Department of Fish and Wildlife to improve management of fish and wildlife habitat on the Forest

   Management can increase opportunities for viewing wildlife through projects such as nature trails, habitat manipulation, and nest boxes.

   Within available budgets, maintenance and/or development of new improvements for wildlife habitat can be more actively pursued, including the following:

   a. Specific habitat improvement practices can be further evaluated and implemented, i.e., topping live wildlife trees to prevent blowdown, leaving some brush piles in areas where harvest residues are handpiled.

   b. With planning, maintaining or improving some wildlife habitat can be maintained or improved through timber harvest, reforestation, and hardwood conversion projects.

   c. Special areas can be managed for specific wildlife needs.

   d. Temporary or permanent road closures can be used to minimize wildlife disturbance by timber harvest, reforestation, and hardwood conversion projects.

   e With planning, future shortfalls of specific seral stages/habitat types, such as brushfields, can be avoided

   f. The opportunity exists to cooperate with Oregon Department of Fish and Wildlife and private landowners in managing elk habitat

   g Low intensity wildfires can be allowed to burn under controlled conditions in key wildlife habitat areas to increase grass, forb, and shrub production.

   h. Undisturbed areas can be connected by corridors of suitable habitat that is needed for species that are dependent on mature and old-growth timber

   i Range management and range rehabilitation practices can be implemented to better balance livestock-use and wildlife-use range areas

   j Habitat improvement projects can be implemented in Wildernesses providing they maintain the natural character of the area and meet Wilderness requirements

7 Fertilizers can be used to improve the nutrient status and productivity of soils. Additionally, nitrogen-fixing plants can be interplanted with timber species to increase site fertility.

Bare soil areas can be revegetated with native plant species to decrease erosion. Logging slash could be chipped and used as a soil mulch to cover bare soil areas

8. While river management opportunities are limited to those allowable under direction of the Wild and Scenic Rivers Act, management plans may establish varying degrees of protection and development based on special attributes of the area The Forest could nominate other rivers for possible addition to the National Wild and Scenic Rivers System

9 In cooperation with acknowledged scientific and research groups, a long-range plan can be developed to inventory endangered, threatened, and sensitive plants on Federal and state lists. On a continuing basis with the same groups, the Forest can assess the threats to endangered, threatened, or sensitive species in areas proposed for timber harvesting, other developments, chemical use, or mining.

The Forest can develop programs which inform the public about the values and needs of endangered, threatened, or sensitive plants. These plants can be further protected from collectors. In some cases, this may be accomplished by restricting vehicle access.

The Forest has the opportunity to identify critical areas of endangered, threatened, and sensitive plants, and set aside additional Botanical areas or Research Natural Areas for these species. Training of Forest personnel can aid in protecting these plants through being alert for certain indicator species and habitat types, and in prescribing appropriate measures to provide protection

10. Fisheries habitat enhancement opportunities involve: (1) supporting efforts to augment water supply during low flow periods; (2) managing further water withdrawal from Forest lands; and (3) removing or modifying existing stream crossings that obstruct upstream fish passage or have created unacceptable alterations of the riparian habitat

Habitat improvement opportunities exist for spawning, rearing, and migration.

Habitat assessment opportunities exist for (1) completion or updating of Forest stream surveys for determination of fishery potentials, and (2) working with state fish and wildlife agencies and local sportsmen during establishment of instream-flow needs for salmonid fish species and development of long-range fish habitat improvement plans.

11 The Forest can maintain and/or rehabilitate the scenery in selected areas. Visual impacts determined unacceptable can be rehabilitated to meet resource objectives

The opportunity exists to enhance landscapes, where warranted, by creating or retaining variety

12 Informing the public of Forest Service road management objectives and implementation can reduce user conflicts and gain an appreciation for the services provided by a well planned system

The Forest can identify, develop, and implement alternatives to minimize the need for construction of more roads by careful integration of logging and transportation systems.

13 Rehabilitation of mining areas for other resource purposes, such as wildlife and recreation, is an opportunity. Mining spoils can be used for road construction and maintenance needs. Administrative withdrawals can be actively pursued when needed to protect sensitive areas or resources.

14 More trails could be nominated to the National Recreation Trail System

More information on possible recreation opportunities can be made available through various means. A trail guide or directory could be provided. Self-guided tour routes, development of water-oriented recreation sites, and developing recreation facilities for the handicapped provide other avenues for dealing with increased recreation demands. Information can be coordinated with other state and Federal agencies Additional recreation sites can be developed

Trails within the Wildernesses can be proposed, many can be upgraded Local interest groups can be utilized in proposing trail projects and priorities Timber Sale Area Improvement funds can be used to relocate and rehabilitate trails impacted by harvest activities The trail system can be expanded, including day-use trails.

15. For improving the overall recreation industry, seek cooperative funding and development of facilities through local, state, and Federal initiatives

16. Increasing demand for clean water of sufficient quantities presents opportunities to

    a. Assess feasibility of developing upstream reservoirs to meet low-flow and temperature regulation demands

    b Increase efforts to stabilize and revegetate slides, eroding streambanks, and roads.

    c. Purchase older water rights to augment streamflow during low-flow periods

    d Develop guidelines to regulate the rate of cutting in a given watershed in order to reduce potential cumulative impacts on water quality and quantity.

    e. Develop water yield improvement goals for specific drainages to lessen impacts of water withdrawals on instream flows and aquatic life.

17. The continued support of research efforts, such as FIR, COPE, and university sponsored studies, should contribute to an increased understanding of terrestrial and aquatic processes and provide findings that can be applied to improving management practices.

18. Using forest genetics in conjunction with the Tree Improvement Program may further increase yields and possibly develop strains of trees resistant to various insect and disease organisms

DEVELOPMENT OF THE PLANNING PROBLEMS

The ICO's and their different elements described above were analyzed to determine how they could best be addressed in the planning process, or if they should be deferred for resolution elsewhere. Three possible approaches to the resolution of each element are:

1. Deferring resolution to a separate environmental analyses, document, and decision,

2. Developing appropriate Standards and Guidelines that would satisfy the concerns and resolve the issue through implementation of any alternative; or

3. Treating the element differently in various alternatives and measuring the effects to provide the basis for identifying the alternative which best resolves the issue

The first method is appropriate for issues that are, or will be, dealt with in separate environmental (NEPA) documents and subsequent decisions The second method is appropriate for ICO's that do not involve land allocation or scheduling decisions, or where choices do not exist. Where this is not the case, the ICO's are best addressed by using the third method, i e., developing various alternatives which provide choices about the provision of various quantities of each resource over time Often, resolution can best be reached by using both methods two and three.

Many of the elements in the ICO's are closely related. To facilitate addressing these items, they have been grouped or restated in the following Planning Problems, posed as questions regarding resource management options These questions can be used to guide the development and evaluation of alternatives, and to aid in the establishment of Standards and Guidelines.

PLANNING PROBLEMS

1. How Much Timber Should the Forest Produce? (addresses Issues 1, 4, 5, and 17)

This Planning Problem involves allocation of forest land to timber production, and the selection of management intensities including harvest schedules and treatments such as commercial thinning and site preparation. Potential timber production of lands allocated to management that emphasizes other uses is also considered

This problem encompasses the question of whether the Forest should harvest timber on a nondeclining flow schedule. An option is to harvest at a higher level in the near future and plan for a decline in harvest volume in future decades.

Resolution of this problem also involves the consideration of opportunities to convert shrub and hardwood stands to timber producing conifer stands

Another element in this Planning Problem is the cost, hazards, utilization factors, and environmental impacts of treating residues created by timber harvest or stand conversion.

2. How Much Old-Growth Forest Should be Preserved? (addresses Issue 3)

This problem deals with the amount and location of old growth to preserve for various reasons including providing habitat for certain species of wildlife, maintaining the aesthetic quality of large old trees and forests, and retaining portions of the Forest in these older stages as part of the natural biological diversity of the area

3. How Can the Forest's Fish Habitat, Water Quality, and Soil Productivity be Maintained or Improved? (addresses Issues 7, 10, and 15)

Fish habitat is highly dependent on water quality. Water temperature and sedimentation are critical to maintenance and protection of the fisheries habitat Soil erosion and vegetative cover along streams are extremely important aspects in providing for fisheries and other riparian values. Management of the soil and water resources (termed "watershed management") are closely tied with fisheries management on this Forest. These interrelated resources are considered in the same Planning Problem

This problem deals with the potential impacts of timber harvesting, mining, and roading activities on fish habitat, soil, and water resources. In addition to management practices to avoid sedimentation and provide high quality water, there is also concern for maintaining or enhancing soil productivity.

Capital expenditures for fish habitat improvement (principally rearing pools) are also considered Soil and water resource improvements are oriented to both restoration of degraded sites and enhancement projects.

4. How, and to What Extent, Should Lands In and Adjacent to River Corridors Be Managed to Protect, Preserve, and Enhance Wild and Scenic River Attributes? (addresses Issue 8)

Parts of two rivers that flow through the Forest have received designation as National Wild and Scenic Rivers Two other rivers included in the inventory of Wild and Scenic River candidates will be studied and a recommendation will be made for management.

This Planning Problem includes three elements: (1) What management direction for the Recreation, Scenic, and Wild sections of the two National Wild and Scenic Rivers, the Rogue and Illinois, needs to be established or reaffirmed?, (2) Will the Forest recommend designation of either of the inventoried rivers, the North Fork Smith or Chetco as Wild and Scenic?; and (3) What should land management direction be for lands adjacent to the corridors of the eligible and classified Wild and Scenic Rivers?

This problem considers what effects activities such as timber harvest and road construction could have on the recreational setting if these practices occur within sight and sound of the rivers Land management decisions for areas within the viewshed of, or directly adjacent to, the eligible and Congressionally designated rivers must take into account possible repercussions on the values for which each river segment is classified. The impact of river designation on management activities also has to be addressed due to changes in state water quality standards.

Levels of permissible use and the distribution among various user groups will not be addressed in this analysis. A five-agency management group, including the Forest Service, is responsible for determining use capacities on the Rogue to sustain the values for which it was nominated. Capacities, and distribution among users, for the Illinois River were determined through the development of a River Management Plan completed in 1985.

For this analysis, land management decisions within the actual river corridors are limited to the assignment of visual management objectives for site-disturbing activities, trail development schedules, and the specification of standards and guidelines.

Determination of suitability is the final step in the river assessment process. It provides the basis for the recommendation of designation or nondesignation of each river. If the preferred alternative contains a recommendation for National designation, a Water Resource Council's Principles and Standards analysis will be prepared for the legislative EIS to be sent to Congress.

5. How Should Sensitive Plant Resources be Managed? (addresses Issue 9)

This Planning Problem involves the consideration of designating various sites as Botanical areas or Research Natural Areas. Sensitive plants and their habitat will also be addressed though standards to guide project design.

6. How, and To What Degree, Should Forest Scenic Values Be Protected Through Visual Resource Management? (addresses Issue 11)

This Planning Problem considers the degree of protection scenic values are given and the costs and impacts of visual resource management on other activities. The Forest has been inventoried according to the visual management system and stratified by potential Visual Quality Objectives (VQO's) based on the character and variety of the landscape, viewer sensitivity, and distance from the viewer. The inventoried VQO's are used as a guideline for current management This planning analysis considers options for

adopting these inventoried objectives as standards for management on all or part of the Forest. The Forest has been stratified into viewsheds of contiguous areas that are viewed from specific travelways or viewpoints and would be logically managed to meet consistent objectives. This problem involves the question of how many and which viewsheds should be allocated to meet the inventoried VQO's.

7. How Should Wildlife Habitats on the Forest be Managed? (addresses Issue 6)

The controversy in the wildlife question is not found in the desirability of maintaining diverse and healthy populations, but in the management actions needed to accomplish this objective Vegetation altering activities change the character of the habitat and its ability to provide for various species Activities are often beneficial for some species and detrimental for others. Populations, such as big game, benefit from increased forage produced in harvest units; while populations of species dependent on mature or old-growth forest may decline. Cavity nesting species are also impacted by the removal of snags and hollow trees.

Several wildlife species groups have been identified to address their habitat needs. These groups include. (1) species dependent on specialized habitat conditions, such as cavity nesting bird populations, (2) species requiring a particular seral stage, such as grass/forb or old growth, (3) Popular game species, and (4) Endangered, threatened, and sensitive species. Eight indicator species have been selected to represent critical habitat needs The problem is to identify the appropriate balance of habitats that should be maintained, and the acceptable level of effect on timber production resulting from wildlife management prescriptions

8. How Will Management Direction Affect Recreation Opportunities in the Wilderness and Unroaded areas? (addresses Issues 14, and 16)

This Planning Problem deals with management of the existing Wildernesses, and with the allocation and management of remaining unroaded areas.

Wilderness and unroaded areas provide the only Primitive and Semi-primitive Non-motorized recreation experiences on the Forest Under current management direction, all presently unroaded areas are expected to be developed within the next two decades leaving existing Wildernesses to supply Primitive and Semi-primitive Non-motorized recreation. Based on projected increases in use, by the year 2020 demand is expected to exceed the capacity of the Wildernesses to provide these forms of recreational experience.

Management options in Wildernesses range from closure of existing trails and campsites to actions that increase capacity and disperse users. Trail development, maintenance, or improvement; and the use of fire as a management tool are the principal mechanisms for changing the use and capacity while maintaining opportunities for quality experiences

This problem considers the management direction and capital investment schedules for Wildernesses. It also considers the location and number of acres of unroaded areas allocated to management that would maintain their undeveloped status

9. How Should Mineral Resources of the Forest be Developed In Coordination with Management of Other Resources? (addresses Issue 13)

This problem deals primarily with the amount of acres allocated to uses that include, or preclude, road access that would affect the efficiency of mineral exploration or extraction Future options could be limited by the amount of the Forest remaining unroaded, and by the areas allocated to other uses that would not be complementary to mineral development

ISSUES NOT ADDRESSED BY THE PLANNING PROBLEMS

2. Herbicide Use.

This issue will not be considered for resolution in this analysis. It has been and will continue to be dealt with in separate NEPA documents at the Regional and Forest level. Any additional consideration of this issue would be through similar processes at the Regional level, or through site-specific Forest environmental analyses tiering to the Regional document. The estimated timber outputs with or without the availability of chemical release will be calculated and the harvest level adjusted appropriately during implementation and monitoring

12. Roads.

This issue is not dealt with as a Planning Problem General direction for road standards and road closures are incorporated in each alternative to be consistent with the theme of that alternative. The Forest will continue to strive to build and maintain roads at the lowest cost, subject to meeting the management objectives for the particular road. Management direction, including closures, for specific roads will be determined at the project implementation level.

ABILITY TO RESOLVE PLANNING PROBLEMS AND KEY INDICATORS OF RESOLUTION

The following sections describe, by Planning Problem, the Forest's ability to respond to the problem identified. The outputs, uses, or conditions that can be measured or described to gauge the response of the various alternatives are identified here. These are referred to as the Key Indicators.

The Key Indicators are displayed in Table A-1 along with the minimum and maximum values that could be achieved as identified in the Benchmarks, the alternatives considered in this analysis, and associated outputs and effects. Table A-1 follows this section

PLANNING PROBLEM 1

How Much Timber Should the Forest Produce?

This Planning Problem involves the questions of (1) allocation of forest land to timber production, and (2) the selection of management intensities including harvest schedules and treatments such as commercial thinning and site preparation. An associated issue involves timber management policies that depart from the current nondeclining evenflow policy.

ABILITY TO RESOLVE

Land allocations provide the primary means of resolving this issue. From zero to 570,000 acres are suitable for timber production when Management Requirements (MR's) are installed. Running the Forest Plan model (FORPLAN) with a timber objective function can increase initial timber output by as much as 3 percent with minor reductions in economic efficiency. Departures from nondeclining flow harvest schedules can substantially increase timber outputs in early decades, but make reductions in later decades inevitable.

Shortening the rotations to less than 95 percent of culmination of mean annual increment (CMAI) could also substantially increase timber outputs, but may not meet National Forest Management Act (NFMA) requirements. Minor increases in annual harvest can also be realized by converting hardwood stands to conifers, or by intensifying management on lower site class lands. Maximum first decade allowable sale

quantity (ASQ) is 33.4 million cubic feet (MMCF) with the nondeclining flow and CMAI constraints, or 56 4 MMCF without these constraints.

KEY INDICATORS

Selected Suitable Area. This is the total number of acres allocated to management emphases that include timber production as part of the prescription.

First Decade Volume. The programmed ASQ for the first decade of the planning horizon displayed in MMCF.

Fifth Decade Volume. The programmed ASQ for the fifth decade displayed in MMCF This differs only from the first decade output in departure alternatives, but shows the lower level of outputs that would be achieved in future decades under each departure.

Long-Term Sustained Yield. The long-term average annual timber production, in MMCF, is achieved by the combination of all the land allocations and management intensities This level of outputs would generally not be achieved until the tenth decade or beyond.

PLANNING PROBLEM 2

How Much Old Growth Should be Preserved?

The Siskiyou contains 443,000 acres of mature and old-growth forest. Approximately 137,000 acres are protected in areas unavailable or unsuitable for timber harvest. Other areas of mature and old growth can be allocated under any management alternative considered.

ABILITY TO RESOLVE

Land allocations are the primary tool for resolving this Planning Problem. Classified areas such as Wildernesses, Wild and Scenic Rivers, Research Natural Areas, and Botanical, contain old-growth trees and provide old-growth habitat A factor that complicates this issue is that the current inventory information does not have the resolution to stratify stands with old-growth characteristics from other mature stands This results in some acres classed as mature and old growth that do not exhibit old-growth characteristics (although the majority do exhibit old-growth characteristics). Small inclusions of other classes do not render these mature and old-growth acreages as unsuitable as old-growth wildlife habitat.

Designated Wildlife Habitat, serving as specific set asides of mature and old-growth habitat for indicator species, provides for size and distribution of habitat as a Management Requirement.

Alternative allocations considered in this analysis such as Backcountry Recreation, Research Natural Areas, Botanical, Supplemental Resource, Special Wildlife Sites, Riparian, Retention, Partial Retention Management Areas provide varying degrees of old-growth habitat.

General Forest areas deemed unsuitable for the production of timber also contain old-growth.

Standards and Guidelines Activities can be constrained to meet wildlife objectives and protect old-growth stands to meet wildlife needs. An example of this would be road closures.

KEY INDICATORS

Reserved Area. Total number of mature and old-growth acres allocated to Management Areas with no programmed timber harvest, and lands classified as unsuitable for the production of timber in areas subject to programmed harvest.

Available at Fifth Decade. Total number of old-growth acres remaining after the fifth decade.

PLANNING PROBLEM 3

How Can The Forest's Fish Habitat, Water Quality and Soil Productivity be Maintained or Improved?

FISH HABITAT

Major aspects of concern include riparian and up-slope activities, such as timber harvesting, road management, and mineral development, as they affect water temperature and sedimentation Off-Forest water withdrawal and its impact upon Forest fish habitat is also a major concern

The Siskiyou National Forest ranks highest in the production of wild (nonhatchery) salmonids within Region Six (Oregon and Washington). Presently, more than 1,150 miles of river and streams habitat are utilized by salmonids, with at least 600 miles used by both resident and anadromous species. The health and productivity of this fish habitat depend on good watershed management. The quantity and quality of rearing habitat are the most critical habitat factors for juvenile salmonid survival, as well as maintenance of carrying capacity in each stream Naturally low flows, combined with off-Forest water withdrawal, currently limit salmonid capability in several Forest basins.

Current Forest stream temperatures are at or near the tolerance limits of salmonids This situation greatly limits options for reducing streamside vegetative shade if salmonid habitat capability is to be maintained or improved.

ABILITY TO RESOLVE - FISH HABITAT

Water quality and salmonid fish habitat are protected and enhanced in a variety of ways. The following offer opportunities which meet or exceed Management Requirements (MR's) water quality.

Riparian Areas. Riparian Management Area prescriptions can measurably affect salmonid fish habitat capability by its influence on water temperature Through streamside management options, salmonid habitat capability could be maintained or improved by approximately 10 percent Management that would increase stream temperatures and degrade fish habitat would not meet the MR's for water quality. Riparian prescriptions considered viable in this analysis are: *Prescription B,* which is designed to maintain the present quality of fish habitat; *Prescription C*, designed to decrease water temperatures and improve fish habitat; and *Prescription M* (or Minimum Level), which would prevent most vegetative disturbances in streamside areas.

Supplemental Resource Management Areas. Numerous candidate Supplemental Resource areas have been identified. Of these, many are capable of maintaining the productive capability of the Forest's major salmonid producing streams. The Supplemental Resource areas are characterized by an "inner gorge" riverine environment containing high fisheries, recreation, and wildlife values Much of the adjacent slopes associated with this inner gorge setting contain areas where the risk of adverse soil impacts is high when disturbed. The option exists to allocate some or all of these areas to provide additional protection to the salmonid habitat This Management Area has no programmed timber harvest.

Other Land Allocations Management Areas 1 through 9, which have no programmed harvest, and Management Areas 10 through 13, which constrain resource activities associated with ground or vegetative disturbance, play a significant role in protection of various resources and multiple uses. The consequences associated with the level of these allocations will vary greatly by alternative

Standards and Guidelines. The Forest has adopted standards that are intended to minimize soil, water, and vegetative impacts These standards equally apply to the protection of fisheries habitat through mitigating both on-site and off-site impacts.

Capital Investments. Through capital investments, salmonid habitat capability could be improved or enhanced Improvements would consist primarily of installing structures to develop rearing pools, and removing barriers to migration routes.

Basin Harvest Constraints. Constraints on the amount of timber harvest allowed per decade from each Planning Basin could reduce the potential risk of adverse impacts to fish habitat from landslides, sedimentation, and water temperature.

WATER

A central public issue is the maintenance of a sufficient quantity of cool, clear water for the beneficial uses of water which include domestic, fish, recreation, and other uses.

Water Quantity. The Siskiyou yields about 8 2 million acre-feet of water annually. This yield, however, is unevenly distributed throughout the year As much as 80 percent of the total runs off during the winter (December - March). A seasonal drought occurs during the summer. Water on the eastside of the Forest is heavily withdrawn for irrigation and domestic use during this period. Summer flows on the westside are generally adequate to maintain suitable fish habitat and meet domestic needs.

Water Quality. Water flowing from the Siskiyou is generally of exceptional quality Of all Forest activities, timber harvesting and road construction have the greatest potential to degrade water quality. Water temperatures increases may result from harvesting conifers which shade the streams. Soil-disturbing activities may cause an increase in erosion and sedimentation.

ABILITY TO RESOLVE - WATER

Water Quantity. Limited opportunity exists to measurably increase water yield vegetative manipulation. The Forest Service could, however, promote the development of reservoirs, purchase water rights, and support the establishment of minimum instream flows in response to enhancing summer low flows.

Water Quality. Water quality can be maintained or enhanced by application of Riparian Management Area prescriptions and through application of basin or watershed activity constraints (i.e., area disturbance constraints which distribute impacts over both space and time). Riparian Prescription B and the 20 percent basin disturbance per decade are Management Requirements (MR's). The potential impacts of timber harvest and other activities can be further mitigated by applying even tighter basin constraints.

The discussion accompanying FISH HABITAT applies equally to water quality Standards and Guidelines (including Best Management Practices), specific land allocations, and soil and water capital investments all contribute to achieving the Forest water quality goals and state standards

SOIL PRODUCTIVITY

A primary concern for the soil resource is the maintenance of long-term soil productivity Steep slopes, limited surface organic layers, and a high rainfall place the naturally fragile soils at risk. Management activities which expose bare mineral soil with these characteristics can greatly increase erosion and decrease the ability of the soil to absorb and store water Other threats to the soil resource include:

1 Intense slash fires which detrimentally affect the soil nutrient status and biological potential;

2 Use of heavy equipment on fragile soils which increases soil density and reduces soil porosity and root growth, and

3 Logging and road building on unstable soils which increase the potential for mass wasting.

ABILITY TO RESOLVE - SOIL PRODUCTIVITY

Most mitigative measures employed to protect water quality and fish habitat will concurrently maintain soil productivity. The retention of organic matter on and within the soil, and minimizing soil chemical, biological, and physical changes will benefit the protection of site productivity and soil-water functioning, as well as reduce off-site water quality impacts.

Numerous opportunities exist for improving or enhancing soil properties on both disturbed and undisturbed site conditions. Management efforts should focus on avoiding disturbance, thereby eliminating the need for later restoration Numerous measures are currently exercised to prevent soil alteration or loss. Specific measures are provided in Standards and Guidelines, including Best Management Practices designed for protection of water quality. Examples include one-end suspension of logs during harvest, the use of low-ground-pressure skidding equipment, and excluding landslide-prone areas from harvest and road construction.

An inventory of sites in need of restoration is maintained and updated annually. Restoration work is a capital investment item.

The other means of resolution covered in FISH HABITAT and WATER also complement the Forest's ability to manage the soil resource in a quality manner.

KEY INDICATORS

Riparian Prescriptions. Allocation of Planning Basins to Riparian Prescription C and M (Minimum Level) which exceed the MR represented through Prescription B.

Management Areas. Allocation to Management Areas 1 through 9 prescribes no programmed harvest. Minimal disturbance accompanies these allocations.

Capital Investments. The level of capital investments scheduled for fish habitat, and soil and water resource improvements provides varying levels of enhancement and mitigation.

Harvest Dispersion. Basins with specific constraints on maximum acres of timber harvested per decade is another potential mitigation through dispersion of impacts over space and time. The indicator here would be constraints exceeding the MR level of 20 percent

Anadromous Sport Fish. Number of anadromous sport fishing recreation visitor days (RVD's) displayed in thousands of wildlife and fish user days (M WFUD's)

Commercial Fish. Commercial fish catch attributable to Forest production displayed in thousands of pounds.

Sediment. Total average annual sediment output displayed in thousands of tons. This figure includes background natural plus existing road loss rates, along with accelerated rates accounted for in the alternatives, the calculation does not include prior disturbances (harvest units and old burns)

PLANNING PROBLEM 4

How, and to What Extent, Should Lands In and Adjacent to River Corridors be Managed to Protect, Preserve, and Enhance Wild and Scenic River Attributes?

Public concerns range from the desire for the application of a full level of protection within the designated Rogue and Illinois Wild and Scenic River corridors and on lands affecting these rivers, to the impression that management policies are too restrictive. Visuals, timber harvest, mining, water quality standards, and permitted uses are just a few of the concerns surrounding this problem

Both the Chetco and the North Fork Smith Rivers meet the preliminary requirements for Wild and Scenic designation. The question now is whether these rivers should be recommended for National designation or managed under a different option.

Several other rivers were evaluated for their eligibility in a 1988 study. The eligibility of all rivers evaluated is subject to a decision.

ABILITY TO RESOLVE

Tools of resolution include: (1) Land allocation decisions with varying resource emphasis on lands adjacent to the Wild and Scenic Rivers; (2) the use of VQO's to maintain the character of the landscapes adjacent to the river corridors, and (3) decisions affecting vegetative management within corridors of the Recreation and Scenic sections of the designated and eligible rivers

Part of the analysis will also include the suitability evaluation to provide the basis for a recommendation on the North Fork Smith and Chetco Rivers.

KEY INDICATORS

Rivers Recommended. Inventoried and/or "eligible" rivers recommended to either designation or further study as part of the National Wild and Scenic River System

Adjacent Area Meeting VQO's The area adjacent to (as seen from) existing or potential Wild and Scenic Rivers that meet or exceed their inventoried VQO's

PLANNING PROBLEM 5

How Should Sensitive Plant Resources be Managed?

The Siskiyou provides habitat for many sensitive plant species Of the 24 potential Botanical areas identified, five are old-growth sites and 19 are sensitive plant sites. There are three existing Botanical areas and three Research Natural Areas (RNA's). At least three of the four proposed Research Natural Areas contain sensitive plant species.

ABILITY TO RESOLVE

Three ways of resolving the Planning Problem include:

Land Allocations. Allocating land to Botanical areas, or RNA's would protect habitat for sensitive plants and help fill identified cells needs for the RNA system

Standards and Guidelines Standards can be designed to either protect small areas of sensitive plant habitat in nondedicated areas, or to mitigate the impacts of timber management, road building, cattle grazing, or mining activities.

Management direction for protection of sensitive plants is contained in the Forest Service Manual (FSM 2670). The Endangered Species Act provides further guidance. Information on sensitive plants is stored and protected in the Forest's Total Resource Information (TRI) system.

Capital Investment Some opportunities exist to rehabilitate or protect sensitive plant habitat through capital investment projects.

KEY INDICATORS

Botanical Area. The area allocated to Botanical areas displayed in thousands of acres.

Research Natural Area. Area allocated to Research Natural Areas displayed in thousands of acres.

PLANNING PROBLEM 6

How, and To What Degree, Should Forest Scenic Values be Protected Through Visual Resource Management?

VQO's have been identified and delineated for all lands within the Forest boundary. These inventoried objectives identify the apparent aesthetic quality of Forest lands and provide a level of protection necessary to maintain the inventoried level of visual quality. In some cases, the objectives seek to restore an area of past activity not at a desired level to a specified level of visual quality over time. In all cases, VQO's seek to maintain a defined quality level, from natural to highly modified, throughout the Forest.

ABILITY TO RESOLVE

A full scale of visual resource management possibilities exist. Opportunities range from maintenance of the Forest in its existing state, or rehabilitating some areas, to the conversion of considerable area to an intensive timber management scheme (with the exception of those areas designated for other uses such as Wilderness or Wild and Scenic Rivers) Note, however, that the conversion of large tracts of the Forest to timber production would not mean the loss of the visual resource; rather, it would imply the maintenance of the resource at a minimum level for some areas and at inventoried levels for much of the remainder

The Forest has several methods, or "tools," with which to resolve this issue The most effective tool is the allocation of appropriate Forest viewsheds to the inventoried VQO's. Another effective tool is the development of management standards and guidelines designed to meet these objectives Other tools include: (1) corridor studies, including extensive analyses of impacts of harvest activities of other ownerships on the Forest visual resources; (2) extended harvest rotations, (3) harvest dispersal techniques; and (4) capital investments for mitigation

KEY INDICATORS

Allocated Viewsheds. The number of viewsheds which meet or exceed the inventoried VQO's

Area Meeting or Exceeding Partial Retention. Acres which meet Preservation, Retention, and Partial Retention VQO's.

PLANNING PROBLEM 7

How Should Wildlife Habitats on the Forest be Managed?

This Planning Problem encompasses habitat management for all Forest wildlife, including endangered, threatened, or sensitive species Management of habitat (including its change over time) for big-game animals, primarily black-tail deer and Roosevelt elk, is important to the public and to state fish and wildlife agencies (Also see **PLANNING PROBLEM 2**).

Maintenance of long-term habitat diversity on the Siskiyou can be achieved under any management alternative that meets MR's for wildlife. Habitat capability for many wildlife species would vary through time by alternative. Consequences for each indicator species are used to assess the effect an alternative would have on the species group

ABILITY TO RESOLVE

There are three approaches to addressing the distribution of habitats.

Land Allocations Management Areas such as Wilderness, Wild and Scenic Rivers, Research Natural Areas, Botanical, Supplemental Resource, Designated Wildlife Habitat, Special Wildlife Sites, Riparian, Retention, and Partial Retention Management Areas provide mature and old-growth habitat Old-growth timber is also contained in a significant number of areas deemed unsuitable for timber management (irreversible soil damage or nonreforestable five years after harvest).

Areas managed for timber provide forage for big-game animals, as well as habitat for other wildlife species which inhabit early seral stages.

Standards and Guidelines. Many techniques are used to manage wildlife habitat. Size, shape, and scheduling of timber harvest units are manipulated to insure that vegetative stages are well distributed throughout the Forest. Habitat standards have been established for deer and elk, and cavity nesting or denning animals inhabiting old-growth stands (Westside Deer and Elk Standards and Siskiyou Snag Standards, respectively)

Road building activities can be constrained to meet wildlife objectives. Roads can be closed to meet wildlife needs.

A prescription has been developed to insure the rehabilitation and perpetuation of meadow habitat.

Capital Investment Habitat capability can be enhanced through funding of habitat improvement projects.

KEY INDICATORS

Spotted Owl Capability. Potential habitat capability to support spotted owl pairs over time (long term)

Woodpecker Habitat Capability Potential habitat capable of supporting a given percentage of woodpecker populations over time.

Wildlife Wildlife user days displayed as M WFUD's.

Capital Investments. Capital investment dollars for wildlife improvement projects.

Special Wildlife Sites Special wildlife areas (Management Area 9) allocated in thousands of acres.

PLANNING PROBLEM 8

How Will Management Direction Affect Recreation Opportunities in the Wilderness and unroaded areas?

WILDERNESS

The questions related to Wilderness management center on the level of development (such as trail construction), and the methods utilized to protect Wilderness values. Management options for each of the five Wildernesses will be examined during this planning effort.

ABILITY TO RESOLVE - WILDERNESS

The "tools" of resolution relating to Wilderness management include capital investments for trail development, closure, and maintenance; Standards and Guidelines, and use of prescribed fire

UNROADED AREAS

Disposition of the Forest's roadless areas continues as a very polarized problem The continued availability of non-motorized recreation opportunities outside of the designated Wildernesses is served by nondevelopment. On the other hand, the continued availability of much of these unroaded areas in the suitable land base for calculation of annual harvest is likewise crucial to industry and local economic interests.

ABILITY TO RESOLVE - UNROADED AREAS

The most effective tool of resolution is the allocation of land to a prescription that prevents timber harvest and road construction. Other options include capital investment for trail construction; mitigation of any past human-related impacts to these areas; and Standards and Guidelines that enable the Forest manager to maintain the primitive character of the area and associated recreation opportunities

KEY INDICATORS

Unroaded Condition Area allocated to Management Areas 1 through 9 where little or no roading exists, and management objectives are highly oriented to nondevelopment.

ROS Primitive and Semi-primitive Area remaining in the ROS inventory as Primitive and Semi-primitive.

PLANNING PROBLEM 9

How Should Mineral Resources of the Forest be Developed in Coordination With Management of Other Resources?

The minerals issue has been restated as a Planning Problem which focuses on what the Forest Service can do to resolve resource coordination needs

ABILITY TO RESOLVE

The potential to resolve the various facets of the minerals issue involves two options One is the allocation of mineral lands in a way that emphasizes the differences between accessibility to mineral lands and other resource values. The second option involves changing management direction and guidelines

Land Allocations. Land allocations could affect the efficiency of mineral exploration or extraction, or even preclude mineral development. Prescriptions for these land allocations, however, could be designed to complement the existing mining laws through reducing management constraints.

Standards and Guidelines. The Forest Service can initiate some form of protection for the resources associated with mineral lands. Options available to the Forest Service include: (1) the application of surface resource use regulations; (2) the identification of special considerations needed in operating plans and permits; and (3) requesting withdrawal of land from the mining and leasing laws.

KEY INDICATORS

Area Accessible with Limited Restrictions. Area accessible to mineral exploration, development, and extraction with limited (low to moderate) restrictions imposed by other resource protection needs or standards

Table A-1 Key Indicators of Planning Problem Resolution

PLANNING PROBLEMS/ *Key Indicators*	Unit of *Measure*	Range *Maximum*	*Minimum*
1 TIMBER PRODUCTION			
Selected Suitable Area	M Acres	576 0	0
First Decade Volume	MMCF	56 4	0
Fifth Decade Volume	MMCF	33 4	0
Long-Term Sustained Yield	MMCF	58 5	0
2 OLD-GROWTH FOREST			
Reserved Area 1/	M Acres	443	151
Available at End of Fifth Decade	M Acres	443 +	173
3 SOIL, WATER, AND FISHERIES			
Management Areas 1 through 9	M Acres	1,062	176
Riparian Prescriptions C and M 2/	M Acres	176	29
Capital Investments 3/	M $	665	0
Harvest Dispersion Constraint 4/	Number of Basin	18	0
Anadromous Sport Fish User Days	M WFUD's	77	59
Commercial Fish	M Pounds	1,084	880
Average Annual Sediment 5/	M Tons	749	635
4 WILD AND SCENIC RIVERS			
Adjacent Area Meeting VQO 6/	M Acres	184	27
5. SENSITIVE PLANTS			
Research Natural Area	M Acres	5	2
Botanical Area	M Acres	41	4
6 VISUAL RESOURCES			
Viewsheds Meeting VQO 7/	Number	44	5
Meets or Exceeds Partial Retention 8/	M Acres	858	238
7 WILDLIFE HABITAT			
Spotted Owl Capability 9/	Pairs	153	32
Woodpecker Habitat Capability 10/	Percent	60	20
Wildlife User Days	M WFUD's	97	46
Capital Investments	M $	123	0
Special Wildlife Sites	M Acres	45	0
8 WILDERNESS AND UNROADED			
Unroaded Condition - MA 1 through 9 11/	M Acres	552	238
ROS-Primitive and Semi-primitive	M Acres	348	262
9 MINERALS			
Area Accessible with Limited Restriction 12/	M Acres	810	732

1/ Mature and old-growth forest reserved (protected) in Management Areas 1 through 9 (MA 1-9) plus unsuitable acres in Management Areas 10 through 14 (MA 10-14); from 5 3 acre cells

2/ Riparian Prescriptions M (Minimum Level) and C, both exceed the Management Requirement (MR) level for water quality as reflected in Prescription B.

3/ The combination of capital investments from fisheries habitat and soil/water resource improvement projects, includes *appropriated and K-V funds, both enhancement and mitigation work represented*

4/ Timber harvest dispersion ("basin") constraints are applied to planning basins, they are individually tailored based on basin values, characteristics, and activity level, they constrain activity more than the MR of 20 percent

5/ Total average annual sediment output, includes background natural plus existing road loss rates, along with accelerated rates accounted for in the alternatives, calculation does not include other prior disturbances (harvest units or old burns)

6/ Area adjacent to (as seen from) existing or potential Wild and Scenic Rivers that meet or exceed their inventoried VQO

7/ Viewsheds which meet or exceed the inventoried VQO

8/ Area meeting or exceeding Partial Retention (Partial Retention plus Retention plus Preservation)

9/ Potential habitat capability to support spotted owl pairs over time (long term)

10/ *Potential habitat capable of supporting a given percentage of woodpecker populations over time (long term)*

11/ Inventoried unroaded area allocated to Management Areas 1 through 9 (MA 1-9) where little or no roading exists and management objectives are highly oriented to nondevelopment

12/ Area accessible to mineral exploration, development, and extraction with limited (low to moderate) restrictions imposed by other resource protection needs or standards

RELATIONSHIP BETWEEN PLANNING PROBLEMS

Resolution of one Planning Problem often means intensifying another. The greatest conflict or tradeoff occurs between the Planning Problem of timber and Planning Problems dealing with old growth, scenic values, and unroaded areas. To a lesser degree, there are also tradeoffs between the Planning Problem of timber with those of wildlife and fish/soil/water, although impacts can be somewhat offset by increased capital investments, Standards and Guidelines, and other mitigations. There is a moderate direct tradeoff between timber and Wild and Scenic Rivers, and between minerals and sensitive plants These competitive relationships are addressed through the tradeoff analysis presented in the FEIS, Chapter II. The potential degree of conflict expressed between Planning Problems is displayed in Table A-2

Table A-2. Interrelationship of Planning Problems - Degree of Potential Conflict.

Relationship	Timber	Old Growth	Fish/ Water/ Soil	W&S Rivers	Sensitive Plants	Scenic Values	Wildlife Habitat	Unroaded Areas	Minerals
Timber	N/A	# # #	X X X	X X X	* * *	# # #	X X X	# # #

CONSULTATION WITH OTHERS

Consultation with other agencies, local government, interest groups, and individuals has been constant throughout the planning process. The consultation here covers contacts from the initiation of the Forest planning effort in 1979 to issuance of the DEIS and proposed Forest Plan in 1987. Please reference Appendix K for consultations made between the release of the DEIS and issuance of the FEIS.

In addition to numerous individual contacts, the Forest held a number of public meetings and workshops to discuss various aspects of the Plan's development. These took place in Grants Pass, Medford, Cave Junction, Powers, Brookings, Gold Beach, Port Orford, and other locations. Contacts were so frequent that several interest groups tracked our progress on a monthly basis; some individuals communicated at even a far greater frequency.

Specific contacts were made with county officials and planners in Del Norte County, California, and Josephine, Curry, and Coos Counties, Oregon. The development of ICO's and other planning particulars were also discussed with Oregon and California state agencies, the Bureau of Land Management, National Park Service, Environmental Protection Agency, adjacent Forests, and many other Federal agencies. In addition, many Oregon and U.S. legislators have either made inquiries or been given briefings.

Contacts with special interest groups included timber industry representatives, environmental organizations, commercial and sports fishing interests, major private landowners adjacent to the Forest, representatives of the Klamath Indian Tribe, and members of the Rogue (Takelma) Indian Tribe from the reservation lands at Siletz, Oregon

Several meetings were held to discuss specific questions about technical aspects of planning Representatives from several Oregon State agencies, local environmental organizations, and local timber industry most frequently attended these technical sessions.

Specific information on meeting dates and places, those in attendance, and the topics discussed can be found in the Planning Records. Please reference these Planning Records for further details. The records for meetings, conversations, etc., are on file at the Supervisor's Office in Grants Pass, Oregon.

The following list details contacts made with other agencies, Indian Tribes, and interest groups; and the elements reviewed. In addition to those listed, there have been numerable contacts through phone conversations and visits

OTHER AGENCIES AND INDIAN TRIBES

Bonneville Power Administration
- Power Sales Contract EIS

Bureau of Indian Affairs
- Tribal contacts

Bureau of Land Management, Medford and Coos Bay
- Eight Dollar Mountain
- Understanding of Forest planning process
- Agency areas and topics of concern

- Planning strengths and weaknesses
- Fish, wildlife, and riparian concerns
- Management prescriptions

California Department of Fish and Game, Department of Conservation, Department of Water Resources, Boating and Water Resources Agency, Energy Commission, Regional Water Quality Control Board, Air Resources Board, Department of of Forestry, Office of Planning and Research, and Cal-Trans District 1
- Interstate concerns

Coos County Planning Department
- Areas and topics of concern for Forest planning
- Comprehensive Plan

Coos County Roadmaster
- Areas and topics of concern

Coos-Curry Council of Governments
- North Bend Comprehensive Plan

Corps of Engineers
- Draft Timber Resource Management Plan

Curry County Commissioners
- Land allocations
- Impacts on private lands; impacts on cities
- Wilderness and roadless areas
- Recreation and fisheries
- Numerous information requests concerning Siskiyou planning

Curry County Planning Department
- Curry County Land Use Plan
- Areas and topics of concern for Siskiyou planning

Curry County Roadmaster
- Areas and topics of concern

Del Norte County Engineering Department
- Areas and topics of concern

Del Norte County Planning Department
- Agreement to work together on the planning process
- Areas and topics of concern for Siskiyou planning

Intergovernmental Relations Division
- Land use Plans

Josephine County Planning Commission and Planning Department
- Establishment of communication process
- Draft goals and policy statement for County
- Implementation chapter of Draft Comprehensive Plan
- Areas and topics of concern for Forest Plan
- Information sharing

- Eight Dollar Mountain coordination
- County land allocation map
- Zoning ordinances
- Openspace Reserve Zoning District

Josephine County Roadmaster
- Areas and topics of concern

Office of Federal Highway Projects
- Forest plan

Office of Governor, State of California
- Issues for Forest planning

Office of Governor, State of Oregon
- Establishment of communication process and designated contacts

Oregon Department of Energy
- Pacific Northwest Rivers Study

Oregon Department of Fish and Wildlife
- Forest Plan; share information
- Areas and topics of concern for Forest planning
- Forest planning process
- Identification of planning strengths and weaknesses
- Project planning process

Oregon Department of Forestry and Office of State Forester
- Alternative development
- Local areas and planning topics of concern
- Assessment of the management situation
- Status of planning process
- Forestry Program for Oregon
- Current management direction, MR's
- Land suitability; Roadless areas, Cumulative effects
- Prescriptions; Monitoring
- State forest economy
- MR's, land allocations, land suitability
- Rotation ages; age class gaps; other technical aspects
- Ongoing research and research needs

Oregon Department of Land Conservation and Development
- Plan Reviewers
- Areas and topics of concern with Curry County Comprehensive Plan
- County Planning on federal Forest lands
- Report on Josephine County's acknowledgement of compliance
- Need for zoning permits

Oregon State Division of Highways
- Areas and topics of concern

Oregon State Marine Board
- Management prescriptions

Oregon State Project Notification and Review System (Clearinghouse)
- DEIS/Forest Plan (previous draft)

Oregon State Historic Preservation Office
- Analysis of the management situation

Oregon State Joint Legislative Committee-Trade and Economic Development
- Planning process

Rogue River, Six Rivers, Umpqua, and Klamath National Forests
- Planning areas needing coordination

U.S. Departments of Commerce, Interior, and Transportation
- Forest Plan

U.S. Environmental Protection Agency
- Plan and processes
- Treatment of Riparian areas, water quality, etc.

U S. Fish and Wildlife Service
- Planning involvement; names of contacts
- Threatened and endangered species

U.S. Geology Service
- Areas and topics of concern, particularly minerals

U.S Heritage Conservation and Recreation Service
- Decision criteria for Forest planning

U.S. House of Representatives: Jim Weaver, Tom Foley, Robert Smith, and Peter DeFazio, and aides.
- Areas and topics of concern for Forest planning
- Minerals exploration and production

U.S. Senators: Mark Hatfield and Bob Packwood; and aides.
- Areas and topics of concern for Forest planning

OTHER INTEREST GROUPS

(Interest or affiliation was determined by statements in the communication or by the letterheads.)

Adjacent property owners
- Status of planning process
- Alternative development
- Wild and Scenic Rivers process

Conservation and Environmental
- Forest Plan appeal procedure
- *Desire to be informed and involved*
- Plan information
- Concern with herbicides, old growth, Wilderness, roadless areas, recreation, clean water, visuals, and air
- Cultural resources
- Eight Dollar Mountain
- Planning process, RPA and NFMA
- Alternative review and development
- Standards and guidelines
- Special and Botanical areas; Wild and Scenic rivers
- Port-Orford-cedar management
- Assessment of the management situation
- Concern for timber projects in Roadless areas

Economic Development
- Status of planning process
- Alternative review and development

Forest Industries
- Concern for lack of time for in-depth review
- Forest planning process
- Desire to be informed and involved
- Plan information
- NFMA as it pertains to wildlife
- Concern for southwestern Oregon forest industry and economic situation
- Concern for riparian management
- Cost-study data
- Concern for status of planning progress
- Alternative review and development
- Visual objectives
- Assessment of the management situation

Handicapped
- Need to provide access for handicapped

Mining
- *Desire to be informed and involved*
- Eight Dollar Mountain
- Known mineral locations

Minorities
- *Need to be involved in Forest planning process*
- Coos tribe territory in Coos County
- Tolowa Tribe territory near Chetco
- Planning documents
- Concerns for rivers, fish and habitat, game, Wilderness, and Roadless Areas

News Media
- Need to increase public awareness of Forest planning effort
- Establish contacts

No identified Membership or Affiliation
- Forest practices
- Reviews of plans
- Concerns with herbicides
- Eight Dollar Mountain
- Desire to be informed and involved
- Mining opportunities
- Need for more Wilderness; roadless areas; old growth
- Suitability determination
- Soils, visuals, air quality and slash burning
- Special and Botanical areas
- Alternative review and development
- Concern about timber projects going on in Roadless areas
- Port-Orford-cedar management

Petitions (3) - Signatures: (1) 4096; (2) 35, and (3) 21 Concerns for:
- Research Natural Areas, Botanical, and Special areas
- Retention of old growth
- Riparian, fisheries and other wildlife habitat
- Roadless areas
- Visual quality
- Wild and Scenic Rivers

Petroleum
- Restrictions on oil and gas exploration and development
- Roadless areas and Wilderness

Ranching or farming
- Botanical areas
- Control of public access

Recreation
- Government restrictions, permits and economic well-being
- Riparian management
- Provide for adequate off-road opportunities
- Wilderness, Wild and Scenic rivers
- Roadless areas
- Desire to be informed and involved

Scientific and Education
- Offer to be involved by conducting interviews
- Desire to be informed and involved
- Old growth situation
- Eight Dollar Mountain and other Research Natural Areas
- Desire to follow the dynamics of the planning process

Utilities
- Oregon 21 Coos Borrowers Environmental Report
- Transmission corridors and substations
- VQO's
- Cultural locations

INTRODUCTION

PLANNING SITUATION

One of the primary responsibilities of the Forest Service is to decide how best to manage National Forest lands to produce the goods and services the public desires. These lands must be managed to provide *adequate levels of resources and services for both current and future uses* Because National Forest lands and the natural resources they contain are valuable to society, commitments to various uses represent significant and far-reaching decisions.

The Siskiyou National Forest is located in southwestern Oregon and contains 1,092,302 acres of diverse land forms and vegetation. The wide variety of seral and climax-type vegetation communities that exist support a rich and varied wildlife community. The timber industry is important to the local economy In addition, the Forest provides an attractive setting for recreationists who spend money for supplies and services.

Planning under the National Forest Management Act (NFMA) (36 CFR 219) responds to the increasing complexity and social significance of the Forest and magnitude of the analysis and management decisions. The Forest's major planning goal is to provide enough information to help decisionmakers determine which combination of goods, services, and land allocations will maximize Net Public Benefit (NPB) (discussed later in this appendix). The regulations (36 CFR 219) developed under NFMA provide the analytical framework within which these decisions are made.

The NFMA and its regulations also state that the requirements of the National Environmental Policy Act (NEPA) and its regulations (40 CFR 1500-1508) must be applied in this analysis process. The NEPA regulations require that the environmental effects of a proposed action and alternatives to that proposed action must be disclosed in an Environmental Impact Statement (EIS).

CHANGES BETWEEN DRAFT AND FINAL

Several changes have occurred in the analysis process as a result of public and agency comments. Minor changes have also resulted from the 1987 fires and other events of the past year.

The analytical procedures used to project nongame wildlife WFUD's have been modified in response to public input. In the Draft, the nongame wildlife use was assumed to be equal to the game use and was projected based on expected changes in deer habitat. For the alternatives in the Final, the nongame use is projected similar to the demand for recreation assuming that the change in the amount of the wildlife viewing is a function of the change in the human population - not the change in wildlife habitat (values for benchmarks were not recalculated).

An error was identified in in the calculation of deer habitat capability. Habitat capability was underestimated by about 25 percent. This has been corrected and all affected tables and text have been revised This error was consistent in all alternatives and benchmarks so relative differences remain the same.

Timber volumes displayed in board foot measure have been adjusted to more closely reflect the volume expected to be harvested in the first decade.

The volume of salvageable dead timber has been calculated from the inventory and included as a component of timber harvest projections.

Management Area 6, "Custodial (Roadless)," has been modified and renamed "Backcountry Recreation."

Alternatives K-Departure and L of the Draft have been dropped from detailed study. A new alternative (S) has been developed and is the Preferred Alternative in the Final EIS.

The Final Supplement to the Environmental Impact Statement (FSEIS) for an Amendment to the Pacific Northwest Regional Guide was completed in 1988. This amends the Spotted Owl Guidelines used by the Forest to define habitat needs to achieve Management Requirements (MR's) The changes do not substantially affect the habitat proposed for designation on the Siskiyou; there are some minor changes in the location of habitat areas.

A number of changes have implications for minor inventory adjustments. The 1987 Fires changed the vegetation in the burned areas; the intensive field work done in association with the Silver Fire Recovery Project identified additional areas unsuitable for timber management; there are new Wild and Scenic Rivers; and the revised spotted owl habitat guidelines result in an adjustment of the habitat needed for MR's. The Alternatives in the EIS have not been adjusted for these minor changes; they have been kept on the same comparative basis by continuing to run new analyses (including the new alternative) on the same inventory base. These "fine tuning" adjustments are incorporated in the Forest Plan for implementation.

PLANNING PROCESS

The planning and environmental analysis process brings a new outlook and a new technology to National Forest land management, principally: (1) land management planning requires that processes formerly used to make individual resource decisions must be combined into integrated management decisions, and (2) new mathematical modeling techniques are used to represent the elements of the land allocation problem and to help identify the most efficient pattern of land management. This is discussed in the NFMA regulations and Chapter I of the Final Environmental Impact Statement (FEIS) as a 10-element planning process. This appendix is concerned with describing the analysis phase of this process which are elements 3, 4, 5, and 6. The judgement phases, elements 1, 2, 7, and 8, are described in Chapter's I and II and in Appendix A of the FEIS. The execution phases, elements 9 and 10, are presented in the Land and Resource Management Plan (LRMP).

The analytical elements are as follows:

INVENTORY DATA AND INFORMATION COLLECTION (STEP 3)

The interdisciplinary team (IDT) determined what data was necessary, based on the issues and concerns. Data collection is part of normal Forest operations. Existing data were used whenever possible and supplemented with new data where required to help resolve sensitive issues or management concerns. Data, including information on resource capability areas and acreages; resource supply and demand; and expected outputs, values, and costs resulting from management prescriptions, are needed for formulation of the models used in the analysis of the management situation, formulation of alternatives, monitoring, and other phases of the planning process Much of the data and background documentation are on file in the Planning Records.

ANALYSIS OF THE MANAGEMENT SITUATION (STEP 4)

This analysis brings existing information together, puts it into a total Forest perspective, and examines the range of possible solutions to resource issues. It examines supply potentials, market assessments for Forest outputs, and determines suitability and feasibility for meeting needs. A model (FORPLAN) was built to represent Forest resources and assist in allocation and scheduling to address a number of questions regarding potential outputs of goods and services and Forest conditions. This part of the analysis includes the development of benchmarks designed to establish the outputs and conditions that could be expected from specific management scenarios. They include a) the projection of the Forest's current management
