program, b) determining the Forest's ability to produce a range of goods and services, from minimum management to maximum production, c) evaluating the feasibility of reaching the national production goals Forest and Rangeland Renewable Resources Planning Act of 1974 (RPA) targets and social demands identified as issues and concerns, and d) monetary benchmarks which estimate the output mix which maximizes Present Net Value (PNV) of resources having an established market value or an assigned value. This analysis provides the information necessary to formulate a range of reasonable alternatives.

FORMULATION OF ALTERNATIVES (STEP 5)

The information gathered during the first four planning action elements is combined and analyzed to formulate alternative plans suitable for evaluation and presentation in the FEIS. The alternatives reflect a range of resource management direction. Each identified major public issue and management concern was addressed in one or more alternatives. The programs formulated represent the most cost-efficient way of attaining the objective set forth for each alternative. This process provides a basis for identifying the alternative that comes nearest to maximizing the priced component of NPB, consistent with the resource integration and Management Requirements (MR's). This is then considered along with the subjective value of nonpriced outputs to determine NPB.

ESTIMATION OF EFFECTS OF ALTERNATIVES (STEP 6)

The physical, biological, economic and social effects of each alternative were estimated including how each responds to the range of goals and objectives assigned by the RPA Program. The FORPLAN model estimates many of the anticipated consequences of changes in the flow of goods and services from the Forest in terms of resource output levels. Other effects examined outside the model include ecological and social considerations. Specifically, the analysis includes: 1) direct effects, 2) indirect effects, 3) coordination with other Federal, State, and local land use plans, 4) other environmental effects, 5) energy requirements and conservation potential, 6) natural or depletable resource requirements and conservation potential, 7) urban quality, historic and cultural resources and, 8) means of mitigation.

INVENTORY DATA AND INFORMATION COLLECTION

RESOURCE DEVELOPMENT

CAPABILITY AREAS

This is the first step in the analysis phase of the planning process. Inventory data are needed for developing the planning model used in the analysis of the management situation, the formulation and evaluation of alternatives, and monitoring of accomplishments. The IDT collected and assembled the data necessary for making management decisions. Some data existed prior to initiation of the NFMA Forest planning effort while other data were collected to supplement information needed to resolve management issues and concerns. The land base was stratified into capability areas defined by physical and biological attributes, and further delineated by political boundaries. Capability areas represent lands delineated to estimate responsiveness to various management practices, resource values, output coefficients, and multi-resource or joint production functions.

The compilation of the various inventories into the mapping system resulted in more than 40 layers of land attribute and management opportunity delineations. These include:

Ownership
Soil Resource Inventory (SRI)
Ecoclass
Geology
Special Resource Areas
Slope
Aspect
Elevation Zones
Stream Class
River Basin
Visual Quality Objective (VQO)
Recreation Opportunity Spectrum (ROS)
Unroaded
Lands Unsuitable for Timber Production
Wildlife Habitat Areas

ANALYSIS AREAS

Overlaying all of the identified layers would result in thousands of unique strata. Grouping and stepwise analyses were used to aggregate and condense these into the minimum number of areas that still retain sufficient site specificity to analyze resource allocation and scheduling options along with issues and concerns related to specific resources. The result is the stratification of the Forest into 317 analysis areas. The land represented in an analysis area need not be contiguous and generally is not. Each analysis area is composed of similar sites, with similar vegetation, representing similar opportunities; and can be expected to respond in similar ways and amounts to various management activities.

PRODUCTION COEFFICIENTS

Specific resource outputs and uses such as timber harvest and wildlife are analyzed in the planning process in response to the issues and concerns. The resource data for each capability area in the analysis area was combined to form the basis for a number (production coefficient) that serves as a measure of a physical property.

Major production coefficients used on the Siskiyou are expressed in the following units:

Thousand Cubic Feet (MCF) of timber per acre
Miles of Road per acre
Tons of Sediment per acre
Sport Fishing - Fish and Wildlife User Day (WFUD) per basin
Thousand Pounds Commercial Fish per basin
Wildlife - WFUD per acre
Acres of Seral Stages
Recreation Visitor Days (RVD's)

SUITABILITY ANALYSIS

The Forest used empirical data to determine the acres that are tentatively suitable for management practices. All areas are considered available for some form of recreation and some type of wildlife use

Lands were considered through the following step-wise analysis to determine if they would be included in the inventory of land tentatively suitable for timber production.

1. Lands withdrawn from timber production by law or regulation were identified as unavailable.

2. Lands with less than ten percent conifer stocking were identified as nonforest

3. Lands where the technology is not available to prevent irreversible resource damage were identified as unsuitable.

4. Lands where there is not reasonable assurance that adequate restocking can be attained within five years after final harvest were identified as unsuitable (regeneration difficulty).

To complete this analysis, several sources of data were utilized in concert. The SRI, Timber Inventory, reforestation records, and available stand examinations were compiled and evaluated by ranger district personnel most familiar with the land and resources. Unsuitable lands were mapped based on the interpretation of this data with the aid of aerial photographs and with the benefit of first hand knowledge and experience. This was followed up with additional field reconnaissance and review by Forest and Regional Staff, as well as interested members of the public. Maps and rationale for the classification of specific areas are available in the Planning Records. The results of the land suitability classification are displayed in Table III-16 in the FEIS.

Minor inventory adjustments have been made since the DEIS was prepared. The field inventory work done in conjunction with the Silver Recovery Project identified an additional 3,937 acres unsuitable do the risk of irreversible soil damage, and 3,681 acres unsuitable due to reforestation difficulty. The Oregon Omnibus Wild and Scenic Rivers Act of 1988 also withdrew 1,684 acres from the tentatively suitable base These adjustments are not included here and have not been made in the alternatives in the FEIS. The inventory information has been held static for the purpose of alternative comparison. The changes will be incorporated into the alternative selected for development of the Forest Plan. The revised land suitability classification is displayed in Table II-1 of the LRMP.

The monitoring plan and standards and guidelines in the LRMP provide for continual refinement and updating of inventory information. The Plan may be amended or revised if inventory adjustments indicate that outputs or environmental conditions are substantially different.

ALLOCATION AND SCHEDULING

With the economic values and relationships used in this analysis, allocations of land to other resource uses could not compete with allocations to timber management. To evaluate the effects of specific resource needs and to examine a full range of alternatives, land allocations were developed to meet resource objectives or to follow the theme of a particular alternative, and then the FORPLAN model was used for scheduling and estimating the outputs and effects. Productivity Class and Condition class (existing vegetation) data were used along with yield and economic coefficients within the model for scheduling of management activities over time.

MONITORING

Forest planning data used to develop the key production coefficients will also be used to help monitor implementation activities. Forest planning data provides a base or standard from which changes that result from implementation of the LRMP can be measured.

PLAN IMPLEMENTATION SPECIFICATIONS

The Forest planning data base (in planning records) provides biological and physical data that will help develop subsequent programs for plan implementation. As more information is available, the data base will be updated and improved.

State of Oregon Water Resources Department Drainage Basin Reports

Oregon's Statewide Assessment of Nonpoint Source Problems, August 1978, State of Oregon Department of Environmental Quality, Water Quality Program

The streams and rivers were inventoried using the Region Six, USDA, Forest Service, Stream Classes I-IV

Timber data regarding stand locations, volumes and growth were based on the Siskiyou National Forest Timber Inventory, 1979

Road construction and reconstruction costs were developed from the Forest cost records for the period 1975 through 1984 on 305 timber sales. Some adjustments were made to the costs to reflect current conditions. Road reconstruction mileage factors were developed using timber sales programmed from Fiscal Year 1978 through Fiscal Year 1984.

Road Maintenance costs were determined from timber sales appraised in 1981 and 1982 and checked against 1983. Allocated road maintenance were based on 1982 and 1983 program averages with some adjustments for inflation and the addition of new mileage to the road system.

Capital Investment costs for roads were based on timber harvest volumes with adjustments to meet the themes of the alternatives or other mitigation needs.

Road density factors for road construction were developed by modeling four representative planning basins with logical road systems and then applying these factors the other basins with some allowance to compensate for known differences.

FOREST PLANNING MODEL

The planning model consists of information and various analytic techniques combined to address planning questions and issues. The major analytic model is called FORPLAN. An explanation of the FORPLAN model can be found in "FORPLAN Version 2: An Overview" (Johnson and others 1986), and a more general discussion of the use of analysis and models in forest management can be found in "Forest Management" (Davis and Johnson 1987).

OVERVIEW

FORPLAN is a linear program that assigns unique sets of management activities to specific areas of the Forest to compare the productivity of measurable goods and services towards a specific goal called an "objective function." The management activities are combined into compatible sets representative of the multiple uses that could apply to the analysis areas. These sets of management activities are called "management prescriptions."

FORPLAN assigns only those management prescriptions to the analysis areas which produce the goods and services that achieve the objective function in an optimal way given the objective function and constraints used. It also schedules the production of the goods and services over time.

Alternatives are generated by applying constraints to produce a specified range of goods and services, to allow only a specified range of goods and services, or to allow only a specified set of management prescriptions to be assigned to specific analysis areas. These constraints are designed to achieve or maintain a situation considered necessary to meet the overall goal of the alternative. The conditions set by the constraints are satisfied before the objective function is optimized. The final solution of all alternatives had the objective function to maximize PNV. In other words, after meeting all constraints, the FORPLAN model allocated remaining economic choices to maximize PNV.

THE ANALYSIS PROCESS AND ANALYTICAL TOOLS USED

Preliminary analyses leading to the use of FORPLAN included predictions of resource production (timber, wildlife, fish, recreation, and sediment). A social impact assessment study and the identification of base line socio-economic conditions were also used.

Analysis leading up to FORPLAN included designing management prescriptions, assigning practices to prescriptions, developing management costs for each practice and predicting resource outputs, and benefits. Outputs predicted include timber yield, big game forage, sediment, roads, fisheries, costs, and benefits.

FORPLAN was then used to determine optimal allocations and scheduling of management prescriptions for each analysis area. This overall process is key to cost efficient resource allocation. Cost efficiency was considered by the IDT while they were developing a realistic and flexible set of management prescriptions. This combination of identifying cost efficient prescriptions, and then using FORPLAN to identify the mix of prescriptions and scheduling that will produce the highest PNV, provides a method by which the alternative results portrayed represent economically efficient ways of achieving the goals for that alternative.

Decisions that resulted from the preliminary analysis include the following that apply to all prescriptions:

1. All roads will be built and maintained to Forest-wide Standards and Guidelines at the level appropriate to the goals of the alternative. Road construction design standards were developed to minimize impacts on soil and water resources and anadromous fisheries habitat.

2 Timber sales are planned and will be administered according to Standards and Guidelines, including coordination with cultural, visual, wildlife, fisheries, soil, and water resources All harvesting is planned to ensure meeting prescription objectives, including MR's

3 Timber slash disposal and reforestation activities will take place in all prescriptions which include timber harvesting

4. Wildlife habitat management includes practices to ensure adequate browse production and habitat dispersion for big game, the production and protection of habitat for woodpeckers and other cavity nesting birds, and the protection and enhancement of wildlife niches.

5. Baseline socio-economic conditions were identified for the local area In addition, economic (cost) efficiency analysis was used to determine the benefits, costs, and tradeoffs associated with varying levels of goods and services produced on the Forest These are discussed in future sections of this appendix

IDENTIFICATION OF THE ANALYSIS AREAS

The rationale for delineating the analysis areas follows:

Analysis Area Level	Identifier	Reason for Delineation
Basin	1	The Forest was divided into Planning Basins that coincide with the major watersheds to allow analysis of effects by watershed for various resources, water and fisheries in particular Predictions for roads are basin specific
Development Status	2	Identification of unroaded areas and separate unavailable/unsuitable lands Predictions for roads Recreation opportunity analysis
Timber Productivity	4	Predict timber outputs over the long term
Plantation Age	5	Stratify plantations by age for timber output predictions
Condition Class	6	Condition of existing vegetation for predicting timber outputs on the short term

FOREST PLANNING MODEL

LEVEL 1 CRITERIA - BASINS

The Forest was divided into twenty (later reduced to 19) major watershed areas for the purposes of planning These planning basins serve as geographic locators in the model to predict fish and water production, schedule timber harvest and estimate road construction costs. The boundaries were usually placed along major watershed divides. The current total of 19 basins resulted from the split of the old Basin 18 into Basins 15 and 19 A small area of suitable land was remapped from Basin 14 and included in Basin 13 Basin 14 is now entirely Kalmiopsis Wilderness and classified as unavailable for timber production Utilization of watershed areas in the FORPLAN model is more responsive to the issues of fisheries, soil and water resources, and the effects of timber harvest and road construction on these resources.

The following data lists the basin label, the Level 1 identifier and the total acreage.

Identifier	Label	Description	Acreage
01	ELKSIX	Elk and Sixes Rivers	68,043
02	COQUIL	South Fork Coquille River	70,743
03	LOBSTR	Lobster Creek	29,228
04	UP-ROG	Upper Rogue River	78,852
05	LO-ROG	Lower Rogue River	44,843
06	INDIGO	Indigo Creek	49,326
07	SILVER	Silver Creek	42,446
08	GALSLA	Galice and Slate Creeks	41,724
09	LO-ILL	Lower Illinois River	67,382
10	UP-ILL	Upper Illinois River	84,549
11	BRIGGS	Briggs Creek	41,319
12	PISTOL	Pistol River	42,229
13	L-CHET	Lower Chetco River	78,416
14	U-CHET	Upper Chetco River	93,802
15	R&R-JO	Rough & Ready-Josephine Creeks	62,141
16	WNCHUC	Winchuck River	32,481
17	SMITH	North Fork Smith River	57,429
19	EF-ILL	East Fork Illinois River	45,557
20	SUCKER	Sucker Creek	61,791

LEVEL 2 CRITERIA - DEVELOPMENT STATUS

This criteria was used to delineate between roaded (RD) and unroaded (UR) areas on the Forest This classification was necessary to aid in predicting resource outputs for dispersed recreation, road construction, and management costs It is responsive to issues regarding the development of roadless areas on the Forest, the types of recreation opportunities that will be available, and the degree of timber development that is responsive to local, regional, and national needs Unavailable and unsuitable lands (NA) are also identified in this level.

LEVEL 3

(Not Used)

LEVEL 4 CRITERIA - PRODUCTIVITY CLASSES

This criteria was used to define the biological potential of varying land groupings on the Forest, and to link this potential to the response coefficients for timber as a result of treatments performed in the prescriptions. This criteria is responsive to issues concerning levels of timber harvest and future potential The following Level 4 identifiers were used.

Identifier	Label	Description
MN	MIN	Minimum Site 1/
LS	LOW	Low Site
MS	MED	Medium Site
HS	HIGH	High Site

1/ Lands capable of producing less than 20 cubic feet per acre per year

LEVEL 5 CRITERIA - PLANTATION AGE

This level was used to define the ages of the existing plantations Identifiers are P1 through P4 to indicate ages 10, 20, 30, or 40 at the midpoint of the first FORPLAN period This could have been incorporated in Level 6, but it was not included in the original inventory and it was more convenient to insert it here.

LEVEL 6 CRITERIA - CONDITION CLASS

This criteria was used to identify existing vegetation conditions on the Forest. This information was used to predict response coefficients for timber, wildlife habitat, old growth, management costs. It is responsive to timber, and wildlife issues Condition, size, and stocking classes were aggregated into the condition classes shown below:

Identifier	Label	Description
MT	MATURE	Mature Conifer Stands
IE	I/MS/E	Immature Medium Size Sawtimber - Excess Stocking
IP	I/MS/P	Immature Medium Size Sawtimber and Poles
IS	I/S&S	Seedlings and Saplings (primarily plantations)
HD	HRDWDS	Brush and Hardwood Areas Nonstocked With Conifers
SS	SSC	SSC Land (MIN Site from Level 4)
PR	PVTLND	Private and Other Government Lands

IDENTIFICATION OF PRESCRIPTIONS

The NFMA regulations define management prescriptions as "management practices selected and scheduled for applications on a specific area to attain multiple use and other goals and objectives" (36 CFR 219.3). Generally, a multiple use or dominant use management prescription is a set of practices to conserve or preserve resource outputs on any one Management Area.

The Forest IDT constructed the prescriptions by reviewing legal direction, researching appropriate questions, and consulting existing policy direction. The IDT then applied professional judgement to develop multiple-use resource management prescriptions.

These prescriptions represent a range of management direction, intensity, practices, standards, and guidelines The IDT included the necessary mitigation measures and resource coordination measures that are required to satisfy economic, legal, and social constraints when implementing these prescriptions The documentation of these measures are found in the management Standards and Guidelines of the Forest Plan.

Completed prescriptions received full review, discussion, and revision by the IDT Each IDT member evaluated the prescriptions to ensure management direction could be implemented, and that the planning issues, concerns, and opportunities were adequately addressed.

Fourteen different Management Area themes were considered in the planning process The following fourteen Management Areas are represented by a unique management prescription emphasis

No	Name
1	Wilderness
2	Wild River
3	Research Natural Area
4	Botanical
5	Unique Interest
6	Backcountry Recreation
7	Supplemental Resource
8	Designated Wildlife Habitat
9	Special Wildlife Site
10	Scenic/Recreation River
11	Riparian
12	Retention Visual
13	Partial Retention Visual
14	General Forest

The IDT then assigned different prescriptions to different areas of the Forest based on the following criteria

1 Legal obligations such as wilderness designation
2. Ecological characteristics such as riparian zones, unique plant associations, meadows, and old growth timber.
3 Administrative and social obligations such as Research Natural Areas and cultural interest areas
4. Biological capacity for production such as supplemental resource areas and timberland.
5. Need for wide range of alternatives
6. Need for cost efficiency.

Three different groupings of prescriptions were formulated to (1) explore the biological and economic limits of different management strategies (benchmarks), (2) compare with current management (current direction), and (3) implement feasible multiple use applications These groupings permitted the study of the production limits of each resource prescription given minimal attention to other resources, significant changes from current outputs, and cost efficiency of any one alternative compared to maximum outputs or to another alternative.

The IDT then formulated three different hierarchies of prescriptions to further ensure cost efficient solutions. Some areas were designated for simultaneous use with compatible resources, some areas had a single emphasis output, and some areas of land had a minimal level of management. Different alternatives had different amounts of these allocations. This process provided a wide range of prescriptions and cost efficient solutions pursuant to the intent of 36 CFR 219.14(b) and (c)

Subsequent use of the FORPLAN model ensured cost efficient prescriptions by providing solutions to maximize the PNV within given constraints.

A brief discussion of the prescription categories follows. A more detailed explanation is presented in the LRMP.

Each prescription emphasis has driving issues, concerns, or opportunities that provide its purpose, criteria, and assumptions

PURPOSE, CRITERIA, AND ASSUMPTIONS FOR PRESCRIPTIONS

Wilderness

PURPOSE To preserve wilderness

CRITERIA Any activity will provide an environment essentially unaltered and undisturbed by humans

ASSUMPTIONS. Recreational demand will increase, but use will remain within the carrying capacity for the first five decades

COST EFFICIENCY· Different management plans for wilderness were assessed to determine meeting recreational demand at least cost

POTENTIAL ACTIVITIES· Trail construction, trail maintenance, and natural fuels treatment

Wild River

PURPOSE: To maintain the river environment in a natural state while providing for recreational opportunities

CRITERIA. Any activity will provide an experience of a free flowing, free of impoundments river with high quality water inaccessible except by trail.

ASSUMPTIONS· Recreational use will increase over time with potential impacts.

COST EFFICIENCY: Different management strategies were assessed to meet demand at different levels with different costs

POTENTIAL ACTIVITIES· Trail construction, trail maintenance, and natural fuels treatment.

Research Natural Area

PURPOSE: To preserve examples of naturally occurring ecosystems for research and education

CRITERIA: Any activity will ensure the baseline conditions, gene pool preservation, and natural processes in relatively undisturbed environments will not be altered.

ASSUMPTIONS: The experiment station and universities associated with the RNA's will continue to provide direction The need for lands in a natural state will remain constant over the planning period.

COST EFFICIENCY· Other values, such as minerals, which are foregone in this management prescription, are minimized in the site selection. RNA values are assumed to exceed opportunity costs

POTENTIAL ACTIVITIES: Research projects and educational projects

Botanical

PURPOSE. To protect unusual botanical features of the Forest

CRITERIA. Any activity will ensure that endangered, threatened, or sensitive plant species, and other unique biological features will not be adversely affected.

ASSUMPTIONS· The demand for protecting rare plants from disturbance and value of those plants will not decrease within the planning period.

COST EFFICIENCY: Different alternatives have different areas allocated to this Management Area for providing an economic comparison and a wide range of alternatives.

POTENTIAL ACTIVITIES Natural fuels treatment, road maintenance, and road construction

Unique Interest

PURPOSE. Protect significant cultural sites and outstanding geologic features of the Forest

CRITERIA Any activity in this category of land will maintain or protect historic structures or locations of historically significant events, and prominent or unusual rock buttes or waterfalls.

ASSUMPTIONS: Other uses such as recreation, range, minerals, lands, and facilities may occur if they are subordinate to the purpose of this area. The values of these features will not decrease in time.

COST EFFICIENCY: Different alternatives have different allocations of this Management Area providing for examination of economic efficiency.

POTENTIAL ACTIVITIES: Road maintenance, road construction, natural fuels treatment, and activity fuels treatment.

Backcountry Recreation

PURPOSE Maintain areas in an undeveloped condition and provide Primitive and Semi-primitive recreation opportunities. Specific areas may be designated to provide Motorized or Non-motorized recreation

CRITERIA: Any activity will retain the natural or near-natural state of land in this classification

ASSUMPTIONS: Semi-primitive Motorized recreation will be compatible with mineral exploration and development Trail construction and maintenance will also be compatible.

COST EFFICIENCY: Different alternatives had different land allocations for this area providing a wide range of alternatives and a basis for comparing economic efficiency.

POTENTIAL ACTIVITIES· Trail construction, trail maintenance, and natural fuels treatment In Motorized areas, construction or maintenance of primitve roads as ORV or jeep trails.

Supplemental Resource

PURPOSE To protect or enhance critical wildlife and fisheries habitat

CRITERIA: Any activity will maintain high quality watershed conditions, and maintain or improve water quality.

ASSUMPTIONS. Recreation, wildlife and fish habitat improvements, soil and water restoration projects, mineral extractions, and facility construction may occur provided the area's purpose is met.

COST EFFICIENCY· Different alternatives have different areas allocated to this Management Area for providing an economic comparison and a wide range of alternatives

POTENTIAL ACTIVITY: Trail construction, trail maintenance, wildlife habitat improvements, fish habitat improvements, watershed improvements, road maintenance, road construction, and natural fuels treatment

Designated Wildlife Habitat

PURPOSE. To preserve old-growth habitat to maintain populations of old-growth-dependent species

CRITERIA All activities will protect mature and old growth habitat in sufficient amounts to maintain viable populations of indicator species (spotted owls, pine martens, and pileated woodpeckers).

ASSUMPTIONS: The amount and distribution of old growth habitat in this category is sufficient to maintain viable populations of indicator species.

COST EFFICIENCY: Two different options of providing the mature and old growth habitat were examined for economic efficiency. The first option provided for rotating areas and rotation lengths to obtain the desired habitat The second option set aside areas to maintain the desired habitat

POTENTIAL ACTIVITIES. Wildlife habitat improvements, fish habitat improvements, trail construction, trail maintenance, road maintenance, road construction, and natural fuels treatment

Special Wildlife Site

PURPOSE Protect or enhance unique wildlife habitat.

CRITERIA: Designated meadows, wet sites, lakes, tanoak sites, hardwood sites, Roosevelt elk sites, band-tailed pigeon sites, osprey nest sites, rock sites, dispersed old-growth sites, and small wildlife areas and botanical sites will have only activities that maintain or enhance their value for wildlife habitat

ASSUMPTIONS: Other uses may be compatible in this area if the area's purpose is met. Timber harvest would not be programmed

COST EFFICIENCY. Different alternatives have different areas allocated to this Management Area for providing an economic comparison and a wide range of alternatives

POTENTIAL ACTIVITIES: Wildlife habitat improvements, fish habitat improvements, trail construction, trail maintenance, natural fuels treatment, activity fuels treatment, road maintenance, and limited road construction

Scenic and Recreation River

PURPOSE: To provide high quality scenery along a largely undeveloped shoreline and to provide a wide range of river oriented recreation.

CRITERIA All activities will provide or maintain the aesthetic, scenic, archeologic, recreational, and water quality attributes of these areas.

ASSUMPTIONS: Coordination with the five agency group for river management will allocate uses for these areas.

COST EFFICIENCY: Different alternatives have different areas allocated to this Management Area for providing an economic comparison and a wide range of alternatives.

POTENTIAL ACTIVITIES: Wildlife habitat improvements, fish habitat improvements, recreational improvements, trail construction, trail maintenance , road maintenance, road construction, timber sale preparation, timber harvest, reforestation, and timber stand improvements.

Riparian

PURPOSE Maintain integrity and water quality of the riparian ecosystem

CRITERIA. All activities will maintain the vegetative, terrestrial, and aquatic habitats associated with riparian areas. Other objectives such as timber harvest will be secondary to the primary criteria

ASSUMPTIONS: If unresolvable conflict occurs, preferential consideration is given to riparian values

COST EFFICIENCY: Different prescriptions for managing riparian areas are examined to determine economic efficiency and a range of biological responses. Opportunity costs of forgoing secondary benefits are examined.

POTENTIAL ACTIVITIES: Wildlife habitat improvements, fish habitat improvements, timber sale preparation, timber harvest, reforestation, timber stand improvements, trail construction, trail maintenance, watershed improvements, natural fuels treatment, activity fuels treatment, road maintenance, and road construction

There are three options for management of the riparian vegetation in areas available and suitable for timber management. These are referred to as riparian management option B, riparian management option C, and minimum level (M) (There was originally a management option A, but it was dropped when it was determined that MR's could not be achieved under this option.) These prescriptions differ in the amount of vegetation that can be removed in management activities. Application of any of the prescription options will provide flexibility to retain large organic debris in the riparian areas for long-term input to stream systems.

PRESCRIPTION OPTION B allows a moderate level of vegetation removal from the riparian area. A maximum of 70 percent and 30 percent removal of the basal area from Class III, and Class I and II streams are allowed. The actual average harvest used for the FORPLAN model was 50 percent and 20 percent removal because the maximum amount of wood could not be removed in all cases. The prescription is designed to maintain existing water temperatures within the Planning Basin as regrowth of shade in past activity units balances removal associated with new projects. It must be remembered that these prescriptions are applied to a basin as a whole and the expected results are viewed as net change over time. Prescription option B provides the basic level of protection necessary to accomplish the MR for riparian area management because any net increase in the critical summer water temperature would cause an unacceptable adverse impact to the fisheries resource.

PRESCRIPTION OPTION C allows minimal removal of the shade providing vegetation and is estimated to have a net effect of a two degrees Fahrenheit reduction in the summer water temperature over time. The *maximum amount of basal area removed for Class I and II, and Class III streams are 20 percent and 40* percent respectively. The average harvest used in the FORPLAN model are 10 percent and 20 percent since the maximum amount of wood could not be removed each time. This prescription would improve the quality of the habitat for salmonids over the present condition in the basin taken as a whole. Prescription C reduces risk of activity impacts on Class III streams and may offer greater long-term protection of the riparian ecosystem. Greater availability of woody debris and density of overhead canopy would be provided.

PRESCRIPTION OPTION M, the minimum level option, does not allow removal of shade providing vegetation through timber harvest. Improvement in stream temperatures beyond option C are not projected, but this option would provide additional security by minimizing risks of impacts in the riparian areas.

Retention Visual

PURPOSE. To maintain area in near natural condition.

CRITERIA Any management activity will be subordinate to the landscape character and not evident to the casual visitor

ASSUMPTIONS. The value of high quality scenery will not decrease over the planning period

COST EFFICIENCY. Different alternatives have different areas allocated to this Management Area for providing an economic comparison and a wide range of alternatives This allows the examination of forgone benefits.

POTENTIAL ACTIVITIES: Wildlife habitat improvements, fish habitat improvements, timber sale preparation, timber harvest, reforestation, timber stand improvements, watershed resource improvements, natural and activity fuels treatment, recreation improvements, trail construction, road construction, trail maintenance, and road maintenance.

Partial Retention Visual

PURPOSE To maintain area in a near natural state such that human activities are subordinate to the landscape character

CRITERIA Activities may be evident to the casual visitor, but such activities blend with the landscape

ASSUMPTIONS The values of high quality scenery will not decrease over the planning period.

COST EFFICIENCY: Different alternatives have different areas allocated to this Management Area for providing an economic comparison and a wide range of alternatives with different opportunities.

POTENTIAL ACTIVITIES: Refer to the potential activities permitted in the Retention Visual Management Area

General Forest

PURPOSE. To provide a full range of activity with conservation of renewable resources.

CRITERIA. To produce timber within the reasonable constraints of other resources and the capability of the land.

ASSUMPTIONS: Many uses of these areas are compatible.

COST EFFICIENCY: Different timber management options were examined (intensive, moderate, and extensive) to obtain economic efficiency and a full choice of activities. The projected yields for these options were obtained from analysis using DP-DFSIM to choose rotation lengths, thinning regimes, and other silvicultural practices. The FORPLAN model then was used to allocate these options on high, moderate, and low sites using economic criteria.

POTENTIAL ACTIVITIES: Refer to the potential activities permitted in the Retention Visual Management Area.

DEVELOPMENT OF TIMBER HARVEST OPTION INTENSITIES

The site specific selections of silvicultural systems and harvest methods are discussed in FEIS Appendix G. The FORPLAN modeling with the exception of Riparian Management Areas, is based on evenaged systems and the clearcut harvest method This is the predominant system currently in use, and has available yield models Following the analysis process of Appendix G for site specific conditions of the Siskiyou, the evenaged system is expected to be the most common used in the implementation of the Forest LRMP. Application of other systems in some site specific cases is not expected to significantly affect the ability to produce Forest-wide outputs.

Timber harvest options and management intensities were developed to portray a range of investment levels and management practices, and to evaluate the yield and economic consequences. The management practices outlined in Standards and Guidelines 4-1 of the Regional Guide are used in various combinations to derive silviculturally sound management regimes for the Siskiyou National Forest.

Regimes that are not feasible on a broad scale are; those that plan for reforestation to be accomplished by natural regeneration, and those that would program commercial thinning without planning precommercial thinning to achieve stocking control. These regimes are rejected due to the uncertainty of natural regeneration, and the unpredictable nature of natural fill in following planting Both of these factors are complicated by vegetative competition

The intensities developed evolve from three basic schemes· extensive, moderate, and intensive All of the management intensities plan for artificial regeneration of cut over acres and include all management practices necessary to establish future stands, i.e., site preparation, animal control, and release Variations of the three basic intensities include reforestation with or without genetically improved stock; and for intensive and moderate, the option of fertilization. The basic intensities are described as follows·

Extensive.	Following satisfactory reforestation, no further treatment would be planned until final harvest.
Moderate Intensity:	Following satisfactory reforestation, stands would be precommercially thinned as needed to achieve early stocking level control, then no further treatment would be planned until final harvest.
Intensive.	Management practices would include all reforestation treatments, precommercial thinning, and commercial thinnings as needed to cost efficiently optimize timber production.

Allowable entry dates (minimum rotation length) for timber stands not constrained by other resource requirements are set at the age when the yield prediction for that particular regime reaches 95 percent of Culmination of Mean Annual Increment (CMAI). All existing stands classified as sawtimber are at or beyond the minimum rotation ages and are considered available for entry beginning in the first decade Existing seedling and sapling stands are assigned to the managed yield tables depending on productivity class and management intensity; the timing is then dependent on the starting ages of the young stands.

As part of the benchmark analysis, rotations were also identified at the ages when stands first reach the minimum merchantability standards. These rotations are used for analyses where the 95 percent of CMAI constraint is dropped

MOST EFFICIENT INTENSITIES

Analysis of the individual management intensities has identified the intensity and timing of harvest with the highest PNV for each category of land as required by 36 CFR 219.14(b). This is known to some as the

"Stage II suitability analysis." Extensive management produces the highest PNV for Low Site and Moderate Intensity produces the highest for Medium and High Sites. Harvest of existing available stands at the present time (year 0), and harvest of young managed stands at the earliest available age, would yield the highest PNV. The timing of harvests and the PNV's are displayed in the following table These management intensities along with the other combinations described in the section above, and many timing choices, have been allowed as options in the FORPLAN model. Providing numerous options to the model assures that the most efficient combination of intensities and timing of treatments, when taken in context of the entire Forest, can be identified for each alternative.

Economically Efficient Management Intensities By Land Category

Land Productivity Class	Condition Class	Existing Inventory		Managed Rotation		Total PNV ($/Acre)
		Year of Harvest	PNV ($/Acre)	Harvest Year	PNV ($/Acre)	
LOW SITE	Mature	0	2,056	140	-818	1,238
	Existing Plantation	-	-	125	45	45
	Hardwoods	0	-388	140	-818	-1,206
MEDIUM SITE	Mature	0	6,217	85	-20	6,197
	Immature Fully Stocked	0	6,516	85	-20	6,496
	Immature, Not Fully Stocked	0	1,634	85	-20	1,614
	Existing Plantation	-	-	60	1,482	1,482
	Hardwoods	0	-388	85	-20	-408
HIGH SITE	Mature	0	12,373	75	166	12,539
	Immature Fully Stocked	0	6,516	75	166	6,682
	Immature, Not Fully Stocked	0	1,634	75	166	1,800
	Existing Plantation	-	-	50	1,817	1,817
	Hardwoods	0	-388	75	166	-22

SEPARATE SUITABILITY COMPONENT (SSC)

The SSC lands are lands previously delineated which produce less than 20 cubic feet per acre per year This category contains 18,713 acres for which inventory data is not available. Assignment of these acres to Low Site yield tables would greatly misrepresent yield capabilities from the SSC. The average growth potential is estimated to be 14 cubic feet per acre per year. Considering the extraction and reforestation costs, on the average all entries in this component would have negative PNV's Since this component is not allowed to interact with other lands, there could not be allowable cut effects, or scheduling advantages associated with these lands. Modeling any harvest on these lands would reduce the Forest-wide PNV; they would not be selected by FORPLAN Given this plus the projection that their maximum output would be less than one percent of the timber output of any benchmark or alternative, timber harvest prescriptions for the SSC lands were not entered in the FORPLAN model.

DEVELOPMENT OF YIELD COEFFICIENTS

This section describes how the yields of each resource were calculated Additional information regarding each resource can be found in the respective background papers on file in the Forest planning records.

RECREATION

The recreation yield coefficients for the Siskiyou National Forest express potential capacity in RVD's per acre. Capacity coefficients were derived directly in RVD's by considering the specific activity mixes occurring on the Forest. This process requires the application of capacity standards for each activity by ROS class, such as hikers per mile of trail per hour, and summing the individual capacities to obtain one total maximum capacity for an area. The process for determining capacities was derived from the USDA publication, ROS Users Guide.

In general the process worked as follows:

Activities and outputs were determined for each ROS class. The physical characteristics of land were identified that would affect its capacity to support recreation use. Factors were identified that would affect recreation use, such as useable days per year, length of stay, numbers of people per mile of trail, etc. Finally total capacities were determined for each activity and these were combined to reflect the capacity coefficient for each ROS class on the Forest. The final coefficients fell within the range suggested for Region Six for each ROS class.

The capacities arrived at by applying the coefficients do not reflect use or demand. They are gross averages and are useful primarily for comparing the potential capacity to provide recreation outputs in a relative sense under different management emphasis.

Complete documentation for all capacity coefficients is on file at the Supervisors Office, Siskiyou National Forest, Grants Pass, Oregon.

Projected Use

DEVELOPED RECREATION. Developed recreation was not an issue in this analysis; capacity exceeds use and potential capacity far exceeds projected demand. Developed recreation outputs were expressed as current use and a projected demand based on current use. It was assumed that once projected demand reached or exceeded supply, developed sites would be constructed or existing sites expanded to accommodate the demand.

Demand was projected by applying a one-half percent per year increase to the 1980 RIM use data.

Current supply was based on 1980 RIM data and is expressed as maximum optimal capacity or approximately 30 to 40 percent of theoretical capacity.

DISPERSED RECREATION. Dispersed recreation includes Wilderness and general Forest on the assessment output tables. Use was evaluated by ROS class and is based on 1980 RIM data. For all ROS categories, use was projected at the rate one-half percent increase per year over the planning horizon Capacity coefficients were applied to inventoried acreage to identify the apparent capacity.

It was assumed that all Primitive or Semi-primitive Non-motorized acres in areas allocated to management that included timber harvest would shift to the roaded natural end of the spectrum by the end of the first decade.

It was assumed that administrative restrictions on motorized use could be placed on appropriate trail systems in roadless areas and ROS classifications changed accordingly.

VISUAL RESOURCES

The yield coefficients developed for the VQO's on the Siskiyou National Forest are expressed in terms of the percentage of the landscape in disturbed openings at any one time. The coefficients were developed

with consensus among Region Six Landscape Architects and were based on the study, Scheduling Timber Harvest to Meet Visual Objectives, (DeWerff et al, 1981)

Basically, the study process involved the following:

Definition: A visual coefficient as applied to this Forest can be defined as the percentage of commercial Forest land that can be harvested over a given period and still allow the attainment of the Retention, Partial Retention, and Modification/Maximum Modification VQO's

Two methods were used to generate the visual coefficients. The first utilized the Existing Visual Condition (EVC) inventory that was completed in 1981 on the Forest. The second utilized the HP 9845 perspective plot computer system and allowed the graphic assessment of visual impacts of timber harvest over time with the ability to adjust harvest percentages up or down and evaluate the results graphically.

The study resulted in the definition of the following coefficients by VQO.

Retention Visual

0-4 percent Harvested each decade
250-300 year rotation
1-5 acre openings
8 percent of the total area disturbed at anyone time

Partial Retention Visual

5-8 percent harvested each decade
130 year rotation
5-10 acre openings
16 percent of the total area disturbed at anyone time

Other Visual-Modification/Maximum Modification

9-13 percent harvested each decade
80 year rotation
10-60 acre openings
27 percent of the total area disturbed at any one time

For Forest-wide modeling, the percent harvested per decade and the rotation length were used as constraints on the timber harvest schedule, when and where VQO's were assigned

WILDLIFE

Woodpeckers (Snags). Coefficients for wildlife trees (snags) are described in Managed Yield Tables for Siskiyou National Forest (Craig 1984). The following discussion is excerpted from this publication. Production of wildlife trees is planned to provide foraging and nesting habitat in future rotations for species dependent on snags. The basal areas of snags required to sustain various population levels are shown in the table below. The mortality projected by DFSIM would supply the needed snags during the older ages of the stands, however, allowances need to be made for the period between final harvest and the time when regenerated stands begin to produce mortality, and also for periods following commercial thinning The period following final harvest until the future stand will produce snags is approximately twice the length of the average snag life The basal area representing two sets of wildlife trees will be subtracted from the final harvest to provide snags during this period For example, to provide for the 40 percent population level, 1.54 square feet of basal area (.77 x 2) would be subtracted from the final harvest To provide for snags

following commercial thinning, the basal area equivalent to one set of snags would be subtracted for the thinning harvest The table below displays snags required to sustain woodpecker populations

Diameter Breast Height (DBH) in Inches	Trees per Acre	Basal Area per Acre in Square Feet	Snag Life (Years)
20 Percent Population Level			
10	06	03	20
12	38	30	25
		.33	
40 Percent Population Level			
10	50	27	20
12	24	19	25
20	14	31	35
		77	
60 Percent Population Level			
10	93	51	20
12	24	19	25
20	14	31	35
		1 00	

Black-tailed Deer/Roosevelt Elk. Yield coefficients developed for deer also represent elk Coefficients were not developed specifically for elk because this species continues to expand its range on the Forest and changes in population size would be difficult to attribute to environmental changes caused by Forest management practices. Fluctuations in deer herd size should mirror habitat capability for elk (but not necessarily the number of animals) Acre per deer constants were assigned to various seral stages and habitat types. These constants were multiplied by the total acres within each habitat grouping to produce population figures, which were then added together This resulted in a potential Forest-wide winter (April) deer population of approximately 28,300 (present situation) A more detailed description of deer yield coefficients is on file at Siskiyou National Forest headquarters.

Wildlife-related Recreation WFUD's (Wildlife [Fish] User Days) are derived from two sources game (hunting) and non-game (viewing) ODFW and Forest data indicate hunters annually contribute 40,450 WFUD's to the Siskiyou (40,450 x 2 = 80. The Siskiyou assumes game WFUD's are tied to deer habitat capability; when habitat capability goes up or down in response to timber harvest levels, so do the "attached" game WFUD's.9 M WFUD's). This assumption is based on the contention that people will continue to hunt only if their opportunity for success does not diminish. This modeling assumption would not be quite correct if hunters are willing to accept lower success rates, but it provides a fair method for comparing the alternatives at a constant quality level (success rate)

It is also assumed that non-game WFUD's are not tied to timber harvest and will increase by 0 5 percent per year (predicted increase in demand for SW Oregon - OSU Research Bulletin # 28, 1979) Because no data are available for the number of WFUD's attributable to nonconsumptive use of wildlife resources on the Siskiyou, nonconsumptive WFUD's are assumed to be equal to the number generated by hunting

FISHERIES

Fish Distribution. The determination was made in cooperation with ODFW biologists through review of State and Forest stream survey records From these records, existing distribution of salmonids on the Forest was placed at 609 miles from anadromous salmonids (salmon, steelhead sea-run cutthroat trout), and 1,147 miles from resident rainbow and cutthroat trout

Habitat Quality and Capability The following basic assumptions were arrived at by the Forest Biologist and Region Six Fisheries Biologist, Gordon Haugen for the Siskiyou National Forest.

1 Each of the Forest drainages has an adequate escapement potential for adult fish
2 Spawning gravel quantity and quality are sufficient to provide for incubation and emergence of enough fry to fully stock existing rearing habitat.
3 The quantity and quality of rearing habitat are the most critical components for the survival of juvenile salmonids.

Known limiting habitat factors on the Siskiyou consist of high summer water temperatures, lack of summer rearing pool depths, lack of sufficient instream fish cover, and low summer stream flows. Existing habitat condition was evaluated against limiting factor ranges for salmonids at various life stages as described in the following literature

Reiser, D W. and T C. Bjornn, 1979 Influence of Forest and Rangeland Management on Anadromous Fish Habitat in North America· Habitat Requirements of Anadromous Salmonids USDA.

Forest Service Pacific Northwest Forest and Range Experiment Station. 54 pp.

ODFW, 1977 Manual of Fish Management 218 pp.

State of Oregon, 1977. Regulations Relating to Water Quality Control in Oregon Sections from Oregon Administrative Rules, Chapter 340 Department of Environmental Quality. pp 1-22, 155-296, 455-456

Coefficients for projecting pounds and WFUD's from capability value for anadromous fish. Coefficients were developed by a three-Forest Coastal Zone Group consisting of the Siskiyou, Siuslaw and Umpqua National Forests. Factors used by the Siskiyou Forest from this effort included; smolt to adult survival, catch to escapement ratios, average weight of adult fish, etc

Salmonid Harvest Determination Process. Working with biologists of the ODFW, determination of existing Forest fisheries output was made This process involved review of annual salmon catch statistics in the offshore commercial fishery for Oregon, Washington and California, plus inland and offshore sport fisheries success for the three States.

DIVISION OF CATCH (COMMERCIAL, OFFSHORE SPORT, INLAND SPORT) For those salmon attributed to Siskiyou National Forest habitat production, a catch division of 66 percent commercial, 27 percent offshore sport, and 7 percent inland sport was made after review of Oregon catch records and information compiled by Pacific Fisheries Marine Council.

SPORT HARVEST RATE (ANGLER DAYS/WFUD's) Sport harvest records as reported by the ODFW are expressed in Angler Days while the Forest Service reports angler effort in terms of WFUD's Relationship of these two terms is shown in Documentation of Existing Sport and Commercial Fish Harvest Attributable to Siskiyou Forest Stream and River Habitat, January 1985 This document is on file at the Siskiyou Forest Supervisor's Office

Salmonid Harvest Attributable to Forest. Average inland sport catch records for 1972-1982 were used as a basis for determination of Forest habitat contribution for each of the 19 Planning Basins Percent of wild fish attributable to Forest habitat was assigned for each major river system involving Forest administered habitat This work was done in cooperation with the ODFW.

Average annual sport and commercial harvest attributable to Siskiyou Forest habitat, under present situations, was determined as shown in the following:

Species	Pounds	WFUD's
Total Anadromous		
Adult Steelhead (Winter and Summer)	-	16,430
1/2 lb Summer Steelhead	-	10,345
Fall Chinook	375,075	11,250
Spring Chinook	484,950	18,954
Coho	19,888	843
Sea-run Cutthroat		1,024
Total Forest Contribution	879,913	58,946
Total Resident		
Rivers and Streams	-	4,984
Lakes and Ponds	-	1,132
Total Forest Contribution	-	6,116
Total Forest Average Annual	879,913	65,062

Fishery Value	Dollars
Average Annual Fishery Value	
Anadromous (WFUD's)	1,945,218
Anadromous (lbs)	923,908
Resident Trout (WFUD's)	91,740
Total Annual Average	2,960,866

Water Temperature The water temperature of streams on the Siskiyou National Forest is an important element of overall water quality. A water temperature model was developed on the Siskiyou National Forest to estimate the potential cumulative effect of different harvesting intensities in streamside areas on downstream water temperature.

During the Forest Planning process, the Siskiyou National Forest was divided into 19 Planning Basins that are in most cases major watershed divisions. For example, the Silver and Indigo Creek watersheds are each distinct Planning Basins Certain basins, 7 in all, were selected to be used in the water temperature model using the following criteria:

1. Planning Basins should have historical data on minimum flow discharge and temperature for major tributaries.
2. Planning Basins should be selected so as to represent the wide range of geomorphological and climatic features present on the Siskiyou National Forest

A formula, based on Brown's equation, was used to estimate the cumulative changes in water temperatures within selected Planning Basins. Key factors considered in the formula are the increase in direct solar radiation due to vegetation removal and the decrease in direct solar radiation from the regrowth of riparian vegetation in previously harvested areas.

The change in stream temperature for the end of the next decade was predicted at the mouth of each main tributary and at the confluence of each main tributary and main stem for each streamside vegetation

management intensity within the selected basins. A mixing formula was used to estimate and track cumulative stream temperature values downstream in the basins

The information from the stream temperature modeling was one of the criteria used to select Riparian Prescriptions B and C for managing the riparian areas on the Siskiyou National Forest The **FISH** section of Chapter IV of the FEIS and the Management Area 11 (Riparian) section in Chapter IV of the Forest Plan describe the riparian prescriptions Table II-3 of the FEIS shows which riparian prescription is applied to each Planning Basin for each alternative.

More information on the stream temperature modeling is contained in the Forest Planning Process Records

Fisheries Yield Projections. Fisheries output projections were developed based on application of the A, B or C management prescription to Riparian areas (average width of riparian area was modeled at 150 feet on each side of Class I and II streams, and 100 feet on each side of Class III). The minimum level prescription is not expected to produce a substantially greater improvement in stream temperature over Prescription C and uses the same yield projection. Considering present stream temperatures and salmonid tolerance limits, projections were made and modeled as follows.

1. Application of the A prescription was modeled as raising existing temperature of Class I and II streams by an average of two degrees Fahrenheit by the end of the third decade Based on salmonid temperature tolerances, anticipated competition from nongame fish, existing high water temperatures, and loss of long term large woody debris input to stream channels, application of the A management prescription was modeled to decrease salmonid habitat capability by 50 percent in Class I and II streams It was determined that this prescription did not meet minimum legal requirements and it was dropped from further consideration
2 Application of the B prescription was modeled to maintain current habitat conditions and fisheries outputs of Class I and II streams
3 Application of the C prescription was modeled to decrease existing water temperatures by two degrees Fahrenheit within Class I and II streams and improve salmonid habitat capability an average of ten percent by the end of the third decade

TIMBER

Yield tables for existing timber stands were developed through statistical analysis of inventory data. Stand volume and growth were projected for each combination of Productivity Class and Condition Class

Yield tables for future stands and existing plantations under management were developed using the stand simulation model for Douglas-fir, DFSIM. Yield projections were made for the various combinations of Productivity Class, Prescription Emphasis, and Management Intensity Additional analysis of thinning and fertilization regimes was done with the aid of the dynamic programing - DFSIM model (DP/DFSIM)

Yield tables for existing and managed stands, and the supporting data and processes used in their development, are part of the Planning Record Development of future yield projections are documented in Managed Yield Tables for Siskiyou National Forest (Craig 1984)

The estimates and analysis of future timber yields uses cubic foot volume measure. Many people are not familiar with cubic measure and it is difficult to relate to the volume amounts displayed in million cubic feet (MMCF) (sort of like going to the metric system cold turkey) To provide information in a measure familiar to many reviewers, the selected volume estimates for the first decade are displayed in million board foot (MMBF) measure This provides a convenient reference for alternative comparisons The board foot values are computed by applying a board foot/cubic foot conversion ratio to the cubic foot volumes A conversion ratio of 5 41 representing the weighted average of all standing timber volume was used to estimate board

foot values for the alternatives in the DEIS. Comments by interested publics and the State of Oregon suggested that a more refined estimate of board foot measure for first decade timber outputs should be used A conversion ratio of 5 58 was calculated as the weighted average of the mature stands that will provide the harvest volume in the first decade This conversion ratio is used to compute the first decade board foot projections in the FEIS.

Another change between the draft and final relates to the salvageable dead volume The volume in salvageable dead trees measured in the inventory is equivalent to two percent of the volume on a per acre basis The ID Team estimates that approximately one-half of this volume will be needed to meet the requirements for large woody material to be left on site for wildlife habitat, long-term nutrient cycling, and other resource considerations From this analysis it follows that, on the average, each acre harvested will yield an additional one percent volume from the dead trees that were not included in calculation of the yield tables An amount equivalent to one percent of the sawtimber ASQ for any alternative has been included as a salvage component of the projected timber outputs that would be expected from that alternative

SEDIMENT

A sediment yield model was developed to predict sediment production by management activity (harvest, thinning, road building), by soil type and eventually by alternative and Planning Basin The following table presents the methods and data sources used in the development of the model.

Source/Activity	Natural Undisturbed	Roads	Accelerated Harvest	Burning
Mass Movement	Landslide Inventory	Landslide Inventory	Landslide Inventory	Landslide Inventory
Surface-Channel	Geomorphic Indices	Literature Values	Literature Values	Literature Values

Natural sediment rates for surface and channel erosion were predicted by geomorphic indices (Maxwell and Marston 1980), while natural landslide activity was predicted from an actual inventory of Siskiyou National Forest landslides (Amaranthus and others 1985) Accelerated surface and channel erosion was predicted by literature values reported from western Oregon and California, northern Rockies, and the Idaho Batholith (Megahan 1974, 1975; Megahan and Kidd 1972; Megahan and Molitor 1975, Rice, Rothacher and Megahan 1972; Platts and Megahan 1975, Anderson 1975; Andre and Anderson 1961, Wischmeier and Smith 1958, 1965, 1968), and local data (Hansen and Amaranthus 1979). The literature was used to document the magnitude of impact and its consequences rather than directly applying a numerical value. Accelerated landslide activity was estimated by the actual Forest-wide inventory

A set of 53 sediment yield tables was compiled to represent the various soil types on the Forest in the FORPLAN sediment yield model. Coefficients that comprise the yield tables were prepared to numerically simulate the erosional processes of mass movement and surface-channel erosion. Estimates were made for these erosional processes under natural conditions and also as the result of forest management

Coefficients for sediment yield key on acres clearcut, but include a weighted average for anticipated road building For each alternative, by Planning Basin, the estimated accelerated sediment yield (index value) above background (natural plus existing road system) is displayed in Chapter IV (**SOIL AND WATER**) of the FEIS The total sediment yields (natural plus existing plus accelerated) are displayed in Chapter II (**SOIL AND WATER**) of the FEIS These data are used to make relative comparisons and indicate trends between alternatives.

Management Requirements will be met by implementing the Forest-wide Standards and Guidelines, Best Management Practices (BMP's) (Standard and Guideline 7-14 and Appendix F of the Forest Plan), the Riparian Management Prescriptions; and the harvest dispersion constraints.

ROADS

Main Access Roads (Arterial and Collector Roads). The arterial road system is considered to be in place with no additions expected If there are arterial additions in the future, it is expected that they will be designated from collector roads with reconstruction to upgrade the road standard at that time.

Most of the collector road system is in place Eighty-seven miles are varied in alternatives to represent collector road additions to the system. This mileage was determined from estimated needs with the completed road system. These collector road additions consists of ten miles of existing private road to be acquired, forty-four miles of new timber sale roads to access primarily the remaining unroaded lands, and thirty-three miles of existing local roads which could change to collectors. The existing local roads extend existing collector roads to new collector roads or join two collectors together to form new loop systems. The additional collectors are added to the system by the end of the fifth decade at rates which correspond generally with timber harvest levels in the alternatives. All costs for the collector roads were placed in the FORPLAN model at the same rate as the local roads. Where the model did not cost the collector construction adequately, a preroading or supplemental amount is added in the capital investment program for each alternative in the decade estimated to be needed. This supplemental funding affected three roads which are included if the area is accessed for timber harvest in the alternative. The primary intent of using supplemental funds was to assure that costs for these three roads were adequately represented in the road costs

Local Road Construction

The density coefficients for all roads were determined by modeling four representative basins with a logical road system and applying these models to the other fourteen basins with roads These basins represented four different Ranger Districts, four different basin sizes, two essentially westside and two eastside basins, and all are approximately equal distance from each other. On maps, the basin boundaries were identified, the roaded area was separated from the unroaded area, the commercially unharvested areas were identified, and helicopter logging areas were identified A map wheel was used to measure the mileage After comparing the outcome with other data previously determined, it was felt that this data best represented the roading for each of the four basins. The other fourteen basins with roads were then grouped with one of the four basins most like it, and a factor used to compensate for known differences Using the acres in each basin of mature, immature, and pole timber (these timber stands are the ones that will develop the road system), the miles per acre for new development in each basin were determined, assuming each acre planned for first time timber harvest would contribute to the construction of some road These coefficients were used in the FORPLAN model to determine the *new* road construction on timber sales at the time an acre is cut. When the "roaded area" new road coefficients are incorporated with the existing road system in each planning basin, the resultant factors exceed the "unroaded area" factors by from one to four miles per square mile.

The coefficients used are

Basin	Roaded Area (New Roads) Harvestable 1/ Acres	Miles/ Acre	Miles/ Square Mile	Unroaded Area Harvestable 1/ Acres	Miles/ Acre	Miles/ Square Mile
1	21,249	00255	1 63	10,912	00491	3 14
2	44,740	00268	1 72	1,355	00517	3 31

20	25,259	00309	1 98	3,856	00648	4 15

1/ Acres mature, immature, and pole timber in the planning basin
2/ Basin contains no designated unroaded area
3/ Basin contains all wilderness acres

The economic objective of the FORPLAN model tended to set back the higher cost road construction into later decades by selecting acres with high timber volume in relation to the volume per acre This did not represent feasible solutions due to the spatial limitations that are not represented in the model. A constraint on the Purchaser Credit funding was placed on the first six decades to provide a more realistic distribution of the road construction in this period. This constraint did not permit these funds to increase over the previous decade amount, thus forcing the model to distribute the road costs and harvest of some low site land into earlier decades

Another situation with the FORPLAN model is that miles per acre or timber volume harvested tended to not fully recognize construction miles needed to reach the initial stands The harvesting of the later stands can often be accomplished on roads previously built to enter the area The result is to underestimate the new construction in the early decades and overstate the mileage needed in later decades. The total miles of new roads would be accounted for once the stands are all initially harvested No logical means was determined to adjust the miles and costs either in the FORPLAN model or outside the model.

The road construction costs were developed from actual Forest cost records for the period of fiscal year 1975 to 1984 on 305 timber sales. A study was then made to assess the accuracy of the costs to meet current design and construction methods resulting in lower cost roads On the basis of this study, adjustments were made on the costs for most basins to represent current costs expected to be used in the coming years Costs were adjusted for inflation to the base year of 1982 and then increased 2 4 percent for contract changes based on 89 recently completed timber sales The following are the road construction costs used in the FORPLAN model

The following data displays timber sale new road construction:

Planning Basin	$/Mile Roaded	$/Mile Unroaded
1	115,668	133,000
2	86,199	94,800
3	78,317	NA
4	78,342	82,300
5	72,802	80,100
6	83,078	87,200
7	52,473	73,500
8	52,107	NA
9	74,873	86,100
10	54,153	65,000
11	45,856	45,900
12	71,506	71,500
13	69,825	76,800
15	48,580	55,900
16	77,601	81,500
17	87,040	87,040
19	50,953	63,700
20	65,040	74,800

ROAD RECONSTRUCTION - Reconstruction densities for all roads were developed from all timber sales programmed from fiscal years 1978 through 1984. The miles of road reconstructed and the acres of harvest were compared by basin to determine the miles per acre resulting in the following data displayed along with dollars per mile of reconstruction and miles per MCF of commercial thinnings discussed below

Planning Basin	Mile/Acre	$/Mile	(Commercial Thinning) Mile/MCF
1	0 03773	39,515	004339
2	0 03417	29,105	004339
3	0 02079	38,750	003792
4	0 03696	36,683	003792
5	0 01888	18,717	003792
6	0 01145	22,660	002310
7	0 00744	31,794	002310
8	0 01209	20,561	002310
9	0 04775	21,930	003792
10	0 00800	27,644	002526
11	0 00800	38,877	002310
12	0 03556	21,010	003792
13	0 03270	21,604	005653
15	0 04962	10,407	002526
16	0 02559	37,896	005653
17	0 00904	36,526	005653
19	0 00827	20,708	002526
20	0 00966	19,783	002526

The cost for road reconstruction was determined on the same basis as the cost for road construction, using the same timber sales The costs were adjusted to the 1982 base year and increased 2 4 percent for contract changes

Two additional corrections were made which affected the reconstruction costs The benchmark runs identified sufficient reconstruction mileage in commercial thinning which could affect cost data Since commercial thinning harvests tend to have a much smaller per acre volume, a new set of criteria was set

up to better represent these reconstruction costs Using Forest data on sales sold from Fiscal Year 1977 through Fiscal Year 1984, the volume per acre was determined by District and correlated to thousand cubic feet per acre by basin The new figures were used to determine the miles per thousand cubic feet of harvest for use with commercial thinnings.

The second correction came about when the percent of road miles closed was varied by alternative The reconstruction costs from past sales included work required on some closed roads, but significant increases in road closures would not be adequately represented in the costs Normally a closed road would have higher reconstruction costs to open, brush and log out, and shape the surface To use the same costs when large mileages of roads were considered closed was in effect no expense if not adjusted To account for added reconstruction costs where needed for increased road closures, the amount of closures were considered for each alternative in choosing a multiplying factor of 1 00, 1 05, or 1 08 The factor chosen for each alternative was used in the FORPLAN model as shown

Alternative	Factor
NC	1 00
A	1 00
A-Departure	1 00
B	1 00
C	1 00
D	1 00
D1	1 00
E	1 08
G	1 05
K	1 08
M	1 00
S	1 08

ROAD MAINTENANCE - Road maintenance mileage considered in Forest planning is based on the Forest inventory as of 1982 and adjusted to March 1984 for total miles and maintenance level of the roads The costs for maintenance were determined and modeled separately for timber sales and for allocated funds

The timber sale road maintenance was determined from sales appraised in the period 1973 through 1982 The total road maintenance allowed in the appraisal was divided by the sale volume for a cost per unit volume. It was noted that the last two years differed significantly from the other years, due largely to an updating of maintenance costs to better reflect actual experienced costs These updated timber sale road maintenance costs better represented the expenses expected for the future, so they were used As a check, the timber sale maintenance costs for all sales in 1983 were compared with the first FORPLAN benchmark runs and found to be in close agreement The following are the timber sale road maintenance costs used in FORPLAN.

The following data display timber sale road maintenance cost:

Planning Basin	$/MBF
1	13 00
2	13 00
3	21 50
4	21 50
5	21 50
6	21 50
7	17 00
8	17 00
9	21 50
10	17 00
11	17 00
12	13 00
13	13 00
15	13 00
16	13 00
17	13 00
19	13 00
20	13 00

The budget for allocated maintenance funds were based on the 1982 to 1984 program average adjusted for inflation. These cost figures were used to calculate the constrained funding base and a sequential cost of each mile of road added to the system by alternative for use in the FORPLAN model The base cost was determined by the percent of miles in each maintenance level at the start of decade one for each alternative The sequential cost was determined by the percent of new miles added by maintenance level A higher allocated maintenance of about 125 percent of the current budget was used for an unconstrained funding base and the sequential cost of each mile added to the system by alternative. The following is the allocated road maintenance funding by alternative

The following data display allocated road maintenance funding:

Alternative	$ Base Amount	$/Mile Sequential
NC	984,000	269
A	984,000	269
A-Departure	984,000	269
B	1,152,000	269
C	1,012,000	214
D	1,019,000	296
D1	1,019,000	296
E	1,125,000	273
G	864,000	115
K	1,064,000	253
M	981,000	0
S	1,064,000	253

ROAD CAPITAL INVESTMENT - A study of the Forest past capital investment program could find no rational method on which to base a funding level After several efforts, the decision was made to base the funding primarily on timber harvest volumes with additions as needed to meet the theme of alternatives This decision was made on the concept that about 80 percent of the Forest capital investment funding is timber haul related. The funding level does not include repairs to the road system caused by catastrophic events from major floods and wind storms Even though the Siskiyou National Forest has a history of major floods and storms, these events are too difficult to determine with any accuracy

The capital investment program funds were originally calculated on only timber harvest volumes prior to the FORPLAN runs based on data from the benchmark runs. The formula used in the benchmark runs was

$$CI = \$225{,}000 + \$10{,}000/MMBF$$

The figures from this formula reasonably agreed with past Capital Investment funding except when the Forest timber cut increased significantly from the second growth stands Various methods were tried to keep the funding from increasing to an unreasonably high figure By graphing the results from methods which best represented Forest funding, the following formula resulted in representative funding levels.

$$\$/Decade = \$4{,}000(Decade\ MMBF) - \$2{,}000{,}000$$

with a minimum funding of $250,000/decade since the formula could give a negative value This formula gave values close to the Fiscal Year's 83 and 84 average and assured that any given harvest volume would always have the same value

Since most alternatives are on the basis of no budget constraint, another method was used to increase funding from the constrained budget. The benchmark FORPLAN runs resulted in funding levels for the latter decades which were unreasonably high. After several attempts to find a method which represented a reasonable unconstrained funding level, the following formula was used:

($/Decade = $5,000 x Decade MMBF).

This formula had a reasonable increase from the constrained budget figure and represented funding amounts the Forest would properly invest for support of the timber harvest activities.

Additions to the above capital investment program figures based on harvest volumes were used to represent mitigation or increased efforts on improving water quality and fish habitat impacted by roads, to increase the miles of road open to passenger cars for roaded recreational use and keep these roads repaired to standards, and for accessing three unroaded areas in which the FORPLAN model did not adequately cover the costs. The funding added was based on the alternative theme and on how roads open to the public were varied. Mitigating efforts and increasing roads open to passenger cars were varied on estimates which represented levels of high, medium, low, or no additional funding to meet the alternative theme. The unroaded area access funds varied by alternative and by decade to represent areas entered for timber harvest in the alternative and the timing of the entry.

ANALYSIS DONE OUTSIDE FORPLAN

This section describes how the yields for resources were adjusted, modified, and calculated outside of the FORPLAN model. Additional information regarding these analyses can be found in the respective background papers on file in the Forest planning records.

WATER YIELD

The average annual water yield from the Forest was computed using a linear regression between mean annual basin precipitation and streamflow. Streamflow gauging stations are operated on seven rivers draining the Siskiyou National Forest by the U.S. Geological Survey and the Oregon Watermaster's Office Therefore, actual runoff data is available for seven of the 19 FORPLAN Level 1 basins. A rainfall isohyetal map was constructed from all precipitation measurement stations distributed around the Forest Because precipitation varies greatly within the FORPLAN planning basins, a basin weighted average was computed using mass balance techniques. A simple linear model was developed regressing rainfall (weighted by basin) as the independent variable, and runoff as the dependent variable.

The water yield from ungauged basins was predicted from mean basin rainfall using the rainfall-runoff equation:

Annual Water Yield = 1 5 (Mean Basin Rainfall) - 71 where
units are in inches and "r" squared = 0.98

This equation predicts the **existing** water yield from each planning basin and therefore the Forest

The effect of clearcut harvest was predicted using the results from five clearcut watersheds in Western Oregon (Harr, 1979). Each clearcut acre was estimated to yield an additional 20 inches of water in the first year after harvest and return to preharvest yields in 20 years. The decay of water yield was assumed to be logarithmic in shape (Harr, personal communication). A computer program was written (process records) to numerically simulate the interaction of thousands of clearcut acres in various stages of water yield decay The program was run outside of FORPLAN but utilized final harvest acres generated within the model by decade.

Harvest clearcutting in fog prone areas in known to decrease water yields (Harr, 1982). Since fog prone areas (similar to the Bull Run Watershed where this phenomenon was reported) represent a small proportion of this Forest, we conclude that harvest clearcutting on the Forest will predominantly increase water yield.

ROADS

Classification of Road Type. The classification of collector or local roads was done by alternative based on specific roads representing probable collectors The theme of each alternative identified areas to be roaded, the extent of emphasis on roaded recreation, and helped determine which extensions of existing collectors and connector roads to include for loop roads in the collector system. These specific roads which fit the alternative theme, both new and existing, were classed as collectors and the balance were local roads Distribution of the new collector roads varied by decade in each alternative, with all collector roads built by the fifth decade. The arterial road system did not vary

Classification of Roads Open to Public Use The classification of the Forest road system open to passenger cars, open to high clearance vehicles, or closed was determined outside the FORPLAN model. The miles of road open to passenger cars was figured as all maintenance Levels 3 and 4 roads plus a percentage of the Level 2 roads. The Level 2 roads open to passenger car use are an estimate of the mileage at any period of time in which the surface is graded for timber haul or other project work and the road is suitable for passenger car use during the project operations and for a while afterward.

Maintenance Levels 1, 2, and 3 varied by alternative, to represent the theme of the alternative. A percentage of miles of Levels 1 and 3, both existing and new roads, was used to represent the alternative theme according to a high, medium, or low amount The balance of the miles were classified as Level 2

An additional fifty miles of road not built by timber sales were added to represent other roads built and included on the Forest transportation system. These are roads built under special use permits by miners, to administration sites such as weather or radio sites, for added recreation sites, and private roads added to the system by rights-of-way acquisition The mileage and distribution of these miles varied out to the fifth decade, depending on the alternative theme The private roads acquired were added to the collector system and the balance were local roads.

FIRE MANAGEMENT

Fiscal Trends in Fire Management The fire management budget for the Forest has been decreasing steadily since its peak in the mid 1970's. The base fire planning period budget (Fiscal Year 1978) for the Forest's prevention, detection and presuppression programs was $585,500 or $794,500 in 1982 dollars A presentation of program expenditures is presented in the following data

Fire management program expenditures for the Siskiyou National Forest base fire planning period in actual fiscal year dollars as follows:

Functional Area	Fiscal Year/$ 1977	1978	1979
Consolidated Functional Costs			
Forest Resources	787,900	585,500	623,800
Shared Resources	1,224,200	606,900	521,000
Fuels	-	*164,100*	*52,700*
Approximate Functional Cost for Forest Resources			
Prevention (111)	63,100	112,500	114,000
Detection (112)	57,800	88,000	58,800
Attack (113)	627,000	348,000	372,300
Air (114)	(40,000)	(37,000)	36,600
Support (115)	248,600	236,200	-
Fuels (115)	-	164,100	52,700

Period	Expenditure
Fire Program Costs 1/	
1 Jul 74 - 30 Jun 75	1,964,385
1 Jul 75 - 30 Jun 76	2,391,496
1 Jul 76 - 30 Sep 76 (mini-year)	1,302,680
1 Oct 76 - 30 Sep 78	1,634,922
1 Oct 77 - 30 Sep 78	1,452,730
1 Oct 78 - 30 Sep 79	1,689,544

1/Includes costs for emergency fire fighting and the construction of fire facilities

The funds spent to treat fuels created by management activities have increased steadily over the decade in response to both inflation and the need to mitigate impacts on other resources Average treatment costs on the Forest in fiscal year 1982 dollars are presented below

Base Fire Planning Period Fuels Management Costs for the Siskiyou National Forest in 1982 Dollars follows.

Size (Acres)	$/Acre	Size (Acres)	$/Acre
Average Total Fuel Treatment Costs for Activity Fuels			
Clear Cuts		Partial Cuts	
1-5	916	1-15	776
5-10	727	5-20	753
10-40	576	20-45	679

Activity	$/Acre
Average Costs for Typical Treatment Activities	
Broadcast burning	241
Underburning	196
Pile burning	93
Handpile and burn	345
Burning hardwood conversion areas	71

National Fire Management Analysis and Planning The Fire Planning Process used on the Siskiyou National Forest followed FSH 5109.19, Fire Management Analysis and Planning This handbook provides the basic steps followed in developing the fire management program, to include a level of protection, responsive to management direction and resource objectives stated in the Forest Plan

Two levels of planning were completed to bring the fire planning process to this juncture Level 1 which was a general fire management analysis; and Level 2, which was a technical fire management analysis that evaluated fire management program mixes and program levels, and estimated the costs and effects of each through a detailed analytical process.

The following is a summary of the process followed and some of the key assumptions made in completing the Level 1 and Level 2 analysis.

The first step in the Level 1 process was to compare the master fire occurrence file with the individual fire reports for the 1970 decade and correct any errors in the master file. From this file fires not to be used in the planning process were identified. Typically, these fires were far enough outside the Forest boundary that the Forest Service would no longer respond. The 510 fires shown in the master file were reduced to 495 fires for the 1970 decade These 495 fires burned a total of 2,884 acres.

The next step was to gather all available 1970 decade fire weather data for the Forest This information was collected primarily from the National Fire Weather Data Library.

After gathering the weather data, fuel models and weather stations were assigned to each of the 495 fires This was accomplished by utilizing the planning basins established by the IDT for analysis purposes National Fire Danger Rating System (NFDRS) fuel models were then identified for each basin A basin could be represented by one fuel model or a combination of two models A weather station was assigned to each basin after consultation with National Weather Service Fire Weather Forecasters.

When this step was completed, the daily fire weather data was matched against fire occurrence days in each weather station's zone of influence to see if there was weather data for the day of the particular fire Missing days were identified and then corrected by either using interpolated values for a missing day from the FPL-MOIST fire planning computer file, data from nearby stations, or "best estimates" developed after a review of seasonal climatic data for the station in question. With matching weather data for all fire days, it was then possible to develop tables which reflected the number of fires and acres burned by intensity level and size class for each of the basins This information, plus other data generated by the FPL-FREQUENCY fire analysis computer program, was documented in the Planning Records as part of the analysis of the management situation

The planning basin approach was not conducive to fire management planning, therefore, the basins were collapsed into five Fire Management Analysis Zones (FMAZ's) (see map in Chapter III of the FEIS) These zones were based on fuel types, fire weather climatology and resource management direction

The zones utilized in the process were

Zone 1.	Powers Ranger District
Zone 2.	Chetco and Gold Beach Ranger Districts
Zone 3:	Illinois Valley and Galice Ranger Districts
Zone 4:	Kalmiopsis Wilderness
Zone 5:	Wild Rogue Wilderness

Each FMAZ was assigned an NFDRS fuel model or pair of fuel models and a key fire weather station. The process of matching fire weather data to each fire was repeated, and a new set of fire frequency tables was generated for each FMAZ.

A key decision made at the completion of the Level 1 phase of the analysis was to collapse the six Fire Intensity Levels to three. The FIL's were redefined as:

FIL 1	0-2 feet flame length
FIL 2	2-8 feet flame length
FIL 3	8+ feet flame length

In the Level 2 analysis, only the data generated in the FMAZ portion of the Level 1 analysis was used The first step in the Level 2 analysis was to generate the fiftieth and ninetieth percentile rates of spread for each of the fire FMAZ This data, along with the number of fires by size class, and intensity level developed in Level 1, were utilized later in the process to calibrate the Initial Attack Analyzer computer model.

The selection of representative fires was the next step in the Level 2 analysis. In this particular analysis, fires in each FMAZ were analyzed to determine attack type and mix by attack time This data was then used to define the character of the fire workload in each FMAZ in the Initial Attack Analyzer model

Next, the 1978 base fire organization was identified and a dispatch philosophy developed for each of the 13 representative fire situations, which when combined, represented the fire workload in the five FMAZ's The dispatch levels were then combined with data developed in Level 1 to calibrate the Initial Attack Analyzer model.

In calibrating the Initial Attack Analyzer model, the rate of spread was increased or decreased, the number of fires by intensity level shifted slightly up or down, and the weighting of the representative fires varied as the 1978 organization fought the fires in the computer. The various inputs, excluding the organizational dispatch level, were manipulated until the numbers of fires and acres burned by size class in the model matched closely the actual number of fires and acres burned by size class as experienced in the 1970 decade After the Initial Attack Analyzer was calibrated, the fire workload in each FMAZ was analyzed in detail

The suppression costs for each representative fire situation were calculated and weighted against the annual frequency to determine an annual expected suppression expenditure Costs for escaped fires were based on actual large fire costs experienced on the Siskiyou National Forest. The Pistol Basin Fire (1971) at 1,088 acres; Quail Creek Fire (1970) at 683 acres; and the Shasta Costa Fire (1975) at 471 acres were used for the development of the large fire costs These costs were equated to 1980 dollars and weighted against the annual frequency to determine an annual expected expenditure.

Resource value change was calculated for each representative fire situation in each zone that exceeded ten acres These calculations included an estimate of maximum loss per acre in immature timber stands; both seedling and sapling, and pole stands, an estimation of mature timber value loss, damage to improvements, as well as changes in dollar values of commercial forage, new water, fish habitat, wildlife habitat, and recreation resources (Table B-1).

In calculating timber losses in the "General Forest Zones" (FMAZ 1, 2, and 3), each FMAZ was first analyzed to determine what percent of the area represented old-growth timber, pole timber, seedling and sapling stands, as well as brush Once these values were determined, a weighted timber dollar value for each zone was developed which represented the diversity of the timber stands

Damage to improvements in each zone was based on a best estimate of improvements that could be lost in a large fire. Dollar values for commercial forage were not calculated in the analysis as grazing was of only minor value Inputs of dollar values for new water, fish habitat, and wildlife habitat were obtained from the appropriate resource specialists and geared to fire intensity levels and fire size classes Recreation resources were handled in much the same way.

Dollar value changes were totaled and summarized by FMAZ and then further combined into total Forest value tables An assessment for shared resources; air tankers, smokejumpers, repellers, and light helitack was also developed using guidelines developed by the Region. This assessment was included in the calculation of the Fire Management Effectiveness Index (FMEI).

Once the FMEI for the 1978 base organization (C10) was calculated, the detailed analysis was repeated for five other program level and program mixes. These included.

K10: The 1978 base budget level decreased by 30 percent with a light helicopter located at Merlin, Oregon

K20. The 1978 base budget level decreased by 45 percent with no helicopter located at Merlin, Oregon

K30: The 1978 base budget level increased by 15 percent with a rappel helicopter (Bell 212) located at Merlin, Oregon

K41· The 1978 base budget level decreased by 15 percent with a light helicopter located at Merlin, Oregon.

K42: The 1978 base budget level decreased by 15 percent with a rappel helicopter (Bell 212) located at Merlin, Oregon

In each of the five other detailed analyses, an organization was developed which reflected the dollars available in the various program levels analyzed, and those organizations fought the same fires in the Initial Attack Analyzer as did the 1978 base organization. When all the detailed analyses were complete, the respective FMEI's were compared to identify the most cost efficient organization--the organization with the least cost plus net value change, as well as the organization management felt would best meet the new management direction outlined in the LRMP

The K42 option (Table B-2) was selected by the Forest Supervisor as the organizational level that would most realistically meet the direction provided in the Forest Plan. Although this option was $0 02 per acre more costly in respect to cost plus net value change than the most cost efficient option, it was felt that the budget levels displayed were more realistic, and the expected annual acres burned were more attainable than those generated in the cost efficient option (K30)

After the desired level of protection was selected by the Forest Supervisor, the costs associated with protection (111 to 114 Dollars), fuels management support (115 Dollars) and the shared resource assessment were combined to represent the estimated annual budgetary needs of the fire management program in FORPLAN for the first ten years of the planning period in 1982 dollars

Table B-1. Summary of Resource Values by Fire Management Analysis Zone Used to Calculate Net Value Change for Representative Fires Over Ten Acres

Resources		Zone 1	Zone 2	Zone 3	Zone 4	Zone 5	Remarks
Timber	Regen MBF/Acre	41.9	34.1	26.2	N/A	N/A	$345 per MBF
	Poles $/Acre	4766	4095	3429	N/A	N/A	
	Seed and Sap $/Acre	944	1574	1500	N/A	N/A	
New Water	Acre/Foot	11.5	11.5	10.0	10.0	11.5	$1.50 Per Acre/Foot
Fish Habitat	Lbs/Acre	6.40	4.00	1.60	1.6	0.0	$1.61 per Pound
	RVD/Acre	5.92	4.78	1.97	2.0	2.8	$56.60 per RVD
	$/User Day						Size in Acres at FIL3 (10-100) (100-300) (300+)

Improvements	$/Acre	50	50	50	N/A	N/A	

Table B-2. Expected Siskiyou National Forest Fire Management Program, Annual Costs, and Acres Burned for Program Options Analyzed for Fire Planning Process for the First Decade 1/

Program Option	Level Of Protection (111-114 Dollars)	Suppression Cost	Total Net Value Change	Shared Resources	Fuels Support And Projects (115 Dollars)	Cost Plus Net Value Change	FEMI	Acres Burned
C10	795,000	445,000	254,000	630,000	216,000	2,340,000	2,140	215
K10	635,000	476,000	274,000	505,000	76,000	1,965,000	1,798	232
K20	478,000	649,000	555,000	393,000	91,000	2,165,000	1,981	394
K30	879,000	255,000	81,000	412,000	288,000	1,915,000	1,752	73
K41	671,000	470,000	269,000	479,000	264,000	2,171,000	1,986	228
K42	671,000	410,000	176,000	421,000	264,0000	1,942,000	1,776	171

1/ Dollar values shown are 1982 dollars. Fire Management Efficiency Index (FEMI) calculated on a protection base of 1,093,000 acres.

COST EFFICIENCY AND NET PUBLIC BENEFIT

This section describes how the efficiency criterion of PNV, which is one of the components of NPB was formulated and modeled for the benchmark analysis and evaluation of alternatives. This analysis is required by NFMA regulations and has played an important part in the development and comparison of alternatives in Forest planning

NET PUBLIC BENEFIT (NPB)

NPB is the overall value to the nation of all outputs and positive effects (benefits) less all the associated Forest Service inputs and negative effects (costs) of producing priced and nonpriced outputs from National Forest System Land (NFS) (36 CFR 219.3). Thus, NPB represents the net value of priced outputs PNV plus the net value of nonpriced outputs. NPB cannot be expressed as a numeric quantity because PNV cannot be numerically added to qualitatively valued nonpriced outputs Maximization of NPB is a goal of the Forest planning process.

PRESENT NET VALUE (PNV)

PNV is the quantitative component of NPB. PNV represents the dollar difference between the discounted value of all priced outputs and all Forest Service costs over the 150-year planning period. All costs and benefits are expressed in 1982 dollars. The GNP Implicit Price Deflator was used to adjust values from other years to this base.

Each benchmark and alternative was designed to achieve goals and objectives in a manner that produced the greatest PNV This was accomplished by solving FORPLAN with the objective function of maximizing PNV, while meeting the specified constraints of the benchmark or alternative. PNV is used to assess the economic efficiency of the alternative or benchmark. This section describes how the prices and costs which make up PNV were calculated, and how they are used within the model.

ECONOMIC PARAMETERS GOVERNING PNV

A discount rate of 4 percent was used to solve FORPLAN and to calculate the economic consequences of the benchmarks and alternatives (36 CFR 219.3). The 4 percent rate approximates the real return on corporate long-range investments above the rate of inflation. Inflation is not included in the discount rates, benefits, and costs due to the difficulty of estimating future inflation rates and because inflation is assumed to equally affect both costs and prices. This rate was used to solve FORPLAN in all cases to date. A second rate, seven and one-eight percent, was used to determine the sensitivity of solutions to a higher discount rate. All costs and benefits were discounted from the midpoint of each planning period.

Timber Demand Curves. No local demand curve for timber was used in the FORPLAN model. None of the available techniques for developing Forest level demand functions has a strong enough theoretical basis that it can be suggested for use in Region Six. Available evidence also indicates that if a reliable Forest level demand function could be calculated, the elasticity would be such that the use in FORPLAN would not be significant.

Real Price Increases. A one percent per year price trend was incorporated in the FORPLAN model for timber values. This trend reflects the assumption of scarcity, ie. that future demand increases and, or supply restrictions will increase national product prices. This trend was chosen based on the work of Harold J. Barnett, and Chandler Morse ("Scarcity and Growth", Johns Hopkins Press, Baltimore, 1963, p.213.) No other price or cost trends are used in the analysis.

BENEFITS AND COSTS USED IN THE PNV CALCULATION

Two types of outputs (benefits) are valued in the model; outputs which can be valued with market prices, and those which have no market prices, but can be assigned a proxy value Timber and commercial anadromous fish are the market valued outputs in the FORPLAN model. Willingness to pay values for recreation were derived in the 1980 RPA assessment, and represent what consumers would be willing to pay for a recreational experience rather than forego the opportunity

Other uses which remain fixed among the benchmarks and alternatives are valued within the model These are not used to make resource scheduling decisions. They include fuelwood, special uses, river use fees, power and minerals, campground, and grazing fees. Fuelwood is valued at the 1980 RPA benefit value for Region Six, the remaining benefits were valued from 1984 Forest receipts reports.

Costs. Four types of costs are valued in the FORPLAN model: Variable costs, fixed costs, resource capital investment costs, and logging costs:

VARIABLE COSTS include: Costs incurred as a result of program activities for controllable outputs or controlled use. Costs which vary between benchmarks and alternatives. Examples of variable costs are silvicultural exam and prescription, and road construction and reconstruction.

FIXED COSTS include: Nondeferrable activities for insuring public safety and environmental protection. Activities to protect natural resources on adjacent lands. Costs to keep existing capital assets at agreed levels of service and availability. Long-term management planning and resource inventories. Costs of general administration. Costs that cannot be assessed on a per unit basis Examples of fixed costs are timber management planning and inventory, and coop law enforcement.

RESOURCE CAPITAL INVESTMENT COSTS are costs of implementing resource-specific mitigation or enhancement projects. Decisions to implement these projects are made outside of FORPLAN, for each alternative and benchmark, based on the emphasis and objectives. Project costs and benefits are additions to FORPLAN generated solutions. Examples of these projects are wildlife enhancement (meadow rehabilitation) and recreation enhancement (construction of additional campgrounds).

NONFOREST SERVICE COSTS of production are costs incurred by producers other than the Forest Service. The Siskiyou model incorporates logging costs

All costs but logging costs are components of PNV. Variable costs are linked with prescriptions for Analysis Areas. They and logging costs are the only costs which influence scheduling decisions within FORPLAN. Fixed costs occur as a lump sum per period, regardless of the prescriptions chosen They are equal for all benchmarks and alternatives. Resource capital investment costs are entered uniquely for each alternative or benchmark.

The variable costs for timber related activities are specific to the management areas and type of treatment where significant differences could be identified. Costs were derived from empirical data as much as possible. The costs for Retention, Partial Retention, and General Forest Management Areas are based on even-aged silvicultural systems and the clearcutting harvest method. Costs for Riparian areas are based on partial removal and harvest of these areas in conjunction with the treatment of adjacent areas This categorization is in line with experienced management practices for these types of areas, and the assumption of a similar pattern for the future is supported by the analysis in Appendix G This assumption simplifies the modeling and allows the straightforward use of local empirical data for many of the activities As indicated in Appendix G, individual sites may vary from this pattern, however, the variation is not expected to effect the evaluation of the alternatives nor the Forest-wide economic parameters.

The compilation and analysis of data used to determine cost and benefit information for the alternatives and benchmarks involved two distinct procedures. First, those costs and benefits which contributed to the scheduling of prescriptions in FORPLAN were compiled and entered into the model through the use of common economics tables. These tables relate costs and output values to management prescriptions associated with Analysis Areas. The tables allow FORPLAN to assign the most cost efficient prescription to any given Analysis Area to meet the constraints of the alternatives or benchmarks.

The second procedure in the analysis involved determining the costs and benefits that were not associated with prescriptions, but which were also affected by alternative formulation These include the costs and, or benefits of the resource capital investment programs. Estimation of these costs and benefits were entered as direct yields in FORPLAN to be included in the PNV totals.

PNV CALCULATIONS (BUDGET COSTS)

Budget costs consist of the estimated appropriated costs of management for each alternative and benchmark These costs were reported as average annual. Budget costs were stratified into the following categories:

Fixed costs
Operation and maintenance costs
Capital investments

Purchaser credit road costs were added to show the cost of constructing purchaser credit roads for timber harvests. This cost was not included in the total budget costs, but was added to the total agency cost estimates used to calculate PNV. Budget costs were calculated similarly to the method used to determine cost data by resource component. Variable or allocation costs along with fixed costs were summarized from the FORPLAN economic reports by planning period for each alternative and benchmark.

OPPORTUNITY COSTS

In order to determine the relative cost efficiency of the various alternatives and benchmarks, opportunity costs were derived to show the difference in PNV between FORPLAN runs Opportunity costs are defined as the value of a resource's foregone net benefit in its most economically efficient alternative use. In relation to the economic analysis, it represents the difference in PNV between the Maximum PNV Benchmark or alternative with the highest PNV and subsequent runs. Opportunity costs measure both the change in PNV value for priced resource outputs, and can be used to measure the relative value of nonpriced benefits included in NPB.

DETERMINATION OF ECONOMIC VALUES

The timber values listed below were developed from a Timber Sale Statement of Account data base for 1973-1982. They are cut values, computed at the time that the timber is actually harvested and paid for, adjusted to 1982 dollars with the GNP Implicit Price Deflator.

BENEFIT VALUES

They were developed using the following methodology:

Timber

1. Determine species composition from data base of 2400-17's, 1975 - second quarter 1980

2. Develop weighted average stumpage value. 1/

Species	Percent of Total Volume Sold	Stumpage Value (1982 $/MBF)
Douglas-fir	83	241
Port-Orford-cedar	7	851
Pine 2/	6	284
White fir	3	174
Hemlock 3/	2	150

1/ Weighted average value = $285/MBF
2/ Based on 75 percent sugar pine at $316/MBF, and 25 percent
3/ Value is for a mixture of species including incense cedar, Shasta red fir, noble fir, Englemann spruce and western hemlock

3. Develop selling value by adding logging and manufacturing costs to stumpage value. Costs were derived from the data base of 2400-17s, 1973-1982.

$285		Stumpage value
$150	+	Logging costs
$200	+	Manufacturing costs
$635		Selling Value 1982 $/MBF

4. Convert $/MBF to $/MCF with average board foot/cubic foot conversion ratio for existing stands of 5.41.

   Selling value = $3,435/MCF

   This represents the average selling value for currently harvested old-growth stands.

5. Estimate selling value for smaller diameter future stands and commercial thinning opportunities. This was done with indices developed by Cahill and Snellgrove, PNW, "Young-Growth Douglas-fir Tree Value Indices - Region Six", according to direction from the Regional Office.

   The current average diameter is estimated to be 30" DBH, by a survey of each Ranger District's TMA 30" DBH and Selling Value of $3,435/MCF were used as the base values The indices were applied to this to develop selling values for other diameters.

6. Pond values were developed by subtracting manufacturing costs from selling values. Average manufacturing cost = $200/MBF * 5 41 BF/CF conversion ratio = $1,082/MCF.

   Pond values are used in the FORPLAN model. They will be trended to increase at one percent per year.

The follow data display the computation of timber values

DBH (inches)	Relative Value	Selling Values (1982 $/MCF)	Pond Values (1982 $/MCF)
8	62	2,130	1,048
9	62	2,198	1,116
10	67	2,301	1,219
11	70	2,404	1,322
12	72	2,473	1,391
13	74	2,542	1,460
14	76	2,611	1,529
15	79	2,714	1,632
16	82	2,817	1,735
17	84	2,885	1,803
18	86	2,954	1,872
19	88	3,023	1,941
20	90	3,092	2,010
21	.92	3,160	2,078
22	94	3,229	2,147
23	.95	3,263	2,181
24	96	3,298	2,216
25	96	3,298	2,216
26	97	3,332	2,250
27	97	3,332	2,250
28	98	3,366	2,284
29	99	3,401	2,319
30 Base	1 00	3,435	2,353
31	1 00	3,435	2,353
32	1 01	3,469	2,387
33	1 01	3,459	2,387
34	1 01	3,469	2,387
35	1 02	3,504	2,422
36	1 03	3,538	2,456
37	1 01	3,572	2,490
38	1.05	3,607	2,525
39 +	1 06	3,641	2,559

Other Forest Service Receipts The outputs that follow are tracked on an annual, fixed basis The data source for items 1-5 is the 1984 Forest Receipt Reports adjusted to 1982 dollars with the GNP Implicit Price Deflator The data source for grazing fees is 1984 grazing fee permits (adjusted to 1982 dollars) on file in the Forest Supervisor's Office.

Activity	Total Value (1982 $)
Special Uses	3,178
River Recreation	
Outfitter (Commercial) Use	20,464
Private Use Application Fees	25,497
Power Uses	493
Minerals	245
Campground Fees	28,308
Grazing Fees	1,728
Fuelwood	49,600

Fuelwood is valued at its RPA benefit value of $31/MCF. It is valued up to its current level of consumption of 1,600 MCF (16,000 cords) Presently Forest production of fuelwood and per acre material = 6,400 MCF (64,000 cords). (Source: Assistant Timber Staff)

Wildlife, Fisheries, and Recreation

Assigned RPA values are as follows:

Activity	Value($)/Unit
Recreation	
Wilderness	17 50/RVD
Dispersed (Nonwilderness)	
Primitive	11 25/RVD
Semi-primitive Non-motorized	13 25/RVD
Semi-primitive Motorized	12 13/RVD
Roaded Natural	9 38/RVD
Developed Use	
Includes Camping and Picnicking	6 00/RVD
Wildlife	
Big-game Use	30 00/WFUD
Small Game Use	19 00/WFUD
Nongame Use	25 00/WFUD
Fisheries	
Anadromous Sport Fishing	33 00/WFUD
Anadromous Commercial Fishing	1 05/LB
Resident Sport Fishing	15 00/WFUD

Range

$5 90/AUM * 1.18 = $7/AUM 1982 $
1980 RPA Value GNP Implicit Price Deflator

$7/AUM * 3,000 AUM's per year = $21,000 per year

This value is tracked on an annual, fixed basis.

COSTS

Fixed Costs and Variable Costs. There are two types of costs incurred in FORPLAN, fixed costs and variable costs. Fixed costs are incurred, in a lump sum, regardless of the land management or resource scheduling regime chosen (with the exception of the "minimum level" alternative) Variable costs, as the name implies, vary by prescription n emphasis and/or management alternative

FIXED COSTS include nondeferrable activities for insuring public safety and environmental protection Activities to protect natural resources on adjacent lands Costs to keep existing capital assets at agreed levels of service and availability Long-term management planning and resource inventories. Costs of general administration Costs that cannot be assessed on a per unit basis.

VARIABLE COSTS include road construction and reconstruction Costs incurred as a result of program activities of controllable outputs or controlled use Costs which vary between alternatives

Interim Directive No. 10, September 16, 1981.
1970 Economic and Social Analysis,
U S. Forest Service, Washington D C

Fixed Costs. The following data display Fixed Costs

Activity	1982 $
Developed Recreation Management	191,309
Dispersed Recreation Management	150,218
Cultural Resource Management	13,879
Wilderness Management	15,118
Fish and Wildlife Planning and Maintenance	84,913
Range Planning and Inventory	2,775
Timber Management Planning and Inventory	15,677
Genetic Forest Tree Improvement	718,000
Soil and Water Planning and Inventory	227,410
Administration of Minerals and Mining	32,943
Lands	822,500
Transportation Planning and Inventory	345,341
FA and O Facility Maintenance	246,517
Fire Management Planning and Analysis	673,000
Fire Prevention, Detection, and Fighting	377,000
Coop Law Enforcement	57,820
Fixed Program Management	481,461
General Administration (GA) (Line Management and Common Services)	1,947,866

Variable Costs. Costs for the following activities were collected from the five Ranger Districts for the years 1975 to 1980, when available.

Forest-wide average costs were developed from 1980 costs by weighting the District's costs by volume of timber or number of acres treated. Program management costs, obtained from the 1980 unit summary reports, are included All costs have been converted to 1982 dollars with the GNP Implicit Price Deflator.

Costs were verified with the Supervisor's Office timber staff personnel and with data from the Forest budget unit summary and attainment reports. Costs have also been reviewed by economists from the Umpqua and Rogue River National Forests and the Regional Economist

SILVICULTURAL EXAMINATION AND PRESCRIPTION involves selected timber stands, visual description on aerial photographs and maps, establishing data files, and recommending appropriate management activities.

District's Costs	= $ 26 MBF
Program Management	= $ .06/MBF
Total	$ .32/MBF

Converted to a per acre cost using 30 MBF/acre (Forest average volume per acre derived from District TMA data)

= *$10/acre for Clearcuts*

District timber sale planning personnel estimate that silvicultural exam and prescription will be approximately twice as costly for commercial thins, on a per acres basis, because of the need for more intensive field exams.

= $19/acre for Commercial Thins

TIMBER SALE PREPARATION includes sale area planning and design, tree marking, sale value determination, appraisal, environmental assessment preparation, advertisement, auction, and sale award

District's Costs	= $8 26/MBF
Program Management	= $1.04/MBF
Total	$9.30/MBF

Converted to a per acre cost using Forest average volume/acre of 30 MBF = 279/acre for Clearcut

It is estimated by District timber sale planning personnel that timber sale preparation will be approximately twice as costly for commercial thins, on a per MBF basis. The per MBF cost was doubled, and converted to a per acre cost using the weighted average volume per acre for current commercial thins of 8 MBF/acre = $149/acre for commercial thins.

TIMBER HARVEST ADMINISTRATION includes the supervising and administering of sales, includes activities such as scaling and check scaling, management of sale accounts, contracts modifications, rate redeterminations, and breach actions.

Districts' Costs	= $2 83/MBF
Program Management	= $1 18/MBF
Total	$4 01/MBF

Converted to a per acre cost using Forest average of 30 MBF/acre = $120/acre

It is estimated by District timber sale planning personnel that timber harvest administration will be approximately twice as costly for commercial thins, on a per MBF basis The per MBF cost was doubled and converted to a per acre cost using the weighted average volume per acre for current commercial thins of 8 MBF/acre = $64/acre for Commercial Thins

REFORESTATION

Planting It is assumed that every acre of final harvest will be planted.

Districts' Costs	= $290/acre
Program Management	= $ 4/acre
Total	$294/acre

Replanting The same per acre cost ($294/acre) is used for replanting as for planting Replanting is assumed to occur on 25 percent of all harvested acres. (Estimate of Forest Silviculturist).

Animal Damage Control It is assumed to occur on 10 percent of all planted acres

District' Costs	= $ 91/acre
Program Management	= $ 1/acre
Total	$ 92/acre

PRECOMMERCIAL THINNING is assumed to occur on 65 percent of all planted acres as determined from Forest Silviculturist review of TRI data.

Districts' Costs = $242/acre
No Program Management

RELEASE COSTS (displayed below) were obtained from the analysis done for the 1983 Vegetation Management Program. They include all of the costs of the vegetation management program planning through project preparation, contract bid and administration and concluding with post treatment evaluation.

Type	Cost/Acre (1982 $)
Commercial Aerial	52
Chemical Ground	117
Manual	196

A 1981 review of TRI data revealed that 43 percent of all planted acres were released with chemicals aerially, 2 percent with chemicals on the ground, and 3 percent manually. These are the proportions used for Forest Planning It is assumed that each released acre is treated twice (Source: Forest Silviculturist)

FERTILIZATION costs were derived from a Regional Office study of five Forests with fertilization programs.

A weighted average cost for aerial and hand application was developed for 1983. This was $56/acre 1982 costs were approximately 1/3 higher at $75/acre. These costs were used.

An additional $10/acre was added for project layout and EA preparation, this equaled $85/acre.

An additional 10 percent allowance for increased costs due to fertilization not having been done on the Siskiyou was added, this equaled $94/acre.

BRUSH DISPOSAL (BD) costs (treatment of activity fuels) following timber harvest were derived by computing weighted averages from 1980 experience cost data from each of the five Ranger Districts This data was disaggregated into three unit-size categories for use with the General Forest and visual management prescriptions Costs were updated to 1982 with the GNP Implicit Price Deflator.

Brush Disposal Costs for Clearcut Units:

Prescription Emphasis	Unit-Size (Acres)	$/Acre
Retention	1- 5	916
Partial Retention	5-10	727
General Forest	10-40	576

These costs include those incurred by the Forest Service and the purchaser and reflect the average costs per acre of activities such as yumming, fire line and fuel break line and fuel break construction, manpower (including overtime), helicopter rentals, etc Costs were verified with a Forest average estimate derived from timber Sale Report forms for 1980; average BD cost was $23/MBF, average MBF/Acre = 30, average total cost/acre equaled $690.

Costs for BD for partial cuts were obtained from three Ranger Districts (Galice, Gold Beach, and Illinois Valley) Little actual data was available, thus costs are based on the specialists' judgment and reflect the necessity for more hand piling and other manual techniques and less line construction. Information was also obtained from the Rogue River, Umpqua, and Mt Baker-Snoqualmie National Forests. Per acre costs are shown below. Costs are assumed to occur on 40 percent of thinned acres. (Forest Timber and Fire Management Staff Officers.)

Brush Disposal Costs for Commercial Thinning

Prescription Emphasis	Unit-Size (Acres)	$/Acre
Retention	1-15	776
Partial Retention	15-20	753
General Forest	20-45	679

The cost for BD for riparian areas was obtained from a Westside Fuel Treatments Cost Study undertaken by the Wenatchee National Forest (and including data for nine other Forests) It is assumed that the only fuel treatment method to be undertaken in the riparian areas is hand piling, at a cost of $345/acre.

All costs reflect fuels treatment to the most cost effective level for fire protection, as directed by National policy (Forest Service Manual 5150).

SPECIES TYPE CONVERSION. Costs for species type conversion were developed from 1980 data from the Chetco Ranger District, where most of this activity occurs. Costs were adjusted to 1982 dollars with the GNP Implicit Price Deflator.

Type Conversion Costs

Activity	Cost/Acre
Stand Exams thru Burning	371
Road Construction 1/	17
Total	388

1/ Cost for road construction was developed by (1) computing a weighted average road construction cost per acre, (2) developing a coefficient to reflect the proportion of conversion acres that have associated roading costs by dividing the number of acres with associated road costs by total number of acres of conversion (3) multiplying (a) average costs per acre accessed by (b) proportion of accessed acres with associated road costs $157/acre access * 11 access with road costs/total conversion acres = $17 per all conversion acres

Reforestation costs, following removal, are the same as those for clearcuts

Release costs are also the same as those for plantations following clearcuts with the exception that three applications (instead of 2) are necessary.

OTHER RESOURCE SUPPORT, MITIGATION, AND ENHANCEMENT COSTS RELATED TO TIMBER PRODUCTION Specialists in Cultural Resources, Visual Management, Fish and Wildlife, Soils, and Water Quality all provide input to timber sales This input ranges from review of timber sale Environmental Assessments to field examinations and writing proposals to mitigate the impacts of timber management, or enhance the quality of their resource These costs are charged against final harvest timber prescriptions.

Activity	$/Unit
Cultural Resources	11/Acre
Visual Management	11/Acre
Soil and Water	
General Forest	6/MCF
Riparian Prescription B	35/MCF
Riparian Prescription C	10/MCF
Mitigation and Enhancement	24/Acre
Fish and Wildlife	8/Acre

The data source for cultural resources and visual management support costs was the 1985 RPA estimate of dollars spent divided by total acres of planned timber harvest.

Cultural Resources	= $60,700/5,600	Acres planned	= $11/acre
Visual Resource	= $62,800/5,600	Acres planned	= $11/acre

The data source for soil and water support costs was the Fiscal Year 1980 soil and water support program, also divided by program acres. This information was updated to 1982 dollars and converted to a cost per MCF with the average board foot/cubic foot conversion ratio for existing stands. It was adjusted for management in the riparian areas.

The data source for soil and water and fish and wildlife mitigation and enhancement was a sample of forty 1980-1981 timber sales. Total costs for these activities was divided by total volume harvested to develop a cost/MBF. This was multiplied by the average volume per acre (30 MBF) for existing stands, to develop a cost per acre.

LOGGING COSTS - EXISTING STANDS/CLEARCUT. Logging costs for existing stands were developed from 2400-17 data for 1973-1982. They represent a Forest-wide weighted average, by volume, by year, adjusted to 1982 dollars. The following costs are included.

Activity	$/MBF
Fell and Buck	13 10
Skid and Load	39 88
Haul	28 62
Overhead and Dep	29 24
Erosion Control	2.64
Miscellaneous Amount	1 51
TOTAL	114 99

Road maintenance, temporary road costs and slash disposal are not included in logging costs. They are dealt with elsewhere in the model.

The average board foot/cubic foot conversion ratio for existing stands was used to convert the cost from a MBF to a MCF cost for use in FORPLAN.

$115/MBF * 5.41 average BF/CF conversion ratio = $622/MCF

Logging costs were adjusted for cost increases for harvest in Riparian, Retention Visual, and Partial Retention Visual Management Areas.

LOGGING COSTS - RIPARIAN The additional cost of harvest in riparian areas is directional felling (Forest Logging Systems Specialist). Thirteen Siskiyou National Forest sales with directional felling were sampled. The average cost for tree lining for these sales was $28/MBF. Average cost for conventional felling for the same sales was $10/MBF, therefore, costs increase for directional felling is employed (Forest Logging Systems Specialist), thus the net cost increase for directional felling is $13/MBF. This was converted to a cost increase per MCF with the Forest average BF/CF conversion ratio of 5.41 = $70/MCF.

LOGGING COSTS - VISUAL RESOURCE AREAS Additional harvest costs in Retention and Partial Retention Visual Management Areas result from additional equipment moving because of smaller unit size (Forest Logging Systems Specialist).

The assumptions used to derive the costs are:

Average Sale	=	142 acres
Average Sale Unit Size	=	20 acres
Average Volume/Acre	=	30 MBF

Compute number of moves for average sale.

142 acres 20 acres/unit = 7 units = 7 moves

Compute acreage move in and set up cost per sale.

Regional average move in and setup = $3.43/MBF
Average sale volume = 30 MBF/acre * 142 acres = 4,260 MBF
$3.43/MBF * 4,260 MBF/sale = $14,612 move in and setup/sale
$14,612 total move in move out and set up 7 moves = $2,087 for each move and set up

Partial Retention Visual

Same average volume/sale = 4,260 MBF
Same average sale size = 142 acres
Smaller unit size = 7 acres/unit
142 acres/sale 7 acres/unit - 20 units - 20 moves
20 moves/sale * $2,087/move = $41,740 sale
$41,740/sale 4,260 MBF/Sale = $9.80/MBF
$9.80/MBF converted to $/MCF with Forest average BF/CF conversion ratio of 5.41 = $53/MCF additional logging costs.

Retention Visual

Same average volume/sale = 4,260 MBF
Same average sale size = 142 acres
Smaller unit size = 4 acres/unit
142 acres/sale 4 acres/unit = 35 units = 35 moves
35 moves/sale * $2,087/move = $73,045 sale
$75,045/sale 4,260 MBF/Sale = $17.15/MBF
$17.15/MBF converted to $/MCF with Forest average BF/CF conversion ratio of 5 41 = $93/MCF additional logging costs.

Summary of Existing Logging Costs ($ Per MCF)

General Forest	Riparian	Retention	Partial Retention
622	692	715	675

LOGGING COSTS - MANAGED STANDS AND COMMERCIAL THINS. Logging costs for future (managed) stands and commercial thins were estimated using two sources: equations from the research paper entitled "Logging costs for Young-Growth Management Planning for Coastal Douglas-fir;" Fight, Roger D. et. al. 1984; and Forest experience cost data.

Equations from the paper were used to estimate yarding and changing yarding corridors, felling, bucking and limbing, branding, and loading.

THE EQUATIONS ARE:

Yarding.

Small Diameter (6 to 16" DBH) (VOAC 0.4-15 MCF/acre)

Cost = 491.4 - 40.48 (DBH) + 0.8886 $(DBH)^2$ + 0.1205 (SYD) + 16.1/VOAC

Large Diameter (18 to 24" DBH) (VOAC 0.4-15 MCF/acre)

Cost = 737.4 - 61.90 (DBH) + 1.2926 $(DBH)^2$ + 0.1497 (SYD) + 52.7/VOAC

Yarding Delay (Percent of time that equipment is idle)

Clearcuts and VOAC greater than 5.4 MCF/acre

Percent delay = 9 percent

Partial cuts and VOAC 0.4 - 5.4 MCF/acre

Percent delay = 22.9 - 2.61 (VOAC)

Changing Yarding Corridors (for 300 to 3000' SPAN).

Cost = 43 + 0.0001271 $(SPAN)^2$

Delay

Percent delay = 4.9 + 0.0052 (SPAN for 300 to 1950' SPAN)

Felling, Limbing, and Bucking (for 6 to 24" DBH).

Cost = -17.4 + 876/DBH

Delay - Clearcut and VOAC greater than 4.3 MCF/acre

Percent delay = 4

- Partial cut if VOAC 0.4 - 4.3 MCF/acre

Percent delay = 18.3 - 3.33 (VOAC)

Branding.

Cost = (-47.9 + 1678/DBH) (0.15)

Loading.

Cost = -9.8 + 545/DBH (for 6 to 24" DBH)

Percent delay = -4.0 + 104/DBH (for 6 to 13" DBH)
Percent delay = 4 (for DBH greater than 13")

WHERE:

DBH = Arithmetic mean diameter breast height of trees harvested.

VOAC = Volume per acre harvested in thousands of cubic feet.

SYD = Average yarding distance measured along the slope.

SPAN = Horizontal length of span in feet.

DBH and VOAC vary as shown in columns 1 and 2, respectively, in the following table. Forest Average values, developed by the Logging Systems Specialist, were used for SYD and SPAN They are

SYD = 939 Feet
SPAN = 1,047 Feet

The costs estimated by the above equations are in 1983 $. They were adjusted to 1982 $ with the GNP Implicit Price Deflator (Factor = .94).

Forest experience costs from 2400-17 data, 1973-1982, in 1982 $/MBF were converted to dollars per MCF with the average BF/CF conversion ratio for managed stands of 4.5 and added to the costs obtained from the equations. These costs are

Experienced Costs	$/MBF	BF/CF	$/MBF	Commercial Thins Projected Costs $/MBF
Haul	= 30 00 *	4 5 =	135 00 =	135 00
Erosion Control	= 2 64 *	4 5 =	11 88 =	11 88
Miscellaneous Amount	= 1 51 *	4 5 =	6 80 =	6 80
Move in and Setup 1/	= 3 43 *	4 5 =	15 44 * 2 =	30 87
Total			169 00	185.00

1/ Regional Average Cost

The solutions of the equations, plus the additional experience costs result in logging costs for General Forest managed stands and commercial thins. These are listed in Column 3 of the following table. Riparian, Retention Visual, and Partial Retention Visual logging costs are listed in Columns 4, 5, and 6. They reflect the General Forest logging costs of Column 3, plus the appropriate additions as described in the documentation for existing stands logging costs. The additional costs per MBF were multiplied by 4.5, the average BF/CF conversion ratio for managed stands.

ROADING COSTS. Roading projections and costs are documented under the section on Development of Yield Coefficients previously presented in this appendix.

Capital Investment Costs. The capital investment programs for recreation, wildlife, and fisheries are developed outside of the FORPLAN model. The Forest derives each series of investments as follows

RECREATION. The cost of developed recreation sites is derived from a survey of potential sites, examination of experienced costs, and adjustment of costs related to standards of construction due to anticipated trend of use. These yearly costs range from $4,000 to $92,000 for the first decade representing a wide range of investment strategies.

The cost of constructing and maintaining trails is based on recent historic costs in similar terrain. These costs are $17,000/mile for construction and $300/mile for maintenance. District personnel with experience in managing the maintenance program formulated the maintenance cost

FISHERIES. The cost of fisheries improvements is derived from existing basin action plans. These plans indicate the amount of work planned. Historic costs and professional experience are the basis for costs to accomplish the annual work load. The level of investment varies by alternative ranging from $175,000 to $350,000. The range represents different intensities of fish management.

WILDLIFE. Costs shown in the alternatives are derived from the Forest's Comprehensive Fish and Wildlife Plan and other documents. If wildlife projects listed in the plan are spread out evenly over a ten year period, the cost per year ranges as high as $123,000. This dollar amount represents (annually) as many as 4,550 acres of habitat improvement and 420 new structures. This amount could also be sustained in subsequent decades because most of the projects deal with meadow improvement and other recurring projects. These projects are scheduled to be repeated at ten year intervals (they only produce benefits for ten years). Some of the projects scheduled for the first decade are nonrecurring; however, for each decade throughout the life of the plan, it is expected that the same level of one-time opportunities exist as for the first decade.

SOCIAL AND ECONOMIC IMPACT ANALYSIS

OVERVIEW

Social and economic impact analysis examines the relationships between National Forest activities and the people within the Forest's area of influence. Social and economic impacts resulting from Forest decisions do not occur in a vacuum. These impacts are, in part, determined by other forces operating within an area. Social and economic forces change over time, many of which are independent of National Forest actions and policies.

The Siskiyou National Forest's area of primary influence is Coos, Curry, Jackson, and Josephine counties, in Oregon. Chapter III of the FEIS presents an in-depth description of this area, and its major social and economic features. The Planning Problems, described in Chapter I of the FEIS, and Appendix A also provide valuable insights into the important issues.

POPULATION

Population statistics are important to the selection of alternatives. The total population of the four-county area is approximately 271,500. County populations range from a high of 132,456 in Jackson County to a low of 16,992 in Curry County (Table B-3). Historically, all of the counties have been rural, and population growth has been slow. The decade of the 1970's, however, witnessed rapid increases in the growth rates of the two eastern counties.

DEMOGRAPHICS

Between 1950 and 1970, the median age of Oregonians steadily declined (Figure B-2) In the Siskiyou National Forest four-county area, only Jackson County exhibited a trend similar to this. Median age declined from 1950 to 1960 and then even more rapidly from 1960 to 1970 The median age in Coos and Curry Counties was lower in 1970 than in 1950, but had risen during the decade of the 1960's. Only in Josephine County did the median age increase consistently during this 20-year period. The percentage of the population over 65 rose from 9.4 percent in 1950, to 12.3 percent in 1960, to 15.5 percent in 1970. The State average for 1970 was 10.8 percent. The reason for the age disparity is a large influx of retired people to the county (U.S. Department of Commerce, 1960 and 1970).

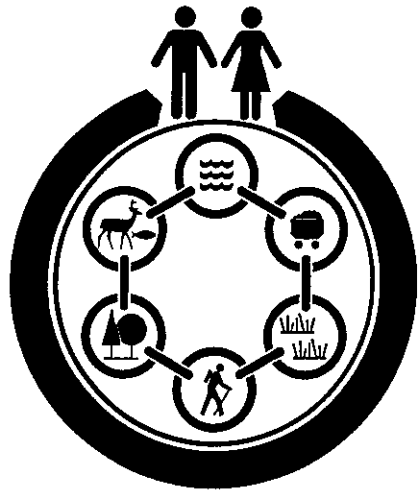

Table B-3. Population 1/

Figure B-2 Median Age, by County and the State 1950-1980

Race. The population in the area as a whole is 96 to 97 percent caucasian. From all indications, it is likely to remain so in the foreseeable future. The following table displays the distribution of population by race, 96 to 97 percent of the area is White; 0.1 percent,Black; 1.5 percent, Native American; 0.5 percent, Asian; and 2 percent, Hispanic. Coos County contains the largest nonwhite population at 3.6 percent (U S Department of Commerce, 1980). (See discussion on American Indians in Chapter III of the FEIS)

Percent of Population by Racial Type, 1980 1/

Curry	97.1	1	2	3	6	1 3
Jackson	96 7	1	9	.6	1 7	3
Josephine	*96 7*	*.1*	*1*	*4*	*6*	2

1/ Source U S. Department of Commerce, Bureau of The Census, 1980 Census of Population and Housing, Oregon
2/ This is a unique category which overlaps several of the others and should not be added with the other categories to form the total

Sex The male/female ratio in the four county area is somewhat higher than the State average and that for the Nation as a whole. In the past (1940 to 1960) this difference was even more pronounced This was, most likely, due to the relatively recent settling of the area and the predominance of male-typed, forest products employment. However, the number of women has been increasing in recent years, particularly in the larger, more service-oriented, east side communities.

Urban-Rural Distribution. The U.S. Bureau of the Census considers an urban place to be a location with 2,000 or more inhabitants. The following table presents population data by urban and rural residence, according to this definition.

Preliminary census figures shown an increase in the urban population in 1980 in Coos County to 53 percent, with little change in Curry County. The Josephine County Plan (1980) estimated that 78 percent of the county population resided within eight miles of Grants Pass in 1978. It should be remembered that urban population is derived according to different criteria here Although it is likely that the urban/rural ratio has increased, the change is probably overstated when comparing the 1970 and 1978 estimates. The census definition undoubtedly underestimates urban population in Josephine County, due to the large number of people who live near Grants Pass but outside of the city limits More recent information for Jackson County was not yet available.

In 1970, more than half the population of three of the four-counties in the area of influence resided in urban areas (Coos, Jackson, Josephine), and, from all indications, this trend toward increasing urbanization will continue. Curry County is the one exception; its population is about 80 percent rural and has been so for the last two decades (U.S. Department of Commerce, 1980).

Percentage of Urban and Rural Populations

County	Percent			
	1960		1970	
	Urban	Rural	Urban	Rural
Coos	47	53	51	49
Curry	19	81	21	79
Josephine	34	66	52	48
Jackson	45	55	55	45

EMPLOYMENT

The most significant employers are lumber and wood products, government, tourism, agriculture, and fisheries. Lumber and wood products manufacturing, which includes logging, is the largest employer, providing total employment of 17 to 18 percent in the four counties. Lumber and wood products jobs have decreased in number from 1979 due to economic adjustments made by industry to remain competitive. Concurrently, other sectors have grown. The flow of people moving into the area has served to promote growth in finance, insurance, real estate, and other trade and service industries Other industries which have provided basic employment growth include apparel, fiberglass, and electronics manufacturing In Coos Bay, the transportation, communication, and utilities sector is relatively large primarily due to the shipping industry.

Government jobs provide a significant percentage of employment in all four counties, exceeding employment provided by the lumber and wood products industry in 1983. Covered employment, by economic sector in the four counties for 1979, 1982,and 1986, is displayed in Table B-4.

LUMBER AND WOOD PRODUCTS is the most important manufacturing industry in the area as a whole, however, the relative dependence of each of the counties on this sector varies widely. Curry County is the most highly timber dependent, followed by Josephine, Coos, and lastly, the more diversified Jackson Counties.

Estimates of log flows from the Siskiyou National Forest lands to mills in these counties are shown below In addition to being the most timber dependent of the four-counties, Curry County is also the most dependent on the Siskiyou, receiving more than half of its timber supply from this source. Josephine County mills obtain about one-fourth of the timber they process from Siskiyou lands Relatively minor proportions are processed in Coos and Jackson counties.

Although lumber and wood products are still the most important industry in the area, it has made adjustments to remain competitive in the marketplace These adjustments mainly are increases in efficiency with corresponding reductions in labor requirements

Total Number of Logs Consumed by Mills within Zone of Influence from the Siskiyou National Forest 1/

	Number of Logs (Year)					
	1972		1976		1982	
County	MBF	Percent	MBF	Percent	MBF	Percent
Coos	49,797	6	37,136	6	33,278	6
Curry	148,390	73	83,364	54	17,845	25
Jackson	--	--	573	--	10,673	3
Josephine	75,612	26	44,300	26	28,282	28

1/Source 1972 data derived from Schuldt and Howard, (1974), 1976 data derived from Howard and Hiserote (1978), and 1982 data derived from Howard, (1984) The volume and percent figures are those amounts attributable to the Siskiyou National Forest

Figure B-3 graphically portrays the decline in the local timber employment, which was most pronounced in Curry County where employment in this industry fell from 65 percent to 21 percent of total employment over the period.

The reason for this adjustment was due to reduced demand for wood products and increasing mechanization in the industry which has resulted in a shift toward more capital and less labor intensive production processes (Wall and Oswald, 1975). The modernization resulted from increased competition from the southern region of the United States and western region of Canada As the South and Canada deplete their supplies of mature timber, the Northwest area (including the area of influence surrounding the Siskiyou National Forest) will experience less competition. Depending on the amount and cost of raw material, the area may experience an increased demand for wood products (Schallau and Maki, 1986) A slow steady increase in demand for wood products due to increased housing starts as the first children of the baby boom generation enter the housing market is predicted.

AGRICULTURE AND FISHERIES are important to the area's economy much more than covered employment statistics show This sector is considered to be second or third in importance Many workers in these fields are self-employed and do not appear in the data, but this sector brings in considerable revenue and is important in supporting the food processing industries Eighty-eight percent of the employment in the food processing industry in Coos and Curry Counties was in seafood processing in 1977.

Coos and Curry Counties ranked second and fourth, in terms of total commercial fish landings, in the State in 1979. They accounted for 26 percent and 12 percent of total commercial fish and seafood landings in the state in that year. Commercial fishing also supports jobs in the food processing industry, which is the number two industry, following wood products, in the manufacturing sector of these counties The industry is located in the coastal communities of Port Orford, Gold Beach, and Brookings in Curry County, and Bandon and Charleston in Coos County. Forest fisheries habitat also provides sport fishing opportunities for local residents and tourists, this contributing to the area's tourism-related employment.

Agriculture is also important to communities in Coos and Curry Counties Dairy farming is a large industry in each, and the specialty crop of Easter lily bulbs is a major cash crop and tourist attraction to Brookings (located in Curry County). Jackson County contains over 10,000 acres of pear orchards, which account for its primary agricultural crop and food processing industry. Josephine is the only county in the Siskiyou's area of influence which has little cropland, 80 percent of the land area is mountainous

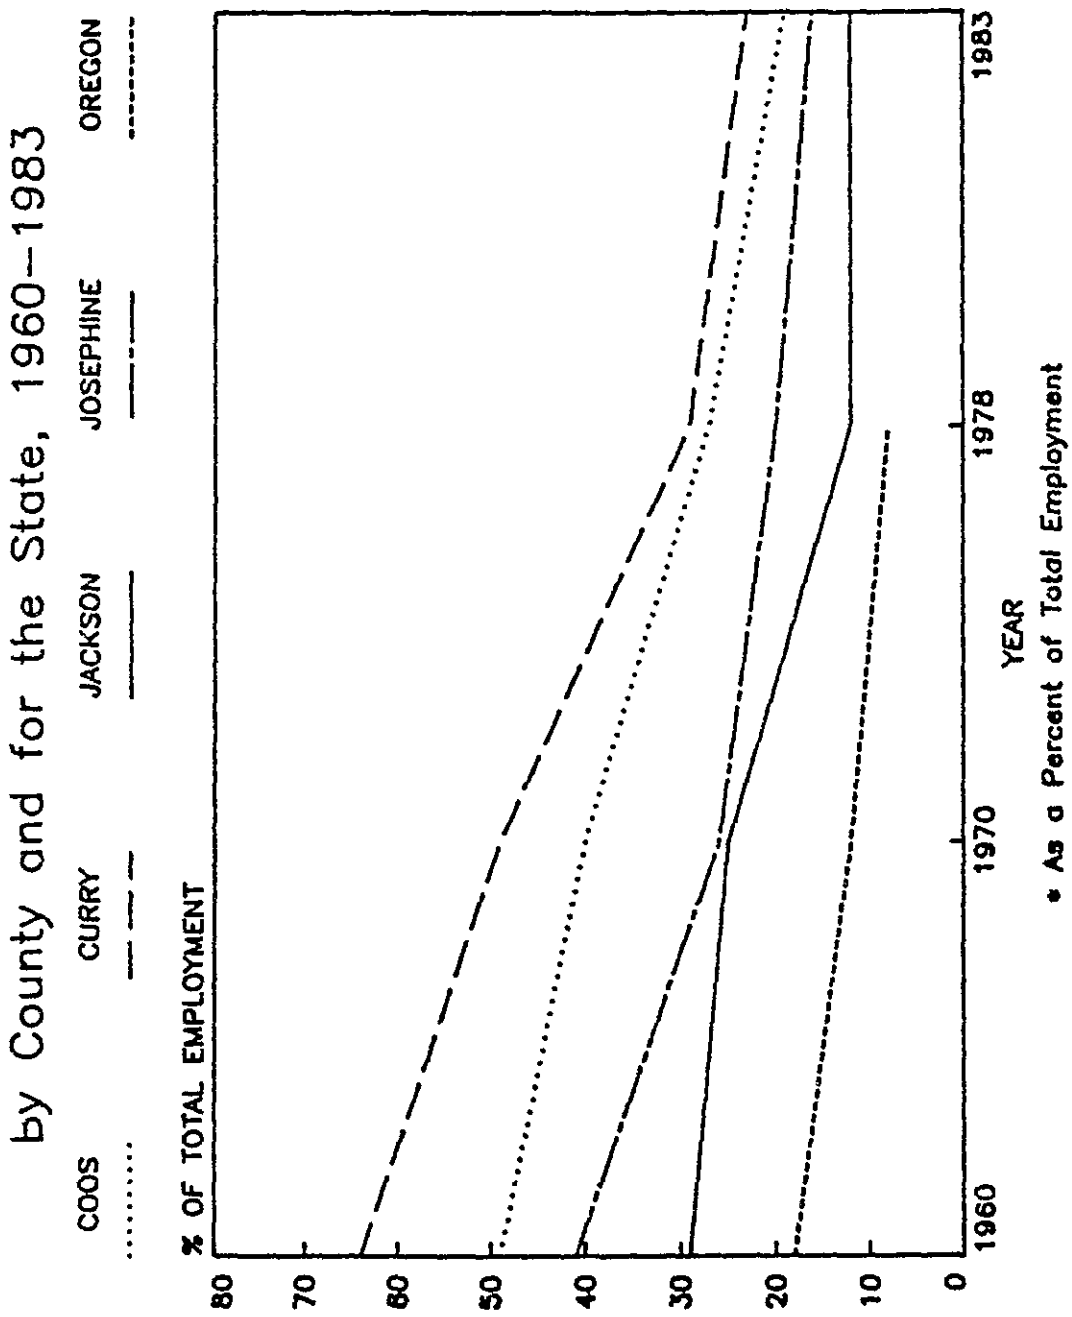

Figure B-3. Lumber and Wood Products Employment *

TOURISM is a key industry in all of the counties. It has been growing in importance during the last decade.

Since tourism is not a homogeneous, or strictly-defined industry, measurement of its economic contribution is less precise than for other sectors. Economic support through tourist expenditures shows up in the trade and service sectors, primarily from the purchases of food, lodging, gasoline, and souvenirs.

Jackson and Josephine Counties are heavily visited by out-of-state tourists. Both of these counties are transected by Interstate-5, the main north-south route through Oregon.

Jackson County has the highest proportion of employment in wholesale and retail trade and services in the four-county area, even higher than in the State. This is primarily due to the nature of its two largest cities The city of Medford is a major shopping and service area for the region and consequently benefits from the secondary benefits of tourism and wood processing. Ashland is the home of the Oregon Shakespearean Festival, which draws vacationers from all over the western United States

Josephine County also has nonmanufacturing strength in trade and services. Tourism along with indirect benefits from the wood products and food processing industries, and the large amount of transfer payments due to social security and retirement incomes,account for this strength. The county shares the Wild and Scenic Rogue River with Curry County. The Rogue is a National attraction, drawing recreationists to its excellent fishing and whitewater opportunities.

The coastal counties, Coos and Curry, are also supported by this industry. Tourists are attracted to the miles of bluffy, scenic coast along U.S. Highway 101, and the many types of recreation that they provide.

The Forest contributes to tourism-related employment in a rather minor way, mostly through the attraction of the Rogue River for boating, fishing, and hiking. Many of the area's features that draw tourists are not located on the forest.

Employment Projections. Projecting future employment trends is tricky, especially now, when trends from the 1970's point in one direction and the occurrences of the last several years point in quite another.

Employment gains have occurred in the trade, finance and service, and government sectors, and these trends are expected to continue. The important point to consider is that employment projections, like population projections, are only as valid as the methods and assumptions used to arrive at them. For the most part, projections are linear extrapolations of historic trends. They cannot foresee and account for different future developments. For example, radical change in wood processing technology or a prolonged energy crisis could profoundly change the structure of the economy in southwestern Oregon.

UNEMPLOYMENT. Average annual rates of unemployment for the four counties and the State are shown below. The average unemployment rate in the four counties is generally two to six points higher than the State, which is generally several points higher than the U.S. This is common for undiversified, rural economies. The area is also sensitive to national and regional economic cycles, primarily because of its dependence on the wood products industry. A significant portion of recent unemployment has resulted from adjustments in the wood products industry and resulting slowdowns in other related industries.

Seasonal fluctuations in unemployment are high, dropping to low points in late summer and early fall and reaching peaks in midwinter months. Seasonal variations reflect the constraints of the winter season on the basic industries of logging and wood products, agriculture, fishing, and tourism As would be expected, Jackson County, with its more diversified and less seasonally-oriented economy, has lower and more stable levels of unemployment

Josephine County experienced the highest unemployment during the late 1970's, but during the 1980's, the coastal counties fared somewhat worse. This was particularly true in the winter of 1981 to 1982, when the coastal counties experienced the highest unemployment since 1958.

Average Annual Unemployment Rates by the Four Counties The State of Oregon and the United States - 1977 to 1982 (Projected)

Year	Percent of Unemployment					
	U S	Oregon	Coos	Curry	Jackson	Josephine
1977	7 0	7.3	8.7	8 6	7 9	11 0
1978	6 0	6.0	7 2	6 9	7 0	9 0
1979	5 8	6 8	8 8	10 2	8 9	10 1
1980	7 1	8 2	13 9	12 6	10 4	13 0
1981	7 5	9 1	15 9	15 9	11 0	14 6
1982	9 3	11.3	15.2	20.5	13 5	15 4

All of the counties in the area of influence were designated as "labor surplus" for the period of June 1, 1981, to May 31, 1982. This designation applied to areas which experienced unemployment at 1.2 times the national rate (in excess of 7.9 percent) for two calendar years. Coos and Curry Counties are recent additions to this list; Jackson and Josephine Counties were classified as "labor surplus" in prior years. This is a federal designation, giving the counties preference in bidding for federal contracts.

Coos and Curry Counties were also identified as economically lagging areas effective April 1981 to April 1983. This is a State designation, and is based on high unemployment, low per capita income, closure or anticipated closure of major employers, or out-migration due to lack of economic opportunity. Josephine County was considered to be such an area until September 1981. State policy is to encourage economic and community development in these areas by providing tax relief for investments in job-producing projects.

Income. The four-county area of influence has traditionally had lower levels of income than the State as a whole, and incomes in Oregon are below the National average. The following table displays that information. This is, again, not unusual for a rural, undiversified, resource-based economy.

The residents of Coos County have traditionally had the highest incomes; those of Josephine, the lowest. Residents of Josephine County earned the lowest income in the state in every year but one from 1977 to 1982. Josephine is also the county with the highest proportion of below-poverty population and food stamp recipients. From 1974 to 1979, 58 percent of the total income for Josephine County was income paid to labor and proprietors, compared with a state average of 72 percent. This is one measure of economic health, as this is the type of income occurring to goods or services-producing segments of the population The other two income types, property income and transfer payments, do not reflect the creation of any economic product. Transfer payments, which are generally government assistance of some sort, accounted for 24 percent of total income in Josephine County in 1979. These payments generally comprise only about 11 percent of a county's total income.

A 1982 State of Oregon publication, Josephine County Economic Review, examined real income growth--or increases in income that remain after inflation is adjusted out--for Josephine County Incomes increased at an average rate of 5.8 percent a year from 1975 to 1977, then actually declined 2.7 percent in 1979 and 6.9 percent in 1980. Similar declines have probably occurred in the other counties, though probably smaller in magnitude.

Future trends in income in this area, like trends in population, employment and unemployment, depend on local and external factors. National economic recovery, the attraction of new industries, the adjustment

of existing industries to remain competitive, and increase in transfer payments will provide any appreciable gains in real income.

Per Capita Income, Oregon and the Four Counties 1976 to 1980

Year	$ Per Person				
	Oregon	Coos	Curry	Jackson	Josephine
1976	6,368	5,722	5,675	5,452	4,926
1977	6,982	6,418	6,256	6,035	5,503
1978	7,800	7,183	7,042	6,800	5,935
1979	8,615	7,974	7,662	7,461	6,424
1980	9,296	8,093	8,192	8,102	6,972

The following table displays payrolls by economic sector, for 1978 and 1983. Lumber and wood products comprises the largest share of payrolls in all counties except Jackson It is 40 percent of Curry County payrolls, and 34 percent and 28 percent of Coos and Josephine County payrolls, respectively. The proportion of total income in each sector, not surprisingly, is closely allied with employment by sector. Wood products also ranks high for individual employee income. It is the highest-paying sector in all but Coos County, where it is second to fisheries Coos County has the highest overall payroll levels (in agreement with the other income information). Curry County is below average in many of the sectors

Payrolls by County, by Sector, 1978 and 1983 1/

Sector	County/Year (M $)							
	Coos		Curry		Jackson		Josephine	
	1978	1983	1978	1983	1978	1983	1978	1983

DISTRIBUTION OF INCOME. The distribution of income is an indicator of a region's economic health and social structure. The following table displays the proportions of population in five income categories. Coos County has the lowest proportion in the lowest income category and is slightly ahead of the State in all but the highest income group. All of the other counties have higher proportions of low-income residents Josephine County, again, is the least well-off, with a full 38 percent of its residents earning less than $8,000 a year and only 9 percent earning above $25,000 (Kohl 1980)

Effective Buying Power Percent of Population in Each Income Class, 1978

	Percent of Population				
Income ($)	Coos	Curry	Jackson	Josephine	State
0- 7,999	24	27	28	38	25
8,000- 9,999	6	6	7	8	6
10,000-14,999	20	17	19	22	17
15,000-24,999	35	34	32	23	33
25,000-+	15	16	14	9	19

Josephine County also contains the greatest proportion of poverty population with 16 6 percent of its population below the poverty level, as opposed to the State average of 11 2 percent. Almost 12 percent of its population receives foodstamps as shown below:

Indicators of Poverty

	Percent		
County/State/Nation	Poverty Population 2/ (1970)	Recipients Rank	Food Stamp 1/ (1979)
Coos	10 1	32	7 6
Curry	13 2	14	5 4
Jackson	12 2	20	8 9
Josephine	16 6	2	11 7
State	11 2	--	--
Nation	13 0	--	--

COUNTY REVENUES

The Siskiyou contributes to revenues for four-county governments: Coos, Curry, and Josephine in Oregon, and Del Norte in California. The counties receive two types of payments.

Oregon and California (O&C) payments were established in 1937 to provide in-lieu-of-taxes revenue from lands repossessed by the Federal Government following a breach of contract by the Oregon and California railroad in 1916. Funds are generated by timber harvest on Bureau of Land Management (BLM) as well as National Forest lands. Counties involved receive 50 percent of sustained-yield timber revenues from all O&C lands in western Oregon O&C funds are also used by the agencies, in cooperation with the respective counties, for resource improvements on the O&C lands within their jurisdiction.

National Forest Fund (NFF) payments remand 25 percent of total Forest revenues to the States in which Forests are located. The payments are then delivered to the counties containing the National Forest lands and must be used for schools and roads as prescribed by the State.

The following table displays the NFF payments received by the counties from 1972 through 1983. The amount of these payments is determined by the bid price, and the amount of timber actually harvested in any given year. Since both bid price and cut volume are highly variable, payments to counties are also highly variable.

Payments increased throughout the 1970's, when timber bid prices were high and much timber was being cut Since 1979 they have fallen off dramatically. This is due to the decline in bid prices, and slowdown in timber harvest activity resulting in a decrease in timber revenues received by the Forest. Future payment trends depend, again, on resumed activity in the national housing market and the resultant creation of demand for stumpage.

Payments to Counties (NFF) in 1982 Dollars

Year	County (M $)			
	Coos	Curry	Josephine	Del Norte
1972	224,659	2,666,297	1,354,134	161,731
1973	297,263	3,543,566	1,789,668	213,905
1974	272,223	3,247,592	1,638,918	195,966
1975	223,087	2,661,412	1,343,098	160,595
1976	219,054	3,807,664	1,920,861	229,678
1977	430,007	5,133,715	2,588,924	309,556
1979	677,079	8,036,590	4,045,243	479,756
1980	383,768	4,555,403	2,292,841	271,922
1981	277,116	3,726,819	1,655,641	196,353
1982	85,040	1,009,452	508,078	60,256
1983	135,134	1,604,009	807,372	95,750

AREA LIFESTYLE

This section is a discussion of the lifestyles, values, and interests of the people living in southwestern Oregon.

The land manager is involved in reconciling and balancing social groups' demands and needs An understanding of the underlying forces which give rise to these needs and expectations can be a very valuable tool. Conflict over natural resources is social conflict The forest land manager can and does have a profound effect on people as well as the land. The use pressures on our natural resources are increasing. Social conflict over this use, and the need to recognize and deal with it, is here to stay

The social climate of southwestern Oregon can be described as extremely diverse, with some social cohesion at the local, city level, but little for the area as a whole.

Curry County can probably be considered the most socially uniform of the four counties in the area of influence. It is rural and conservative, with a majority of its residents conforming to traditional values and lifestyles. Coos County is somewhat more economically developed and diverse, and its residents tend to be slightly more socially diverse and liberal in their attitudes.

Both Jackson and Josephine Counties are composed of a number of very different groups of people. Each has significant alternative lifestyle communities, religious communities, and survivalist groups. Grants Pass, in Josephine County, hosts a very large population of retired people, who tend to be fiscally and socially conservative. Ashland, in Jackson County, is the home of Southern Oregon State College, the Oregon Shakespearean Festival, the State Ballet, and a large number of people aged under 40.

While the residents of southwestern Oregon are extremely diverse in terms of values, attitudes, and beliefs, there is one underlying lifestyle that is common to much of the area. This lifestyle is outdoor, natural resource-oriented. It is pursued in a variety of forms; for example: large scale wood products work, traditional and alternative forms of agriculture, forest products gathering, fishing, and commercial and noncommercial whitewater boating. Despite the variety of pursuits, there is a common theme that unites those involved. All are intimately connected with the outdoor environment and its resources for their economic well-being and/or leisure enjoyment. In order to appreciate exactly what the relationship between the Forest and local lifetypes and values are, however, it is necessary to consider a number of factors.

Despite its location, the Siskiyou is a relatively isolated Forest. The only major transportation route to pass through it is U.S. Highway 199, the Redwood Highway, for less than five miles There are no direct north-south routes. The only east-west route, the Bear Camp Road, is used primarily by Forest Service personnel and Rogue River guides and floaters. It is closed during the winter months, due to snow.

The Forest is similarly isolated from the local communities. BLM and private lands buffer the Siskiyou from populated areas on all sides. Thus, few community viewsheds are impacted by the Forest's management activities. Firewood, berries, ferns, and other products from the woods are generally available on other lands that are more convenient than the Siskiyou.

Terrain on the Siskiyou tends to be rocky and steep; many areas are covered with brush species that render off-trail hiking a near impossibility. The Forest contains few lakes, loop trails, or other day-hike destinations. Short duration recreational opportunities are much more abundant on the neighboring Rogue River National Forest. Because of its terrain, accessibility, and the availability of substitutes, the Kalmiopsis Wilderness is one of the least-used Wildernesses in the Nation. Most recreation takes place on or near the major rivers, which are rather unique in terms of whitewater experience. Another unique feature of the Siskiyou is its array of rare and unusual plants which provide an excellent opportunity for the area's surprisingly high number of professional and amateur botanists. The Forest also has large unroaded areas which are valued by many.

While southwestern Oregon residents exhibit a myriad of different lifestyles, one in general appears common to many residents and is particularly relevant to National Forest management It is what can be called a seasonal, outdoor lifestyle. It is subject to infinite variations, but essentially involves paid employment for part of the year--generally, the late spring-summer-early fall months--and involuntary idleness or living off the land in the remaining cold-weather months. During these months, many residents fill their time and supplement their lowered incomes with outdoor activities such as woodcutting, hunting, fishing, or crabbing. This lifestyle is related not only to the natural environment of the area, but to social forces, such as the economy and social heritage of the region.

Employment in the area has been previously examined. Four of the most important industries, i e., timber, agriculture, commercial fishing, and tourism, rely primarily on the mild weather and growing season months The rural tradition is a primary cultural factor which reinforces the seasonal, outdoor lifestyle This tradition, with its general orientation toward the land and the outdoors, make it seem natural to turn to the land and its resources to satisfy needs.

The seasonal, outdoor lifestyle has elements that crosscut different, sometimes opposing, groups of people; while many different people feel a commitment to the land and the outdoors in southwestern Oregon, they do so in different ways.

Major Values Relating to Resource. Values are very general, underlying beliefs or orientations toward objects, ideas, relationships, goals, etc. Since one's values are learned through social interaction with others from early childhood on, they tend to be held both widely and deeply within a given culture, and are very resistant to change. Because they are held so widely and deeply, they are often difficult to pinpoint They are usually expressed only as themes cutting across specific attitudes and actions, and may not even be apparent to those holding them.

These underlying values are expressed in specific attitudes and opinions which change with the movement of events and the passage of time. While by no means wishing to downgrade the importance of public opinion on the specific issues, it should be remembered that public opinion is very issue-specific, and that the issues change over time. If a social overview is to remain valid for a 5- or 10-year planning period and be applied to a succession of changing issues, it must dig to a deeper level, i.e., the underlying orientations, or values, of the people. Nevertheless, specific issues and controversies are valuable. It is in them that the deeper orientations and values are reflected. A more thorough discussion of this topic may be found in Peterson (1980).

At the very root of many conflicts regarding resource management are two fundamentally different conceptions of the relationship between humanity and nature The human-centered view assumes that humanity is the central reference point and that nature exists for society's use. Any part of nature that is not used is considered either irrelevant or wasted.

Those holding this view would be likely to favor intensive timber management and the liquidation of old-growth forests, and would be opposed to the expansion of wilderness (perceived as producing nothing for people)

The opposite perspective assumes that nature has inherent value in its own right. From this perspective, people are responsible for wisely using, conserving, and protecting the natural environment The proponent of this view is more likely to favor preserving stands of old growth for their own sake, eliminating use of chemical herbicides because of potential dangers to the environment, and protecting fish and wildlife habitat at the cost of reduced timber production.

This portrayal is necessarily over-simplified Rarely is either perspective consistently applied, rather, many intermediate views exist between the extremes However, identifying two essentially-distinct views enables us to follow them as themes that cut across many resource-related issues which are important to the economy and lifestyle of the area--and, hopefully can lead to a better understanding of the basis of many conflicts.

Changing Values. No one can predict with accuracy what a population's values will be for the next twenty years However, there are some trends in evidence that are likely to continue, barring unforeseen change. There are two ways in which the basic value orientations of an area's population can change· the same people may change over time, or new people may bring in new values. Both of these are taking place in southwestern Oregon.

Environmentalism, as a movement, has been gaining strength nationwide for the last decade, southwestern Oregon is no exception. This trend will likely continue. Concurrent with the growth in environmentalism, there is developing what can be called a backlash. Timber industry and other more business-oriented groups and individuals are becoming more focused and vocal regarding their interests. As these issues sharpen and more people realize that there are ever-greater pressures on public lands, there could be even further polarization.

This greater pressure on public lands stems from increased population pressure due to an influx of residents relatively new to the Forest influence area. There has been no work done on the value differences between new residents and those with longer histories and ties to the local area, but several characteristics can be inferred. First, the rise in the number of new residents has accompanied a decline in the timber sector employment. Additionally, no statistical relationship could be established between harvest levels and employment in the timber sector, and increasing numbers of new residents (Owen 1979).

New residents may either be retired or are finding work in sectors other than timber; consequently, fewer people have a direct interest in timber production.

Another aspect involving the growing number of new residents that may have important implications for the Forest Service is the particular location of population growth. If it occurs in rural areas, more people are likely to develop an interest in "what goes on in their own backyards." Forest management objectives and activities will acquire much more than an abstract significance. On the other hand, if new residents concentrate in urban areas the result may be increased demand for local outdoor recreation experiences.

In summary, it is unlikely that the Forest Service will enter a period of calm. If present trends continue, there will undoubtedly be a continuing increase in the diversity of values, lifestyles, and demands for forest resource use.

The Community Stability Issue. Forest planning has long recognized the issue of community stability, or a community's capacity to handle change without major hardships or disruptions to component groups or institutions The NFMA regulations also require that alternative management strategies be analyzed in terms of their impacts on affected communities.

In Region Six, most affected communities have generally been synonymous with a timber-dependent community. A timber-dependent community relies on the harvesting and processing of wood, especially National Forest timber, for much of its economic base. It follows that providing a consistent, sustained supply of National Forest timber would promote community stability.

Employment in the lumber and wood products sector, as previously shown, has been declining for the past several decades. Coincident with the employment decline in this sector has been the growth in population, employment, and incomes from other sectors of the local economy, including industries that benefit from resources such as clean water, scenic vistas, and recreational opportunities.

In-migrants in the survey conducted by Stevens (1980) found such things as recreational opportunities and air and water quality to be important in their decisions to move to this area.

The communities and counties in the Siskiyou's area of influence are economically dependent on the Forest for much more than its timber resource. The resource values of air and water quality, visual resources, and diverse recreational opportunities are, increasingly, economic, as well as social, values which are important to community stability.

Sustained growth in the area will depend on the quality of resource conditions as well as the supply of timber. The Siskiyou National Forest is in a position of contributing to community stability with all resource outputs.

The Forest interacts with its surrounding area economically by providing commodities (timber and fish) and an appealing environment to draw outdoor recreation-oriented tourists. It is one of many suppliers in this area Demand for these goods and services is affected primarily by nation-wide phenomena, such as conditions in the housing market, people's preferences for recreation, and the price of gasoline Therefore, the Forest's economic effects on its area of influence are also indirect. Changes in national economic factors cause a much more profound impact on the economy of southwestern Oregon than do changes in Siskiyou National Forest policies and programs.

PLANS, POLICIES, AND CONTROLS OF OTHER AGENCIES

County Comprehensive Plans. In 1973, Oregon instituted a State-wide land use planning system. The process of implementing this system was directed by a state commission - the Land Conservation and Development Commission (LCDC). LCDC was directed to develop and adopt State-wide Goals and Guidelines for management of lands, air, and water resources. Nineteen goals were developed and adopted and they have formed the foundation for all of the County Comprehensive plans prepared in the state. LCDC oversees the operations of the Department of Land Conservation and Development which, in turn, was responsible for working with all of the counties in the State to ensure that the State-wide goals were consistently applied.

All of the counties which include Forest land have either completed their comprehensive planning or have plans in the draft stage. These plans have been reviewed and the zoning designations on adjacent and intermingled non-Federal lands inspected for compatibility with the actions proposed in the alternatives In most instances, the zoning designations on adjacent and intermingled non-Federal land is for forest or agricultural management. These are broad designations which cover a wide variety of uses. None of the activities proposed in the alternatives are incompatible with these designations.

Coastal Zone Management Act (CZMA). In 1972, the Coastal Zone Management Act was passed, requiring that "Each Federal agency conducting or supporting activities directly affecting the coastal zone shall conduct or support those activities in a manner which is, to the maximum extent practicable, consistent with approved state management programs." (Subsection 307(c)(1) of the CZMA of 1972, as amended). Although Federal lands are excluded from the boundaries of the coastal zone, the "directly affecting" provision necessitates a consistency review be performed if the Federal action has significant off-site effects. The significance of the Federal action must be reviewed in terms of the primary, secondary, and cumulative effects on the Coastal Zone.

The LCDC has administered the Oregon Coastal Management Program (OCMP) since 1975. The Federal Government officially recognized and approved that program in 1977. The OCMP is based on the 19 State-wide Planning Goals, particularly the four coastal goals adopted by LCDC in December 1976: Goal 16, Estuarine Resources, Goal 17, Coastal Shorelands; Goal 18, Beaches and Dunes; and, Goal 19, Ocean Resources. These goals form the basis of County Comprehensive Plans; the Coastal Zone Management Program in Oregon is implemented through these county plans.

Portions of Oregon's coastal zone in Curry county has the potential to be directly affected by activities included in the alternatives. The activities: silviculture, including timber harvest, road construction, fish habitat improvement, wildlife habitat improvement; recreation development; land acquisition; and, mineral resource development. These actions can affect water quality, water quantity, aquatic resources, water aesthetics, and water surface area (page 17 of the OCMP). The alternatives include all of the above actions and effects. The coastal zone and estuaries on Del Norte and Coos Counties are far removed from the source of activities; the potential for adverse effects is negligible.

The coastal compliance portions of the Comprehensive Plans in the two Oregon counties have been acknowledged by the LCDC. These plans have been reviewed and the actions and effects predicted for the alternatives compared with them. At the programmatic level the alternatives are consistent with the

coastal portions of the county comprehensive plans. Some site-specific actions may have to be examined in more detail before a final consistency determination can be completed. Project implementing actions will be examined to determine if they have the potential to directly affect Oregon's Coastal Zone. If the directly affecting test is met, a site specific consistency determination will be made. This approach is consistent with the OCMP (page 44 of the Program).

SOCIAL AND ECONOMIC SUMMARY

The primary zone of influence of the Siskiyou National Forest consists of Coos, Curry, Jackson, and Josephine Counties. The area is primarily rural in character, although urbanization has been increasing and, most likely, will continue. The population is currently at approximately 270,000, and could reach 420,000 by the year 2000. Jackson County, with the city of Medford, is the most populous county; Curry County, the least.

In-migration has become a dominant force in the area's growth. It accounted for more than 90 percent of the population growth of Josephine County during the first eight years of the 1970's. In-migrants favor the area because of its high amenity and quality of life characteristics, i.e., clean air and water, the pace of daily life, and outdoor recreation. A significant proportion are retired persons. Employment opportunities and incomes are not the counties' main attractions.

A primary employer in the area is still the lumber and wood products industry, (with the exception of Jackson County which is more diversified and service-oriented). This industry accounted for 24 percent of total employment in 1978. Other important industries are agriculture and fisheries, in the coastal counties, and tourism. The area presently operates on a largely seasonal cycle, with the three primary industries most active during the summer months. Unemployment, which tends to be several points above the state average, worsens during the off-season. The trade, finance, communications, and transportation sectors have been gaining in importance and appear to be the region's keys to economic growth in the future.

Incomes in the four-county area tend to be low. Coos County leads the group in this parameter, just slightly below the State average. Josephine County exhibited the lowest median effective buying power in the State in 1978, and almost the highest proportion of population below the poverty line in 1970.

A predominant, though far from the only, lifestyle in southwestern Oregon can be categorized as "seasonal-outdoor." Many residents work part of the year and depend on outdoor activities, fishing, wood cutting, and gardening, to name a very few, for income or leisure time supplements.

This lifestyle is relatively dependent on natural resources and fosters two distinct and strongly-held value structures, which are of relevance to the forest manager. The human-centered view holds that man's relationship to nature is one of dominance, i.e., natural resources exist for man's use alone; to not fully utilize them is wasteful. The humanity-in-nature view holds that the natural environment has value apart from human use. These highly-polarized views, and the nearly infinite intermediate views, result in conflicting opinions on forest resource management issues.

Further pressure on resources, and increasing diversity of values, is likely to result from the in-migration of people who are either more economically aligned with amenity-based resources, or are retired-and are, therefore, not reliant on economic growth at all.

The traditional, implicit equation of community stability with health in the timber industry has expanded to include fisheries and tourism which require high quality resources such as water, air, visuals resources, and recreation. This formerly timber-dependent community is rapidly becoming forest-dependent, in a multiple-resource sense. The Siskiyou National Forest is in a position of being able to contribute to local community stability by responding to economic and social needs for a supply of many goods

The largest employers in the four-county area are the manufacturing industry (primarily wood and food processors), government, wholesale and retail trade industries, and the services industry. These industries provide 86 percent of the employment in the four-county area.

Economic activity in the Coos, Curry, Jackson, and Josephine County areas is affected by activity on the Forest. Some communities rely on a variety of Forest outputs for a significant portion of their economic activity.

Economic activities which affect local areas include logging, wood processing, Port-Orford-Cedar timber exports, river rafting, commercial fishing, sports fishing, hunting, camping, backpacking, and other forms of tourist activity. Employment and income data for these areas of the economy are summarized

Comparison of Economic Sectors in the Area of Influence

Aggregate Sector	No of Firms	Total Average Employment	Total Payroll (M $)
Forestry/Woods Products	404	12,100	274,500
Fishing/Hunting/Trapping	106	200	3500
Eating/Dining/Hotel/Lodging/ Amusement and Recreation	731	8,100	49,000
Mining	34	200	3000
(Transfer Payments/Social Security Payments, etc)			563,100
(Siskiyou National Forest/ Total Forest Budget)			15,800

The most important industries affected by the Forest are the forestry and wood products industry, the fishing, hunting, and trapping industry, the eating/dining industry, hotel and lodging, amusement and recreation industry, and mining industry. These industries employ approximately 21,000 people in the four-county area which represents 28 percent of the employed labor force. The forestry/wood products industry employ the largest number of people (12,100) and pay about 80 percent of the wages of the listed categories.

Transfer payments, including such items as social security payments, retirement incomes, and disability payments, are about double the amount of wages paid by all the listed categories. Most of this income is due to the large percentage of retired citizens who have moved into the area due to its attractions. These attractions are a low cost of living, low population densities, mild climate, and opportunities for outside activities such as gardening, fishing, firewood cutting, and motorized recreation. Primitive recreation opportunities such as backpacking and hiking are not major attractions for this expanding group of citizens

The Forest itself impacts the local economy with its employees, wages, and contracts. This impact is most dramatic in rural isolated towns adjacent to the Forest. A good example is the town of Powers, Oregon Here, the Forest Service is the largest employer in town and provides additional income through silviculture, recreational facilities, and resource enhancement contracts. The community stability provided by this income is an important consideration.

One other major industry is affected by the Forest - Marijuana. It is purported to be the largest cash crop of southwestern Oregon bringing in more dollars to the area than the timber industry This illegal crop is grown on public land where the risk of punishment due to discovery of growing plants is limited.

SOURCES OF DATA

Economic and social characteristics of communities and areas are related, but also exist somewhat independently, and are best examined through different means. Forest-related economic impacts are derived quantitatively, through use of IMPLAN (an input-output model) and FORPLAN, a linear programming model. Effects on local employment and incomes, are estimated with IMPLAN using outputs generated by the FORPLAN model and other predictive tools. Effects on local government revenues are also estimated, but this is done outside of the IMPLAN model. Forest-related social impacts are in part caused by these economic impacts. The latter are considered, along with other, more qualitative information on local lifestyles, attitudes, beliefs, values, and social organization in the social impact analysis.

ECONOMIC IMPACT MODEL

Overview. The IMPLAN input-output model was used to estimate the employment and income impacts of Forest outputs and activities on the local area. Direct, indirect, induced and total impacts were calculated.

Economic input-output (I-O) analysis is a procedure for describing the structure of inter-industry and labor force relationships, and predicting short-term impacts that result from changes in product supply or demand in one or more of these sectors. I-O analysis is based upon the interdependence of the production and consumption sectors in the impact area. Industries must purchase inputs from other industries, as well as primary sources, (i e. natural resources) for use in the production of outputs which are sold either to other industries or to final consumers. A set of I-O accounts can be thought of as a numerical "picture" of an impact area's economic structure.

Flows of industrial inputs can be traced via the I-O accounts to show linkages between the industries composing the economy. The accounts are also transformed into a set of simultaneous equations that permit the prediction of economic effects (employment and income) resulting from changes in Forest outputs and activities.

The National Model. The IMPLAN model has a data base consisting of two parts: (1) a national level technology matrix, and (2) a county-by-county file of estimated activity levels for total gross output, six components of final demand, three components of final payments, and employment for 466 industrial/business sectors.

The national technology matrix is based on a 1972 U S. Department of Commerce I-O model that was converted to an "industry by industry" basis and updated to 1977 using the RAS procedure (Clopper, Almon, et al., 1983. The county level information is based on a 1977 data set constructed by Engineering Economics Associates of Berkeley, California. The end product is a model that represents the structure of the economy in 1972, but uses actual data for prices and product output levels for 1977.

National Data Base Reduction to Impact Area. Utilizing the national technology matrix and the control totals for the local, multi-county impact area, a data reduction method was employed to develop a regional input-output table. The method used incorporates the property of "openness" displayed by regional economies in comparison with the National economy (Richardson 1972. Smaller, regional economies are less self contained, and hence are more "open" to import and export than the national economy Based on the assumption that trade balances are the principal difference between national and regional purchase

patterns (i.e, industry production functions are identical but regional imports and exports make local inter-industry transactions different), the supply-demand pool technique Schaffer, W A. and K. Chu. 1969) for data reduction was adopted.

Region Six Adaptation - Final Demand Expenditures. The I-O model translates NFS outputs and activities into employment and income impacts. An intermediate step in this process is the translation of NFS outputs (timber, range, recreation, etc.) into final demand dollars. Final demand expenditures are different from the "values" used in the cost efficiency analysis. Final demand expenditures represent the dollars spent by consumers to purchase the finished products that are made from NFS outputs. For instance, timber (a Forest output) is processed into lumber which is sold, as a final product, to consumers. The consumers' final demand expenditures represent the amount of new money that is directly input to the local economic impact area (under the assumption that most of the lumber is purchased by buyers who reside outside of the impact area).

This modeling step is accomplished by applying a final demand expenditure per unit of output to total outputs and linking the resulting dollar amount to the sectors in which the direct expenditure takes place This process determines the direct impact that can be expected to take place in the economy The IMPLAN model, through the inter-industry and labor force linkages, uses this information to compute the indirect, induced, and finally, the total impacts predicted to occur in the area.

Final demand expenditures for Oregon and Washington were developed by the Regional Economist and a team of Forest Economists, in 1984. Expenditures were developed by RIM activity and then allocated to each individual sector impacted, based on patterns established in studies specific to the activity, or assumptions about similar activities Expenditures are reported by RVD, using Region Six estimations of activity durations. Expenditure information is contained in the planning records on file in the Siskiyou National Forest Supervisor's Office, and in the office of the Regional Economist.

One important assumption of the model is that consumption occurs as predicted and that the other segments of the economy are static. Examination of this assumption with regards to timber outputs is revealing.

The amount of trees harvested on the Siskiyou National Forest is correlated with the number of jobs that is connected with harvest and processing. The IMPLAN model coefficients range in date from 1977 to 1984. Since that time there have been substantial increases in productivity of the wood products industry; the projections of the IMPLAN model may over-estimate the jobs associated with timber volumes. Though the nature of the relationship is evolving due to technological changes, a relationship still exists and is valid for relative comparison purposes.

In practice, examination of the historic sale amount reveals no apparent relationship between the Forest's allowable sale quantity and employment in the wood products' sectors. Due to the projected lack of timber available on private ground (Peinecke 1986), an assumption is made for future employment projections that the allowable sale quantity will be harvested at an average rate equal to its amount.

Base Year Alternative and Benchmark - Related Employment and Income. Forest outputs for the existing conditions and current direct alternative were determined and run through the I-O model to provide a base situation from which employment and income changes can be measured.

RETURNS TO LOCAL AND FEDERAL GOVERNMENT. Predicted returns to the U.S. Treasury and local governments were calculated for each alternative and benchmark. These returns illustrate the impact of management on both Federal Government receipts collected as a result of revenue-producing programs on the Forest, and the Forest's payments to local governments.

Returns to the U.S Treasury were calculated by deriving the revenue of income producing programs on the Forest which correspond to FSM 6531.12b "Annual Collections Statement," or the NFF. Total Treasury returns include revenues from timber, grazing, fuelwood sales, recreation, special uses, power, and mineral fees. Timber returns were calculated for each FORPLAN run from the net value of timber revenues All other returns are assumed to be constant at their base year level.

Resource	U S Treasury Returns (1982 MM $)
Timber	49 0200
Range	0017
Fuelwood	0496
Recreation	0743
Special Uses	0032
Power	0005
Minerals	0002

Returns to local governments are Treasury funds paid to the States of Oregon and California and passed on to local county governments. There are two types of payments to counties: NFF and O&C payments The NFF payments were assumed to be 25 percent of all commodity receipts except minerals where 50 percent of the receipts were paid to counties. The O&C payments were assumed to be 75 percent of gross revenues on the percentage of O&C lands managed on the Forest. These funds are paid to the State of Oregon who distributes them to the counties. Both funds are commonly referred to as payment in lieu of taxes.

Social Measures. Social impact analysis is the estimation of how Forest Service policies and actions affect the quality of life or social well-being. The analysis is accomplished by projecting future social conditions in an area influenced by Forest Service actions if current management were unchanged, then comparing this projection with conditions likely to occur as a result of implementing management alternatives.

Social measures include two aspects of social impact analysis· social variables and social zones of influence Social zones of influence identify who is affected by Forest Service activities, and social variables define how people are affected and the relationship between people and the natural environment The following describes the social measures and how they are used.

Social Zones of Influence. The following is a description of the groups of people or communities within the impact analysis area

LOCAL ZONE. The local social impact area was divided into four types of communities The first type of community is the urban service and government centers including Grants Pass, Coos Bay, and Medford. These cities, although still highly dependent on wood products-related employment, have other industries which are well developed and have been expanding. Industries such as electronics, other light manufacturing, wholesale and retail trade, and service sectors, provide nonresource oriented basic employment and incomes. They offer county and regional business, medical, and social services.

The interests of the urban community are diverse. Forest issues which may affect different interests of the urban community are timber outputs, primitive recreation opportunities, Wild and Scenic River recreation opportunities, motorized recreation opportunities, Botanical areas, hunting and viewing wildlife, mining opportunities, and interest in old-growth wildlife species.

Two predominant types of rural communities exist in the area. Eastside rural communities are scattered throughout Jackson, eastern Coos, and Josephine Counties. They include such towns as Selma, Kerby, Powers, and Myrtle Point, which are highly dependent on wood products and farming, and generally offer

few other employment opportunities and limited retail trade and services Residents tend to travel to the more urban centers for shopping, entertainment, medical care, and government services.

The interests of the rural eastside communities are timber outputs, motorized recreation, wildlife habitat primarily dealing with big-game hunting, and mining

The westside rural communities, such as Brookings, Gold Beach, Port Orford, and Bandon are larger and more diversified than the eastside towns. Wood products are important, but tourism, fishing, and agriculture also play major roles in their economies and lifestyles. These communities are located along the coast and are bordered by mountains to the east. Tourism and the relative isolation of these communities have promoted economic diversification and the development of retail, medical, and entertainment services.

The interests of the westside rural communities are related to timber outputs, river recreation, motorized recreation, primitive recreation, fisheries outputs, wildlife hunting and viewing, old-growth habitat, and mining opportunities.

Alternate lifestyle areas are found in the Illinois and Applegate Valleys of Josephine and Jackson counties. These areas, particularly the communities of Takilma and Ruch, were resettled primarily by younger people during the 1960's. Many of the residents gain income in nontraditional ways Takilma contains a cooperative forestry corporation which engages in tree planting and labor-intensive silvicultural management. Several organic food and herb growing and processing industries operate in the Applegate Valley.

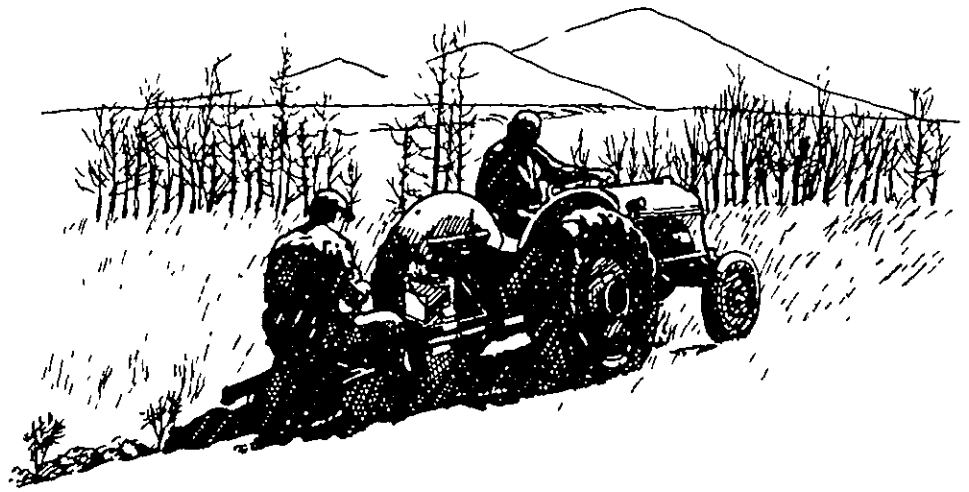
The interests of the alternate lifestyle communities are projected to be related to timber production, primitive recreation opportunities, river recreation opportunities, botanic areas, old-growth preservation and habitat, and mining opportunities.

NATIONAL ZONE The national zone of influence is not significantly affected in terms of response to changes in Forest outputs for a given level of management. For instance, a change in timber output would not significantly vary supply or demand on a national scale. However, changes in policy affecting resource values such as scenic quality, timber production, water quality, wildlife and fisheries management, and similar values will continue to draw attention from special interest groups at the state and national levels. This is evidenced in the presently by these interest groups' involvement in issues regarding allocations of roadless areas.

Social Variables. The following social variables are considered for each local social group. Disruptions due to change from the current situation result in economic dislocation and/or social change. This change can be estimated by examining changes in lifestyles, attitudes, beliefs, values, social organization, and land use patterns.

INFORMATION GENERATED FROM THE SOCIAL AND ECONOMIC IMPACT ANALYSIS

Chapters II and IV of the FEIS present the summary of the social and economic effects of alternatives A more detailed narrative of the findings is presented here. The modeling of economic impacts was derived from the generated changes in planned outputs compared to the current direction Alternative A. These changes were used as inputs into the IMPLAN model to determine **relative** (not absolute) changes in the economy due to direct, indirect, and induced effects. For example, a decrease in 1 MMCF of wood harvest would result in an estimated reduction of 91 jobs and $2,149,000 of income in all segments of the economy. One must emphasize these figures are only to be used for comparison between alternatives and should not be interpreted as absolute numbers of jobs and wages. The actual number of jobs affected and income



generated would depend on the economic adjustments needed in response to national markets, local labor supply conditions, and fluctuations in the local and national economy at one time and place

Employment and Income Response Coefficients by Resource

Output	Unit of Measure	Change in Employment (Jobs)	Change in Income (M $)
Roaded Dispersed Recreation	M RVD	1 3	20 9
Unroaded Dispersed Recreation	M RVD	99	14 5
Softwood Timber	M MCF	90 67	2,149 3
Big Game	M WFUD	1 1	18 8
Small Game	M WFUD	1 5	23 9
Nonconsumptive Wildlife	M WFUD	3 24	54 9
Freshwater Fisheries	M WFUD	1 23	19 6
Saltwater Fisheries	M WFUD	3 64	51 8

In general, alternatives which emphasize timber outputs tend to produce the most jobs, income, returns to the U.S Treasury, and payments to local governments. Timber receipts are the largest source of returns to the Treasury, local governments, and local economy. Recreational values tend to be constant from alternative to alternative due to the excess capacity of the Forest to supply present-day use

The anticipated social impacts of the alternatives can be compared by examining the degree of change from current outputs of commodities and amenities. In general, those alternatives which produce a large decrease in commodity outputs negatively affect the lifestyles, social organization, and attitudes of those who perceive the area as serving humankind's needs. Those alternatives which produce decreased outputs of nonmarket derived goods such as old growth, wildlife, and esthetically pleasing landscapes negatively affect the lifestyles, social organization, and attitudes of those who generally perceive nature as being preserved for its own value and economic benefits Conversely, increased outputs of desirable products would affect each group in a positive manner. The views are not mutually exclusive, as many people understand and accept both opinions.

ANALYSIS PRIOR TO DEVELOPMENT OF ALTERNATIVES

This analysis process included compiling data (i.e , issues, concerns, demand projections, the current situation assessment, etc.), and using the FORPLAN model to process or develop information on Forest output production capability, economics, and resource interrelationships During the analysis of the management situation, resource supply potentials were determined by establishing minimum and maximum production levels called benchmarks A point of reference was also defined (Base Runs) from which the costs and effects of applying regulation and policy constraints were measured Production capabilities were determined for single resources as well as for sets of multiple resource outputs produced in the most cost efficient way. This analysis established the benchmark levels required by National planning direction. Those benchmarks served as references from which the costs and effects of various objectives and constraints used in developing alternatives were evaluated

The benchmark analysis was performed prior to the formulation of alternatives and used the FORPLAN model. The purpose of the benchmark analysis was fourfold:

1 Estimate the schedule of management activities, resource outputs, effects, discounted benefits and costs, PNV, and acreages of prescription assignments appropriate to achieving the purposes of the benchmarks;
2. Define the resource production levels associated with maximizing single resource outputs,
3. Analyze the implications of legal and policy constraints.
4. Comply with the analysis of MR's of 36 CFR 219 27.

In order to fulfill these requirements, the Forest developed three types of benchmarks. These are:

1. Max PNV Benchmark. Maximizes PNV for the Forest and displays the associated resource outputs.
2. Resource Benchmarks. Defines the maximum potentials for timber production, fisheries, visuals, wildlife, recreation and unroaded areas
3. Min Level Benchmark. Defines the minimum outputs associated with custodial management of the Forest and the unavoidable costs and benefits of public ownership.

Several variations of the PNV and Resource benchmarks were analyzed to determine the opportunity cost and resource tradeoffs of meeting specific constraints, objectives, regulations, and policies. In addition to these requirements, all benchmarks were designed to be approximately implementable, were not constrained by budget, and used a maximization of PNV as the objective function to obtain comparable solutions

DEVELOPMENT OF MANAGEMENT REQUIREMENTS

In order to perform the stepwise analysis in the benchmarks, various sets of management requirements were modeled in FORPLAN to insure that the purposes of the benchmark analysis could be achieved. These management requirements are discussed in the following categories in this section: (1) MR's of 36 CFR 219 27; (2) timber harvest dispersion constraints, (3) timber policy requirements; and, (4) maximum resource output constraints. The management requirements were incorporated into FORPLAN in two ways First, many of the standards and guidelines for prescriptions were developed to include specific management requirements. These requirements are included in FORPLAN as cost and yield table variations reflecting management under these assumptions. Second, various management requirements were incorporated into FORPLAN by imposing constraints on the linear program. These constraints were used to insure that outputs, effects, and Forest conditions will be produced in the proportions required to achieve the particular purposes of a benchmark.

In linear programming analysis, constraints override the objective function Thus, if a predetermined level of outputs or minimum physical condition is entered as a constraint, it is always achieved (or no feasible

solution is found). In the design of the benchmarks, care was taken to insure that the various constraints or sets of constraints used constituted the most cost efficient method for attaining the desired results.

Following is a discussion of the management requirements used in the Siskiyou FORPLAN model

MANAGEMENT REQUIREMENTS OF 36 CFR 219.27 (MR'S)

The MR's are designed to meet the requirements of applicable laws and regulations, specifically those of 36 CFR 219.27. Many if these items were at one time refered to as Minimum Management Requirements (MMR's). A February 9, 1983 Regional Office memo on "Regional Guidelines for Incorporating MMR's in Forest Planning" fostered consistency among different Forests in the implementation of MR's Treatment of wildlife indicator species was further described by the Regional Office in a 1920 memo on April 16, 1984 Clarification of Wildlife MMR Direction. And finally, two documents were issued by the Regional Office in June 1986: **A Report on Minimum Management Requirements for Forest Planning on the National Forests of the Pacific Northwest Region, USDA Forest Service**; and **A Background Document on the Development and Review of Minimum Management Requirements for Forest Planning on the National Forests of the Pacific Northwest Region, USDA Forest Service**. Additional background information on the development of the MR's, and the tradeoff analysis done to assure that methods selected efficiently achieve the required condition, can be found in Appendix J.

The MR's included in this analysis are those that impose substantive standards, can be incorporated in the analysis, and are likely to have an impact on the analysis. There are many other requirements that the Forest Service must meet which are not discussed here including substantive requirements that do not have significant impacts when viewed on a Forest-wide scale, as well as procedural requirements Examples of substantive requirements that are not included in the modeling include those for cultural resources, and those for threatened and endangered species These requirements are part of the Standards and Guidelines in the LRMP; while significant in themselves, they do not have significant affects on the Forest-wide analysis and are not discussed here. Specific requirements and how they were modeled through cost and yield adjustments in the prescriptions, or constraints on the linear program, are discussed below.

Conservation of Soil and Water Resources. The basic soil, water quality, and water yield resources were protected by the application of: (1) specific management standards, guidelines, and practices integrated within management prescriptions, and (2) area harvest dispersion constraints in the FORPLAN model. This methodology provides a baseline necessary to protect the physical integrity of the land and water systems. Soil resources were protected by employing standards, guidelines, and practices within the management prescriptions, particularly those which allow ground disturbing activities (i.e., timber harvesting and road construction). Costs developed for the prescriptions allow for these mitigating practices.

Water quality resources were protected by a combination of standards, guidelines, and practices within the management prescriptions, and area harvest dispersion constraints in the FORPLAN model These measures were taken to minimize stream sedimentation, maintain stream water temperatures and minimize the occurrence of landslides. Costs and yields developed for the Riparian Management Area prescriptions allow for these practices. Area harvest constraints were also used to distribute timber harvest and road building activity around the Forest using planning basins as geographic locators within the model Timber harvest was limited to 20 percent of the suitable land base per decade by planning basin (see **TIMBER HARVEST DISPERSION CONSTRAINTS** in this section). These area constraints limit the acres of final harvest by basin to avoid concentrating landslides, hillslope erosion, and stream sedimentation inordinately within some drainages. These measures will also protect minimum viable fisheries populations on each watershed available for timber harvest on the Forest, and meet the general harvest dispersion requirements.

MINIMIZE HAZARDS FROM FLOOD, WIND, WILDFIRE, EROSION, OR OTHER NATURAL PHYSICAL FORCE. The Forest-wide management standards and guidelines incorporated in management prescriptions include the necessary mitigation and protection from the above hazards A floodplain assessment including a flood hazard analysis is required for any construction within the 100 year floodplain of streams and rivers Specific requirements are included which prevent the compaction and bare mineral exposure of the soil from timber harvest activities. Erosion control measures, such as grass seeding or mulching, are implemented on highly erosive sites. Costs developed for the prescriptions include allowances for such measures

Reduce Hazard from Pest Organisms. Activities to prevent conditions favorable to pest organisms are included in management prescriptions and Standards and Guidelines

Protection of Riparian Areas. Riparian areas are protected by specific management standards, guidelines, and practices within the management prescriptions (see the Riparian Management Area Prescriptions described previously in this appendix). All identified Riparian areas are managed to avoid stream water temperature increases, and protect riparian ecosystem resources. Riparian Prescription option B is the MR since vegetation removal above this level would result in detrimental changes in water temperature which are not allowed (36 CFR 219.27(e)). Timber harvest in Riparian areas is also dispersed in time and space by constraining first entry harvest to 11 percent per decade by planning basin

Diversity. Animal and vegetative diversity is currently very high and is well distributed on the Forest. Diversity is maintained through Standards and Guidelines and a combination of old growth maintenance in some areas with harvesting in others to regenerate the younger seral stages. A minimum of 15 percent of the Forest is maintained at any one time as old growth. This is modeled by constraining harvest on specific habitat areas in the FORPLAN model.

Adequate Fish and Wildlife Habitat to Maintain Viable Populations.

FISH. Requirements for fish habitat to maintain minimum viable populations is met by the application of requirements for riparian areas and requirements for soil and water described above, and by application of the Riparian Prescription option B which does not allow detrimental changes in water temperature.

WILDLIFE. One or more selected indicator species are used to represent wildlife species that have similar biological requirements. Seven species and one species group were selected as indicators. Species selected are either impacted by management direction, emphasized in Forest management, or endangered, threatened or sensitive. For instance, osprey, a species which could be affected by Forest management, was used as an indicator for riparian habitat along major river courses. Osprey nests are located and monitored to detect population changes Maintenance of viable populations of wildlife was a part of the design for management prescriptions As a result, all alternatives and benchmarks, except the No Change Alternative, maintain at least those minimums.

In the case of cavity nester habitat, we analyzed the snag data collected during our 1979 timber inventory. Natural background snag levels were calculated, and the values generated were used to estimate percent habitat capability for cavity nester populations in unmanaged stands. Information in the Blue Mountain and Westside Wildlife Habitat Guidelines (Thomas 1979, Brown 1985) were used in determining habitat needs and rating habitat capability for woodpecker populations on the Siskiyou (and therefore for cavity nesters in general). Averaged plot data from the Siskiyou's 1979 timber inventory showed that unmanaged stands contain approximately 2 65 snags per acre, regardless of whether the stand is immature or mature/old growth (counted snags were at least 10 inches DBH and 15 feet tall).

The present Siskiyou Wildlife Tree (Snag) Guidelines are designed to maintain woodpecker populations at 60 percent of maximum habitat capability in managed stands The MR level to maintain viable populations of the indicator species-group (woodpeckers) for this habitat is 20 percent of maximum habitat

capability. Application of the snag guidelines (60 percent level) reduces timber yields of managed stands by less than one percent and has even less effect on current harvest levels. The minor reduction in yield expected from managed stands is built into the timber yield tables used in FORPLAN

Three wildlife indicator species (spotted owl, pine marten, and pileated woodpecker) have optimum habitat in mature or old growth ecosystems; an involved procedure was used in the development of their MR's A series of Washington (WO) and Regional Office (RO) documents have guided our interpretation of MR's for these species:

1. February 24, 1982. WO 2620 Wildlife and Fish Viable Populations in Forest Planning, by J. B Hilmon
2. February 9, 1983. RO 1920 Regional Guidelines for Incorporating MMR's on Forest Planning, by J Sirmon.
3. April 16, 1984. RO 1920 Clarification of Wildlife MMR Direction, by J. Sirmon. (Based in part on results of Westside Cascades Wildlife Zone Coordination meeting in Eugene, December 5-6, 1983.)
4. June 1986. (RO). A Report on Minimum Management Requirements for Forest Planning on the National Forests of the Pacific Northwest Region, USDA Forest Service.
5. June 1986. (RO). A Background Document on the Development and Review of Minimum Management Requirements for Forest Planning on the National Forests of the Pacific Northwest Region, USDA Forest Service.
6. July 1988. (WO). Final Supplement to the Environmental Impact Statement for an Amendment to the Pacific Northwest Regional Guide, Spotted Owl Guidelines. USDA Forest Service.

These documents form the basis for the Siskiyou's approach to providing well distributed habitat for indicator species inhabiting mature or old-growth forest. For each species, the scheme provides enough well distributed habitat to maintain the Siskiyou's portion of a Region-wide viable population (western Washington and Oregon, plus northwestern California).

The objectives for our approach were: (1) provide enclaves of mature and old-growth habitat throughout the Forest for indicator species, and (2) minify the effect of the scheme on commercial forest land A composite habitat network was developed for spotted owls, pileated woodpeckers, and pine marten. Three steps were used in the selection of required habitat areas. First, dedicated areas were used as the initial building blocks (Wildernesses, RNA's, Wild and Scenic River corridors). Second, additional mature and old-growth sites were located in areas unsuitable for timber harvest (forest regeneration or soil stability problems). As the last step, remaining required habitat enclaves were selected from commercial forest land; whenever possible, we utilized sites with other current or proposed land assignments (such as visuals, RNA's, Botanical areas, etc.).

In February 1984, a "first cut" mockup map of potential habitat enclaves for spotted owls, pileated woodpeckers, and pine marten was put together. The map was shown to various Forest Service personnel, they agreed that the concept was sound and met the intent of Washington and Regional Office direction. Concurrently, a prescription was developed to provide management direction for these mature and old-growth habitat areas. In March 1984 the MR map was presented at our annual meeting with the Oregon Department of Fish and Wildlife in Roseburg, and at a Forest staff meeting. In April three news releases were prepared on mature and old-growth indicator species and the MR concept. During May 1984 the Forest Wildlife Biologist coordinated with district personnel in selecting actual habitat enclaves for the network. Habitat areas were selected which had the least impact on commercial forest land and the five year timber action plan, and still met the requirements of the network. During July through September 1984 the network map was revised to take into account site-by-site concerns of district personnel. In 1987, as part of the analysis process for the Supplement to the Environmental Impact Statement for an Amendment to the Pacific Northwest Regional Guide (Spotted Owl Guidelines), personnel from the Regional Office conducted a formal review of the Siskiyou habitat network; minor revisions were made to the network Copies of the network (MR) map have been given to representatives of forest industry, environmental groups, and others who requested them.

The network of mature and old-growth habitat enclaves established to meet wildlife MR's has been closely coordinated with managers of adjacent public lands: Rogue River National Forest, Klamath National Forest, Six Rivers National Forest, Medford District BLM, Coos Bay District BLM. The Siskiyou's habitat enclaves interlock with theirs.

A minimum network for mature and old-growth indicator species on the Siskiyou requires approximately 92,000 well dispersed acres; this includes 36,712 acres of commercial forest land. An additional 67,862 acres of mature/old-growth habitat not needed for the minimum network exists in Wildernesses, this means that approximately 160,000 acres are actually available to the three indicator species as part of the MR network. Acre figures listed in this paragraph and the following two tables reflect minor changes made as a result of the 1987 Regional Office review Although in the FEIS only Alternative S includes the revised acre figures, they would be incorporated in any alternative developed for implementation in the Forest Plan

The following data show mature or old-growth Forest habitat acres needed to meet MR's for spotted owls, pileated woodpeckers, and pine martens on the Siskiyou National Forest It does **not** include "extra" mature/old-growth habitat present in Wildernesses which is not actually required for a minimum network.

	Indicator Species 1/			
Land Category 2/	Spotted Owl	Pileated Woodpecker	Pine Marten	Total
Number of Pairs Supported	47	63	85	-
Acres*				
Unavailable	19,000	5,700	3,882	28,582
Unsuitable	5,142	12,862	8,789	26,793
Tentatively Suitable	24,935	6,349	5,428	36,712
Total	49,077	24,911	18,099	92,087
Percent of Total.				
Tentatively Suitable	4.0	1.0	0 8	5 9
Tentatively Suitable, but Under Other Land Assignments per Current Direction (Estimated)	2.0	0.5	0 4	3 0

1/ Pileated woodpeckers utilize spotted owl habitat Pine martens utilize pileated woodpecker and spotted owl habitat However, acres and numbers of pairs are not double-counted in this table

2/ Unavailable = Wildernesses, RNA's, Wild Rivers; Unsuitable = Areas unmanageable for timber production because of soil instability or forest regeneration problems; Tent Suitable = Areas otherwise tentatively suitable for timber harvest Many acres in this category have restrictions in land use (VQO's, recreation sites, etc)

The following table shows the combined mature or old-growth Forest habitat acres needed to meet MR's for spotted owls, pileated woodpeckers, and pine martens; **and** the additional habitat (Mature/Old-Growth) in Wildernesses not actually needed for a minimum network.

In this table long-term habitat capability for spotted owls is 62 pairs; the Spotted Owl SEIS lists the Siskiyou at 71. The Forest Plan Preferred Alternative (S) shows 75 pair over the long term (see Table II-48); this is because Alternative S contains slightly more habitat outside of wildernesses than needed to meet Minimum Requirements This table ONLY reflects habitat needed to meet MR's (in this instance MR habitat is defined as ALL acres in areas otherwise unsuitable for timber management, plus 37,000 acres of land otherwise suitable for timber management). The 62 pairs also reflects the Siskiyou's list of named and numbered habitat areas, while the 71 pairs listed in the SEIS analysis were calculated from figures based on gross acres of habitat. The 62/71 difference comes mainly from calculations of habitat capability for wildernesses, and the two numbers represent a reasonable "range" for long-term habitat capability of spotted owls on the Siskiyou National Forest.

Land Category 2/	Indicator Species 1/ Spotted Owl	Pileated Woodpecker	Pine Marten	Total
Number of Pairs Supported	62	63	85	-
Acres

Total	102,982	38,868	18,099	159,949
Percent of Total				
Tentatively Suitable	4 0	1 0	0 8	5 9
Tentatively Suitable, but Under Other Land Assignments per Current Direction (Estimated)	2.0	0.5	0 4	3 0

1/ Pileated woodpeckers utilize spotted owl habitat Pine martens utilize pileated woodpecker and spotted owl habitat However, acres and numbers of pairs are not double-counted in this table
2/ Unavailable = Wildernesses, RNA's, Wild Rivers (not all of this habitat is needed to meet MR's, but total acres of this land category are shown); Unsuitable = Areas unmanageable for timber production because of soil instability or forest regeneration problems, Tent Suitable = Areas otherwise tentatively suitable for timber harvest Many acres in this category have restrictions in land use (VQO's, recreation sites, etc)

Two options were considered for managing enclaves of mature and old-growth habitat in commercial forest land: designation (allocation) and rotation. Habitat for wildlife species dependent on mature or old-growth Forest can be provided through two modeling methods:

1. *Designation of suitable habitat areas where timber harvest will not be allowed, or*
2. Projection of long rotations on enough acres to maintain the necessary habitat through time, with all areas being rotated

For this planning period, habitat areas will be ***designated*** *(not rotated) for the three indicator species. For* the current planning effort on the Siskiyou National Forest, designation of suitable areas would have the least impact on the timber harvest schedule and would be the most efficient for implementation and record keeping. The following provides the rationale supporting the designation conclusion.

The Siskiyou is a deficit inventory forest. Per acre volumes projected for managed stands are higher than the volumes inventoried in existing stands. To manage habitat on a rotated basis, existing stands would be protected until replacement areas could provide suitable habitat. The minimum time required to produce mature forest habitat is 100 years. At that time the replacement area would contain more volume than the original habitat area, according to our yield estimates. Rotating the areas would result in less timber yield than harvesting the replacement area and leaving the original area to continue providing habitat. This is demonstrated by the following comparison of the empirical yield table volumes after 100 years with the volumes from the intensive managed yield tables at age 100:

Site	Volumes After 100 Years Empirical (MCF)	Managed (MCF)
High	9 226	11 830
Medium	5 049	9 704
Low 1/	3 687	3 225

1/Low site would not provide mature Forest habitat at this age

The implications for LTSY present a different picture in that the mean annual increment (MAI) would be higher for the areas managed for mature forest habitat. The following figures present the MAI's for the

intensive General Forest at 95 percent of culmination, Spotted Owl Areas at age 300, and mature forest habitat at age 140 Also presented are per acre PNV's for General Forest and mature habitat regimes

	MAI's (Cubic Feet)		
Site	(100) General Forest	(300) Owl	(140) Mature Habitat
High	127 5	76 4	141 4
Medium	114.3	57 9	124 0
Low	34.3	19 6	37 9
Per Acre PNV (bare land)·			
High	-142 84		-386 30
Medium	-214 09		-427 70
Low	-331 94		-457 25

In the case of spotted owl sites, long run timber yields would be impacted the least by dedicating existing habitat areas (no designated replacement areas). This is because more volume could be produced if the acres planned for replacement areas (two acres per each existing habitat acre) are allocated to General Forest (100 year rotation), than if these acres plus the existing habitat are allocated to a rotation for spotted owls (300 years). In the case of mature Forest habitat, the long run timber yields would be higher if the areas are rotated. However, per acre PNV suffers a 170 percent loss relative to General Forest while yields increase only 11 percent. The key points here are:

1 Modeling these areas as designated for this planning period does not preclude future planners from identifying replacement areas as substitution opportunities can be identified (i.e., some existing pole stands could be substituted for originally designated areas by the 5th decade).
2. Whether areas are modeled as designated or rotated, there is essentially no difference in implementation for the first planning period.
3. With the volume projections higher in the managed stands than the existing, the timber outputs will be as great or greater for the first 8 or 9 decades if areas are designated, instead of rotated

Designation concurrently results in savings in mapping, record keeping, monitoring, and FORPLAN analyses.

The word "designated" carries the connotation of permanency, i.e., as with Wilderness, Wild and Scenic Rivers, RNA's, etc. designated by the Chief or higher authority. Although these habitat enclaves are allocated to Designated Wildlife Habitat (Management Area 8), these areas can be adjusted, or substitutions made, in future planning efforts

Forest Service wildlife biologists realize that perceived habitat needs for mature/old-growth species may change based on research now in progress. For the next 10 to 15 years the Siskiyou will maintain the option to increase the size and number of habitat enclaves for spotted owls. Additionally, the Siskiyou network of habitat areas for spotted owls was developed using standards and guidelines described in the Supplement to the Regional Guide ("Spotted Owl SEIS"); these standards and guidelines will be evaluated five years after implementation of the Final SEIS At the present time the Siskiyou has approximately 393,000 acres of old-growth habitat suitable for spotted owls (and approximately another 50,000 acres of mature forest), under most alternatives, not much over 50,000 acres of mature and old growth forest would be harvested in the next ten years There will be a monitoring plan in place which will be used to evaluate the influence of the Forest Plan on habitat for indicator species; adjustments in the Plan can be made if necessary

Road Construction Standards. Access roads are necessary for efficient timber harvest and management of the Forest Road standards are determined from several sources to ensure that they are appropriate

to the planned uses, considering safety, cost of transportation, and effects upon lands and resources. Costs commensurate with these standards are included in the roading costs of the prescriptions, and capital investments scheduled for each FORPLAN run depending on the objective of the run (or theme of the alternative) and the level of activity projected.

The purpose or objective identified for the road determines the amount and type of traffic expected or to be managed and the safety requirements for planned users. Economic considerations help identify standards for lowest construction, user costs, and maintenance of the road Resource prescriptions identify standards such as avoiding meadows for wildlife or special water protection needs to meet the prescription or to mitigate adverse effects on the resource. The known physical land and weather features help set standards such as road surfacing depths and subsurface drains to protect the road structure both during use and when not being used.

Specific road standards involve the clearing width, the width of the driving surface, the sharpness of curves, road grade, cut and fill slope steepness, surface drainage and cross drain requirements, and amount and type of surfacing

Clearing limits are normally five feet beyond the top of the road cut to the toe of the road fill Special project or site requirements may adjust these requirements.

The width of road and sharpness of curves is primarily determined by the type, amount, and speed of planned traffic. The minimum single lane driving width is ten feet; however, equipment requirements usually dictates a minimum twelve foot width with fourteen feet being the common width for safety. Turnouts of six to ten feet width for passing are added as required for safety. The minimum curve is a fifty foot radius with larger radii designed for special equipment and for higher speeds. The minimum curve radius is used as a check since the free flow alignment design being used does not result in true geometric curves. Curve widening is designed as needed based on approximate radius, equipment needs, and length of curve.

The grades of the road vary by planned future use. Roads maintained for passenger cars have a maximum 12 percent sustained grade with pitches to 18 percent. Roads not planned for use by passenger cars have maximum grades up to 18 percent and may exceed this when justified. Pitches over 18 percent are exceptions. The steeper grades are used to reduce costs, but the resulting shorter road can benefit wildlife and reduce visual impacts. The impact of steeper grades can adversely affect soil and water if not properly mitigated.

Surface drainage and cross drain designs, along with revegetation measures and control of the construction period, help to maintain water quality and reduce damage to fisheries by limiting the amount of sediment that enters the streams. Paving, additional riprap in ditches and slopes, energy dissipation at culvert outlets, pit run or larger crushed rock surfacing, and additional culverts are procedures used to reduce erosion and sediment movement. A major part of road maintenance is to assure that drainage features are operating as designed or to improve on the drainage designs.

Surfacing of rock or asphalt is placed on the driving road width for various reasons. Some of these reasons are to provide access when the ground is saturated with moisture or provide support to heavy machinery on soils with low bearing strength, to protect the road surface from erosion caused by surface water flow, and to provide a cushion on very rough subgrade materials.

Temporary Roads. Temporary roads are short term (normally less than one year) structures used to harvest timber, control fires, or complete a project activity. Permanent structures such as retaining walls, and materials not easily removed such as asphalt pavement, are normally not proper for these roads Following use, the roads are treated to, as much as practical, return the land to the original condition. Such roads are planned and designed to re-establish vegetative cover on the disturbed area within a reasonable

period of time, not to exceed 10 years after the termination or contract, lease or permit. The treatment normally includes removing culverts and establishing water bars, ripping the surface to loosen the soil, and establishing vegetative cover by seeding or planting. The costs developed for the prescriptions include these activities.

Maintaining Air Quality. This requirement was handled outside of FORPLAN. The Regional Guide directs the Forest to work through cooperative agreements with the States to manage smoke emissions Scheduling the time and number of prescribed burns is done outside the FORPLAN model and in cooperation with the State of Oregon.

Reforestation. In order to have reasonable assurance of regeneration in five years, seedlings are planted on most harvested areas. Planting occurs because of the long periods between cone crops, insect effects on seed viability and seedlings, and the intensity of competition that occurs if the seedlings are preceded by other species of vegetation. The stocking rate varies to provide flexibility for establishing the optimum stocking level needed to capture the growth potential over widely varied site conditions. Site preparation is required in most cases because native conifer species cannot grow efficiently if existing vegetation competes for soil nutrients, water, and sunshine. Reforestation is included in the prescriptions with timber harvest as a management practice.

Sixty Acre Clearcut Limit. Clearcutting is one silvicultural system used on the Forest for even-aged timber harvest. The Regional Guide establishes that the openings created by even-aged silviculture normally will be 60 acres or less. Costs and practices used with clearcutting are based on units of 60 acres or less and are included in the management prescriptions.

TIMBER HARVEST DISPERSION CONSTRAINTS

The objective of timber harvest dispersion is to disperse activities over time and space, to reduce the potential for landsliding and sedimentation, and detrimental effects to the beneficial uses of water. The constraints were formulated to limit the acres harvested in a planning basin in any decade. The timber harvest dispersion constraints are also known as the *basin constrains*. As discussed earlier, the constraint set at 20 percent was identified as the minimum necessary to achieve the MR's for watershed and fish habitat protection. This also provides flexibility to comply with the opening size and dispersal requirements of the Regional Guide. The ID Team developed discretionary options for the harvest dispersions constraints that are specific to each planning basin. These optional discretionary constraints are evaluated through the range of alternatives The basin constraints applied to each alternative are shown in Table II-3 of the FEIS.

The only identified opportunity cost of tightening the dispersion constraints is a reduction in timber harvest level. The timber harvest dispersion constraint has a nonlinear relationship with timber production; as it is made more restrictive, it becomes increasingly more binding on timber production. In the range around 20 percent it somewhat disperses harvests between the basins, but has little effect on Forest-wide timber outputs With average rotation lengths of 90 to 100 years, allowing harvest of 20 percent of the suitable land base per decade leaves the flexibility to maximize (or nearly so) timber outputs Tightening the constraint from 20 to 16 percent results in less than one percent change in the ASQ. It becomes more binding between 16 and 10 or 11 percent, as optimum scheduling options are eliminated. The relationship would become nearly linear if the constraint were made tighter than 10 or 11 percent on all basins, each percentage reduction would directly reduce the total number of acres that could be harvested Forest-wide In other words, above 11 percent this constraint distributes the harvest across the Forest and, while it does become limiting as it approaches 11 percent (it becomes a cap on harvest acres below that), it has little effect on total timber outputs at the MR level of 20 percent.

The ID Team ranked the planning basins based on past harvest activities, geologic hazard, recovery potential, and beneficial uses. An index was then used to adjust the harvest constraints to fit the specific

conditions of individual planning basins. The initial analysis arranged the basin constraints around 11 percent and resulted in constraints ranging from 9 to 13 percent of the suitable acres for individual planning basins. These are used in a number of the alternatives, including Alternative K which was the Preferred in the DEIS.

Based on the information contained in the DEIS and associated process records, several individuals and organizations commented on the use of these constraints in the analysis, suggesting that they go beyond the original objective of dispersing activities, arbitrarily limiting timber harvest. Additional analysis indicated that the constraints were more binding on timber than originally thought (due to changes made in the FORPLAN model). The ID Team developed another set of constraint coefficients with more refinement ranging from 7 to 17 percent, but arranged around 15 percent as the initial point. These constraints also include some adjustment based on the watershed recovery needed after the 1987 fires. This set of constraints is evaluated in Alternative S in the FEIS.

More detailed information on the timber harvest dispersion constraints is located in the Planning Records.

TIMBER POLICY REQUIREMENTS

Nondeclining Yield (NDY). A constraint on timber outputs which limits the per period harvests to levels greater than or equal to the preceding period level, and less than the LTSY level.

Sequential Upper and Lower Bounds and Harvest Floors. In lieu of the NDY constraint on timber outputs, Sequential Upper and Lower Bounds and Harvest Floors were used to constrain the fluctuation of harvest to reasonable levels in specific benchmark runs. Floors were to establish a lower limit on timber harvests which would invoke substantial change in local consumptive patterns. The initial floor was calculated at 80 percent of the base harvest level (190 MMBF), or approximately 150 MMBF. This is equivalent to the floor of 28 MMCF used in the model. A ceiling or upper limit on harvest level was not used because the market area for the Siskiyou National Forest has the capacity to absorb any level of outputs expected from the FORPLAN model.

Long-term Sustained Yield (LTSY). For departure runs, LTSY was constrained to be equal to or greater than the LTSY of the base run.

Culmination of Mean Annual Increment (CMAI). 36 CFR 219.16 (2) (iii) directs the Forest Service to timber rotation lengths based on the time required for stands to reach the culmination of net growth. Unless specifically analyzing an exception to this requirement, all prescriptions are constrained to not allow final harvest prior to stands reaching 95 percent of CMAI. This sets the minimum age when harvests could occur.

Timber Rotation Lengths Based on Utilization Standards. In order to evaluate the effects of timber rotation lengths constrained by CMAI, rotation lengths based on Regionally proposed utilization standards were used to determine what, if any, change in timber harvest levels or PNV could be attributed to the more constraining CMAI levels.

BENCHMARK ANALYSIS

Resource supply potentials were determined by establishing minimum and maximum production levels called benchmarks. A level (Base Run) was also established from which the costs and effects of applying regulation and policy constraints were measured. Production capabilities were determined for single resources and for a set of multiple resource outputs that maximized PNV. This analysis established the benchmark levels required by NFMA (36 CFR 219.12(e).

BENCHMARK LEVELS

Nine benchmark levels were developed to define resource supply potentials and economic relationships on the Forest. Production capabilities were determined for a minimum level, for single resources and for a set of multiple resource outputs that maximize PNV. A level was also established from which the costs and effects of applying regulation and policy constraints were measured. The FORPLAN model was used to determine the resource supply potentials.

The benchmark levels and results are summarized in this section. A detailed discussion of benchmark descriptions and results follows in the next section of this chapter.

BENCHMARK CONSTRAINTS AND REQUIREMENTS

Regulation and policy constraints applied to benchmarks have, in most cases, the effect of reducing the maximum resource supply potential. NFMA (36 CFR 219.27) specifies that certain MR's be included in the planning process. The methods to meet these MR's include developing standards, guidelines, and appropriate management practices for inclusion in multiple-use management prescriptions; assignment of management prescriptions and intensities containing specific practices to analysis areas in FORPLAN; and applying specific constraints in FORPLAN.

The MR's used in this analysis are designed to:

- conserve soil and water resources.
- minimize serious or long-lasting hazards from flood, wind, wildfire, erosion or other natural physical forces.
- reduce serious, long-lasting hazards or damage from pest organisms
- protect Riparian areas.
- maintain diversity of plant and animal communities.
- provide adequate fish and wildlife habitat to maintain viable populations
- conform with multiple-use laws.
- prevent the destruction or adverse modification of critical threatened and endangered species habitat.
- provide for utility and transportation rights-of-way corridors to avoid adverse resource impacts
- ensure roads are designed to standards appropriate to planned uses.
- revegetate temporary roads within ten years
- maintain air quality.
- assure that cuttings are made in such a way that lands can be restocked within five years after final harvest.
- adhere to clearcut size limits.

Except for the Min Level Benchmark, the resource supply potential benchmarks described below were constrained as follows:

- all benchmarks complied with MR's.
- an ending timber inventory constraint was used so that the timber inventory in 150-years will equal or exceed the volume that would occur on a regulated forest.
- timber rotation length was based on 95 percent of CMAI determination.
- a timber harvest flow constraint of nondeclining yield was used.
- an objective function of maximizing PNV was used.
- a minimum level of the existing Wildernesses was maintained in all benchmarks
- the Min Level Benchmark was constrained to produce no management outputs such as timber harvest and livestock grazing to determine the basic cost of Federal ownership.

BENCHMARK DESCRIPTIONS

MAX PRESENT NET VALUE

This benchmark established the mix of resource uses and schedule of outputs and costs that maximized PNV using market and nonmarket assigned values. It is displayed in order to provide a reference point to compare other benchmarks and alternatives to the maximum PNV potential considered, and thus to assess opportunity costs.

MAX TIMBER

The maximum legal capability of the Forest to produce timber was determined by this benchmark. Timber production was maximized in the first decade; for fifteen decades; then "rolled over" under a "Maximum PNV" objective function.

MAX VISUALS

The purpose of this benchmark was to analyze the potential for producing other resource outputs and services while meeting all of the inventoried VQO's on the Forest.

MAX UNROADED

This benchmark was designed to analyze the potential for producing other resource outputs and services while maintaining all presently unroaded areas in their unroaded condition.

MAX RECREATION

This benchmark determined the potential for utilizing all of the primitive ROS classification on the Forest Recreation was maximized by assigning all inventoried roadless areas to an unroaded status and allocating 25 Supplemental Resource Management Areas to a dispersed recreation emphasis.

MAX FISH AND WATERSHED

The purpose of this benchmark was to establish the highest reasonable level of anadromous fisheries outputs. Management that was designed to improve overall watershed conditions was also included in this benchmark

MAX WILDLIFE

This benchmark was designed to maximize biotic diversity in an attempt to achieve a desirable mixture of wildlife habitats. This benchmark emphasizes a balance of all habitat types

MIN LEVEL

This benchmark defined the minimum costs of public landownership and the resource outputs which are incidental to Forest management. This benchmark served as a reference point to develop or test alternative outputs and costs which result from Forest Service management activities. This benchmark is displayed in this FEIS when a comparison of alternatives is made in order to provide a reference to the minimum level considered

CURRENT DIRECTION

This benchmark defined the level of goods and services that the Forest could produce if current management direction is followed with no budget constraint, and the most likely amount of goods and services expected in the future.

Tables B-5 and B-6 summarize the results of the eight benchmarks developed in the analysis of the management situation.

Table B-5. Land Assignments by Management Area for Benchmarks

1/ Recreation/Administrative sites and road acreage are included in General Forest.
2/ Wildlife MR's in Unavailable (i.e. Wilderness) lands are 96,602. Total acres Forest-wide are 160,000.
3/ Wild River acres not included are 12,459 with 3,280 acres Botanical included. Total Wilderness acres are 232,495.
4/ Botanical acres in Wilderness and Wild River are 3,408. Total Botanical acres are 4,475.
5/ Botanical acres included in Wild River acres (128). Unavailable acres in designated rivers total 17,758; (14,495 in Wild, 386 in Scenic and 923 in Recreation rivers). Wildlife MR acres in Scenic are 1,255 available suitable (454 unsuitable) and 225 available suitable (20 unsuitable) in Recreation rivers. Wildlife MR's, visuals, etc. areas reduce acreage of tentatively available/suitable/unsuitable acres in Scenic/Recreation rivers from run to run. Total designated River acres are 26,680.

1/ These decades represent an average annual output or effect for their 10-year periods.
2/ Total miles completed by the end of Fifth Decade or sooner.
3/ The method of calculating WFUD's was changed and corrected between draft and final for alternatives, but not for benchmarks.

The following tables display PNV's and discounted benefits and costs for the benchmarks by major resource Timber is the main component of PNV and discounted costs and benefits Recreation is the next major component of all three economic variables. The fisheries resource contributes the next greatest amount to PNV and total discounted costs and benefits. Wildlife is approximately 5 percent of PNV in all benchmarks. Wilderness accounts for less than 2 percent of all three variables in all of the benchmarks.

PNV, Discounted Benefits, Discounted Costs, by Major Resource, by Benchmark *1/* (MM $, Discounted at 4 percent for 15 periods)

	Discounted Benefit (MM $)					
	PNV	Timber	Recreation	Fish	Wildlife	Wilderness

BENCHMARK RESULTS

Modeling assumptions and environmental consequences associated with each Benchmark are discussed in this section. FORPLAN specifications for the benchmarks and runs designed to evaluate constraints are displayed in Table B-7 which precedes this section.

MIN LEVEL BENCHMARK

Purpose.

The Min Level Benchmark is a determination of the custodial costs and resulting incidental outputs necessary to maintain the Forest, subject to certain environmental constraints and an obligation to the protection of life, health and safety of the casual visitor. The objective of this benchmark is to minimize cost while meeting limited public ownership obligations.

Assumptions and Modeling Constraints.

- the minimum management level prescription was selected for all analysis areas.
- costs reflect the fixed costs of Federal ownership. Costs associated with the prevention of damage to adjoining ownerships, administration of unavoidable special uses, and maintenance of long-term productivity are included.
- only incidental outputs and uses, such as recreation, wildlife, and fisheries are given economic value for purposes of this benchmark.
- transition, or "close down" costs, needed in the event this benchmark is implemented, are not included.

Summary of Environmental Consequences

WILDLIFE. The Min Level Benchmark would have major effects on wildlife resources. The Forest land base is presently 41 percent old-growth habitat; it would continue at this level under this benchmark. More than four times as much old-growth habitat is preserved indefinitely than required under MR constraints. Wildlife species inhabiting mature/old-growth forest communities will have a very adequate habitat base; this additional habitat will provide a very good margin of safety to insure that well-dispersed viable populations of all native species will not perish from this Forest. This safety margin is doubly important, given that very little mature/old-growth habitat will remain on private lands outside the Forest boundary

Deer herd levels will be considerably lower than at present, especially after recently harvested areas progress into older seral stages; WFUD's are correspondingly reduced.

Habitat capability for cavity nesters would be maintained at high levels.

Most meadow habitat would slowly disappear as forest encroachment slowly obliterated this valuable component of habitat diversity. No hardwood stands are converted into conifer plantations, thereby prolonging this habitat type.

Riparian areas would not be entered and would retain their value to wildlife

FISH. Riparian areas would be at minimum level which would have positive benefit to fish habitat capability. Water temperatures would reduce and input of large organic debris would improve. Minimum level management would allow water temperature reduction by at least two degrees Fahrenheit at the end of the third decade. Minimal ground disturbance would reduce input of sediment to streams.

WATER. Under a minimum level or custodial management, watershed condition will improve generally for about eight decades (or until the recent clearcut acreage has reforested and grown to maturity). Sediment production is estimated to remain stable at 623 M tons per year. Slight reductions in water yield will be evident compared to the current situation.

MAX PRESENT NET VALUE (B30-1)

Purpose.

This benchmark provides the mix of goods and services necessary to maximize PNV over a 150-year planning horizon at a four percent discount rate when all resources are valued according to specifications in the 1985 RPA DEIS. The results also provide a basis, or reference point, for the evaluation of opportunity costs associated with the attainment of other resource objectives, four percent discount rate when all resources are valued according to specifications in the 1985 RPA DEIS. The results also provide a basis, or reference point, for the evaluation of opportunity costs associated with the attainment of other resource objectives, as well as evaluations concerning the impact of legal and policy constraints

Assumptions and Modeling Constraints.

- economically efficient capital investments for fish and wildlife improvements are included.
- no economically efficient capital investments for recreation were identified.
- no viewshed allocations were found to be economically efficient.
- no special areas were allocated.

Resource-specific Environmental Consequences.

RECREATION.

Developed Recreation. Current use is approximately 115,700 RVD's and is expected to increase to approximately 148.4 RVD's by the fifth decade under this management scheme. Current developed capacity is approximately 157,600 RVD's and can be increased to approximately 172,000 RVD's through the capital investment program by the fifth decade under this management scheme.

Dispersed Recreation. Dispersed recreation is presented by ROS classes. The discussion includes Wilderness and Wild and Scenic River use in the capacity totals and demand projections. Each of these categories will be summarized individually in addition to the information presented in this section

Roaded Natural (RN). 653,283 acres of the Forest land is currently inventoried as RN and is expected to increase to 739,333 acres in the second decade under this management scheme. Current RN use is approximately 479,100 RVD's and is expected to increase to approximately 614,700 RVD's by the second decade of the planning horizon. Current capacity is approximately 1,059,400 RVD's and can be increased to approximately 1,197,700 RVD's by the fifth decade.

Semi-Primitive Motorized (SPM). 115,393 acres of the Forest land is currently inventoried as SPM and will remain the same over the planning horizon Current SPM use is approximately 80,500 RVD's and is expected to increase to approximately 103,200 RVD's by the fifth decade. Current capacity is approximately 151,800 RVD's and will remain constant over the planning horizon because of the difficulty of determining the degree of impact necessary to distinguish between roaded natural and semi-primitive.

Semi-Primitive Non-Motorized (SPNM). 195,175 acres of the Forest land is currently inventoried as SPNM and will decrease to approximately 119,494 acres in the second decade of this management scheme due to the impacts of road construction and timber harvest. 294,181 acres will be harvested

over five decades, and 1,596 miles of road will be constructed under this management scheme. Current SPNM use is approximately 17,800 RVD's and is expected to increase to approximately 22,800 RVD's by the fifth decade. Current capacity is approximately 41,300 RVD's and will decrease to approximately 25,000 RVD's in the second decade of this management scheme, and can be increased slightly to 25,100 RVD's with the current capital investment program

Primitive. 128,440 acres of the Forest land is currently inventoried as Primitive and will decrease to approximately 114,070 acres by the second decade, and will remain constant over the planning horizon. Current Primitive use is approximately 11,400 RVD's and is expected to increase to approximately 13,600 RVD's by the fifth decade. Current capacity is approximately 13,100 RVD's and will decrease to approximately 11,400 RVD's in the second decade and can be increased to approximately 13,400 RVD's through the current capital investment. Demand is expected to reach capacity in the second decade.

VISUAL RESOURCE. Visual resources will be managed at the minimum level under this management scheme. 8,910 acres of Recreation/Scenic Rivers can be managed under the Retention VQO. All other inventoried areas will be managed under the Modification VQO.

WILDERNESS. 232,495 acres of Wilderness will be carried. No additional areas will be proposed

WILD AND SCENIC RIVERS. The Forest has two designated Wild and Scenic Rivers, the Rogue, and the Illinois. No additional rivers will be considered for evaluation under this management scheme.

WILDLIFE. The Min Level Benchmark would have benefits for wildlife resources in general. The Forest land base is presently 41 percent old-growth habitat; after five decades it drops to 13 percent. A minimum 13 percent of the Forest is maintained as old growth at all times. Twenty percent more old-growth habitat is preserved indefinitely than required under MR constraints; most of the 'extra' habitat is in Wildernesses, and dispersion of old-growth habitat would be at minimum levels. In the first two decades the deer herd averages five percent lower than at present; WFUD's follow a similar pattern.

Forest-wide habitat capability for cavity nesters is maintained at 51 percent at the end of the first five decades, a fairly low level. The proportion of mature (age 101-200) and young (age 41-100) forest fluctuates rather widely throughout the planning period, mostly due to the Forest's uneven distribution of stand age classes. Meadows (4,700 acres) on land classified as nontimber are preserved, but no buffer strips around meadows are managed for wildlife. No small "special habitat sites" are managed exclusively for wildlife No hardwood stands on the Forest are converted into conifer plantations until the fifth decade, thereby preserving this habitat type until its value as wildlife habitat can be better understood.

As unmanaged timber stands are harvested and brought into rotation, associated Riparian areas are converted from even-aged (mainly old growth) to uneven-aged timber stands; in this benchmark a maximum of 84,000 acres of riparian habitat (45 percent of the Forest total) are ultimately converted to this type of forest management; the rest of the riparian habitat will not be entered and will essentially remain in its present condition.

FISH. Under this benchmark forest habitat capabilities for anadromous and resident salmonids are enhanced through maintaining the natural habitat plus project work primarily designed to improve rearing capability of juvenile salmonids. Stream temperatures are maintained by maintaining streamside canopy cover through application of the Riparian Prescription option B. Stream sediment input is held at current levels by basin constraints which allow no more than 20 percent timber harvest entry per decade, and 11 percent entry in the Riparian areas

TIMBER. The annual harvest level is 32.375 MMCF during the first decade and LTSY (51.938 MMCF) is not achieved until the tenth decade.

Harvest is conifer except for an insignificant amount (118 acres) of hardwood conversion in the fifth decade.

Riparian harvest ranges from about 1,800 acres in the first decade to about 3,400 acres in the fifth decade. This gradually declines to 1,125 acres in the fifteenth decade. There could be some detrimental effects on stream quality and wildlife habitat during periods of high level Riparian harvesting.

Reforestation is a high level program and will require higher than current budget and more people than currently employed.

SOIL AND WATER. Forest watershed condition (as indicated by total sediment production) will improve compared to the current direction in the first two decades. In Decades 3-5, watershed condition will decline because of the increased levels of timber harvest and road building.

FACILITIES. The new road construction in the Forest decade is about 40 percent the mileage of the last five year period. New construction decreases considerably in the sixth decade and is completed in the seventh decade. The decrease takes place when the Forest starts obtaining large amounts of the annual timber cut from commercial thinnings and from second growth stands.

Reconstruction miles increase to a high of 265 miles per year in the fifth decade, which is higher than the Forest has experienced in the past (Fiscal Year 1982 had 177 miles).

The local road miles will increase 84 percent, from an existing 1,807 miles to an estimated 3,317 miles, when the system is complete sometime in the seventh decade. Over 95 percent of this increase is in the first five decades.

The existing road system of 2,645 miles will expand to 4,242 miles, an increase of 60 percent. The road system open to passenger cars will increase from 1,504 miles (57 percent) existing to 1,802 miles (42 percent) with the completed system. At the same time, 883 miles (33 percent) of the road system now open to high clearance vehicles will increase to 1,276 miles (30 percent) of the completed system. The remaining 10 percent (258 miles) of the current road system and 27 percent (1,164 miles) of the completed system will be closed to vehicles except for intermittent project use.

MAX TIMBER (B11-3)

Purpose.

This benchmark establishes the highest level of sustainable timber production possible on the Forest under a policy of nondeclining yield, subject to MR's. It provides a basis for a basis for the estimation of physical timber harvest tradeoffs when compared to runs having other resource objectives.

Assumptions and modeling Constraints.

- no special areas are allocated to other uses.
- VQO's are not achieved except for modification and maximum modification.

Resource Specific Environmental Consequences.

RECREATION.

Developed Recreation. Current use is approximately 115,700 RVD's and is expected to increase to approximately 148.4 RVD's by the fifth decade under this management scheme. Current developed

capacity is approximately 157,600 RVD's and can be increased to approximately 172,000 RVD's through the capital investment program by the fifth decade under this management scheme.

Dispersed Recreation Dispersed recreation is presented by ROS classes. The discussion includes Wilderness and Wild and Scenic River use in the capacity totals and demand projections Each of these categories will be summarized individually in addition to the information presented in this section.

RN. 653,283 acres of the Forest land is currently inventoried as RN and is expected to increase to 739,333 acres in the second decade under this management scheme. Current RN use is approximately 479,100 RVD's and is expected to increase to approximately 614,700 RVD's by the second decade of the planning horizon. Current capacity is approximately 1,059,400 RVD's and can be increased to approximately 1,197,700 RVD's by the fifth decade.

SPM. 115,393 acres of the Forest land is currently inventoried as SPM and will remain the same over the planning horizon. Current SPM use is approximately 80,500 RVD's and is expected to increase to approximately 103,200 RVD's by the fifth decade. Current capacity is approximately 151,800 and will remain constant over the planning horizon because of the difficulty of determining the degree of impact necessary to distinguish between RN and semi-primitive.

SPNM. 195,175 acres of the Forest land is currently inventoried as SPNM and will decrease to approximately 119,494 acres in the second decade of this management scheme due to the impacts of road construction and timber harvest. 294,181 acres will be harvested over five decades, and 1,596 miles of road will be constructed under this management scheme. Current SPNM use is approximately 17,800 RVD's and is expected to increase to approximately 22,800 RVD's by the fifth decade. Current capacity is approximately 41,300 RVD's and will decrease to approximately 25,000 RVD's in the second decade of this management scheme, and can be increased slightly to 25,100 RVD's with the current capital investment program.

Primitive. 128,440 acres of the Forest land is currently inventoried as Primitive and will decrease to approximately 114,070 acres by the second decade, and will remain constant over the planning horizon. Current Primitive use is approximately 11,400 RVD's and is expected to increase to approximately 13,600 RVD's by the fifth decade. Current capacity is approximately 13,100 RVD's and will decrease to approximately 11,400 RVD's in the second decade and can be increased to approximately 13,400 RVD's through the current capital investment. Demand is expected to reach capacity in the second decade.

VISUAL RESOURCE. Visual resources will be managed at the minimum level under this management scheme. 8,910 acres of Recreation and Scenic River can be managed under the Retention VQO. All other inventoried areas will be managed under the Modification VQO.

WILDERNESS. 232,495 acres of Wilderness will be carried. No additional areas will be proposed.

WILD AND SCENIC RIVERS. The Forest has two designated Wild and Scenic Rivers; the Rogue and Illinois. No additional rivers will be considered for evaluation under this management scheme.

WILDLIFE. This benchmark has major effects on wildlife resources. The Forest land base is presently 41 percent old-growth habitat; after five decades it drops to 20 percent. A minimum of 15 percent of the Forest is maintained as old growth at all times. Fifty percent more old-growth habitat is preserved indefinitely than required under MR constraints. Wildlife species inhabiting mature and old-growth forest communities will have an adequate habitat base. In the first two decades the deer herd averages 21 percent above current levels; WFUD's follow a similar pattern.

Habitat capability for cavity nesters is maintained at 59 percent at the end of the first five decades. The proportion of mature (age 101-200) and young (age 41-100) forest fluctuates rather widely throughout the planning period, mostly due to the Forest's uneven distribution of stand age classes. Meadows (4,700 acres) on land classified as nontimber are preserved, but no buffer strips around meadows are managed for wildlife. No small "special habitat sites" are managed exclusively for wildlife Thirty-eight percent of the hardwood stands on the Forest are converted into conifer plantations in the first decade, which effectively removes a large proportion of this habitat type before its value as wildlife habitat can be adequately understood.

As unmanaged timber stands are harvested and brought into rotation, associated Riparian areas are converted from even-aged (mainly old growth) to uneven-aged timber stands; in this benchmark a maximum of 84,000 acres of riparian habitat (45 percent of the Forest total) are ultimately converted to this type of forest management; the rest of the riparian habitat will not be entered and will essentially remain in its present condition.

FISH Under this benchmark, forest habitat capabilities for anadromous and resident salmonids are enhanced through maintaining the natural habitat plus project work primarily designed to improve rearing capability of juvenile salmonids Stream temperatures are maintained by maintaining streamside canopy cover through application of the B management prescription. Stream sediment input is held at current levels by basin constraints which allow no more than 20 percent timber harvest entry per decade, and no more than 11 percent entry in the Riparian areas.

TIMBER. The annual harvest level is 33.441 MMCF during the first decade and LTSY (58.529 MMCF) is not achieved until the tenth decade.

Harvest is conifer except hardwood conversion scheduled in the first (3,614 acres), second (83 acres), third (3 acres), fourth 74 acres), and fifth decades (218 acres).

Commercial thinning acres are scheduled through all decades. The quantity fluctuates but increases significantly through the tenth to the fifteenth decade. Final harvest acres also fluctuate but peak in the fifth decade at 8,170 acres. The combined effect of this relatively high level of harvesting is to move more rapidly toward a smaller product size.

SOIL AND WATER. Forest watershed condition (as indicated by total sediment production) will decline compared to the current direction benchmark, especially in the first two decades. In the third decade, sediment production will roughly equal the current direction. Thereafter, watershed condition will further decline.

The contribution from Riparian areas is very significant in the first decade (6,900 acres). Fluctuations in riparian harvesting continues high through most of the planning horizon but decline to a reasonable level in the fifteen decade.

This relatively high workload program will require significant increases in budget and people.

FACILITIES. The new road construction in decade one is about 40 percent the mileage of the last five year period The decrease in new construction in the sixth decade is when the Forest starts obtaining large amounts of the annual timber cut from commercial thinnings and from second growth stands

Reconstruction miles increase to a high of 256 miles per year in the fifth decade, which is higher than the Forest has experienced in the past (Fiscal Year 1982 had 177 miles).

The local road miles will increase 84 percent, from an existing 1,807 miles to an estimated 3,316 miles, when the system is complete sometime in the seventh decade. Over 95 percent of this increase is in the first five decades

The existing road system of 2,645 miles will expand to 4,241 miles, an increase of 60 percent. The road system open to passenger cars will increase from 1,504 miles (57 percent) existing to 1,802 miles (42 percent) with the completed system. At the same time, 883 miles (33 percent) of the road system now open to high clearance vehicles will increase to 1,276 miles (30 percent) of the completed system. The remaining 10 percent (258 miles) of the current road system and 27 percent (1,163 miles) of the completed system will be closed to vehicles except for intermittent project use

MAX VISUALS (B12-1)

Purpose.

This benchmark achieves the inventoried VQO on each acre of the Forest.

Assumptions and Modeling Constraints.

- all Retention and Partial Retention VQO acres are allocated to their respective management prescription.

Resource-specific Environmental Consequences

RECREATION

Developed Recreation. Current use is approximately 115,700 RVD's and is expected to increase to approximately 148.4 RVD's by the fifth decade under this management scheme. Current developed capacity is approximately 157,600 RVD's and can be increased to approximately 172,000 RVD's through the capital investment program by the fifth decade under this management scheme.

Dispersed Recreation. Dispersed recreation is presented by ROS classes. The discussion includes Wilderness and Wild and Scenic River use in the capacity totals and demand projections Each of these categories will be summarized individually in addition to the information presented in this section

RN. 653,283 acres of the Forest land is currently inventoried as RN and is expected to increase to 724,963 acres in the third decade under this management scheme. Current RN use is approximately 479,100 RVD's and is expected to increase to approximately 614,700 RVD's by the second decade of the planning horizon. Current capacity is approximately 1,059,400 RVD's and can be increased to approximately 1,174,400 RVD's by the fifth decade.

SPM. 115,393 acres of the Forest land is currently inventoried as SPM and will be increased to 129,763 acres by the third decade. Current SPM use is approximately 80,500 RVD's and is expected to increase to approximately 103,200 RVD's by the fifth decade. Current capacity is approximately 151,800 and will increase to 170,700 RVD's in the third decade.

SPNM. 195,175 acres of the Forest land is currently inventoried as SPNM and will decrease to approximately 119,494 acres in the third decade of this management scheme due to the impacts of road construction and timber harvest. 266,818 acres will be harvested over five decades, and 1,588 miles of road will be constructed under this management scheme Current SPNM use is approximately 17,800 RVD's and is expected to increase to approximately 22,800 RVD's by the fifth decade. Current capacity is approximately 41,300 RVD's and will decrease to approximately 25,000

RVD's in the third decade of this management scheme, and can be increased slightly to 25,100 RVD's with the current capital investment program.

Primitive 128,440 acres of the Forest land is currently inventoried as Primitive and will decrease to approximately 114,070 acres by the third decade, and will remain constant over the planning horizon. Current Primitive use is approximately 11,400 RVD's and is expected to increase to approximately 13,400 RVD's by the fifth decade Current capacity is approximately 13,100 RVD's and will increase to approximately 13,400 RVD's in the fourth decade when demand will reach reach capacity.

VISUAL RESOURCE. Visual resources will be managed at the current level under this management scheme. 87,747 acres of Retention, 300,215 acres of Partial Retention and 524,534 acres of Modification will be allocated under this management scheme.

WILDERNESS. 232,495 acres of Wilderness will be carried. No additional areas will be proposed

WILD AND SCENIC RIVERS. The Forest has two designated Wild and Scenic Rivers; the Rogue and Illinois. No additional rivers will be considered for evaluation under this management scheme.

WILDLIFE. This run has major effects on wildlife resources. The Forest land base is presently 41 percent old-growth habitat; after five decades it drops to 22 percent. A minimum of 16 percent of the Forest is maintained as old growth at all times. Fifty percent more old-growth habitat is preserved indefinitely than required under MR constraints. Wildlife species inhabiting mature/old-growth forest communities will have an adequate habitat base.

In the first two decades the deer herd averages three percent below current levels; WFUD's follow a similar pattern.

Habitat capability for cavity nesters is maintained at 63 percent at the end of the first five decades.

The proportion of mature (age 101-200) and young (age 41-100) forest fluctuates rather widely throughout the planning period, mostly due to the Forest's uneven distribution of stand age classes. Meadows (4,700 acres) on land classified as nontimber are preserved, but no buffer strips around meadows are managed for wildlife. No small "special habitat sites" are managed exclusively for wildlife. No significant acres of hardwood stands are converted into conifer plantations until after the fifth decade, thereby preserving this habitat type until its value as wildlife habitat can be better understood.

As unmanaged timber stands are harvested and brought into rotation, associated Riparian areas are converted from even-aged (mainly old growth) to uneven-aged timber stands; in this benchmark a maximum of 83,000 acres of riparian habitat (45 percent of the Forest total) are ultimately converted to this type of forest management; the rest of the riparian habitat will not be entered and will essentially remain in its present condition.

FISH Under this benchmark, forest habitat capabilities for anadromous and resident salmonids are enhanced through maintaining the natural habitat plus project work primarily designed to improve rearing capability of juvenile salmonids. Stream temperatures are maintained by maintaining streamside canopy cover through application of the B management prescription. Stream sediment input is held at current levels by basin constraints which allow no more than 20 percent timber harvest entry per decade, and no more than 11 percent of the Riparian area.

TIMBER. The annual harvest level is 30.501 MMCF during the first decade and the LTSY (52.886 MMCF) is not attained until the eleventh decade

Harvest is all conifer except for an insignificant quantity of hardwood (tanoak) conversion.

During the middle of the planning horizon, around the tenth decade final harvest acres are low (1,920 acres) and commercial thinning acres are quite high (8,694 acres). This will cause a decrease in future product size. This tends to come into balance toward the fifteenth decade.

Low site is the primary source of final harvest acres in future decades. The high occurs about the tenth decade. An improved blend of High Site, Medium Site and Low Site begins to occur toward the fifteenth decade.

SOIL AND WATER. Forest watershed condition (as indicated by total sediment production) will improve compared to the current direction benchmark in the first two decades. In subsequent decades watershed condition will decline as timber harvest and road building intensify.

FACILITIES. The new road construction in decade one is about one-third the mileage of the last five year period. New construction decreases considerably in the sixth decade and again in the ninth decade. The first decrease takes place when the Forest starts obtaining large amounts of the annual timber cut from commercial thinnings. The second decrease takes place when the old-growth stands available for timber harvest are mostly gone, the road system is largely in place, and the Forest is harvesting the second growth stands.

Reconstruction miles increase to a high of 210 miles per year in the eleventh decade, which is higher than the range of reconstruction miles the Forest has experienced in the past (Fiscal Year 1982 had 177 miles).

The local road miles will increase 83 percent, from an existing 1,807 miles to an estimated 3,308 miles, when the system is complete sometime in the fourteenth decade. Almost 80 percent of this increase is in the first five decades.

The existing road system of 2,645 miles will expand to 4,233 miles, an increase of 60 percent. The road system open to passenger cars will increase from 1,504 miles (57 percent) existing to 1,801 miles (43 percent) with the completed system. At the same time, 883 miles (33 percent) of the road system now open to high clearance vehicles will increase to 1,275 miles (30 percent) of the completed system. The remaining 10 percent (258 miles) of the current road system and 27 percent (1,157 miles) of the completed system will be closed to vehicles except for intermittent project use.

MAX UNROADED (B20-2)

Purpose.

This benchmark maximizes the preservation of presently unroaded areas on the Forest. In addition to designated Wildernesses, all Roadless Area Review and Evaluation II (RARE II) areas that remain unroaded are assigned to a minimum level of management.

Assumptions and Modeling Constraints.

All analysis areas with an unroaded identifier are constrained to minimum level management.

Resource Specific Environmental Consequences.

RECREATION

Developed Recreation. Current use is approximately 115,700 RVD's and is expected to increase to approximately 148,000 RVD's by the fifth decade under this management scheme. Current developed

capacity is approximately 157,600 RVD's and can be increased to approximately 164,500 RVD's through the capital investment program by the fifth decade under this management scheme

Dispersed Recreation. Dispersed recreation is presented by ROS classes. The discussion includes Wilderness and Wild and Scenic River use in the capacity totals and demand projections Each of these categories will be summarized individually in addition to the information presented in this section

RN 653,283 acres of the Forest land is currently inventoried as RN and is expected to remain at that level over the length of the planning horizon. Current RN use is approximately 479,100 RVD's and is expected to increase to approximately 614,700 RVD's by the second decade of the planning horizon. Current capacity is approximately 1,059,400 RVD's and will not be increased over this planning horizon.

SPM. 115,393 acres of the Forest land is currently inventoried as SPM and will be decreased to approximately 102,593 acres in the first decade of this management scheme. Current SPM use is approximately 80,500 RVD's and is expected to increase to approximately 103,200 RVD's by the fifth decade. Current capacity is approximately 151,800 and will be reduced to approximately 135,400 RVD's by the second decade.

SPNM 195,175 acres of the Forest land is currently inventoried as SPNM and will increase to approximately 207,975 acres in the second decade of this management scheme. 251,730 acres will be harvested over five decades, and 1,849 miles of road will be constructed under this management scheme. Current SPNM use is approximately 17,800 RVD's and is expected to increase to approximately 22,800 RVD's by the fifth decade. Current capacity is approximately 41,300 RVD's and will decrease to approximately 43,800 RVD's in the fifth decade of this management scheme

Primitive. 128,440 acres of the Forest land is currently inventoried as Primitive and will increase to approximately 141,880 acres by the first decade, and will remain constant over the planning horizon Current Primitive use is approximately 11,400 RVD's and is expected to increase to approximately 14,600 RVD's by the fifth decade. Current capacity is approximately 13,100 RVD's and will increase to approximately 16,300 RVD's in the fifth decade. Demand is not expected to reach capacity.

VISUAL RESOURCE Visual resources will be managed at the minimum level under this management scheme in order to emphasize non-motorized recreation opportunities. 8,910 acres of Recreation/Scenic River can be managed under the Retention VQO. All other inventoried areas outside of allocated roadless areas will be managed under the Modification VQO.

WILDERNESS 232,495 acres of Wilderness will be carried. No additional areas will be proposed

WILD AND SCENIC RIVERS. The Forest has two designated Wild and Scenic Rivers, the Rogue, and the Illinois. No additional rivers will be considered for evaluation under this management scheme

WILDLIFE. This benchmark has major effects on wildlife resources. The Forest land base is presently 41 percent old-growth habitat; after five decades it drops to 27 percent A minimum of 24 percent of the Forest is maintained as old growth at all times. More than twice as much old-growth habitat is preserved indefinitely than required under MR constraints. Wildlife species inhabiting mature/old-growth forest communities will have a more than adequate habitat base; this additional habitat will provide a margin of safety which insures that well-dispersed viable populations of all native species will not perish from this Forest. This safety margin is doubly important, given that very little mature/old-growth habitat will remain on private lands outside the Forest boundary.

In the first two decades the deer herd averages 16 percent lower than at present; WFUD's follow the same pattern

Habitat capability for cavity nesters is maintained at 67 percent at the end of the first five decades.

The proportion of mature (age 101-200) and young (age 41-100) forest fluctuates rather widely throughout the planning period, mostly due to the Forest's uneven distribution of stand age classes. Meadows (4,700 acres) on land classified as nontimber are preserved, but no buffer strips around meadows are managed for wildlife. No small "special habitat sites" are managed exclusively for wildlife No hardwood stands are converted into conifer plantations until the fifth decade, thereby preserving this habitat type until its value as wildlife habitat can be better understood.

As unmanaged timber stands are harvested and brought into rotation, associated Riparian areas are converted from even-aged (mainly old growth) to uneven-aged timber stands; in this benchmark a maximum of 59,000 acres of riparian habitat (32 percent of the Forest total) are ultimately converted to this type of forest management; the rest of the riparian habitat will not be entered and will essentially remain in its present condition.

FISH. Under this benchmark, Forest habitat capabilities for anadromous and resident salmonid is enhanced through maintaining the natural habitat plus project work primarily designed to improve rearing capability of juvenile salmonids. Stream temperatures are maintained by maintaining streamside canopy cover through application of the B management prescription. Stream sediment input is held at current levels by basin constraints which allow no more than 20 percent timber harvest entry per decade, and no more than 11 percent harvest of Riparian areas per decade.

TIMBER. The annual harvest level is 23.126 MMCF during the first decade and LTSY (40.472 MMCF) is not achieved until the ninth decade.

Harvest consists of conifer except for 911 acres of hardwood conversion scheduled in the fifth decade.

Reforestation acres increase significantly toward the fifth decade due to increased harvesting in Riparian areas (about 2,300 acres). The contribution from Riparian areas then decreases to about 900 acres in the fifteenth decade.

There are no extreme fluctuations in the overall program except as noted for reforestation.

SOIL AND WATER. Forest watershed condition (as indicated by total sediment production) will improve compared to the current direction benchmark, especially in the first three decades In decades 4 and 5, sediment production under this alternative will exceed current direction.

FACILITIES. The new road construction in decade one is about one-fifth the mileage of the last five year period. The decrease in the sixth decade is when the forest starts obtaining large amounts of the annual timber cut from commercial thinnings and from second growth stands.

The local road miles will increase 42 percent, from an existing 1,807 miles to an estimated 2,569 miles, when the system is complete sometime in the seventh decade. Almost 95 percent of this increase is in the first five decades.

The existing road system of 2,645 miles will expand to 3,494 miles, an increase of 32 percent. The road system open to passenger cars will increase from 1,504 miles (57 percent) existing to 1,697 miles (49 percent) with the completed system. At the same time, 883 miles (33 percent) of the road system now open to high clearance vehicles will increase to 1,082 miles (31 percent) of the completed system The remaining 10 percent (258 miles) of the current road system and 20 percent (715 miles) of the completed system will be closed to vehicles except for intermittent project use.

MAX RECREATION (B19-2)

Purpose.

This benchmark estimates the maximum capability of the Forest to provide both dispersed and developed recreational opportunities.

Assumptions and Modeling Constraints.

- developed recreation facilities are installed or upgraded to meet anticipated future demands
- primitive ROS demand is satisfied through the allocation of all unroaded areas to a minimum level of management
- both candidate Wild and Scenic Rivers are allocated.
- 25 Supplemental Resource areas are allocated to minimum level of management.

Resource-specific Environmental Consequences.

RECREATION

Developed Recreation. Current use is approximately 115,700 RVD's and is expected to increase to approximately 148,000 RVD's by the fifth decade under this management scheme. Current developed capacity is approximately 157,600 RVD's and can be increased to approximately 164,500 RVD's through the capital investment program by the fifth decade under this management scheme.

Dispersed Recreation. Dispersed recreation is presented by ROS classes. The discussion includes Wilderness and Wild and Scenic River use in the capacity totals and demand projections. Each of these categories will be summarized individually in addition to the information presented in this section.

RN 653,283 acres of the Forest land is currently inventoried as RN and is expected to remain at that level over the length of the planning horizon. Current RN use is approximately 479,100 RVD's and is expected to increase to approximately 614,700 RVD's by the second decade of the planning horizon. Current capacity is approximately 1,059,400 RVD's and will not be increased over this planning horizon.

SPM. 115,393 acres of the Forest land is currently inventoried as SPM and will be decreased to approximately 102,593 acres in the first decade of this management scheme Current SPM use is approximately 80,500 RVD's and is expected to increase to approximately 103,200 RVD's by the fifth decade. Current capacity is approximately 151,800 and will be reduced to approximately 135,400 RVD's by the second decade.

SPNM. 195,175 acres of the Forest land is currently inventoried as SPNM and will increase to approximately 207,975 acres in the second decade of this management scheme 251,730 acres will be harvested over five decades, and 1,817 miles of road will be constructed under this management scheme. Current SPNM use is approximately 17,800 RVD's and is expected to increase to approximately 22,800 RVD's by the fifth decade. Current capacity is approximately 41,300 RVD's and will decrease to approximately 43,800 RVD's in the fifth decade of this management scheme.

Primitive. 128,440 acres of the Forest land is currently inventoried as Primitive and will increase to approximately 141,880 acres by the first decade, and will remain constant over the planning horizon Current Primitive use is approximately 11,400 RVD's and is expected to increase to approximately 14,600 RVD's by the fifth decade. Current capacity is approximately 13,100 RVD's and will increase to approximately 16,300 RVD's in the fifth decade. Demand is not expected to reach capacity

VISUAL RESOURCE. Visual resources will be managed at the minimum level under this management scheme in order to emphasize non-motorized recreation opportunities. 8,910 acres of Recreation/Scenic River can be managed under the Retention VQO. All other inventoried areas outside of allocated roadless areas will be managed under the Modification VQO.

WILDERNESS. 232,495 acres of Wilderness will be carried. No additional areas will be proposed.

WILD AND SCENIC RIVERS. The Forest has two designated Wild and Scenic Rivers, the Rogue, and the Illinois. No additional rivers will be considered for evaluation under this management scheme.

WILDLIFE. This run has major effects on wildlife resources. The Forest land base is presently 41 percent old-growth habitat; after five decades it drops to 27 percent. A minimum of 25 percent of the Forest is maintained as old growth at all times. More than twice as much old-growth habitat is preserved indefinitely than required under MR constraints. Wildlife species inhabiting mature/old-growth forest communities will have a more than adequate habitat base; this additional habitat will provide a margin of safety which insures that viable populations of all native species will not perish from this Forest. This safety margin is doubly important, given that very little mature/old-growth habitat will remain on private lands outside the Forest boundary.

In the first two decades the deer herd averages 17 percent below current levels, WFUD's follow a similar pattern.

Habitat capability for cavity nesters is maintained at 67 percent at the end of the first five decades. The proportion of mature (age 101-200) and young (age 41-100) forest fluctuates rather widely throughout the planning period, mostly due to the Forest's uneven distribution of stand age classes. Meadows (4,700 acres) on land classified as nontimber are preserved, but no buffer strips around meadows are managed for wildlife. No small "special habitat sites" are managed exclusively for wildlife. No hardwood stands are converted into conifer plantations until the fifth decade, thereby preserving this habitat type until its value as wildlife habitat can be better understood.

As unmanaged timber stands are harvested and brought into rotation, associated Riparian areas are converted from even-aged (mainly old growth) to uneven-aged timber stands; in this benchmark a maximum of 57,000 acres of riparian habitat (30 percent of the Forest total) are ultimately converted to this type of forest management; the rest of the riparian habitat will not be entered and will essentially remain in its present condition.

FISH. Under this benchmark Forest habitat capabilities for anadromous and resident salmonid is enhanced through maintaining the natural habitat plus project work primarily designed to improve rearing capability of juvenile salmonids. Stream temperatures are maintained by maintaining streamside canopy cover through application of the B management prescription. Stream sediment input is held at current levels by basin constraints which allow no more than 20 percent timber harvest entry per decade, and no more than 11 percent of Riparian areas harvested per decade.

TIMBER. The annual harvest level is 22.304 MMCF during the first decade and LTSY (39.246 MMCF) is not achieved until the ninth decade.

Harvest consists of conifer except for 850 acres scheduled for hardwood conversion in the fifth decade.

The flow of reforestation acres increases from 4,032 acres in the first decade to 7,818 acres in the fifth decade then declines to 4,575 and 4,226 acres in the tenth and fifteenth decades respectfully. Final harvest makes up the bulk of these acres but harvesting in the Riparian areas is the major contributor to the high points in reforestation acres.

There are no unacceptable extremes in the flow of this program

SOIL AND WATER. Forest watershed condition (as indicated by total sediment production) will improve compared to the current direction benchmark. Of all the benchmarks evaluated to date, Max Recreation produces the least sediment because the fewest acres are clearcut and fewest miles of road are built. From a watershed standpoint, this benchmark produces the fewest detrimental effects.

FACILITIES The new road construction in decade one is about one-fifth the mileage of the last five year period The decrease in new construction in the sixth decade is when the forest starts obtaining large amounts of the annual timber cut from commercial thinnings and from second growth stands

The local road miles will increase 40 percent, from an existing 1,807 miles to an estimated 2,537 miles, when the system is complete sometime in the fifteenth decade. Almost 95 percent of this increase is in the first five decades.

The existing road system of 2,645 miles will expand to 3,462 miles, an increase of 31 percent The road system open to passenger cars will increase from 1,504 miles (57 percent) existing to 1,693 miles (49 percent) with the completed system. At the same time, 883 miles (33 percent) of the road system now open to high clearance vehicles will increase to 1,073 miles (31 percent) of the completed system The remaining 10 percent (258 miles) of the current road system and 20 percent (696 miles) of the completed system will be closed to vehicles except for intermittent project use.

MAX FISH AND WATERSHED (B16-1)

Purpose.

Improved fish habitat and watershed conditions are maximized in this benchmark.

Assumptions and Modeling Constraints.

- timber yield in Riparian areas is limited to incidental harvest associated with skyline corridors and other operational considerations.
- harvest flow constraints are limited to between nine and 13 percent per watershed basin per decade
- 27 Supplemental Resource areas are allocated to minimum level of management.
- fish habitat improvement projects are maximized.

Resource-specific Environmental Consequences.

RECREATION

Developed Recreation. Current use is approximately 115,700 RVD's and is expected to increase to approximately 148.4 RVD's by the fifth decade under this management scheme. Current developed capacity is approximately 157,600 RVD's and can be increased to approximately 172,000 RVD's through the capital investment program by the fifth decade under this management scheme.

Dispersed Recreation. Dispersed recreation is presented by ROS classes. The discussion includes Wilderness and Wild and Scenic River use in the capacity totals and demand projections. Each of these categories will be summarized individually in addition to the information presented in this section.

RN 653,283 acres of the Forest land is currently inventoried as RN and is expected to increase to 739,333 acres in the second decade under this management scheme. Current RN use is approximately 479,100 RVD's and is expected to increase to approximately 614,700 RVD's by the

second decade of the planning horizon. Current capacity is approximately 1,059,400 RVD's and can be increased to approximately 1,197,700 RVD's by the fifth decade.

SPM. 115,393 acres of the Forest land is currently inventoried as SPM and will remain the same over the planning horizon. Current SPM use is approximately 80,500 RVD's and is expected to increase to approximately 103,200 RVD's by the fifth decade. Current capacity is approximately 151,800 and will remain constant over the planning horizon because of the difficulty of determining the degree of impact necessary to distinguish between roaded natural and semi-primitive.

SPNM. 195,175 acres of the Forest land is currently inventoried as SPNM and will decrease to approximately 119,494 acres in the second decade of this management scheme due to the impacts of road construction and timber harvest 248,938 acres will be harvested over five decades, and 1,546 miles of road will be constructed under this management scheme. Current SPNM use is approximately 17,800 RVD's and is expected to increase to approximately 22,800 RVD's by the fifth decade. Current capacity is approximately 41,300 RVD's and will decrease to approximately 25,000 RVD's in the second decade of this management scheme, and can be increased slightly to 25,100 RVD's with the current capital investment program.

Primitive. 128,440 acres of the Forest land is currently inventoried as Primitive and will decrease to approximately 114,070 acres by the second decade, and will remain constant over the planning horizon. Current Primitive use is approximately 11,400 RVD's and is expected to increase to approximately 13,600 RVD's by the fifth decade. Current capacity is approximately 13,100 RVD's and will decrease to approximately 11,400 RVD's in the second decade and can be increased to approximately 13,400 RVD's through the current capital investment program. Demand is expected to reach capacity in the second decade.

VISUAL RESOURCE. Visual resources will be managed at the minimum level under this management scheme. 8,910 acres of Recreation/Scenic River can be managed under the Retention VQO All other inventoried areas will be managed under the Modification VQO.

WILDERNESS. 232,495 acres of Wilderness will be carried. No additional areas will be proposed.

WILD AND SCENIC RIVERS. The Forest has two designated Wild and Scenic Rivers, the Rogue, and the Illinois. No additional rivers will be considered for evaluation under this management scheme.

WILDLIFE. This run has major effects on wildlife resources. The Forest land base is presently 41 percent old-growth habitat; after five decades it drops to 22 percent. A minimum of 16 percent of the Forest is maintained as old growth at all times Sixty percent more old-growth habitat is preserved indefinitely than required under MR constraints. Wildlife species inhabiting mature/old-growth forest communities will have an adequate habitat base.

In the first two decades the deer herd averages one percent below current levels; WFUD's follow a similar pattern.

Habitat capability for cavity nesters is maintained at 63 percent at the end of the first five decades. The proportion of mature (age 101-200) and young (age 41-100) forest fluctuates widely throughout the planning period, mostly due to the Forest's uneven distribution of stand age classes. Meadows (4,700 acres) on land classified as nontimber are preserved, but no buffer strips around meadows are managed for wildlife. No small "special habitat sites" are managed exclusively for wildlife. No hardwood stands are converted into conifer plantations until after the fifth decade, thereby preserving this habitat type until its value as wildlife habitat can be better understood.

As unmanaged timber stands are harvested and brought into rotation, associated Riparian Areas are converted from even-aged (mainly old growth) to uneven-aged timber stands, in this benchmark a maximum of 66,000 acres of riparian habitat (33 percent of the Forest total) are ultimately converted to this type of forest management; the rest of the riparian habitat will not be entered and will essentially remain in its present condition. Uneven-aged Riparian areas will be managed under Riparian Prescription option C, which maximizes the value of the habitat for wildlife.

FISH. Through application of the Riparian Prescription option C to 18 basins and minimum level management to one basin, water temperatures are projected to decrease by two degrees Fahrenheit by the end of the third decade within Class I and II streams. This situation is projected to improve salmonid habitat capability by 10 percent by the third decade. Inclusion of 27 Supplemental Resource areas will maintain the high production capability of streams involved. Application of the Riparian Prescription option C also provides for long-term input of large organic debris which is essential to good stream stability and salmonid rearing capability. Nine to 13 percent basin specific harvest dispersion constraints provide additional protection against adverse effects from sediments.

TIMBER. The annual harvest level is 29.063 MMCF during the first decade and LTSY (50.071 MMCF) is not achieved until the ninth decade.

Harvest consists of conifer except for 3,971 acres of hardwood conversion scheduled in the sixth decade. About 47,000 acres of hardwoods are available for conversion.

Except for the lack of hardwood conversion scheduling, there are no significant fluctuations in this program.

SOIL AND WATER. Forest watershed condition (as indicated by total sediment production) will improve compared to the current direction benchmark, especially in the first decade. Watershed condition will also improve due to the application of Riparian Prescription option C and the area harvest constraints.

FACILITIES. The new road construction in decade one is about one-third the mileage of the last five year period. New construction decreases in the sixth decade and again in the eighth decade. The first decrease takes place when the forest starts obtaining large amounts of the annual timber cut from commercial thinnings. The second decrease takes place when the old-growth stands available for timber harvest are mostly gone, the road system is largely in place, and the forest is harvesting the second growth stands.

The local road miles will increase 81 percent, from an existing 1,807 miles to an estimated 3,266 miles, when the system is complete sometime in the thirteenth decade. Over 75 percent of this increase is in the first five decades.

The existing road system of 2,645 miles will expand to 4,191 miles, an increase of 58 percent The road system open to passenger cars will increase from 1,504 miles (57 percent) existing to 1,794 miles (43 percent) with the completed system. At the same time, 883 miles (33 percent) of the road system now open to high clearance vehicles will increase to 1,262 miles (30 percent) of the completed system. The remaining 10 percent (258 miles) of the current road system and 27 percent (1,135 miles) of the completed system will be closed to vehicles except for intermittent project use.

MAX WILDLIFE (B13-3)

Purpose.

This benchmark is designed to maximize biotic diversity in an attempt to achieve optimum wildlife habitat without jeopardizing the viability of any one species.

Assumptions and Modeling Constraints.

- habitat for spotted owls is adequate for 80 pairs (twice the minimum requirements).
- habitat capability for cavity nesters is at the 60 percent level.
- riparian habitat disturbance is limited to 35 percent of the total.
- 6 unroaded watershed basins are allocated to minimum level of management (no harvest)
- meadows, including 200 foot buffer strips, and other special habitat sites are managed for the benefit of wildlife.
- habitat improvement projects are planned at maximum levels.

Resource-specific Environmental Consequences.

RECREATION

Developed Recreation. Current use is approximately 115,700 RVD's and is expected to increase to approximately 148.4 RVD's by the fifth decade under this management scheme. Current developed capacity is approximately 157,600 RVD's and can be increased to approximately 172,000 RVD's through the capital investment program by the fifth decade under this management scheme.

Dispersed Recreation. Dispersed recreation is presented by ROS classes. The discussion includes Wilderness and Wild and Scenic River use in the capacity totals and demand projections. Each of these categories will be summarized individually in addition to the information presented in this section.

RN. 653,283 acres of the Forest land is currently inventoried as RN and is expected to increase to 739,333 acres in the fourth decade under this management scheme. Current RN use is approximately 479,100 RVD's and is expected to increase to approximately 614,700 RVD's by the fifth decade of the planning horizon. Current capacity is approximately 1,059,400 RVD's and can be increased to approximately 1,197,700 RVD's by the third decade.

SPM. 115,393 acres of the Forest land is currently inventoried as SPM and will remain the same over the planning horizon. Current SPM use is approximately 80,500 RVD's and is expected to increase to approximately 103,200 RVD's by the fifth decade. Current capacity is approximately 151,800 and will remain constant over the planning horizon because of the difficulty of determining the degree of impact necessary to distinguish between roaded natural and semi-primitive.

SPNM. 195,175 acres of the Forest land is currently inventoried as SPNM and will decrease to approximately 123,495 acres in the third decade of this management scheme due to the impacts of road construction and timber harvest. 259,372 acres will be harvested over five decades, and 1,143 miles of road will be constructed under this management scheme. Current SPNM use is approximately 17,800 RVD's and is expected to increase to approximately 22,800 RVD's by the fifth decade. Current capacity is approximately 41,300 RVD's and will decrease to approximately 25,000 RVD's in the third decade of this management scheme, and can be increased slightly to 26,000 RVD's with the current capital investment program.

Primitive. 128,440 acres of the Forest land is currently inventoried as Primitive and will decrease to approximately 114,070 acres by the third decade, and will remain constant over the planning horizon. Current Primitive use is approximately 11,400 RVD's and is expected to increase to approximately 13,600 RVD's by the fifth decade. Current capacity is approximately 13,100 RVD's and will increase to approximately 13,400 RVD's in the third decade and can be increased to approximately 13,600 RVD's through the current capital investment. Demand is expected to reach capacity in the third decade.

VISUAL RESOURCE. Visual resources will be managed at the minimum level under this management scheme. 8,910 acres of Recreation/Scenic River can be managed under the Retention VQO. All other inventoried areas will be managed under the Modification VQO.

WILDERNESS. 232,495 acres of Wilderness will be carried. No additional areas will be proposed

WILD AND SCENIC RIVERS. The Forest has two designated Wild and Scenic Rivers, the Rogue, and the Illinois. No additional rivers will be considered for evaluation under this management scheme.

WILDLIFE. This benchmark has major effects on wildlife resources. The Forest land base is presently 41 percent old-growth habitat; after five decades it drops to 26 percent. A minimum of 21 percent of the Forest is maintained as old growth at all times. More than twice as much old-growth habitat is preserved indefinitely than required under MR constraints. Wildlife species inhabiting mature/old-growth forest communities will have a more than adequate habitat base; this additional habitat will provide a margin of safety which insures that well-dispersed viable populations of all native species will not perish from this Forest. This safety margin is doubly important, given that very little mature/old-growth habitat will remain on private lands outside the Forest boundary.

In the first two decades the deer herd averages 10 percent below current levels; WFUD's follow a similar pattern.

Habitat capability for cavity nesters is maintained at 77 percent at the end of the first five decades. The proportion of mature (age 101-200) and young (age 41-100) forest fluctuates rather widely throughout the planning period, mostly due to the Forest's uneven distribution of stand age classes. Meadow habitat is maximized at 6,500 acres, with associated 200 foot buffer strips managed for the benefit of wildlife species utilizing this type of habitat. A variety of small "special habitat sites" are managed exclusively for wildlife (2,200 acres). No hardwood stands are converted into conifer plantations until the fifth decade, thereby preserving this habitat type until its value as wildlife habitat can be better understood.

As unmanaged timber stands are harvested and brought into rotation, associated Riparian areas are converted from even-aged (mainly old growth) to uneven-aged timber stands; in this benchmark a maximum of 65,000 acres of riparian habitat (35 percent of the Forest total) are ultimately converted to this type of forest management; the rest of the riparian habitat will not be entered and will essentially remain in its present condition.

FISH. Under this benchmark, Forest habitat capabilities for anadromous and resident salmonid is enhanced through maintaining the natural habitat plus project work primarily designed to improve rearing capability of juvenile salmonids. Stream temperatures are maintained by maintaining streamside canopy cover through application of the B management prescription Stream sediment input is held at current levels by basin constraints which allow no more than 20 percent timber harvest entry per decade, and no more than 11 percent of Riparian areas harvested per decade.

TIMBER. The annual harvest level is 25.771 MMCF during the first decade and LTSY (43.848 MMCF) is not achieved until the ninth decade.

Harvest consists of conifer except for hardwood conversion scheduled in the fourth decade (166 acres), the fifth decade (2,170 acres) and the fifteen decade (2,044 acres).

The contribution to harvest is significant in regard to Riparian area acres. Riparian harvesting increases from 1,322 acres in the first decade to 5,106 acres in the fifth decade, then declines to 1,380 acres and 946 acres in the tenth and fifteenth decades respectfully.

Reforestation acres double from the first decade (4,979 acres) to the fifth decade (10,326 acres). This will require significant increases in budget and people.

SOIL AND WATER Forest watershed condition (as indicated by total sediment production) will improve compared to the current direction benchmark, especially in the first decade. In subsequent decades this alternative will be very comparable to the current situation.

FACILITIES. The new road construction in decade one is less than one-third the mileage of the last five year period. The decrease in new construction in the sixth decade is when the forest starts obtaining large amounts of the annual timber cut from commercial thinnings and from second growth stands.

Reconstruction miles increase to a high of 210 miles per year in the fourth decade, which is higher than the forest has experienced in the past (Fiscal Year 1982 had 177 miles).

The local road miles will increase 58 percent, from an existing 1,807 miles to an estimated 2,863 miles, when the system is complete sometime in the seventh decade. Nearly 95 percent of this increase is in the first five decades.

The existing road system of 2,645 miles will expand to 3,788 miles, an increase of 43 percent. The road system open to passenger cars will increase from 1,504 miles (57 percent) existing to 1,739 miles (46 percent) with the completed system. At the same time, 883 miles (33 percent) of the road system now open to high clearance vehicles will increase to 1,158 miles (31 percent) of the completed system. The remaining 10 percent (258 miles) of the current road system and 23 percent (891 miles) of the completed system will be closed to vehicles except for intermittent project use.

CONSTRAINT ANALYSIS

Additional FORPLAN runs were made to evaluate the impacts and costs of various constraints and objectives. Runs were also made to test the sensitivity of the solutions to changes in certain run parameters. The opportunity costs and sensitivity analysis are documented below. Additional background on the development and selection of methods to meet MR's can be found in Appendix J

OPPORTUNITY COST OF MANAGEMENT REQUIREMENTS

Tradeoffs associated with MR's were analyzed by comparing Base Runs having no provisions for MR's with runs that incrementally added the various components of MR's until the entire MR package was incorporated. MR's that have significant timber and economic tradeoffs fall into two categories; those necessary to meet the distribution of viable fish and wildlife populations, and those necessary to meet soil productivity and water quality standards. Opportunity costs are defined as the difference in PNV between the Base Run (B22-2) and the runs that include MR's. This reduction in PNV represents the opportunity cost of managing the Forest for optimum market and nonmarket resource outputs, while continuing to provide for MR's.

Each component of the MR package was evaluated in separate FORPLAN runs with timber harvest activity controlled by NDY and CMAI.

Soil, Water, and Fish Objectives

Runs compared:	B22-2	(PNV 1,645 10 MM $)
	B28-1	(PNV 1,394.72 MM $)
Opportunity Cost:	250.38 MM $	(15.2 percent reduction)

The analysis showed that when applied separately, MR's for soil and water (B28-1) reduced average annual first decade timber harvest to 34 6 MMCF (13 percent reduction) and LTSY to 55.0 MMCF (5 percent reduction). PNV fell 15 percent (250 MM $), while total discounted costs declined 9.6 MM $ (-1 percent). The major response of applying these MR's was to limit harvest in Riparian areas to 50 percent reduction in basal area during the first commercial entry on Class III streams and 20 percent on Class I and II streams. Created openings were also limited to no more than 20 percent per watershed basin per decade.

Fish MR's require maintenance of existing habitat conditions. Soil and water MR's form the basis for current management direction on the Forest. No additional constraints were necessary to meet fish requirements, since existing fish habitat is the result of implementing soil and water MR's.

Wildlife Objectives.

Runs compared:	B22-2	(PNV 1,645.10 MM $)
	B29-2	(PNV 1,508.48 MM $)
Opportunity Cost:	136.62 MM $	(8.3 percent reduction)

Application of the wildlife MR's (B29-2) reduced average annual first decade timber harvest to 37.1 MMCF (7 percent reduction) and LTSY to 56.0 MMCF (-3 percent). PNV was reduced 137 MM $ (-8 percent), while total discounted costs declined 10 MM $ (-1 percent). Wildlife MR's are principally attained through the maintenance of 1,000, 300, and 160 acre old-growth/mature blocks of timber distributed for spotted owl, pileated woodpecker, and pine marten, respectively.

All MR's with NDY and CMAI.

Runs compared:	B22-2	(PNV 1,645.10 MM $)
	B30-1	(PNV 1,300.55 MM $)
Opportunity Cost:	344.55 MM $	(20.9 percent reduction)

When all MR's are applied (B30-1), average annual first decade timber harvest is reduced to 32 4 MMCF (19 percent reduction) and LTSY to 52 MMCF (-10 percent). PNV is reduced 345 MM $ (21 percent)), while total discounted costs decline 38 5 MM $ (5 percent). The opportunity cost resulting from the simultaneous application of both constraints is less than the sum of the two parts, which indicates wildlife requirements help satisfy soil and water requirements.

All MR's in the Absence of NDY and CMAI.

Runs compared.	B18-3	(PNV 1,909.08 MM $)
	B31-1	(PNV 1,449.04 MM $)
Opportunity Cost:	460.04 MM $	(24.1 percent reduction)

The effect of all MR's was also evaluated in the absence of timber policy constraints. Sequential upper and lower bounds, with a harvest floor of 80 percent of current (28 MMCF), were substituted for the NDY

constraint and rotations based on utilization standards were used in lieu of CMAI to model the Base Run. Refer to Table B-7 for the FORPLAN specifications.

Average annual first decade timber harvest declined 24 percent (18 MMCF) and LTSY by 10.5 percent (6 MMCF), relative to the base without NDY or CMAI, when all MR's were applied PNV declined 24 percent while total discounted cost were reduced 81 MM $ (-8 percent).

Opportunity costs for MR's are higher in the absence of NDY and CMAI than those associated with comparable evaluations which include timber policy constraints. The presence of NDY and CMAI effectively control the rate of access which simultaneously contributes to the satisfaction of the water quality requirements.

OPPORTUNITY COST OF TIMBER POLICY CONSTRAINTS

Rotation ages determined by the general (95 percent) attainment of CMAI and decadal harvest rates that can increase or remain constant, but never decline (NDY) comprise the timber policy constraints that are evaluated in this section. Opportunity costs are determined by applying these constraints to the FORPLAN model and comparing the results with Base Runs that represent the "without condition". Timber policy constraints were evaluated when MR's were installed and in their absence to show what tradeoffs, or opportunity costs, might be masked by the presence of other model parameters such as MR's.

Nondeclining Yield Constraint (NDY).

Runs compared:	B31-1	(PNV 1,449.04 MM $)
	B27-1	(PNV 1,340.03 MM $)
Opportunity Cost:	109.01 MM $	(7.5 percent reduction)

A Base Run with upper and lower sequential bounds and rotations based on Regional utilization standards, governed by MR's (B31-1) was compared to a run with the same specifications except NDY replaced sequential upper and lower bounds (B27-1). Average annual first decade timber yield declined 35 percent (20.1 MMCF) under the NDY scenario while LTSY fell 2 MMCF (4 percent). Replacing sequential bounds with NDY reduced PNV 109 MM $, as total discounted costs declined 103 MM $.

Culmination of Mean Annual Increment (CMAI).

Runs compared:	B31-1	(PNV 1,449.04 MM $)
	B30-4	(PNV 1,386.14 MM $)
Opportunity Cost:	62.9 MM $	(4.3 percent reduction)

The same Base Run referenced above (B31-1) was compared against a run with identical FORPLAN specifications, except rotations based on the general attainment of CMAI were substituted for rotation determinations based on utilization standards (B30-4). Average annual first decade timber yield declined 8 MMCF (14 percent), while LTSY increased 4 MMCF (7.8 percent) because harvest generally occurred at CMAI which produces the greatest amount of wood in the long-term. PNV declined 63 MM $ (4 percent), as total discounted costs fell 98 MM $ (10.8 percent). As CMAI tends to produce more wood, the extra time (about 20 years) does not produce enough extra value to compete with the 4 percent discount rate used to calculate present value. Opportunity costs would be zero if no discount rate were used to make present value calculations; however, as the discount rate is increased, opportunity costs become greater.

Combination of NDY and CMAI.

Runs compared:	B31-1	(PNV 1,449 04 MM $)
	B30-1	(PNV 1,300.55 MM $)
Opportunity Cost:	148.49 MM $	(10.25 percent reduction)

The net effect of NDY and CMAI applied in concert was determined based on a comparison of the Base Run with a run having both policy constraints installed (B30-1). Average annual first decade timber yield was reduced 24 MMCF (43 percent) when both constraints are applied in unison. LTSY, however, increases 1 MMCF (2 percent) due to the longer rotations. The net loss in PNV (148 MM $) is less than the sum of the two parts, which indicates that one of the two policies helps satisfy the objectives of the other.

CMAI in the absence of MR's.

Runs compared:	B18-3	(PNV 1,909.08 MM $)
	B17-3	(PNV 1,834.99 MM $)
Opportunity Cost:	74.09 MM $	(3.9 percent reduction)

The effect of CMAI relative to rotation determinations using Regional standards was also evaluated in the absence of MR's to determine whether tradeoffs (opportunity costs) were being over or understated. Percentage reductions in PNV are less in the absence of MR's, but only by a marginal amount. Average annual first decade timber harvest declines 8 MMCF (11 percent) with CMAI in the absence of MR's which is identical to the reduction experienced with MR's. LTSY increases in the absence of MR's by 6 MMCF (11 percent) as opposed to the 4 MMCF increase realized with MR's in place. The impact of CMAI is essentially the same with, or without MR's.

Combination of NDY and CMAI in the absence of MR's.

Runs compared:	B18-3	(PNV 1,909.08 MM $)
	B22-2	(PNV 1,645.10 MM $)
Opportunity Cost.	263.96 MM $	(13.8 percent reduction)

The combined impact of CMAI and NDY, applied simultaneously in the absence of MR's was also evaluated. Percentage reductions in PNV are greater in the absence of MR's than opportunity costs calculated with MR's by approximately 4 percent. Average annual first decade timber yield is reduced 34.6 MMCF (47 percent) when both timber policy constraints are applied, which is greater than the impact associated with MR's. The impacts on LTSY are identical to those experienced in the presence of MR's (i e., plus 1 MMCF, or a 2 percent increase).

OPPORTUNITY COST OF MAXIMUM PRODUCTION, MIN LEVEL AND CURRENT DIRECTION BENCHMARKS

An analysis of benchmarks was conducted to ascertain opportunity costs associated with the resolution of ICO's. These evaluations were completed using a common constraint set to localize the effect directly attributable to achieving specific resource objectives. Except for the Minimum Level Benchmark, all benchmarks are bound by the following constraints.

- all benchmarks complied with NFMA MR's
- an ending timber inventory constraint was used so that the timber inventory in 150-years will equal or exceed the volume that would occur on a regulated forest.

- timber rotation length was based on 95 percent of CMAI determination
- a timber harvest flow constraint of NDY was used.
- an objective function of maximizing PNV was used.
- a minimum level of the existing Wildernesses was maintained in all benchmarks.
- the Min Level Benchmark was constrained to produce no management outputs such as timber harvest and livestock grazing to determine the basic cost of Federal ownership.

Min Level Benchmark.

Runs compared:	B30-1	(PNV 1,300.55 MM $)
	MINLVL	(PNV 4 99 MM $)
Opportunity Cost:	1,295.56 MM $	(99.6 percent reduction)

The Min Level Benchmark defines the costs and benefits of operating the Forest in a custodial fashion with no production of controllable goods and services such as timber, developed recreation, etc. Management under this benchmark reduces PNV by 99 percent (1296 MM $) and essentially terminates all market outputs with the exception of anadromous fish for commercial harvest. Total discounted cost of .67 MM $ represent the administrative costs necessary to maintain the Forest in public ownership and fulfill public safety and resource protection obligations.

Current Direction Benchmark.

Runs compared.	B30-1	(PNV 1,300.55 MM $)
	B06-5	(PNV 1,170.34 MM $)
Opportunity Cost:	130.21 MM $	(10.0 percent reduction)

Land assignments in this benchmark are identical to those of the "No Action" Alternative, except that NFMA MR's are substituted for the interim direction of 300 acre spotted owl management areas (SOMA's). Budget constraints associated with the No Action Alternative are also relaxed in this benchmark. The mutiple-use orientation of this benchmark reduces average annual first decade timber harvest 2 8 MMCF (9 percent), and LTSY 1 MMCF (2 percent), relative to Max PNV. PNV declines 130 MM $ to meet the resource objectives specified in existing management plans

Max Timber Benchmark.

Runs compared:	B30-1	(PNV 1,300.55 MM $)
	B11-3	(PNV 1,276.24 MM $)
Opportunity Cost:	24.31 MM $	(1.87 percent reduction)

Land assignments selected by FORPLAN to maximize timber production (568,000 acres) are essentially identical to those selected to maximize PNV (546,000 acres). This is primarily due to timber's significant contribution to PNV, relative to other resource values Opportunity costs associated with maximizing timber production occur because less efficient acres (principally hardwood stands) are brought into solution earlier in the planning horizon than would occur under Max PNV (22,000 acres of hardwoods go to custodial management). PNV declines 2 percent (24 MM $) while total discounted costs increase 8 percent (59 MM $). Average annual first decade timber production increases 3 percent (1 MMCF), while LTSY increases 13 percent (7 MMCF).

Max Unroaded Benchmark.

Runs compared.	B30-1	(PNV 1,300 55 MM $)
	B20-2	(PNV 953.92 MM $)
Opportunity Cost.	346.63 MM $	(26.65 percent reduction)

All presently unroaded land (258,101 acres) was placed under custodial management in this benchmark which reduced the available/suitable timber base by 100,198 acres, relative to Max PNV Average annual first decade timber yield is reduced 9 MMCF (29 percent), while LTSY falls 12 MMCF (23 percent). A similar reduction in PNV (27 percent) occurs with the reduction in timber harvest as the increased recreational use is not sufficient to offset the loss in timber revenues. Total discounted costs also decline 144 MM $ (20 percent) with the reduction in available timber land.

Max Recreation Benchmark.

Runs compared:	B30-1	(PNV 1,300 55 MM $)
	B19-2	(PNV 917.60 MM $)
Opportunity Cost:	382.95 MM $	(29.4 percent reduction)

In addition to the assignment of all unroaded lands to custodial management, 25 areas with high dispersed recreation potential were allocated to Supplemental Resource areas. The two inventoried Wild and Scenic River candidates were also treated as classified in this benchmark Available/suitable timber acreage was reduced 28,437 acres, in addition to the 101,000 acres removed for custodial management in unroaded areas Average annual first decade timber yield declined 10 MMCF (31 percent), while LTSY fell 13 MMCF (25 percent). PNV was reduced 347 MM $ because increased recreational use could not offset the foregone timber values

Max Visuals Benchmark.

Runs compared:	B30-1	(PNV 1,300.55 MM $)
	B12-1	(PNV 1,205.55 MM $)
Opportunity Cost:	95.0 MM $	(7.3 percent reduction)

Inventoried VQO's were achieved on all acres of the Forest in this benchmark. The reduced average timber yield necessary to meet retention and partial retention VQO's reduced average annual first decade timber harvest 1.9 MMCF (6 percent), and dropped LTSY 1 MMCF (2 percent). PNV fell 95 MM $, while total discounted costs declined 28 MM $ (4 percent).

Max Fish and Watershed Benchmark.

Runs compared:	B30-1	(PNV 1,300.55 MM $)
	B16-1	(PNV 1,170.34 MM $)
Opportunity Cost:	130.21 MM $	(10.0 percent reduction)

High levels of capital expenditures for habitat improvement, a reduced level of riparian disturbance, and the allocation of 27 valuable fishery streams and rivers to custodial (roadless) management, are utilized to maximize fish production in this benchmark. Average annual first decade timber yield is reduced 3.3 MMCF (10 percent), while LTSY declines 2 MMCF (4 percent). The increased fish production does not yield

enough value (both sport and commercial) to offset the loss in timber revenues, resulting in a net loss of 130 MM $.

Max Wildlife Benchmark.

Runs compared:	B30-1	(PNV 1,300.55 MM $)
	B13-3	(PNV 1,040.61 MM $)
Opportunity Cost·	259.94 MM $	(19.98 percent reduction)

Land assignments required to achieve optimum habitat diversity for all wildlife species left an available/suitable timber base of 414,809 acres; 91,342 acres less than the base governing Max PNV Average annual first decade timber harvest declined 6.6 MMCF (20 percent), while LTSY fell 8 MMCF (15 percent). Reductions in PNV (20 percent) are primarily due to the land required to maintain 80 pair of spotted owl (twice the MR level) and custodial management in six unroaded watershed basins.

SENSITIVITY ANALYSIS

Structuring the FORPLAN model to produce solutions that represent reality is the challenge facing analysts with the responsibility of running and interpreting FORPLAN. The degree of data reliability needed to foster confidence in FORPLAN solutions can be determined by examining the sensitivity of FORPLAN solutions to incremental changes in various model parameters. Changes that have little or no effect on the solution indicate that a high degree of data reliability is not necessary, nor would greater precision improve the solution. Those parameters that have a significant impact on solutions deserve special attention during the preparation of the data and in the interpretation of results. A thorough understanding of the model components, their interrelationships, and recognition of their ability to affect the solution is essential to correctly interpret results during implementation

Sensitivity analysis is a procedure used to respond to concerns about data reliability, modeling assumptions, and the effectiveness of measures employed to achieve management objectives. It is an effective means of evaluating "what if" type questions. Sensitivity analysis was used on the Siskiyou to evaluate economic assumptions, and timber harvest and roading patterns.

ECONOMIC ASSUMPTIONS

A level of uncertainty surrounds literally all economic assumptions concerning projections of the future. *Economic parameters such as unit values, trends in time, and the discount rate used to express dollars* in present (1982) terms can exercise considerable influence on a mathematical model driven by an economic selection criterion. In particular, the relative economic merits of different land types may change significantly as economic parameters are varied. The following evaluations were made to apprise the responsible official of the consequences should the future prove the economic assumptions in error.

Market Verses Nonmarket Values.

Runs Compared:	B30-1	(PNV 1,300.55 MM $)
	B30-2	(PNV 1,300 36 MM $)
Sensitivity:	-.19 MM $	(.015 percent reduction)

Both runs have identical FORPLAN specifications, with NDY, CMAI, and MR's governing the solutions. Values for goods and services not necessarily traded in the open market are suppressed, however in B30-2, leaving economic value for those goods and services for which a market exists Because of the consistently high contribution of timber to total PNV (averages between 85 and 90 percent), very little

change occurs in PNV. Reductions in WFUD's were the most significant difference between the two runs Average annual wildlife benefit values declined 41 M $ in the first decade, bringing big-game, and nongame use down 3 and 2 percent, respectively.

Long-term Stumpage Value Trends (0 Percent).

Runs compared:	B30-1	(PNV 1,300.55 MM $)
	B32-1	(PNV 960 41 MM $)
Sensitivity:	-340.14 MM $	(26 25 percent reduction)

The maximum FORPLAN specification (B30-1) was reoptimized without the benefit of a 1 percent per annum projected increase in timber stumpage value (B32-1). Significant reductions in PNV occur in the absence of a timber price trend. Average annual timber yield remains constant in the first decade, but LTSY suffers a 3 MMCF loss (6 percent) relative to Max PNV. Selected suitable timber land assignments drop from 546,000 acres to 535,000 acres.

Long-term Stumpage Value Trends (3 Percent).

Runs compared:	B30-1	(PNV 1,300 55 MM $)
	B33-1	(PNV 2,482.80 MM $)
Sensitivity:	+1,182 25 MM $	(90 9 percent increase)

The 3 percent per annum timber price trend substituted in B33-1 significantly increased PNV, relative to Max PNV. Average annual harvest activity remained unchanged until the tenth period where it increases 6 percent. LTSY increases 3 MMCF (6 percent) as a result of the higher discount rate Selected suitable timber land assignments increase to 566,000 acres.

Discount Rate (7.125 Percent).

Runs compared:	B30-1	(PNV 1,300.55 MM $)
	B30-3	(PNV 1,292 85 MM $)
Sensitivity:	-7.7 MM $	(.59 percent reduction)

Lands that are economically marginal with respect to timber production should become even less attractive (economically) as the discount rate increases. To determine which, if any, lands might fall out of solution under such a scenario, a 7.125 percent discount rate was substituted for the standard 4 percent assumption used in other runs. As illustrated above, the change in discount rates reduced PNV 8 MM $ (less than 1 percent). Average annual timber production declined .2 MMCF (1 percent) in the first decade, while LTSY remained unchanged. Selected suitable timber land was 560,000 acres

HARVEST AND ROADING PATTERNS

The feasibility of implementing the timber management part of the FORPLAN solutions was examined with respect to the acres of commercial thinning (CT) programmed for future decades; the distribution of harvest on low, medium, and high site lands through time; and the trend of road construction and reconstruction.

Constraining CT acres to only 4,500 per decade resulted in a reduction in first decade timber production from 32.4 MMCF to 31.4 MMCF (3 percent). Because this extreme constraint resulted in only 3 percent

change, and the acres of CT in future decades has little or no effect on current implementation, constraints for CT acres were not included in the data sets for future runs

Examination of the distribution of harvests over the productivity groups indicated that FORPLAN would harvest only high and medium sites for the first few decades and then harvest most low sites in the fifth through the seventh. A more realistic schedule for implementation would include some of all site groups in each decade. A constraint was installed to force harvest of a minimum of 3,000 acres of low site per decade in the early decades This resulted in no appreciable change in timber outputs and was installed in all future runs.

Initial FORPLAN runs selected acres for harvest that had lowest road costs in the first decades and then those with higher costs in subsequent decades resulting in a trend of increasing road costs over decades one through six after dropping well below the current level in the first. This is not realistic for implementation as acres with low cost per volume could not be singled out in a logical harvesting pattern A constraint was installed to prevent increasing roading costs over the first six decades This resulted in no appreciable change in the timber outputs and was used in future runs

In addition to these constraints, there was also some minor refinement of the economic data for road construction, reconstruction, and maintenance to be used in future analysis. The net effects of the changes in the model for these implementation feasibility constraints and the data refinements can be seen by comparing the following runs. These changes will be carried into the analysis of alternatives.

Runs compared·	B30-1	(PNV 1,300 55 MM $)
	A09-1	(PNV 1,276 25 MM $)
Change:	-24.3 MM $	(1.87 percent reduction)

Timber production for these runs was nearly identical with first decade harvest going from 32.4 MMCF to 32.3 MMCF, and LTSY going from 53.2 MMCF to 51.9 MMCF. Since these data refinements and feasibility constraints resulting from the knowledge gained during the benchmark analysis are carried into all of the alternatives, Run A09-1 will be used for the Max PNV Benchmark in the tradeoff analysis done with the alternatives

FORMULATION OF ALTERNATIVES

INTRODUCTION

A Forest planning alternative is a mix of management prescriptions applied in specific amounts and locations to achieve a desired management emphasis as expressed in goals and objectives To be viable (36 CFR 219.12(f)), the alternative must:

- exist between maximum and minimum resource potential of the Forest.
- facilitate analysis of opportunity costs and of resource use and environmental tradeoffs among alternatives.
- facilitate evaluation of PNV, benefits, and costs of achieving various outputs as well as values that are not assigned monetary values.
- show a different way to address and respond to major public issues, management concerns, and opportunities (ICO's).
- represent the most cost efficient combination of management prescriptions that can meet the objectives of the alternative.
- state the condition and uses that will result from implementation.
- state what goods and services will be produced including timing and flow of outputs and the costs and benefits generated.
- state the resource management standards and guidelines used
- state the purpose of the management direction used.

Formulating alternatives was step five in the Forest planning process following the analysis of the management situation. During the analysis of the management situation a determination was made of the ability of the Forest to supply goods and services. Maximum and minimum output levels were established based on the composite results of benchmarks and constraint analyses. These levels form the range within which the alternatives were developed Five specific alternatives are required. Alternative A was developed to reflect the expected level of goods and services that could be produced should current management be continued (the "No Action" alternative). Alternative B was developed to respond to and incorporate the RPA program tentative resource objectives Goods and services that have value, as determined in the open market, are emphasized in Alternative D Alternative E was developed to favor the production of goods and services that do not necessarily have market determined values, such as dispersed recreation use. Alternative E also satisfied the fifth requirement retaining the unroaded portions of the Forest in an undeveloped status while continuing commodity production at a high level in those areas already roaded.

The process for formulating alternatives can best be explained in a series of steps.

Step 1. Major public issues were identified through public involvement. Internal management concerns were added to the list of issues (further explained in Appendix A of the FEIS). These issues and concerns were reviewed by an IDT and consolidated into a set of planning problems to be addressed.

Step 2. A comprehensive multi-resource data base was formed based on the identified issues and concerns and stored in a computer retrieval system.

Step 3 Land analysis areas with similar physical and biological attributes were identified and mapped. The capability, suitability, and management opportunities of specific areas of the Forest were considered in this step.

Step 4. A set of management prescriptions was prepared to represent a variety of possible ways and intensities to manage the Forest.

Step 5. The 317 analysis areas identified in Step 4 were assigned management prescriptions that could be applied optionally to build the alternatives. Analysis areas, except those allocated by higher authority (e.g., previously designated Botanical areas), were assigned at least two prescriptions including minimum level. Most of the lands available and suitable for timber production were assigned a variety of prescriptions that could be applied.

Step 6. Resource outputs and the associated costs and dollar values that would result when a prescription was implemented were calculated and entered into the computer model FORPLAN

Step 7. Demand was estimated for the resources involved in the planning problems.

Step 8. Supply potentials were determined. Various assumptions, constraints, and objectives were used to establish benchmarks for supply potentials of each resource. Benchmarks were established for the minimum, maximum, and constraint analysis levels and maximum PNV. Existing resource supply and projected demand were compared to supply potentials of each benchmark. *Opportunities to resolve issues and management concerns were identified for each resource by* comparing existing and projected demand to potential production levels. These potentials, when compared to the Current Direction, indicate opportunities or need for change This step concluded the analysis of the management situation - benchmark analysis.

Step 9. Alternative objectives were established to provide a broad range of options for future management of the Forest. Selected benchmarks were used to define upper and lower limits for the production of each resource. These upper and lower limits outlined the decision space boundaries for the resources involved. The IDT considered expected use, supply potential (upper and lower limits), and evaluated public input to establish the range of alternatives within the decision spaces Descriptions were written to define the resource management intent for each alternative.

Step 10. The FORPLAN model was again used to estimate the outputs and costs for each alternative by reflecting the theme of the alternative through a given set of objectives and constraints.

Step 11. The results of the FORPLAN analysis for each alternative were evaluated to assure conformance with laws, policies, and guidelines, and to assure that each alternative could be implemented.

The IDT incorporated cost efficiency at several steps in the planning process. Prescriptions were developed using least cost methods that would meet the objectives of the prescription. For the timber resource additional analysis was done to develop a range of management intensity levels within each timber prescription. The IDT developed a range of alternatives and identified the necessary constraints to address specific objectives and planning problems. The prescriptions were combined with the land assignments and constraints to form alternatives that would most efficiently accomplish the goals and objectives for the specific alternative. Each alternative was analyzed through FORPLAN to identify the most efficient prescriptions and intensities for the given objectives and constraints, and to project the stream of anticipated priced and nonpriced outputs. The feasibility of satisfying the package of constraints for each *alternative is also checked with FORPLAN. All constraints must be satisfied or a feasible solution will not* be reported. Using this combination of least cost prescriptions, FORPLAN analysis of prescription options with the PNV objective function, and efficient design of land assignments and constraints, cost efficient solutions in accordance with the themes of individual alternatives are assured

COMMON CONSTRAINTS

The constraints developed in the analysis of the management situation formed the basis for constraints applied to all alternatives. The development of these constraints culminated in FORPLAN run A09-1, Max

PNV with the alternative data set. The result is somewhat different than the Max PNV benchmark due to the constraints that were developed during the benchmark analysis to assure that alternatives would be implementable. Throughout the benchmark and tradeoff analysis common constraints were developed, examined, and tested to see how well they addressed their stated purpose. They also represent the most cost efficient approach to meeting the intended purpose. These constraints were discussed previously in this appendix. The following constraints are common to all alternatives, and to run A09-1. The tradeoff information presented is from comparisons of applying the constraints individually; synergistic or compensating effects are not evaluated.

1. Constraint: All alternatives except departures require nondeclining yield for timber harvests (NDY).
   Purpose: Provides a sustained yield of timber harvests.
   Rationale: Assumes a constant supply or upward trend in timber supply.
   Tradeoff: PNV reduced 7.5 percent, first decade ASQ reduced 35 percent

2. Constraint: Insure an appropriate level of timber inventory at the end of the planning horizon (LTSY link).
   Purpose: To assure that harvestable timber will be available in the decades immediately following the end of the planning horizon.
   Rationale: Assure a future sustained yield of timber harvest.
   Tradeoff: Not evaluated.

3. Constraint: Minimum timber rotations are based on 95 percent of the CMAI for existing and regenerated stands (except Alternative D1).
   Purpose: Assure that timber stands generally reach their maximum mean annual growth rate prior to harvest.
   Rationale: Provide rotation ages that maintain high productivity and meet the requirements of 36 CFR 219.16(a)(2)(iii).
   Tradeoff: PNV reduced 4.3 percent, first decade ASQ reduced 14 percent, LTSY increased 7.8 percent.

4. Constraint: Limit created openings to 20 percent, or less, of watershed basins per decade. (Except some alternatives which have more stringent constraints)
   Purpose: Disperse harvest among the basins to assure that basic soil productivity, water quality, fisheries objectives, and legal size of opening requirements are maintained.
   Rationale: Soil, water, and fisheries resources must be maintained at legally defined levels.
   Tradeoff: Not evaluated independently; applied in concert with the following riparian area constraint (5).

5. Constraint: Riparian zones are protected by limiting timber harvest to 11 percent of the riparian area acres per decade by planning basin; and by reducing projected timber yield to 50 percent of inventoried volume per acre on Class III streams, and 20 percent on Class I and IIs (Riparian Prescription option B).
   Purpose: Protect the areas that are most critical to a wide range of resources including timber, wildlife and fish, recreation, and water.
   Rationale: Riparian ecosystems require special attention to assure that no practices will cause detrimental changes in water quality. (Riparian Prescription option B affords the minimum legal protection.)
   Tradeoff: Not evaluated independently. In combination with the created openings constraint above (4), PNV reduced 15.2 percent, first decade ASQ reduced 13 percent.

6. Constraint: All alternatives except No Change require a minimum network or mature and old-growth habitat to be maintained on land that would otherwise be suitable for timber production.
   Purpose: Maintain viable wildlife populations of species dependent on mature and old-growth habitats.
   Rationale: These habitats would not be maintained with the dispersion needed to maintain minimum viable populations without this constraint
   Tradeoff: PNV reduced 8 3 percent, first decade ASQ reduced 7 percent.

7. Constraint: Low Productivity Group harvest in early decades.
   Purpose: Force harvest of some Low Productivity Group acres in early decades.
   Rationale: The model would put off all harvest in low site until later decades without this constraint. The productivity groups are somewhat interspersed and logical project layout will occasionally include some low site. This constraint forces a mix of productivity groups in all decades representing a more logically implementable solution.
   Tradeoff: No appreciable effect.

8. Constraint: Roading costs are constrained to not increase from decade to decade for the first six decades.
   Purpose: This produces more implementable solutions.
   Rationale: Without this constraint, the model selects acres for harvest in early decades that have low road costs in proportion to the volume harvested. Given the distribution of these acres, this was not feasible to implement. This constraint forces a better balance of road costs and volume outputs spread over the decades when road development would occur.
   Tradeoff: Timber outputs are not affected. PNV is reduced by 1.9 percent.

DEVELOPMENT OF THE ALTERNATIVES

Following the definition of the alternatives, the criteria and assumptions of each were translated into the land assignments, capital investment schedules, and modeling objectives and constraints necessary to represent the alternative in the FORPLAN model. Complete descriptions of the alternatives, including the objectives, land assignments and capital investment schedules, are found in Chapter II of the FEIS. The modeling constraints specific to each alternative are presented in this section.

Each alternative was formulated and run in the FORPLAN model as a package. Iterative runs to quantify the effects (tradeoffs) of individual constraints within the alternative formulation were not made The greatest differences among the alternatives are generally associated with the land assignments which were modeled by applying constraints requiring a minimum number of acres to be assigned to Partial Retention, Retention, Riparian, or Minimum Level prescriptions. Management Area 10 (Scenic and Recreation River) acres are assigned to the Retention FORPLAN prescription for alternatives that allow programmed timber harvest from these areas. The Minimum Level FORPLAN prescription was used for all acres that would not have programmed timber outputs (i.e. Management Areas 1 through 9 and unsuitable lands). Differences in other resource yields associated with these assignments that were not a function of timber activity or age were directly entered for each alternative. Unconstrained suitable timber acres were allowed to go to the General Forest prescription. In all cases, the Minimum Level option was allowed for all acres.

ALTERNATIVE NC

Goals. The goals of this alternative are to continue management direction as set out in previous plans, and that included in existing policies, standards, and guidelines. It does not include all MR's developed for

old-growth indicator species (pileated woodpeckers and pine martens) The designated habitat for spotted owl areas is limited to 300 acre SOMA's. This is the "no change" alternative.

Criteria and Assumptions. The criteria and assumptions underlying the development of this alternative are:

1. Timber production is increased over time, not to exceed the LTSY. Timber merchantability standards, yield tables, and inventory data are updated to current or proposed standards Tentatively suitable timber land inventory was updated according to Regional direction.
2 Wildlife MR's, developed for old-growth dependent species, are not included.
3 The entire complement of inventoried VQO's from the land use plans are included.
4. Management options for candidate Wild and Scenic Rivers will be maintained as per current direction.
5 Riparian areas will be managed under Prescription option B (current Siskiyou riparian policy)
6. A moderate rate of hardwood conversion would be allowed.

The constraints used to meet the criteria and assumptions are:

1. All common constraints except number 6 which requires protection of network of mature and old-growth habitat.

2. Constraint. Constrained available suitable acres:

Allocated Minimum Level	46,850
Retention	33,115
Partial Retention	145,019

Purpose. Constrain acres with timber management options to those of current plans
Rationale: Represent the no action alternative with current direction land assignments

3 Constraint: Hardwood conversion not to exceed 7,500 acres in any decade.
Purpose: Limit conversion acres to a level consistent with the theme of the alternative.
Rationale: When not constrained, FORPLAN sometimes scheduled large blocks of hardwood acres in a single decade.

ALTERNATIVE A

Goals. The goals of this alternative are to continue management direction as set out in previous plans, and that included in existing policies, standards, and guidelines. It also includes the MR's of current laws and regulations This is the "No Action" alternative required by NEPA.

Criteria and Assumptions. The criteria and assumptions underlying the development of this alternative are:

1 Timber production is increased over time, not to exceed the LTSY. Timber merchantability standards, yield tables, and inventory data are updated to current or proposed standards. Tentatively suitable timber land inventory was updated according to Regional direction.
2. Wildlife MR's, which were not required by law when previous plans were completed, are included.
3. The entire complement of inventoried VQO's from the land use plans are included.
4. Management options for candidate Wild and Scenic Rivers will be maintained as per current direction.

5. Riparian areas will be managed under Prescription option B (current Siskiyou riparian policy).
6. A moderate rate of hardwood conversion would be allowed.

The constraints used to meet the criteria and assumptions are:

1. All common constraints.

2 Constraint: Constrained available suitable acres·

Allocated Minimum Level	46,850
Retention	33,115
Partial Retention	145,019

Purpose: Constrain acres with timber management options to those of current plans.
Rationale: Represent the no action alternative with current direction land assignments.

3. Constraint: Hardwood conversion not to exceed 7,500 acres in any decade.
Purpose: Limit conversion acres to a level consistent with the theme of the alternative.
Rationale: When not constrained, FORPLAN sometimes scheduled large blocks of hardwood acres in a single decade.

ALTERNATIVE A-DEPARTURE

Goals. The goals of this alternative are similar to Alternative A. It would continue management direction as set out in previous plans, and that included in existing policies, standards, and guidelines. It also includes the MR's of current laws and regulations. In addition, it would maintain the current level of timber outputs for the next two decades.

Criteria and Assumptions. The criteria and assumptions underlying the development of this alternative are:

1. Timber production must equal 31.2 MMCF ASQ for the first two decades. It is allowed to decrease in the third and fourth decades, then holds steady or increases over following decades. Timber merchantability standards, yield tables, and inventory data are updated to current or proposed standards. Tentatively suitable timber land inventory was updated according to Regional direction.
2. Wildlife MR's are included.
3. The entire complement of inventoried VQO's from the land use plans are included.
4. Management options for candidate Wild and Scenic Rivers will be maintained as per current direction.
5. Riparian areas will be managed under Prescription option B (current Siskiyou riparian policy).
6. A moderate rate of hardwood conversion would be allowed.

The constraints used to meet the criteria and assumptions are:

1. All common constraints except 1 NDY released first and fifth decades.

2. Constraint: Constrained available suitable acres:

Allocated Minimum Level	46,850
Retention	33,115
Partial Retention	145,019

Purpose: Constrain acres with timber management options to those of current plans.
Rationale: Represent the no action alternative with current direction land assignments.

3. Constraint. Harvest volume equal to 31.2 MMCF decades 1 and 2, and 30 3 decade 3.
Purpose: Produce current timber outputs for two decades and then provide transition to floor described below
Rationale: Releasing NDY without these constraints would result in a more radical departure. These constraints provide the moderate departure and smooth transition desired for the alternative

4. Constraint: Floor of 29.4 MMCF.
Purpose: Avoid fluctuating harvest schedule following the departure.
Rationale: This level was determined from the base run as that which could be maintained following the departure until the swing up toward LTSY.

5. Constraint: Minimum LTSY set at 52.7 MMCF.
Purpose: LTSY of departure must be equal to or greater than LTSY of the base run
Rationale: Satisfy requirement.

6. Constraint: Hardwood conversion not to exceed 7,500 acres in any decade.
Purpose: Limit conversion acres to a level consistent with the theme of the alternative.
Rationale: When not constrained, FORPLAN sometimes scheduled large blocks of hardwood acres in a single decade.

ALTERNATIVE B

Goals. This alternative is formulated to meet RPA targets. Timber and fish outputs are the hardest to achieve so this alternative is built from a land assignment which emphasizes timber and fisheries management. Targets for other resources are met coincidentally without additional emphasis, or are achieved through increasing capital investments. Fisheries also has a high level of capital investment programmed. In addition to the land assignment, it is also necessary to depart from NDY to achieve the timber target for the first two decades.

Criteria and Assumptions. The criteria and assumptions underlying the development of this alternative are:

1. Timber production must equal 36.8 MMCF ASQ for the first two decades. It is allowed to decrease in the third, fourth, and fifth decades, then holds steady or increases over following decades.
2. Wildlife MR's are included.
3. The full range of inventoried VQO's would only be allocated in the highest priority viewsheds.
4. Six Planning Basins with high fisheries potential would be allocated to Riparian option C.
5. A high rate of hardwood conversion would be allowed.

The constraints used to meet the criteria and assumptions are:

1. All common constraints except 1 NDY released decades 1 - 5.

2. Constraint: Constrained available suitable acres:

Allocated Minimum Level	47,078
Retention	6,817
Partial Retention	77,969

Purpose: Constrain acres with timber management options to allow for the Supplemental Resource Areas allocated for fisheries and minor allocations to other Management Areas which do not allow timber management. Also to constrain harvest on the areas with allocated VQO's.

Rationale: Represent the land assignment designed to accomplish the goals of the alternative

3. Constraint: Harvest volume equal to 36.8 MMCF decades 1 and 2, 33.0 decade 3, and 28.0 decade 4.

   Purpose: Produce timber outputs at the RPA target level for two decades and then provide transition to floor described below

   Rationale: These constraints provide the target timber outputs and smooth transition to the floor level.

4. Constraint: Floor of 25.0 MMCF.

   Purpose: Avoid fluctuating harvest schedule with extreme low points following the departure

   Rationale: This level is 80 percent of the current output and it was determined from the base run that it could be maintained following the departure until the swing up toward LTSY.

   Constraint: Minimum LTSY set at 54.8 MMCF.

   Purpose: LTSY of departure must be equal to or greater than LTSY of the base run.

   Rationale: Satisfy requirement.

5. Constraint: Hardwood conversion not to exceed 14,000 acres in any decade

   Purpose: Limit conversion acres to a level consistent with the theme of the alternative.

   Rationale: When not constrained, FORPLAN sometimes scheduled large blocks of hardwood acres in a single decade.

6. Constraint: Riparian areas constrained to Prescription option C in Basins 01, 04, 05, 07, 13, and 16. Also limited created openings to Basin specific constraints (9 to 13 percent) in these Basins in lieu of common constraint 4.

   Purpose: Increase fish production capability in these Basins to achieve RPA fish targets.

   Rationale: Affording more habitat protection through the prescription option and harvest dispersion results in increased fish outputs as well as increased benefits from the capital investments.

ALTERNATIVE C

Goals. Alternative C is designed to provide the highest sustainable level of timber outputs from the Forest. It includes minimal allocations for other resources beyond MR's.

Criteria and Assumptions. The criteria and assumptions underlying the development of this alternative are:

1. Timber production will be relatively unconstrained beyond MR's, general multiple use considerations and NDY.
2. Wildlife MR's are included.
3. Only the highest priority viewsheds have VQO's allocated and in these areas the Retention acres are reduced to Partial Retention. The only acres managed for Retention would be the Scenic and Recreation Rivers.

4 Riparian areas will be managed under Prescription option B.
5 A high rate of hardwood conversion would be allowed.

The constraints used to meet the criteria and assumptions are:

1. All common constraints.

2. Constraint: Constrained available suitable acres:

Allocated Minimum Level	39,523
Retention	3,361
Partial Retention	67,657

Purpose: Constrain acres with timber management options to meet MR's and minimal allocations to other resource emphasis.
Rationale: Represent the land assignment designed to accomplish the goals of the alternative.

3. Constraint: Hardwood conversion not to exceed 14,000 acres in any decade.
Purpose: Limit conversion acres to a level consistent with the theme of the alternative.
Rationale. When not constrained, FORPLAN sometimes scheduled large blocks of hardwood acres in a single decade.

ALTERNATIVE D

Goals. This alternative is formulated to emphasize the production of goods and services that have market values It is similar to the RPA alternative (B) except that it has NDY (actually the base run for Alternative B).

Criteria and Assumptions. The criteria and assumptions underlying the development of this alternative are:

1. Timber production would be at a high level under NDY.
2. Wildlife MR's are included.
3. The full range of inventoried VQO's would only be allocated in the highest priority viewsheds.
4. Six Planning Basins with high fisheries potential would be allocated to Riparian Prescription option C
5. A high rate of hardwood conversion would be allowed.

The constraints used to meet the criteria and assumptions are:

1. All common constraints.

2. Constraint: Constrained available suitable acres:

Allocated Minimum Level	47,078
Retention	6,817
Partial Retention	77,969

Purpose: Constrain acres with timber management options to allow for the Supplemental Resource Areas allocated for fisheries and minor allocations to other Management Areas which do not allow timber management. Also to constrain harvest on the areas with allocated VQO's.

Rationale: Represent the land assignment designed to accomplish the goals of the alternative

3. Constraint: Hardwood conversion not to exceed 14,000 acres in any decade.
   Purpose: Limit conversion acres to a level consistent with the theme of the alternative.
   Rationale: When not constrained, FORPLAN sometimes scheduled large blocks of hardwood acres in a single decade.

4. Constraint: Riparian areas constrained to Prescription option C in Basins 01, 04, 05, 07, 13, and 16 Also limited created openings to Basin specific constraints (9 to 13 percent) in these Basins in lieu of common constraint 4.
   Purpose: Increase fish production capability in these Basins.
   Rationale: Affording more habitat protection through the prescription option and harvest dispersion results in increased fish outputs.

ALTERNATIVE D1

Goals. *This alternative is very similar to Alternative D. It also emphasizes the production of goods and* services that have market values. It differs in that it further emphasizes short-term timber outputs by allowing rotations shorter than 95 percent of CMAI.

Criteria and Assumptions. The criteria and assumptions underlying the development of this alternative are:

1. Timber production would be at a high level under NDY, with short rotations allowed
2. Wildlife MR's are included.
3. The full range of inventoried VQO's would only be allocated in the highest priority viewsheds
4. Six Planning Basins with high fisheries potential would be allocated to Riparian Prescription option C.
5. A high rate of hardwood conversion would be allowed.

The constraints used to meet the criteria and assumptions are:

1. All common constraints except 3, minimum timber rotations at 95 percent of CMAI.

2. Constraint: Constrained available suitable acres:

Allocated Minimum Level	47,078
Retention	6,817
Partial Retention	77,969

   Purpose: Constrain acres with timber management options to allow for the Supplemental Resource Areas allocated for fisheries and minor allocations to other Management Areas which do not allow timber management. Also to constrain harvest on the areas with allocated VQO's.
   Rationale: Represent the land assignment designed to accomplish the goals of the alternative

3. Constraint: Hardwood conversion not to exceed 14,000 acres in any decade
   Purpose: Limit conversion acres to a level consistent with the theme of the alternative.
   Rationale: When not constrained, FORPLAN sometimes scheduled large blocks of hardwood acres in a single decade.

4 Constraint: Riparian areas constrained to Prescription option C in Basins 01, 04, 05, 07, 13, and 16. Also limited created openings to Basin specific constraints (9 to 13 percent) in these Basins in lieu of common constraint 4.
Purpose: Increase fish production capability in these Basins.
Rationale: Affording more habitat protection through the prescription option and harvest dispersion results in increased fish outputs.

5. Constraint: Minimum timber rotations are set at two decades prior to reaching 95 percent of CMAI.
Purpose: Allow a higher rate of harvest.
Rationale: This approach would allow the Forest to produce more timber in the early decades without a decline in yield in future decades. It provides another way of addressing the timber supply issue without departing from NDY.

ALTERNATIVE E

Goals. This alternative emphasizes aesthetic and other nonmarket values. All of the unroaded areas would remain undeveloped.

Criteria and Assumptions. The criteria and assumptions underlying the development of this alternative are.

1. Timber production would be subordinate to other resource allocations.
2. Wildlife MR's are included.
3. The full range of inventoried VQO's would be allocated in all viewsheds.
4. Riparian areas would not have programmed timber harvest.
5. No hardwood conversion would be allowed
6. Areas with special resource values, such as sensitive plants, wildlife habitat, and supplemental fish and watershed protection zones, would not have programmed timber harvest
7. Candidate rivers would be recommended for Wild and Scenic River designation.

The constraints used to meet the criteria and assumptions are:

1 All common constraints except 4 and 5. (4 is made more stringent below and 5 is made unnecessary by the land assignment.)

2. Constraint: Constrained available suitable acres:

Allocated Minimum Level	318,470
Retention	16,973
Partial Retention	94,202

Purpose: Constrain acres with timber management options to allow for the Supplemental Resource Areas, areas with special resource values, Wild Rivers, and wildlife habitat areas which do not allow timber management. Hardwood stands and riparian acres are assigned to Minimum Level. Also harvest is constrained on the areas with allocated VQO's. Scenic and Recreation River acres are included in Retention.
Rationale: Represent the land assignment designed to accomplish the goals of the alternative.

3. Constraint: Created openings limited to Basin specific constraints (9 to 13 percent) in lieu of common constraint 4.

Purpose: Provide better dispersion of harvest activities across the Basins.
Rationale: Lessen the risks to soil, watershed and fisheries resources by evening out peaks in ground disturbing activities.

ALTERNATIVE G

Goals. This alternative emphasizes the protection and enhancement of the Forest's nontimber resources, particularly the water related resources associated with the rivers and streams. It favors unroaded recreation and a high level of visual quality management.

Criteria and Assumptions. The criteria and assumptions underlying the development of this alternative are:

1. Timber production would be at a high level for those areas not allocated to other management emphases.
2. Wildlife MR's are included
3. The full range of inventoried VQO's would be allocated for all viewsheds
4. All Planning Basins would be allocated to Riparian Prescription option C.
5 A low rate of hardwood conversion would be allowed
6. Some areas with special resource values, such as sensitive plants, wildlife habitat, and supplemental fish and watershed protection zones, would not have programmed timber harvest
7. Candidate rivers would be recommended for Wild and Scenic River designation.

The constraints used to meet the criteria and assumptions are:

1. All common constraints except 4 and 5. (4 is made more stringent below and 5 is changed to Riparian Prescription option C)

2. Constraint: Constrained available suitable acres:

Allocated Minimum Level	177,519
Retention	19,085
Partial Retention	115,040

Purpose: Constrain acres with timber management options to allow for the Supplemental Resource areas, areas with special resource values, Wild Rivers, and wildlife habitat areas which do not allow timber management Also harvest is constrained on the areas with allocated VQO's. Scenic and Recreation River acres are included in Retention.
Rationale: Represent the land assignment designed to accomplish the goals of the alternative

3. Constraint: Created openings limited to Basin specific constraints (9 to 13 percent) in lieu of common constraint 4.
Purpose: Provide better dispersion of harvest activities across the Basins.
Rationale. Lessen the risks to soil, watershed and fisheries resources by evening out peaks in ground disturbing activities.

4. Constraint: Hardwood conversion not to exceed 4,000 acres in any decade.
Purpose: Limit conversion acres to a level consistent with the theme of the alternative.
Rationale: When not constrained, FORPLAN sometimes scheduled large blocks of hardwood acres in a single decade

ALTERNATIVE K

Goals. This alternative is designed to produce a wide range of resource outputs It produces a moderate level of timber outputs with some land assigned to other resource emphasis.

Criteria and Assumptions. The criteria and assumptions underlying the development of this alternative are.

1. Timber production would be at a moderate to high level under NDY.
2. Wildlife MR's are included.
3. The full range of inventoried VQO's would only be allocated in the highest priority viewsheds Some of the moderate priority viewsheds have allocations to Partial Retention.
4. Planning Basin 01 would be allocated to Prescription Option C.
5 A moderate rate of hardwood conversion would be allowed.
6 Some areas with special resource values, such as sensitive plants, wildlife habitat, and supplemental fish and watershed protection zones, would not have programmed timber harvest.

The constraints used to meet the criteria and assumptions are:

1 All common constraints except 4. (4 is made more stringent below)

2 Constraint Constrained available suitable acres:

Allocated Minimum Level	72,531
Retention	7,155
Partial Retention	97,253

Purpose· · Constrain acres with timber management options to allow for the Supplemental Resource Areas, areas with special resource values, and wildlife habitat areas which do not allow timber management. Also harvest is constrained on the areas with allocated VQO's. Scenic and Recreation River acres are included in Retention

Rationale: Represent the land assignment designed to accomplish the goals of the alternative

3 Constraint. Created openings limited to Basin specific constraints (9 to 13 percent) in lieu of common constraint 4.

Purpose: Provide better dispersion of harvest activities across the Basins

Rationale: Lessen the risks to soil, watershed and fisheries resources by evening out peaks in ground disturbing activities.

4. Constraint: Hardwood conversion not to exceed 7,500 acres in any decade.

Purpose: Limit conversion acres to a level consistent with the theme of the alternative.

Rationale: When not constrained, FORPLAN sometimes scheduled large blocks of hardwood acres in a single decade

5. Constraint: Riparian areas constrained to prescription option C in Basin 01

Purpose Increase fish production capability in this Basin.

Rationale. Affording more habitat protection through the prescription option results in increased fish outputs.

ALTERNATIVE M

Goals. This alternative emphasizes preservation rather than human use of the resources All unroaded areas would remain undeveloped. Areas not accessed by current roads would not be managed for timber production. Areas selected for timber production would be managed on a long rotation to mimic natural stands.

Criteria and Assumptions. The criteria and assumptions underlying the development of this alternative are:

1. Timber production would be subordinate to other resource allocations Minimum rotation length is 250 years.
2. New access roads would not be built.
3. Wildlife MR's are included.
4. The full range of inventoried VQO's would be allocated in all viewsheds.
5. Riparian areas would not have programmed timber harvest
6. No hardwood conversion would be allowed.
7. Areas with special resource values, such as sensitive plants, wildlife habitat, and supplemental fish and watershed protection zones, would not have programmed timber harvest
8. Candidate rivers would be recommended for Wild and Scenic River designation.

The constraints used to meet the criteria and assumptions are:

1. All common constraints except 4 and 5. (4 is made more stringent below, and 5 is made unnecessary by the land assignment.)

2. Constraint: Constrained available suitable acres:

Allocated Minimum Level	371,483
Retention	105,004

   Purpose: Constrain acres with timber management options to allow for the Supplemental Resource Areas, areas with special resource values, Wild Rivers, and wildlife habitat areas which do not allow timber management. Hardwood stands, acres not accessible by existing roads, and riparian acres are assigned to Minimum Level Also, harvest is constrained on the areas with allocated VQO's. Scenic and Recreation River acres are included in Retention.
   Rationale: Represent the land assignment designed to accomplish the goals of the alternative

3. Constraint: Created openings limited to Basin specific constraints (9 to 13 percent) *in lieu* of common constraint 4.
   Purpose: Provide better dispersion of harvest activities across the Basins.
   Rationale: Lessen the risks to soil, watershed and fisheries resources by evening out peaks in ground disturbing activities.

4. Constraint: All acres with timber management allowed are assigned to the Retention prescription in FORPLAN.
   Purpose: Access the Retention yield tables with minimum rotations of 250 years.
   Rationale: This provides for the long rotation required by the definition of this alternative.

ALTERNATIVE S

Goals. This alternative is designed to produce a wide range of resource outputs. It incorporates many suggestions and changes resulting from public comments on the DEIS.

Criteria and Assumptions. The criteria and assumptions underlying the development of this alternative are.

1. Timber production would be at a moderate to high level under NDY.
2. Wildlife MR's are included.
3. The full range of inventoried VQO's would only be allocated in the highest priority viewsheds. Some of the moderate priority viewsheds have allocations to Partial Retention.
4. Planning Basins 01, 03, 05, 06, 07, 12, and 13 would be allocated to Prescription Option C.
5. A moderate rate of hardwood conversion would be allowed.
6. Some areas with special resource values, such as sensitive plants, wildlife habitat, and supplemental fish and watershed protection zones, would not have programmed timber harvest.

The constraints used to meet the criteria and assumptions are·

7. All common constraints except 4. (4 is made more stringent below.)

8 Constraint: Constrained available suitable acres:

Allocated Minimum Level	91,910
Retention	13,021
Partial Retention	101,664

Purpose: Constrain acres with timber management options to allow for the Supplemental Resource Areas, areas with special resource values, and wildlife habitat areas which do not allow timber management. Also harvest is constrained on the areas with allocated VQO's. Scenic and Recreation River acres are included in Retention

Rationale: Represent the land assignment designed to accomplish the goals of the alternative.

9. Constraint: Created openings limited to Basin specific constraints (7 to 17 percent) in lieu of common constraint 4.
   Purpose: Provide better dispersion of harvest activities across the Basins.
   Rationale: Lessen the risks to soil, watershed and fisheries resources by evening out peaks in ground disturbing activities.

10. Constraint: Hardwood conversion not to exceed 7,500 acres in any decade.
    Purpose: Limit conversion acres to a level consistent with the theme of the alternative.
    Rationale: When not constrained, FORPLAN sometimes scheduled large blocks of hardwood acres in a single decade.

11. Constraint: Riparian areas constrained to prescription option C in Basins 01, 03, 05, 06, 07, 12, and 13.
    Purpose· Increase fish production capability in these Basins.
    Rationale· Affording more habitat protection through the prescription option results in increased fish outputs.

SUMMARY OF EFFECTS

A comparative analysis between alternatives and benchmarks is the basis for evaluating alternatives and selecting a preferred alternative. This section displays the differences between alternatives, their outputs, constraints, foregone opportunities, and economic efficiencies. For additional information, refer to the previous sections of this appendix and Chapter IV of the DEIS.

First, the process for evaluating constraints is discussed Then, the different responses of alternatives to the Planning Problems are compared. Last of all, the explanations for different economic benefits among alternatives are presented and compared with the differences in outputs and effects

PROCESS FOR EVALUATING SIGNIFICANT CONSTRAINTS

Management objectives of benchmarks and alternatives were achieved by constraining the FORPLAN model as described in previous sections. The opportunity costs of individual objectives were determined by calculations comparing the FORPLAN solution which achieves a specific objective with a solution which does not (usually the Max PNV Benchmark) When all other objectives are the same, the difference in outputs and effects are the opportunity costs of achieving the objective when both solutions have the same choice of prescriptions.

Opportunity costs were not determined for individual elements of alternatives using FORPLAN because of the prohibitive costs of analyzing every constraint used to develop alternatives. However, the economic tradeoffs of sets of constraints were determined by comparing alternatives, benchmarks, and sensitivity analysis runs. This information was then used to identify the opportunity costs associated with land allocations, objective functions, and riparian prescriptions (see tables at end of section).

Incremental changes in PNV and the timber production opportunities are displayed for each alternative. The opportunity costs for the recreation, fisheries, and wildlife programs are calculated using the PNV benchmark and the alternative with the next highest PNV for comparison For the recreation program, changes in the budget directly affect the opportunity costs since recreation benefits change little between the alternatives. The fisheries opportunity costs are a result of capital investments and riparian prescriptions The foregone timber harvest due to riparian prescriptions is displayed under the timber program For the wildlife program, the opportunity costs are associated with the wildlife capital investments and the benefits derived from the amount of seral vegetation produced by the Forest.

The effects of each change in the constraints are then displayed in order of decreasing PNV by alternatives with the nondeclining harvest constraint

All alternatives, including the departures (Alternatives B and A-Departure) and those with the different rotation lengths (Alternatives D1 and M), were then examined in order of decreasing PNV The constraints associated with the departure alternatives are the residual opportunity costs after all other previously discussed opportunity costs have been calculated. Selected suitable acres also change due to the departure scheduling and are displayed. The opportunity costs and selected suitable acres associated with the change in rotation length were calculated using the same technique The selected suitable acres change for the departures due to the increased flexibility when the nondeclining flow constraint is relaxed and outputs are allowed to drop in decades 3 through 6. Allowing shorter rotations also allows greater flexibility resulting in fewer acres being selected. These opportunity costs and changes in selected suitable acres associated with these variations in harvest flow and rotation constraints are also displayed.

ECONOMIC EFFICIENCY ANALYSIS OF ALTERNATIVES

The purpose of this section is to display and compare the differences in economic costs and benefits of the alternatives, and to discuss the general reasons for these differences. More complete discussions of the relationship between economic values and net public benefits appear in the following section, **MAJOR TRADEOFFS AMONG ALTERNATIVES.**

COMPARISON OF COSTS AND BENEFITS

Table B-8 displays Present Net Value (PNV) and total discounted costs and benefits for the alternatives and the Maximum PNV Benchmark. PNV is the primary measure of economic efficiency used by the Forest Service It is the sum of priced benefits minus the sum of costs for the 150-year planning horizon, discounted to the present at the rate of four percent per year Testing a discount rate of 7 1/8 percent per year has been documented in the section on sensitivity testing

Table B-8 PNV, Discounted Costs, and Discounted Benefits, with Incremental Changes for Alternatives ranked in order of decreasing PNV (MM $ discounted at four percent for 15 periods)

	MM $					
Alternative	PNV	Change	Costs	Change	Benefits	Change
Maximum PNV Benchmark	1,278		785		2,062	
		-37		+15		-21
B	1,241		800		2,041	
		-27		-8		-35
D1	1,214		792		2,006	
		0		-61		-61
NC	1,214		732		1,946	
		-17		+85		+68
C	1,197		817		2,013	
		-37		-37		-73
D	1,160		780		1,940	
		0		-37		-37
A-Departure	1,160		743		1,903	
		-10		-7		-18
A	1,150		736		1,885	
		-19		-24		-42
S	1,131		712		1,843	
		-48		-3		-51
K	1,083		709		1,792	
		-239		-132		-371
G	844		577		1,421	
		-165		-60		-225
E	679		517		1,196	
		-407		-187		-594
M	272		330		602	

Generally, both discounted costs and discounted benefits decrease as PNV decreases. All three variables are directly related to the level of timber harvest As the amount of timber harvested increases, PNV, discounted benefits, and discounted costs all increase (and conversely decrease as timber harvest declines). Benefits generally decline faster than costs. PNV and level of timber harvest range from the highest in Alternative B to the lowest in Alternative M.

Exceptions to the relationship described above occur in Alternatives NC, B, C, and D1. Alternatives B and C were modeled to maximize timber production They would achieve higher timber outputs by including lands and management regimes that are less economically desirable than those selected for alternatives designed to maximize PNV. Alternative NC would operate on the largest suitable land base, but would not maximize timber production as would Alternatives B and C Alternative D1 has a shorter rotation length

which increases harvest levels of existing old-growth, but would provide less benefits in the future due to the smaller diameter of timber harvested.

Benefits associated with nonmarket goods, such as recreation, do not vary as much between the alternatives as do timber benefits. Recreational benefits are very similar between alternatives due to existing excess capacity compared to present and near-future use Fisheries benefits increase with increased capital improvements and increased protection due to riparian prescriptions. With increased vegetative diversity, wildlife benefits also increase. Benefits associated with minerals production are presently not quantified except for recreational mining and mineral use fees The mineral benefits could become greater in the future if the demand for minerals increases.

Table B-9 displays PNV and discounted benefits for the major resources, and Table B-10 displays discounted costs. Timber is the main component of PNV, discounted costs and discounted benefits Wilderness accounts for less than four percent of each variable in all alternatives

Direct comparisons of benefits and costs displayed for individual resource outputs provide general indications of relationships However, many activities of multiple-use forestry have common costs and benefits, and cannot be exclusively separated and attributed to individual resources. For example, harvest clearcuts produce additional forage while decreasing cover which changes the population of big-game animals with subsequent effects on wildlife benefits

Table B-9. PNV and Discounted Benefits by Major Resource, by Alternative (MM $ discounted at four percent for 15 periods)

	MM $	Discounted Benefits (MM $)					
Alternative	PNV	Timber	Recreation	Fish	Wildlife	Wilderness	Misc
Maximum PNV Benchmark	1,278	1,712	175	106	55	10	3
B	1,241	1,691	175	104	58	10	3
D1	1,214	1,666	175	96	55	10	3
NC	1,214	1,614	175	90	53	10	3
C	1,197	1,674	175	92	59	10	3
D	1,160	1,601	175	96	54	10	3
A-Departure	1,160	1,572	175	90	53	10	3
A	1,150	1,554	175	90	52	10	3
S	1,131	1,486	175	103	67	10	3
K	1,083	1,454	175	101	50	10	3
G	844	1,092	175	98	43	10	3
E	679	871	175	97	39	10	3
M	272	286	175	98	29	10	3

Table B-10 Major Resource Discounted Costs by Alternative, (MM $ discounted at four percent for 15 Periods) 1/

	Discounted Costs (MM $)						
Alternative	Timber	Roads 2/	Recreation	Fish	Wildlife	Wilderness	Fixed and Misc Costs
Maximum PNVBenchmark	378	195	12	13	2	2	181
B	415	181	12	10	3	2	177
D1	404	181	12	7	2	2	183
NC	358	162	11	7	2	1	190
C	428	187	11	8	2	3	177
D	405	172	12	7	2	2	179
A-Departure	373	162	11	7	2	1	187
A	366	162	11	7	2	1	185
S	336	142	15	12	7	2	196
K	345	153	12	9	2	2	187
G	251	107	13	8	2	1	195
E	211	88	12	7	2	1	195
M	90	16	13	8	2	1	199

1/ Direct comparisons of benefits and costs displayed for individual resource outputs provide general indications of relationships However, many activities of multiple use forestry have common costs and benefits, and cannot be exclusively separated and attributed to individual resources

2/ Costs for roads includes Forest Service and purchaser costs for road construction and reconstruction but not maintenance

COSTS

Two types of costs are included in Forest management: (1) operation and maintenance, and (2) capital investment

Operation and maintenance costs are the costs of activities required to plan and manage outputs, and maintain existing capital assets at standard levels These include fixed costs such as general administration, and variable costs which vary with different levels of outputs. Fixed costs are constant across all alternatives, whereas variable costs differ among alternatives The major determinant affecting variable costs is the quantity of timber produced, timber production generates the analyses and project support needed to assure quality management of the fisheries, wildlife, and watershed resources.

Capital investment costs are the costs of creating or enhancing capital assets, such as roads, trails, or fish habitat improvement structures. Road construction costs are the main component of capital investments; they are also a direct function of timber harvest activity. Other capital investment costs such as fish and wildlife vary independently of the timber program. Total costs for alternatives vary both above and below the current direction (Alternative A) budget level of 21 million dollars per year.

NET CASH FLOWS, ECONOMIC BENEFITS, AND COSTS

Table B-11 displays average annual net cash flows, total receipts, total costs, and noncash economic benefits, by alternative, for the first and fifth decades. The fifth decade is shown because it represents the RPA planning horizon and captures most of the changes within the alternatives that occur in later decades.

In Table B-11, annual net cash receipts are total Forest receipts minus total Forest costs This economic indicator, like others discussed earlier, varies directly with the level of timber outputs Net cash flow would be positive for all of the alternatives with the exception of Alternative M. In Alternative M, costs of operating and maintaining the Forest would be greater than the receipts from selling timber and other outputs

Table B-11 Average Annual Net Cash Receipts, Total Costs, Total Cash Receipts, and Noncash Benefits for Decades 1 and 5 (MM $)

	MM $/Decade							
	Net Cash Receipts		Total Cost		Total Receipts		Noncash Benefits	
Alternative	1	5	1	5	1	5	1	5
B	43 0	25 0	24 9	26 0	67 9	51 0	8 8	10 8
D1	38 2	29 8	23 1	27 0	61 3	56 8	8 6	10 4
NC	36 0	41 1	21 0	27 1	57 0	68 2	8 6	10 2
A-Departure	35 8	35 4	21 6	27 3	57 4	62 7	8 6	10 2
A	34 1	37 8	21 1	27 1	55 3	64 9	8 6	10 2
C	32 1	45 3	26 3	27 9	58 4	73 2	8 6	9 9
S	31 9	34 3	21 7	25 0	53 6	59 2	9 1	11 0
D	31 6	42 0	24 2	26 2	55 8	68 2	8 5	10 3
K	29 0	35 8	21 6	24 5	50 6	60 3	8 7	10 5
G	20 1	20 5	17.8	20.7	37 9	41 2	8 6	10 5
E	13 2	12 6	16 7	18 4	29 9	31 0	8 7	10 4
M	-1 4	-0 9	12 2	13 0	10 8	12 1	8 7	10 5

The alternatives are listed in order of decreasing first decade net cash flows The ranking of the alternatives is somewhat different than under the decreasing PNV ranking. The primary difference is that the departure Alternatives A-Departure and B would have higher first decade net cash flows because they would harvest more timber in the first decade. Alternatives C and D (which have higher PNV for 15 decades than Alternative A-Departure) are modeled somewhat differently than the other alternatives. They would have higher costs because they include less economically desirable lands and practices in order to increase overall timber outputs. Alternative S is different due to the more intensive timber management of lands currently roaded; fertilization of plantations and the exclusion of expensive road construction in areas allocated to Backcountry Recreation allow cash flows to be higher. Net cash flows for the other alternatives follow the same pattern as that for PNV

Economic benefits are reported in two columns. as total receipts, and as noncash benefits. Total receipts are money that the Forest receives from the sale of products and uses They include timber, fuelwood, developed recreation, river permit fees, range fees, special use permits, and power and minerals use fees. Commercial timber sales represent approximately 99 percent of total receipts across the alternatives, with the exception of Alternative M where they comprise approximately 50 percent because of reduced harvests due to longer rotations and no additional roading. Changes in the amount of timber sold also account for virtually all of the differences in total receipts among the alternatives. The other components of total receipts remain relatively constant through all alternatives.

Noncash benefits are economic values that have been assigned to uses of Forest resources that have value, but have not been generally traded in a marketplace where money is exchanged. They are based on research of individuals' willingness to pay for certain types of experiences. The noncash benefits *included in the Siskiyou's planning model are Recreation Visitor Day (RVD) use values for various types* of wildlife, fishing, and general recreation experiences. General recreation use does not vary much between the alternatives due to excess capacity over existing use. The increase shown in future decades is the result of projections of increased demand for outdoor recreation on the Forest. The RVD values for *fishing experiences depend on the fisheries outputs. As more fish are produced as a result of capital* investments or more restrictive riparian prescriptions, more use is predicted. Wildlife use is modeled by projecting increasing use with increased habitat capability for big game and game birds, and with increased recreational use over time for nongame wildlife use.

PAYMENTS TO COUNTIES

National Forest Funds (NFF), which comprise 25 percent of all Forest receipts to the U S Treasury, are distributed to counties based on the amount of Forest land in each county. O&C funds, which are 50 percent of funds generated from O&C lands, are distributed on the basis of a percentage established by Federal law. The returns projected for each alternative (Figure B-4) vary due to the level of Allowable Sale Quantity and land allocations.

RELATED EMPLOYMENT AND INCOME CHANGES

Projected changes in timber harvest, recreational use, and fish harvest would result in changes in employment and income for the four-county area of influence. The total employment and income for the four-county area in 1983 were 76,000 jobs and 1.163 billion dollars. The estimated changes in employment are calculated using Alternative A (Current Direction) as the basis, with two base conditions for timber outputs: the 10-year average annual historic harvest of 128.1 MMBF, and the Allowable Sale Quantity for Alternative A of 167.9 MMBF. The variation among alternatives in projected employment and income changes (Figures B-5 and B-6) is primarily due to timber harvest related activities. The figures represent direct, indirect, and induced effects of producing outputs.

Alternative B has the highest projected gain in jobs and income, while Alternatives NC, A, A-Departure, C, D, D1, and S project sizable increases (greater than 500 jobs and greater than 13 million dollars income). Moderate increases in jobs and income are projected for Alternative K. Alternative G projects moderate decreases in jobs and incomes (less than 350 jobs and greater than 7 million dollars). Alternatives E and M have sizable decreases in projected jobs and incomes.

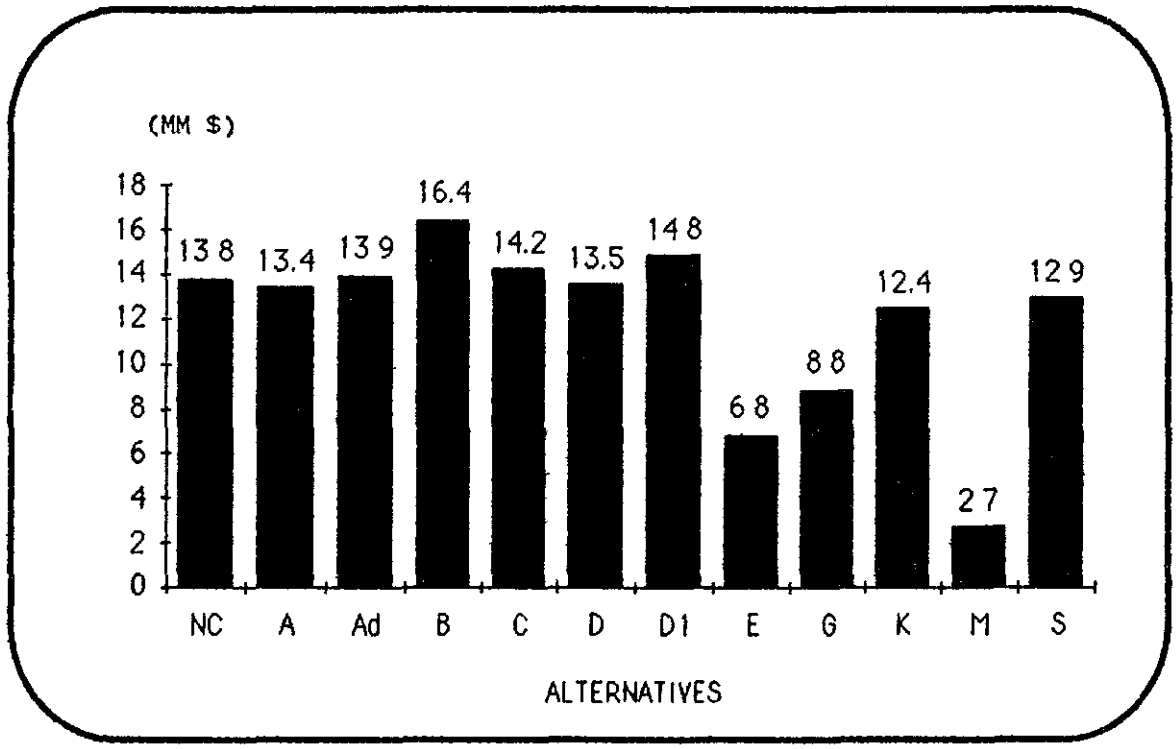

Figure B-4. Predicted Payments to Counties

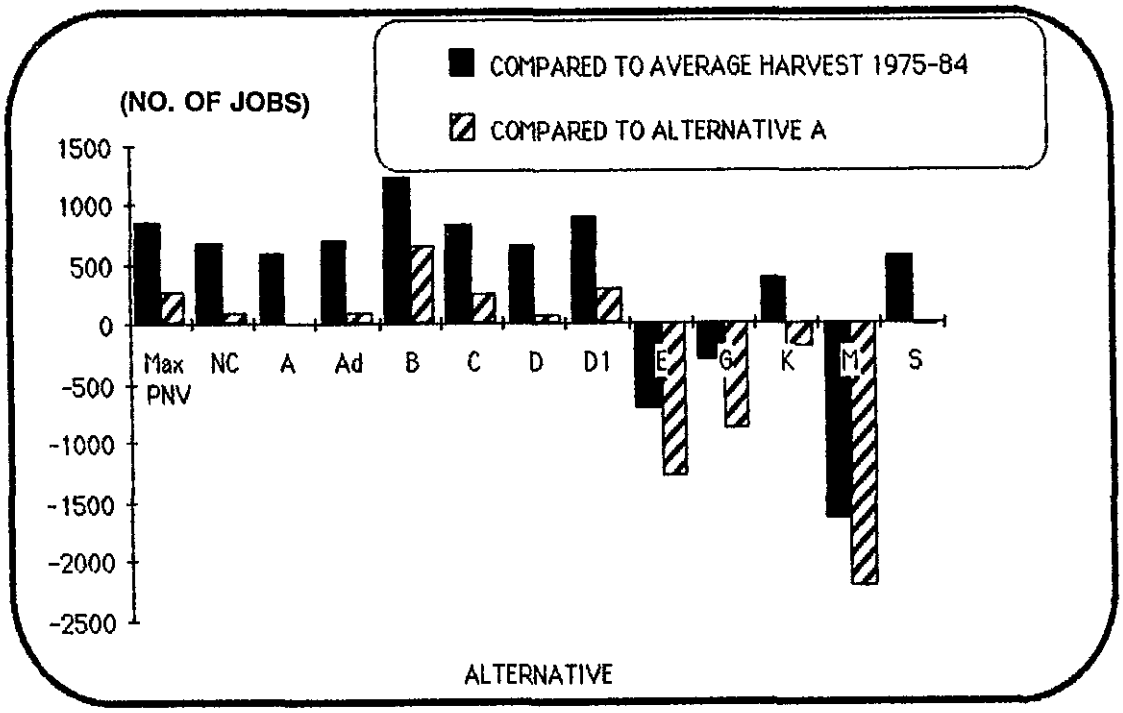

Figure B-5. Predicted Effects on Jobs

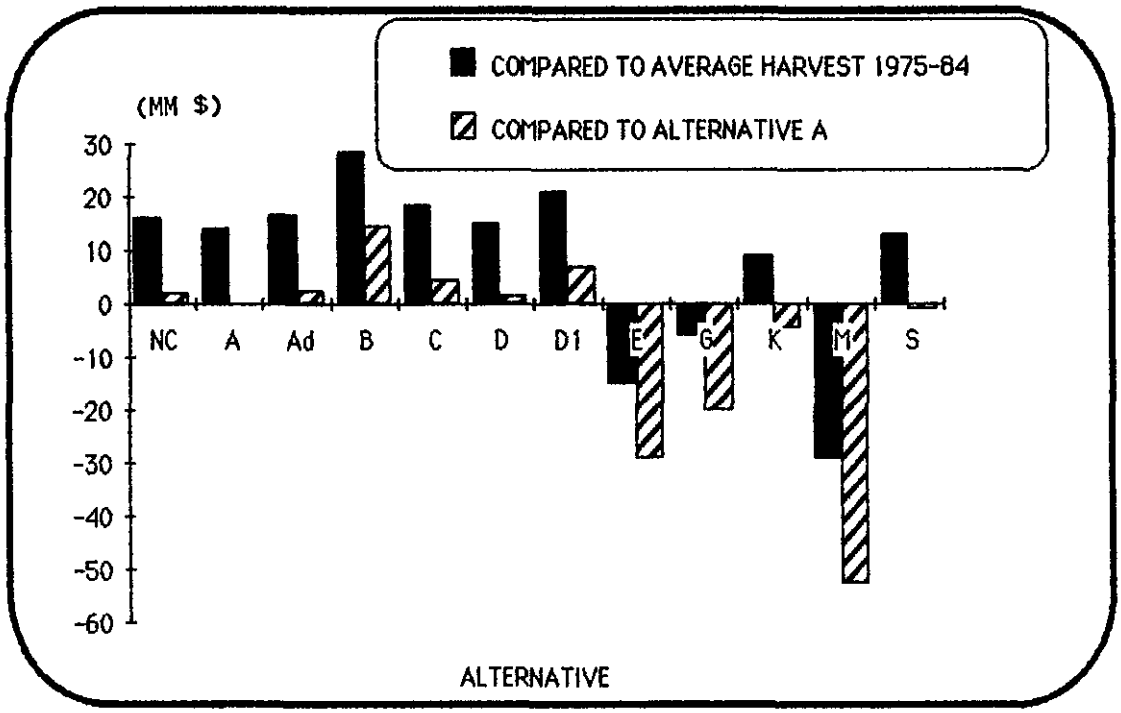

Figure B-6 Predicted Effects on Income

COMMUNITY EFFECTS

The previous discussion has considered only the economic programs of the Forest The social effects of the alternatives including the effects on community stability, lifestyles, and community cohesion are also important considerations.

"Community stability" is defined as a community's capacity to handle change without major hardships or disruptions to component groups or institutions. Slow, steady growth is the desired condition for economic and social stability. It allows for limited economic displacement of jobs due to sudden change with steadily increasing opportunities. Sudden economic booms are also avoided An acceptable range for change will be defined as a predicted increase of less than two percent in jobs or income in the area of influence due to changes in Forest outputs. Any decrease in present jobs or future outputs is deemed less desirable Within this range, the communities would be able to readily adjust to the changes brought on by an increase in jobs and income. If economic stagnation is prevalent, a loss of jobs, now as in the future may require significant community adjustment.

Of course, these communities do not operate in a vacuum and forces other than Forest outputs influence the economic climate. However, for this analysis, these other forces are assumed to be constant. In general, Alternatives NC, A, C, D, D1, K, and S are classified as being more desirable for community stability. Alternatives A-Departure, B, E, G, and M are labeled as being less desirable for community stability due to decreases in either present jobs or future outputs and associated jobs.

Lifestyles are a result of the economic climate and local environment The freedom, individualism, and security associated with the existing local lifestyles are affected little by any alternative, except perhaps Alternative M which greatly reduces Forest-related employment Increases in Forest outputs could increase personal incomes which might provide added security to an individuals chosen lifestyle, provided the economic climate is not favoring development to the point of encroaching on individual freedom.

Alternatives NC, C, D, and D1 have the potential to increase incomes significantly (greater than one percent of total income in the area). Alternatives A-Departure and B would also boost income significantly in the first decade, but would have decreased outputs in the future. Alternatives A, K, and S would not tend to affect incomes very significantly (less than one percent total change in income). Alternatives E, G, and M have potential to decrease incomes significantly (greater than three percent decline in total income in the area of influence).

"Community cohesion" is defined as the degree of unity and cooperation evident in a community as it defines problems and attempts to resolve them. As with lifestyles, community cohesion is not significantly affected by different alternatives due to the degree of existing conflict. The many differing opinions about Forest management can only be resolved by participation and communication of the parties with conflicting opinions. Alternatives that emphasize timber production at the expense of preservation of old growth and unroaded areas, or favor the preservation of old growth and unroaded areas at the expense of timber production, may tend to accentuate the conflict over Forest management Alternatives NC, A-Departure, B, C, D, D1, G, E, and M may then aggravate conflict in those communities where conflict already exists. Alternatives A, K, and S, because they tend to continue present direction or seek a better balance, will not solve conflict, but should not encourage conflict beyond its present evolution

OPPORTUNITY COSTS

Opportunity cost is the value of the opportunity lost or foregone when implementing an alternative instead of the Maximum PNV Benchmark It is calculated as the difference in total PNV between the PNV benchmark and the alternative. Most of the opportunity costs (Figure B-7) for each alternative are related to foregoing timber harvest due to unroaded designation, riparian prescriptions, suitable wildlife habitat, quality visuals management, or old growth preservation.

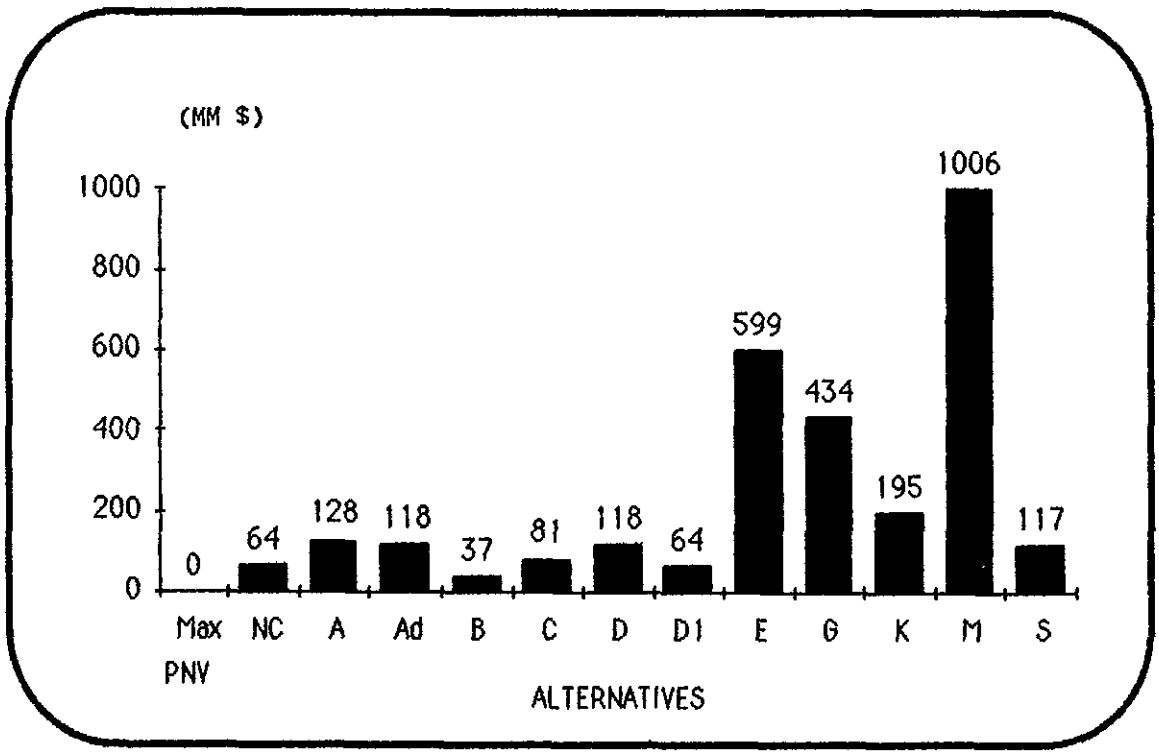

Figure B-7 Change in Opportunity Costs Compared to Maximum PNV Benchmark (MM $)

MAJOR TRADEOFFS AMONG ALTERNATIVES

This section summarizes the relationships among the economic values and community effects discussed in the previous section, **ECONOMIC EFFICIENCY ANALYSIS OF ALTERNATIVES**, and the differing responses among alternatives to the selected Planning Problems discussed in Appendix A The purpose is to highlight major economic and non-economic tradeoffs or combinations of differences that can be quantified as indicators of response to the Planning Problems However, a complete understanding of the differences among alternatives requires reading all of Chapters II and IV, and Appendix B.

To provide a partial framework for assessing these tradeoffs, the long-term resource demands or needs of the Nation, region, and local communities are briefly summarized; then selected economic values and quantified indicators of responsiveness to the Planning Problems are tabulated. Finally, differences and similarities among individual alternatives are summarized in terms of major tradeoffs among competing objectives or responses to expressed public issues, management concerns, or resource use and development opportunities

NATIONAL, REGIONAL, AND LOCAL OVERVIEW

National (RPA) planning estimates that total National demands will rise for outputs from all National Forests. At the same time, there is a strong demand to protect and enhance the quality of the environment. Demands and prices for production are generally determined in National markets and the Nation benefits most when supplies are provided using the most efficient sources of production.

The demands for outdoor recreation uses and wildlife uses are mainly local and regional, although the Rogue River does attract National attention Recreationists that visit the Siskiyou National Forest generally

come from southwestern Oregon and northern California. Total recreation growth is predicted to increase by one-half percent per year

The 1980 population in the four-county area was 271,500 This was an increase of approximately 35 percent from 1970, at least moderate growth is predicted for the next 10 years. In 1980, total employment was about 76,000 for the area of influence with approximately 3,500 of those jobs coming from direct, indirect, and induced effects of Forest outputs Approximately 70 percent of the Forest-dependent jobs are due to consumption of timber outputs Recreation, wildlife, and fisheries activities generate the rest of the Forest-derived employment

ECONOMIC VALUES AND RESPONSES TO MAJOR ISSUES, CONCERNS, AND OPPORTUNITIES

Alternatives differ so that each responds to the Planning Problems identified for this Forest in a different way. This section summarizes many of these differences in response by defining quantitative indicators for gauging the resolution of the Planning Problems It also discusses indicators of central concern to the Nation as a whole. Appendix A and Chapter I discuss the development of the Planning Problems from the issues, concerns, and opportunities identified during scoping, and provides the linkages between the Planning Problems and key indicators. The indicators for the Planning Problems which incorporate the major issues, concerns, and opportunities, and the local and National indicators used in this comparison are.

1. Indicators for TIMBER PRODUCTION
   - Selected suitable area (M Acres)
   - First decade Allowable Sale Quantity (ASQ) (MMCF)
   - Long-term sustained yield (LTSY) (MMCF)

2. Indicators for OLD-GROWTH FOREST preservation
   - Reserved area (M Acres)
   - Old-growth habitat available at end of fifth decade (M Acres)

3. Indicators for maintaining or improving the Forest's SOIL PRODUCTIVITY, WATER QUALITY, and FISH HABITAT
   - Anadromous sport Fish User Days (M WFUD's)
   - Average annual sediment (M Tons per decade)

4 Indicator for management of lands in and adjacent to river corridors to protect, preserve, and enhance WILD AND SCENIC RIVER attributes
   - Adjacent area meeting Visual Quality Objectives (M Acres)

5. Indicators for SENSITIVE PLANT resource management
   - Area allocated to Botanical Areas (M Acres)
   - Area allocated to Research Natural Areas (M Acres)

6. Indicators for management of the VISUAL RESOURCES
   - Area allocated to meet Preservation, Retention, and Partial Retention Visual Quality Objectives (VQO's) (M Acres)
   - Area that meets or exceeds Partial Retention (M Acres)

7 Indicators of WILDLIFE HABITAT management
   - Wildlife User Days (M WFUD's)
   - Old-growth habitat in fifth decade (Percent of Forest acreage)

8 Indicator of recreation opportunities in the WILDERNESS and UNROADED areas

- Areas allocated to remain unroaded (M Acres)

9. Indicator of MINERAL resources development
   - Area accessible with limited restrictions (M Acres)

Indicators of LOCAL ECONOMIC and SOCIAL STABILITY.
- First decade payments to counties (MM $)
- First decade changes in employment (Jobs)
- First decade changes in income (MM $)

Indicators of NATIONAL INTEREST.
- PNV (MM $, discounted at four percent over 150-year period)
- Net cash flow (MM $)
- Noncash economic benefits (MM $)

In Table B-12, the indicators identified above are used to suggest the degree of response of each alternative to these Planning Problems. Other displays in Chapter II and discussions in Chapter IV provide more detailed information about specific effects and tradeoffs The alternatives are arranged in order of decreasing PNV.

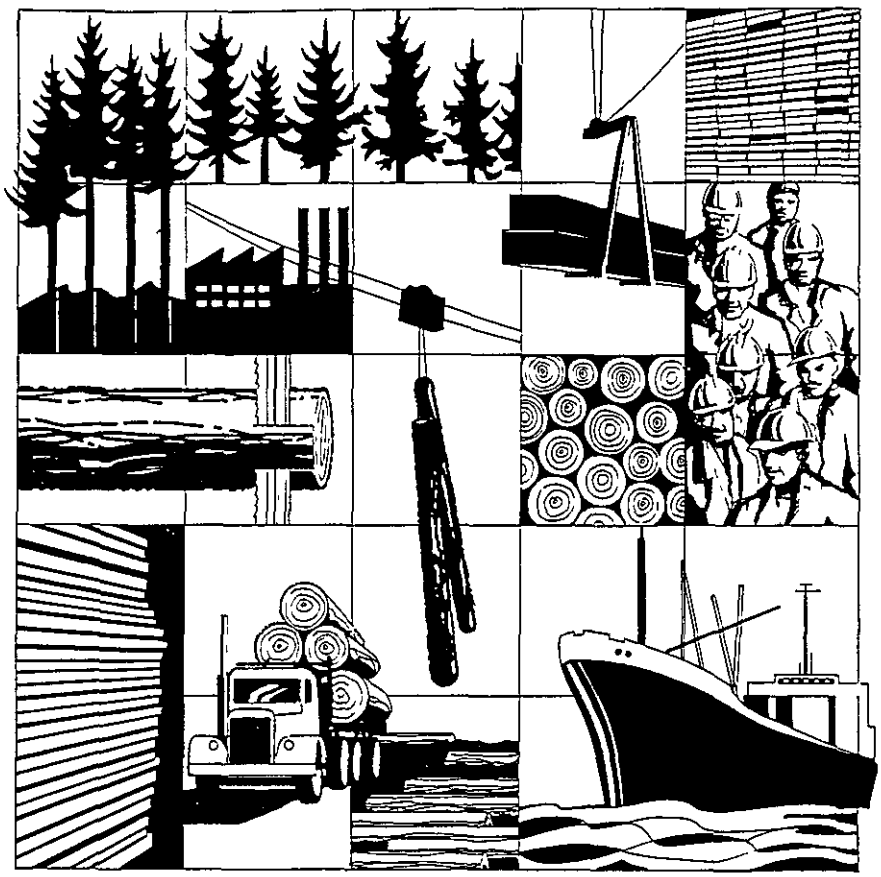

Table B-12. Indicators of Responsiveness to Planning Problems. Alternatives are Ranked in Order of Decreasing PNV.

1/ Alternative H includes 98,000 acres of General Forest which was not selected suitable for timber harvest.

Full titles of planning problems:

1 How Much Timber Should the Forest Produce?
2 How Much Old growth Forest Should be Preserved?
3 How Can the Forest's Fish Habitat, Water Quality, and Soil Productivity be Maintained or Improved?
4 How, and to What Extent, Should Lands in and Adjacent to River Corridors be Managed to Protect, Preserve, and Enhance Wild and Scenic River Attributes?
5 How Should Sensitive Plants Resources be Managed?
6. How, and to What Extent, Should Forest Scenic Values be Protected Through Visual Resource Management?
7 How Should Wildlife Habitats on the Forest be Managed?
8 How Will Management Direction Affect Recreation Opportunities in the Wildernesses and Unroaded Areas?
9. How Should Mineral Resources of the Forest be Developed in Coordination with Management of Other Resources?

Maximum PNV Benchmark

PNV $1,278 MM
Opportunity Cost. None

The Maximum PNV Benchmark identifies the mix of goods and services with market and assigned values that results in the largest excess of discounted benefits over discounted costs It meets MR's for resource protection and produces a high level of timber harvest on a nondeclining yield schedule It is summarized here for comparison purposes

The Maximum PNV Benchmark provides 32 4 MMCF of timber the first decade with an LTSY of 51 9 MMCF Protection of old-growth vegetation amounts to 164,000 acres, while 74,000 WFUD's for fisheries, 69,000 WFUD's for wildlife uses, and 735,000 RVD's per year are projected for the first decade

All unroaded areas outside designated Wildernesses would be developed Allocations to Botanical and Research Natural Areas are 1,000 acres and 2,000 acres, respectively A total of 820,000 acres would be available for mineral development.

Average net receipts are $37 8 MM with noncash benefits of $8 8 MM for the first decade In the fifth decade, the net receipts increase to $48 1 MM with noncash benefits of $10 7 MM.

Alternative B

PNV: $1,241 MM
Opportunity Cost $37 MM

INCREMENTAL CHANGE COMPARED TO MAXIMUM PNV BENCHMARK

Alternative B has the highest PNV of any alternative, primarily because first decade timber outputs are high The departure from nondeclining flow allowing more timber harvest in the first decade increases the PNV by $75 MM A reduced land base results in approximately a $13 MM reduction in PNV. The production of the maximum amount of timber given the land base reduces the PNV by approximately $35 MM Other opportunity costs are reflected in reduced harvest levels in riparian areas and General Forest areas in six basins (which reduces PNV by $21 MM). The additional allocation of visual management areas reduces the PNV by $26 MM. The remainder of the changes compared to the PNV Benchmark are due to wildlife, recreation, fisheries, and other miscellaneous programs (net $17 MM reduction).

Returns to the U.S Treasury are increased by $5 2 MM in the first decade The returns decline in the third decade due to reduced timber harvests By the fifth decade, the federal receipts drop by $23 1 MM. Noncash economic benefits, for which no fees would be collected, would stay relatively constant, averaging about $8.8 MM per year in the first decade and increasing to $10 8 MM in the fifth decade

High timber harvests and a large road construction program would result in the largest contributions to community employment (more than 1,220 jobs), income (more than $28.7 MM), and the largest payments to counties ($16.4 MM annually) for the first decade. These would lead to increased economic growth assuming demand for wood products is high enough to result in consumption of all timber offered

Acreages of old-growth trees, Botanical areas, and Research Natural Areas would be increased. The amount of scenic vistas would increase while the area allocated to Backcountry Recreation would remain constant. The projected demand for Primitive and Semi-primitive recreation opportunities exceeds capacity in later decades and Primitive recreation opportunities would be limited to designated Wilderness and Wild River areas by the second decade

Fisheries values are increased due to an intensive capital investment program. Though timber harvest from Riparian Management Areas would be implemented in all planning basins, six basins have more restricted timber harvest constraints in riparian areas and more restrictive scheduling constraints in General Forest areas. This alternative would place the least restrictions on mineral accessibility

INCREASED INDICATORS COMPARED TO MAXIMUM PNV BENCHMARK

1. First decade ASQ (+3.6 MMCF)
2. LTSY (+2 9 MMCF)
3 Botanical areas (+5 M Acres)
4 Research Natural Areas (+1 M Acres)
5 Wildlife (+14.6 M WFUD's)
6 Visual areas (+132 M Acres)
7. Amount of reserved old growth (+6 M Acres)
8 First decade annual net receipts (+$5 2 MM)

DECREASED INDICATORS COMPARED TO MAXIMUM PNV BENCHMARK

1 Selected suitable area for timber production (-9 M Acres)
2. Fisheries (-2 M WFUD's)
3. Fifth decade annual net receipts (-$23.1 MM)
4 PNV (-$37 MM)

Alternative D1

PNV $1,214 MM
Opportunity Cost. $27 MM Compared to Alternative B

INCREMENTAL CHANGES COMPARED TO ALTERNATIVE B

This alternative is second to Alternative B in PNV, net receipts, payments to counties, jobs, and income for the first decade

The major difference between Alternative D1 and Alternative B is the shorter timber rotation and the nondeclining yield timber harvest constraint. The nondeclining yield constraint results in lower first decade timber outputs This accounts for most of the opportunity costs ($75 MM reduction in PNV). The shorter rotation increases PNV by $54 MM The fisheries capital investment program is also reduced with a reduced PNV ($5 MM) for the fisheries program Other benefits and costs do not substantially change

The old-growth trees, unroaded areas, Botanical areas, and area managed for visual resources for this alternative are very similar to Alternative B. Six basins would still be managed with the more restrictive timber harvest within Riparian Management Areas and in General Forest, but fisheries would be managed with a lower capital investment program compared to Alternative B, resulting in slightly lower fisheries benefits. Predicted sedimentation, on the average, would be lower than for Alternative B However, projected sediment would increase in the third, fourth, and fifth decades due to a larger number of acres harvested per year No substantial change would occur in mineral access.

INCREASED INDICATORS COMPARED TO ALTERNATIVE B

1 Increased harvest in the third through fifth decades
2 Amount of reserved old growth (+1 M Acres)
3 Fifth decade annual receipts (+$4 8 MM)

DECREASED INDICATORS COMPARED TO ALTERNATIVE B

1. First decade ASQ (-3 6 MMCF)
2. Selected suitable area for timber production (-8 M Acres)
3. LTSY (-5.8 MMCF)
4. Wildlife (-2 8 M WFUD's)
5. Old-growth habitat fifth decade (-0 2 percent of Forest)
6. Sedimentation (-46 M tons per decade)
7. Fisheries (-3 M WFUD's)
8. First decade payments to counties (-$1.6 MM)
9. First decade jobs (-350) and income (-$8.0 MM)
10. First decade annual net receipts (-$4 8 MM)
11. PNV (-$27 MM)

Alternative NC

PNV· $1,214 MM
Opportunity Cost: None Compared to Alternative D1

INCREMENTAL CHANGES COMPARED TO ALTERNATIVE D1

Although the No Change Alternative (Alternative NC) has the same PNV as Alternative D1, there are significant differences in the timber, recreation, fisheries, and wildlife programs.

Alternative NC has a larger land base for timber production, which increases the PNV by approximately $33 8 MM. It also has a longer rotation which decreases PNV by $54 MM. Because this alternative does not maximize timber production where costs exceed benefits, its PNV is increased by $35 7 MM compared to Alternative D1 The increased land base allocated to visual management reduces the PNV by $29 3 MM Streamside management with Prescription B in all basins increases PNV by approximately $20.8 MM The total change in the timber program is a $7 MM increase in net benefits.

Other programs are significantly different. A decreased budget for capital investments for recreation improvements results in a $1 MM increase in net benefits due to surplus recreational capacity Lower amounts of fisheries capital investments produce lower net benefits for the fisheries program. Last of all, the lower amount of seral vegetation in the Alternative NC leads to decreased wildlife benefits compared to Alternative D1.

Annual net receipts, payments to counties, and jobs are lower than Alternative D1 in the first decade However, due to the large land base, the fifth decade annual net receipts are larger

Areas reserved for botanical objectives are reduced by approximately 4,000 acres and old-growth habitat reserves are reduced by 39,000 acres. Old-growth habitat existing in the fifth decade would be about 16.9 percent of the Forest, which is an increase compared to Alternative D1 This increase is due to longer rotation on the land base for timber management.

Other changes for key indicators are noted This alternative has the largest land allocation for retention and partial retention visual management. Sediment yields are projected to increase compared to Alternative D1, partially due to less restrictive basin constraints on six sensitive basins.

INCREASED INDICATORS COMPARED TO ALTERNATIVE D1

1 Selected suitable area for timber production (+26 M Acres)
2. LTSY (+5.2 MMCF)
3. Old growth habitat - fifth decade (+1.1 percent of Forest)
4. Visual Management (+207 M Acres Retention and Partial Retention)
5 Annual Net Receipts - fifth decade (+$11 3 MM)

DECREASED INDICATORS COMPARED TO ALTERNATIVE D1

1 Payments to counties (-$1 MM)
2 Jobs (-220) and Income (-$5 MM)
3 First Decade ASQ (-2.2 MMCF)
4 Old-growth Reserves (-39 M Acres)
5. Botanical Areas (-4,600 acres)
6. First Decade Annual Net Receipts (-$2.2 MM)

Alternative C

PNV $1,197 MM
Opportunity Cost: $17 MM Compared to Alternative NC

INCREMENTAL CHANGES COMPARED TO ALTERNATIVE NC

Alternative C has a lower PNV than Alternative NC due to a reduction in the timber base and due to production of the maximum amount of timber on the land base. The maximum timber objective function has timber produced where the additional costs exceed the marginal benefits The change in the land base and the timber objective function decrease PNV by $58.5 MM Decreased allocations to visual management offset the decreased land base by $35.5 MM.

First decade net annual receipts are decreased due to the additional cost of timber management Payments to counties and local jobs are increased due to additional first decade ASQ. Fifth decade annual net receipts are increased due to the payoff from additional investment in the timber program with increased harvest levels.

The amount of reserved old-growth habitat, the area allocated to Botanical Areas, and the amount of WFUD's would be increased compared to Alternative NC. The change in the old-growth habitat would be mainly due to increased land allocation for Management Requirements (MR's) for old-growth dependent species.

Projected sediment yields are significantly increased compared to Alternative NC due to increased hardwood conversion activity. Area managed for visuals would also be decreased significantly

INCREASED INDICATORS COMPARED TO ALTERNATIVE NC

1. Increased payments to counties (+$0.4 MM)
2 Jobs (+170) and income (+$2 5 MM)
3 First decade ASQ (+0.8 MMCF)
4 LTSY (+2 8 MMCF)
5 Reserved old-growth habitat (+36 M Acres)
6. Botanical areas (+5 M Acres)
7 Annual net receipts - Fifth Decade (+$2 2 MM)

DECREASED INDICATORS COMPARED TO ALTERNATIVE NC

1. Selected suitable area for timber production (-10 M Acres)
2. Sedimentation (+110 M tons per decade)
3. Visual management (-223 M Acres of Retention and Partial Retention)
4 Average annual net receipts - First Decade (-$3 9 MM)
5 PNV (-$17 MM)

Alternative D

PNV: $1,160 MM
Opportunity Cost. $37 MM Compared to Alternative C

INCREMENTAL CHANGES COMPARED TO ALTERNATIVE C

This alternative has the next lowest PNV (-$37 MM) primarily due to a mixed emphasis on all commodity production. Unlike Alternative C, less intensive timber harvest in Riparian Management Areas and more restrictive watershed harvest constraints are planned for six basins, thus reducing timber outputs while increasing fisheries outputs The cumulative effect on reduced timber outputs then reduces the net receipts, payments to counties, and other indicators for the first decade. LTSY is less by 2 2 MMCF due to operating on a smaller land base

The major reason for reduction of PNV compared to Alternative C is due to reduction in selected suitable acres (-$12 MM), an increase in visual management areas (-$5 MM), and more restricted harvest in Riparian Management Areas with stricter harvest constraints in six basins (-$20 MM) Less intensive timber management of the riparian areas and more restrictive harvest constraints are planned in six basins, so fisheries benefits are relatively high (+$5 MM) compared to Alternative C.

The amount of old growth that is in a preserved status is 171,000 acres. Backcountry Recreation, Research Natural Areas, Botanical, Wild River, and Scenic and Recreation River Management Areas are identical to previous alternatives. There is an increase of 24,000 acres for visual management Sediment production would be lower than Alternative C due to less road construction in the first decade, though still at a relatively high level. Access to lands for mineral production changes little Wildlife use is expected to decrease due to reduced seral vegetation in the first decade.

INCREASED INDICATORS COMPARED TO ALTERNATIVE C

1. Amount of reserved old growth (+2 M Acres)
2. Sedimentation (-108 M tons per decade)
3. Fisheries (+1 M WFUD's)
4. Visual areas (+24 M Acres)
5. Old-growth habitat fifth decade (+0.6 percent of Forest)
6 Area available for mineral development (+1 M Acres)

DECREASED INDICATORS COMPARED TO ALTERNATIVE C

1. First decade ASQ (-1.4 MMCF)
2. LTSY (-2 2 MMCF)
3 First decade payments to counties (-$0 7 MM)
4. First decade jobs (-190) and income (-$3 2 MM)
5. Wildlife (-9.0 M WFUD's)
6 PNV (-$37 MM)
7. First decade annual net receipts (-$0 5 MM)

Alternative A-Departure

PNV $1,160 MM
Opportunity Cost· None compared to Alternative D

INCREMENTAL CHANGE COMPARED TO ALTERNATIVE D

Though the opportunity costs of Alternatives A-Departure and D are equal, each program is different The increase in Supplemental Resource area reduces the acres for timber production This reduces the PNV by $8 MM The removal of the timber objective function increases PNV (+$35 MM) The increase in areas managed for visuals lowers the lands available for intensive timber management and PNV (-$48 MM). Managing all basins with the least restrictive riparian harvest prescriptions increases PNV by $19 MM Using Prescription B and lowering capital investments for fisheries result in decreased fisheries benefits Lower investment in recreation does not significantly affect benefits, due to surplus capacity.

The first decade outputs for net receipts, payments to counties, jobs, and income are greater due to the departure of timber outputs However, by the third decade, the timber outputs are reduced.

The amount of old-growth habitat, reserved old growth, and Backcountry Recreation areas are slightly increased. The land dedicated to Botanical areas and RNA's would be the least of any alternative The land allocated to visual management would be the highest of any alternative. The fisheries outputs are expected to decrease due to the implementation of Prescription B in the Riparian areas while projected sedimentation is somewhat lower than Alternative D.

INCREASED INDICATORS COMPARED TO ALTERNATIVE D

1. First decade ASQ (+0.8 MMCF)
2. Amount of reserved old growth (+2 M Acres)
3 Visual areas (+193 M Acres)
4. Unroaded areas (+5 M Acres)
5. Area available for mineral development (+4 M Acres)
6. County payments (+$0 4 MM), jobs (+40), and income (+$1.1 MM)
7. Sedimentation (-6 M tons per decade)
8. First decade annual net receipts (+$4.2 MM)

DECREASED INDICATORS COMPARED TO ALTERNATIVE D

1. LTSY (-2 1 MMCF)
2. Fisheries (-2 M WFUD's)
3. Botanical (-5 M Acres) and Research Natural Areas (-1 M Acres)
4. Wildlife (-0.8 M WFUD's)
5. Reduced ASQ, annual net receipts, and payments to counties in future due to departure scheduling

Alternative A

PNV. $1,150 MM
Opportunity Cost· $10 MM Compared to Alternative A-Departure

INCREMENTAL CHANGE COMPARED TO ALTERNATIVE A-DEPARTURE

The only significant difference between Alternatives A and A-Departure, which explain the $10 MM opportunity cost, is the decrease in first decade timber outputs in Alternative A Since A has the nondeclining yield timber harvest constraint, the first and second decade outputs are significantly less than the departure alternative Wildlife values are reduced by $1 MM due to the decreased production of seral stages. Other factors are equal including land allocation, program costs, and other benefits

The change compared to Alternative A-Departure in payments to counties, net receipts, and social indicators of jobs and income changes follows the same trend as the amount of timber harvest for the first decade. Third decade outputs are higher due to the use of the nondeclining yield constraint

Most other indicators including mineral accessibility, do not change significantly. However, the first decade sediment outputs are less by 6,000 tons due to less harvest and road construction in the first decade

INCREASED INDICATORS COMPARED TO ALTERNATIVE A-DEPARTURE

1. Amount of reserved old growth (+2 M Acres)
2. Sedimentation (-20 M tons per decade)
3. Higher ASQ, annual net receipts, and payments to counties in third, fourth, and fifth decades

DECREASED INDICATORS COMPARED TO ALTERNATIVE A-DEPARTURE

1. First decade ASQ (-1.1 MMCF)
2. Wildlife (-1.1 M WFUD's)
3. First decade payments to counties (-$0.5 MM)
4 First decade jobs (-100) and income (-$2 3 MM)
5. First decade annual net receipts (-$1.7 MM)
6. PNV (-$10 MM)

Alternative S

PNV: $1,131 MM
Opportunity Cost. $19 MM Compared to Alternative A

INCREMENTAL CHANGES COMPARED TO ALTERNATIVE A

All program costs are different for Alternatives A and S An increase in the land allocated to Research Natural Areas, Botanical, Backcountry Recreation, Supplemental Resource, and Special Wildlife Sites Management Areas reduces the land available for timber harvest. However, the land available for timber production is managed more intensively with fertilizer applications The land available for timber production drops by 52,000 acres with a corresponding drop in PNV (-$18 MM). Use of the timber objective function in Alternative S reduces the PNV by approximately $31 MM compared to Alternative A A reduction in the area allocated to visual management increases the land available for intensive timber management. Relative to Alternative A, the percent increase in General Forest acres corresponds with a $40 MM increase in PNV The change of seven basins to Riparian Prescription C reduces PNV by $2 MM.

The capital investment programs for recreation are increased over those of Alternative A However, all benefits remain the same due to excess capacity for recreation and wilderness experiences in the first decade. The capital investment program for fisheries is increased and results in increased net benefits of $6 MM

Because of timber outputs, changes in wildlife habitat, and increased fish production, a slight increase of jobs, payments to counties, net receipts, and incomes are predicted

The fish outputs are increased due to implementation of a more restrictive riparian harvest in several basins and due to an increased capital investment program Sediment projected in the first decade is lower (-114 tons) due to less acres harvested. Mineral access would be highly restricted on an additional 32,000 acres. Wildlife use would increase due to an increased wildlife capital investment schedule The amount of reserved old growth is also increased.

INCREASED INDICATORS COMPARED TO ALTERNATIVE A

1. Wildlife (+21 M WFUD's)
2. Amount of reserved old growth (+23 M Acres)
3. Sedimentation (-114 M tons per decade)
4 Fisheries (+11 M WFUD's)
5 Old-growth habitat (+1.4 percent of Forest in fifth decade)
6 Unroaded areas (+78 M Acres)
7 Botanical areas (+15 M Acres)
8. Research Natural Areas (+1 M Acres)
9 Average annual Noncash Benefits (+ $0.5 MM)

DECREASED INDICATORS COMPARED TO ALTERNATIVE A

1. First decade ASQ (-1.1 MMCF)
2. LTSY (-4.7 MMCF)
9 Acres available for mineral development (-32 M Acres)
4 Visual areas (12 M Acres)
6. First decade payments to counties (-0.5 MM $/Yr)
7. First decade jobs (-20) and income (-$0.9 MM)
5 PNV (-$19 MM)
11 First decade annual net receipts (- $2 2 MM)

Alternative K

PNV· $1,083 MM
Opportunity Cost· $48 MM Compared to Alternative S

INCREMENTAL CHANGES COMPARED TO ALTERNATIVE S

Alternative K has some differences in land allocations and constraints compared to Alternative S A decrease in land allocations for Backcountry Recreation, Special Wildlife Sites, and Scenic/Recreation Rivers provides a larger land base (+13,000 acres) for timber management which results in a plus $28 MM for PNV A small reduction in visual management results in a slight increase in PNV (+$0.7 MM)

Taking away fertilization as a treatment option and the tighter constraint for watershed management result in a significant decrease in PNV (-$63 MM) The capital investment program for fisheries is the highest for all alternatives, resulting in high fisheries benefits. The recreation and wildlife programs are lower than

Alternative S The recreation program has an increased PNV of $2 8 MM due to existing surplus capacity. The wildlife program has a decreased PNV compared to Alternative S of $13 MM due to a reduced capital investment program.

Decreases in the annual net receipts, payments to counties, change in jobs, and change in income would occur in the first decade

Alternative K would have slightly less old-growth habitat suitable for wildlife use in the fifth decade. Sediment production projected for the first decade is slightly less than Alternative S due to the lower level of harvest and roading Fish production decreases some due to more intensive timber management in six basins. The accessibility of minerals is slightly increased to that in Alternative S.

INCREASED INDICATORS COMPARED TO ALTERNATIVE S

1 Average Annual Net Receipts - 5th Decade (+$1.5 MM)
2. Suitable Land for Timber Production (+24 M Acres)
3. Sedimentation (-28 M Tons/Decade)
4. Minerals (+15 M Acres)

DECREASED INDICATORS COMPARED TO ALTERNATIVE S

1. First decade ASQ (-1.2 MMCF)
2. Payments to counties first decade (-$0 5 MM)
3. Number of jobs (-180) and income (-$3.9 MM) first decade
4. Wildlife (-22 M WFUD's)
5. Old Growth Preserved (-9 M Acres)
6 Botanical and RNA Areas (-9 M Acres)
7 Fisheries (-7 M WFUD's)
8 PNV (-$48 MM)
9 Annual net receipts first decade (-$2 9 MM)
10 Average annual noncash benefits (-$0.4 MM)

All other indicators remain relatively constant

Alternative G

PNV: $844 MM
Opportunity Cost. $107 MM Compared to Alternative K

INCREMENTAL CHANGE COMPARED TO ALTERNATIVE K

This alternative has significantly lower PNV compared to the previous Alternative (K) with spin-off decreases in payments to counties, net revenues, jobs, and incomes.

Alternative G's increasing opportunity costs are mainly due to the reduction of investment in the timber program The opportunity costs for timber riparian management are $11 MM Additional areas in Backcountry Recreation, Supplemental Resource, Botanical, and Designated Wildlife Habitat Management Areas reduce the investment opportunities for timber production and PNV by $84 MM. An increase in the visual management areas reduces the land available for intensive timber production. The resulting decrease in General Forest acres equals $10 MM reduction in PNV Due to high capital investments and the lack of harvest in riparian areas, the fisheries benefits are high with an increased PNV (+$3 MM).

The amount of reserved old growth (+27,000 acres) increases in connection with the unroaded areas. Projected sediment decreases significantly in the first decade due to a decrease in road construction and harvest

INCREASED INDICATORS COMPARED TO ALTERNATIVE K

1. Amount of reserved old growth (+74 M Acres)
2. Sedimentation (-182 M tons per decade)
3. Fisheries (+1 M WFUD's)
4. Botanical areas (+28 M Acres outside of Wilderness)
5. Visual areas (+219 M Acres)
6. Old-growth habitat fifth decade (+4.5 percent of Forest)
7. Unroaded area (+70 M Acres)

DECREASED INDICATORS COMPARED TO ALTERNATIVE K

1. First decade ASQ (-7.3 MMCF)
2. LTSY (-10.1 MMCF)
3. Selected suitable area for timber management (-123 M Acres)
4. Wildlife (-8.9 M WFUD's)
5. Acres available for mineral development (-37 M Acres)
6. Payments to counties (-$3.6 MM)
7. Number of jobs (-680) and income (-$15 4 MM)
8. PNV (-$239 MM)
9. Annual net receipts (-$8.9 MM)

All other indicators are relatively constant.

Alternative E

PNV. $679 MM
Opportunity Cost: $165 MM Compared to Alternative G

INCREMENTAL CHANGES COMPARED TO ALTERNATIVE G

The PNV for Alternative E is $165 MM less than Alternative G. The decreases in net receipts, county receipts, jobs, and incomes occur mainly due to a decrease of 4.3 MMCF in timber outputs The decrease is due to fewer acres managed for timber with a corresponding decrease in the LTSY (-6.5 MMCF).

Alternative E's emphasis on preserving unroaded areas foregoes timber management opportunities on 302,000 acres The increase in unroaded areas and subsequent decrease in land managed for timber production reduce PNV by $149 MM. Alternative E also foregoes timber management opportunities in all riparian areas. This management reduces PNV by $22 MM Other economic programs are not significantly different The capital investment program for fisheries is reduced The lack of timber harvest in unroaded areas, Riparian areas, and Supplemental Resource areas provide fisheries benefits (though slightly reduced from Alternative G)

The unroaded area allocation and area of preserved old growth are increased The old-growth habitat suitable for wildlife would be increased as would visual management areas. The area allocated to Botanical and RNA's would be decreased by 11,000 acres. Projected sediment is less due to lower harvest levels and less road construction. The areas open to mineral development would be decreased by 148,000 acres

INCREASED INDICATORS COMPARED TO ALTERNATIVE G

1. Amount of reserved old growth (+63 M Acres)
2. Sedimentation (-108 M tons per decade)
3. Visual areas (+66 M Acres)
4. Old-growth habitat fifth decade (+4.3 percent of Forest)
5. Unroaded areas (+10 M Acres)

DECREASED INDICATORS COMPARED TO ALTERNATIVE G

1. First decade ASQ (-4.3 MMCF)
2. LTSY (-6.5 MMCF)
3. Selected suitable area for timber management (-119 M Acres)
4 Wildlife (-6.1 M WFUD's)
5. Acres available for mineral development (-148 M Acres)
6. Botanical areas (-11 M Acres outside of Wilderness)
7. Payments to counties (-$2.0 MM)
8. Number of jobs (-400) and income (-$8.9 MM)
9 PNV (-$165 MM)
10 Annual net receipts (-$6.9 MM)

All other indicators remain relatively constant.

Alternative M

PNV· $272 MM
Opportunity Cost: $407 MM Compared to Alternative E

INCREMENTAL CHANGES COMPARED TO ALTERNATIVE E

Alternative M has the highest opportunity costs due to the long rotation length for timber management on a much reduced land base. Compared to Alternative E, the longer rotation of Alternative M reduces PNV by $239 MM. The maximum area is allocated to an unroaded status, Supplemental Resource, Botanical, RNA's, and Designated Wildlife Habitat areas. The opportunity costs of the reduced area allocated to timber production equals $161 MM compared to Alternative E. These costs are offset somewhat because some of these acres allocated to management not allowing programmed harvest were visual management acres. This reduces the opportunity costs by approximately $10 MM. No harvest is programmed from riparian areas and the maximum amount of land is allocated to scenic vistas including preservation status The increased fisheries budget combined with the lack of timber harvest in riparian areas results in high fisheries benefits, though slightly less than Alternative G. Other economic programs such as recreation and wilderness benefits do not increase due to projected surplus supply of unroaded areas compared to projected use in the near future.

The incremental decrease in county receipts, net cash flow, jobs, and income is the greatest of any alternative. As with the other alternatives, the amount of planned timber harvest accounts for most of this change. The amount of area managed for timber is the lowest for all alternatives and the planned rotation for the Forest is the longest, resulting in a lower LTSY.

The most old growth of any alternative would be preserved with corresponding habitat for old-growth-dependent species. The maximum amount of land of all alternatives would be allocated to Preservation, Retention, and Partial Retention visual management Fish production would also be high, with sediment production the lowest of all alternatives Due to lack of activities that would create forage areas and habitat diversity, big game, small game, and nonconsumptive wildlife use would decline

INCREASED INDICATORS COMPARED TO ALTERNATIVE E

1 Amount of reserved old growth (+63 M Acres)
2. Sedimentation (-334 M tons per decade)
3 Botanical areas (+11 M Acres outside of Wilderness)
4 Visual areas (+11 M Acres)
5 Old-growth habitat (+5.5 percent of Forest in fifth decade)
6 Unroaded areas (+94 M Acres)

Decreased Indicators Compared to Alternative E

1. First decade ASQ (-10 1 MMCF)
2. LTSY (-10.0 MMCF)
3 Wildlife (-14 9 M WFUD's)
4. Payments to counties (-$4.1 MM)
5. Number of jobs (-950) and income (-$23.5 MM)
6. Fisheries (-1 M WFUD's)
7. PNV (-$407 MM)
8. First decade annual net receipts (-$14.6 MM)

CONSTRAINT ANALYSIS

The following tables describe the constraints placed on different alternatives and their effects on costs, benefits, and PNV. The constraints that are discussed include the land assignment changes, departure scheduling, rotation lengths, basin harvest constraints, and capital investments for watershed, fisheries, recreation, and wildlife programs.

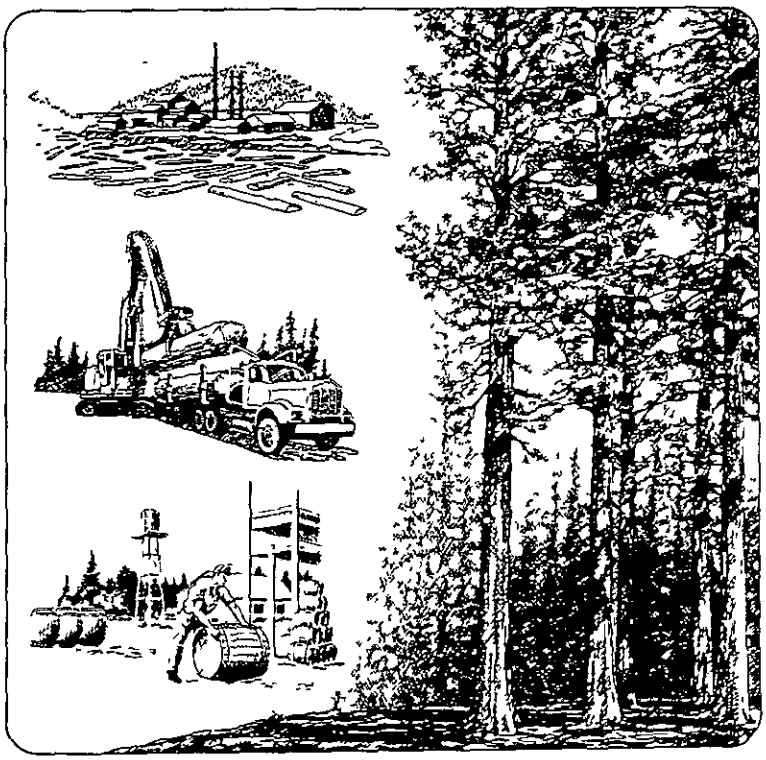

Table B-13. Constraint Comparisons

Alternative B

The following constraints were different between Alternative B and Max PNV Benchmark.

	Compared to Max PNV	
	Item	Opportunity Cost
Change in Land Assignments		
Research Natural Areas	+ 1,411 Ac

ROADLESS AREAS (1988)

SISKIYOU NATIONAL FOREST

INTRODUCTION

Appendix C provides the description of the environment, alternate management, and **site-specific** consequences for each inventoried roadless area. Treatment of each unroaded area versus treating various arrays of unroaded areas by alternatives is the primary distinction between this Appendix and the Final Environmental Impact Statement (FEIS). In the body of the FEIS, the issues, analysis, and alternative ways of managing currently unroaded areas are evaluated **in the aggregate** as a resource, land use, or environmental condition across the Forest as a whole.

If roads, timber harvest, or other development occurs in these unroaded areas within this planning period (10-15 years), eligibility for Wilderness consideration will be adversely affected This, in itself, may be a significant consequence. For this reason, the unroaded area's attributes for Wilderness, such as its *capability, availability, and need, are considered so that any decision to allocate the area for particular uses* will be made with full disclosure of the environmental effects.

Since the intent of **Appendix C** is to provide site-specific analysis of each unroaded area, the objective herein is to evaluate the allocation of each of these areas to either (1) continued unroaded status, (2) development, or (3) an intermediate level of development. Along with the description and other resource information, the environmental consequences of the alternatives on each area is provided (i e., the evaluation of effects of different management strategies as proposed by each alternative on the specific unroaded area) NOTE: Considerable information and analysis accompanied Roadless Area Review and Evaluation II (RARE II) in the late 1970's; this information is on file in the Supervisor's Office.

The following is provided to help clarify Congressional direction as to future management and evaluation of the roadless areas covered in this FEIS and accompanying appendix. According to the Oregon Wilderness Act of 1984 (and, similarly, the California Wilderness Act of 1984): "...with respect to the National Forest System lands...which were reviewed...in the second Roadless Area Review and Evaluation (RARE II),...(RARE II) shall be deemed for the purpose of the initial land management plans...to be an adequate consideration of the suitability of such lands for inclusion in the National Wilderness Preservation System and the Department of Agriculture shall not be required to review the wilderness option prior to the revision *of the [Forest] plans, but shall review the wilderness options when the plans are revised which will ordinarily* occur on a ten-year cycle... [Roadless areas] shall be managed for multiple use in accordance with land management plans pursuant to Section 6 of [RPA], as amended by [NFMA]..." Since Congress has not designated the remaining roadless areas as Wilderness, this appendix does not made a recommendation on Wilderness options for the unroaded areas. Congress has done this job.

CHANGES BETWEEN DRAFT AND FINAL

The Forest has 18 inventoried roadless areas that total 284,000 acres as of the end of 1988. In 1984, the inventoried area totalled 314,000 acres. Due to continuing management activities, prior activities, and the Silver Fire and resulting decision, the inventoried portion has been reduced by 30,000 acres. The decision covering the salvage timber sales and associated roading of the Silver Fire accounted for 19,000 acres. This reduction was all within the inventoried North Kalmiopsis Roadless Area. The project received National *coverage and extreme notoriety. For specifics, please refer to the Silver Fire Recovery Project FEIS (1988).*

Some reduction is attributable to two inventoried areas that were partially roaded years earlier but not indicated in the 1984 update. The balance of the change comes from timber harvest and associated roading between May of 1984 and the end of 1988. This includes timber sales completed, operating, or *under contract. For specifics of inventory updates for each inventoried roadless, see* **Table C-3.**

APPENDIX C ORGANIZATION

Appendix C is divided into two sections. The first section (pages C-1 through C-10) summarizes the individual roadless area facts and figures. One map (**opposite page**) and three tables provide for rapid review of the individual roadless area narratives. **Table C-1** displays, by alternative, roadless area acres remaining unroaded by the end of decades 1, 2, and 5. **Table C-2** provides a summary of acres remaining unroaded by alternative. **Table C-3** lists each area's acreage and denotes changes, if any, from the inventoried (RARE II) roadless area boundary. **Table C-4** summarizes each area's attributes

In the second section, each unroaded area is treated as a separate entity. Maps of the 18 areas (**Figure C-1a through q**) accompany this listing. **Table C-5a through r** display the Management Areas by alternative (from **FEIS Chapter II**). The narrative evaluation and characterization of Management Area strategies by alternative formulations are provided under the following major headings.

I. **DESCRIPTION** - The existing condition (planning and current use status; physiographic and biological conditions)
II. **CAPABILITY** - The presence of Wilderness characteristics, including manageability and special features; the basic features that made the area appropriate and valuable for Wilderness regardless of the area's availability or need.
III. **AVAILABILITY** - The opportunities of other resources (potentials and management considerations) for indicating the area's availability for Wilderness.
IV. **NEED** - The relevance to other areas and use, ecosystem representation, and public involvement; various factors considered in assessing the Wilderness need of each area.
V. **ENVIRONMENTAL CONSEQUENCES** - The scientific and analytical basis for comparing the alternatives (discussion of environmental effects, and important interrelationships between resources, land uses, and environmental conditions; both quantitative and qualitative aspects of information is provided). The potential consequences of a development (non-Wilderness) and non-development (retaining the potential for Wilderness designation) alternatives are described.

Each Roadless Area will cover all elements under the following headings; detail for each varies depending on size of area, resource complexities, and concerns expressed through public involvement:

DESCRIPTION
- Status of Roadless Area
- Changes Between Draft and Final
- Location and Access
- Physiographic and Biologic Features
- Resource Uses
- Appearances, Surroundings, and Attractions

CAPABILITY
- Manageability
- Natural Integrity and Appearance
- Opportunities for Solitude and Primitive Experience
- Special Features

AVAILABILITY
- Resource Potentials
- Management Considerations

NEED
- Other Areas and Public Use
- Ecosystem Representation
- Public Involvement

ENVIRONMENTAL CONSEQUENCES
- Significant Effects
  - Cultural Resources
  - Energy and Minerals
  - Improvements
  - Wilderness Potential
  - Wild and Scenic Rivers
  - Soil, Water, and Fish
  - Fire
  - Vegetation
  - Sensitive Plants
  - Air Quality
  - Wildlife
  - Visual Resource
  - Recreation Settings
  - Economic and Social
- Mitigation Measures
- Potential Conflicts with Other Jurisdictions

ROADLESS AREA REMAINING OVER TIME

Table C-1 summarizes the approximate area remaining roadless at the end of Decades 1, 2, and 5. The acres are the decade total of the 18 roadless areas by each alternative. The estimates are made with the following assumptions:

1. Areas only counted if (a) greater than 5,000 acres, or (b) contiguous to designated Wilderness;
2. Only the first decade can be estimated with any reliability as based on the Ten-year Timber Sale Action Plan for Alternative S (Appendix C, Forest Plan);
3. The second and fifth decades are extended estimates of the alternative theme and land assignments;
4. The greatest variance in estimates occur in the South Kalmiopsis where large areas of land unsuited for timber production exist; these lands are assumed to remain unroaded over time; and
5. In Alternatives E, G, and M, portions of approximately 25,000 to 30,000 acres are allocated to Backcountry Recreation which would require restoration. Many of these acres have nonconforming features such as roads or timber harvest units attributable largely to the Silver Fire Recovery Project and other timber sales between 1984 and 1988. These acres are not included in Table C-1.

Table C-1. Acres of Roadless Areas Remaining at End of Decades 1, 2, and 5, by Alternative

Alternative	Acres Remaining End of Decade 1/		
	1	2	5
A, A-Dep, and NC	102,000	90,000	85,000
B, C, D, and D1	86,000	74,000	69,000
E and M	284,000	284,000	284,000
G	186,000	173,000	173,000
K	109,000	97,000	92,000
S	135,000	126,000	126,000

1/ Minimum criteria is 5,000 unroaded contiguous acres, or adjacent to designated Wilderness

Table C-3. Summary of Roadless Area Acreage and Change from Inventoried Roadless Area (Siskiyou National Forest; December 31, 1988)

RARE II				
Number	Name	Acres 1/	Revised Acres 1/	Reason for Change
N/A	Grassy Knob	23,137	5,428	Area allocated to nonwilderness in the Mt. Butler-Dry Creek Land Use Plan (FEIS, 1976) Added to inventory in 1983 (not RARE II). 17,200 acres designated Grassy Knob Wilderness by Oregon Wilderness Act of 1984. Approximately 500 acre reduction due to China Peak Timber Sale
6171	Copper Mountain	10,884	9,354	Small areas added on fringe, other areas deleted in the northwest and northeast by North Shelter, Dixie Knot and the Salmon Mountain Timber Sales (approximately 1,500 acres)
6172	Mule Creek	250	352	Wild Rogue Wilderness boundary adjusted to exclude nonconforming uses, the additional acres added have low standard roads Recent mining has reduced the area by 150 acres near Boliver Creek
6173	Rogue	6,744	3,839	Area adjusted by timber sales in Billings Creek (1,100+ acres), Devils Timber Sale along the northern edge; and timber sales in mid-drainage of Stair Creek.
6174	Potato Mountain	8,060	5,963	Area reduced by timber sale activity between Stonehouse Creek and Potato-Illahe Mtn Painted Picture and Waters Timber Sales divided area
6175	Shasta Costa	16,312	14,261	Area reduced by timber sales on the east and west edges (Squirrel Camp, Whitten Prairie, and South Shasta Timber Sales).
6176	North Kalmiopsis	113,254	88,582	Silver Fire Recovery Project removed 19,000 acres in Silver and Indigo drainages. The Chinaman Hat Timber Sale and access road reduced most of unroaded area in South Fork Silver Creek; part of the sale in Silver Fire South Indigo and Lawson Saddle Timber Sales reduced area near Indigo Prairie and Saddle Mountain, respectively. A few other timber sales reduced minor acreages along fringes of the inventoried area.
6177	Quosatana	5,514	5,097	Adjusted along the northern portion near the Rogue River and Fritsche Cabin by the Skookumhouse, Moorsky, and Fritsche Timber Sales.
6178	Briggs	5,762	5,544	Adjusted due to Onion Bowl Timber Sale near Waterdog Creek
6179	Squaw Mountain	8,064	7,704	Adjusted due to timber sale north of Squaw Mountain.
6180	Windy Valley	13,491	10,214	Road construction and timber sales have divided the area All of the area has been eliminated in Eagle Creek drainage due to timber sales. Area reduction west of Snow Camp Mountain-Panther Lake due to roading and timber sales.
6183	Kalmiopsis Addition	1,178	1,166	(-) Data base difference, no activity.
6184	Mount Emily	5,947	5,945	(+) Data base difference; no activity

Table C-3. Summary of Roadless Area Acreage and Change from Inventoried Roadless Area (Siskiyou National Forest; December 31, 1988) (Continued)

RARE II Number	Name	Acres 1/	Revised Acres 1/	Reason for Change
6701	Siskiyou	8,294	3,284	Most of the 5,323 acres designated Siskiyou Wilderness by California Wilderness Act of 1984. No other changes due to activity
6702	Indian Creek	950	0	DOES NOT CURRENTLY MEET MINIMUM CRITERIA due to road construction and timber harvest activities on the Klamath National Forest
6703	Kangaroo	14,192	6,651	Siskiyou National Forest portion reduced to 10,832 acres as a result of nonconforming features existing before RARE II and more recent timber sales. Area situated between Left Fork and main Sucker Creek has been deleted A portion of southwestern edge north of Tannen Lake reduced Another 3,414 acres designated Red Buttes Wilderness by Oregon Wilderness Act of 1984 Siskiyou National Forest portion only
6707	North Fork Smith	950	952	(+) Data base differences, no activity Siskiyou National Forest portion only.
6708	Packsaddle	9,315	5,289	Considerable reduction in the western side (Bear Ridge and Sankey Creek) of the Siskiyou National Forest portion due to timber sales and road construction activity Area divided by roading west of Rowdy Creek Siskiyou National Forest portion only
6709	South Kalmiopsis	111,315	104,620	Timber harvest and road construction, principally in western and southern portion, has reduced area's size since RARE II Also included private land with county road and homes. Siskiyou National Forest portion only
Total 1/		363,613	284,245	

1/ Gross Acres

KEY to Attributes: HIGH - High
Mod - Moderate
L - Low
0 - None, or negligible

NOTE: Explanation of Attribute Ratings follow this table.

Table C-4 KEY to Attributes Ratings

Attribute Rating (**HIGH** - High; **Mod** - Medium; **L** - Low; **0** - None or Negligible)

Accessibility - Ability to access perimeter of unroaded area.

HIGH - Boundary readily accessible (>3/4) by maintained roads and trails for most of the year.

Mod - Most sides accessible (1/2-3/4) for greater part of year.

L - Access (1/4-1/2) to boundary adequate, some seasonal difficulties.
0 - Major portions inaccessible (<1/4) due either to area size, lack of roads/trails, or physical barriers and seasonal difficulties.

Use Conflicts - Degree of conflicting resource uses within area or directly adjacent contributing to area's visual, sound, or physical impairment. (Generally, these are mining, grazing, special use roads within; various activities on boundaries, e g., harvest areas, logging, road building, traffic)

HIGH - Several uses which are quite apparent and/or are of such size or timing to be of obvious detraction.

Mod - Few (<3) whose size and timing may detract, but not for an extended period of time or over a large area.

L - Few (<3) whose size and timing are of minor detraction and of limited extent.
O - Activity not apparent or of very limited size and detraction.

Key Resource Values (Potentials) - The existence or potential (capabilities).

HIGH - Inherent productivity, development potential, or outputs high.

Mod - Moderate inherent productivity, etc.

L - Low inherent productivity, etc. (limited in extent or amount).
O - Resources very limited or nonexistent in amount, extent, or development potential.

Manageability - Ability to manage and protect the area's natural character considering such factors as size, shape, and position (including boundary location) relative to external influences.

HIGH - Inherently protected through excellent topographic positioning, favorable external influence (i.e., land allocation, physical conditions), or very limited hazards/risks to natural character.

Mod - Part of area subject to external influences, or overall positioning and physical conditions are at some risk.

L - Considerable portions at risk or subject to external influences; manageability highly dependent on degree of protection provided in areas outside unroaded part.
O - Protection largely unattainable due to present activities and conditions that are not inherently mitigated. Risks to natural character and processes high

Natural Integrity - Extent to which long-term ecological processes are intact and operating, or are free of disturbances; consideration of extent to which human influences have altered natural conditions and are apparent to user.

HIGH - Extremely limited, or not apparent

Mod - Small portions of area affected by human activity, or recovery of past impacts approaching natural state and not perceived by user.

L - Considerable area impacted, or perceived recovery of past change incomplete or apparent to user.

O - Much of present ecosystem is primarily a result of recent or past activity by man; or major portion is directly or indirectly (from periphery) influenced by human activity; readily noticed by user.

Opportunities for Solitude - Area's feeling of solitude (how it provides for remote and backcountry setting).

HIGH - Most of area free of external influence and provides a strong feeling of remoteness and solitude.

Mod - Fringes influenced by sight and/or sound of human activity; solitude aided by vegetative or topographic conditions.

L - External influences persist over much of area; vegetation and topography generally only aid to providing solitude.

O - Most of area within sight or sound of human activity; topography and vegetation provides only limited relief.

Primitive Experience - Opportunity for primitive and unconfined types of recreation activities; how well the area provides outstanding opportunities for unusual adventures or excitement.

HIGH - Varied type (more than those associated with foot travel only); unique experience, or experience of adventure/excitement.

Mod - Varied type (good mix of foot travel associated activity); potential for adventure exists.

L - Limited type; adventure or challenge related to topographic difficulty and distance from nearest roaded access.

O - Type and adventure not different than much of adjacent lands.

Special Features - Unique, abundant, or varied flora, fauna, historic, scientific, and physiographic features; where protection from nonconforming activities would enhance management of unusual or sensitive species or features.

HIGH - Existence over much of area or very unique.

Mod - Existence of species or features over much of area that would be enhanced; limited extent of unique or sensitive elements.

L - Limited enhancement opportunity; unique or sensitive elements limited to very small areas, or other allocations, standards or guidelines afford adequate protection.

O - Species and features not different than surrounding areas.

Other Areas - Need for area based on nearby Wilderness or other roadless areas.

HIGH - Few tracts of similar protected areas, either by designated status or inherent, nearby (within 2 hours; 30 miles).

Mod - Like tracts nearby, but of limited size or availability.

L - Large tracts nearby.
O - Adjacent sizeable tracts of land supplying similar opportunities.

Relative Use - Need for area based on use demands for primitive forms of recreation and experience levels.

HIGH - Current demand high or projected demands to exceed capacity.

Mod - Current demand moderate, but not expected to approach capacity within planning horizon.

L - Low existing or expected demand.
0 - Very light use; demand not expected to change.

Ecosystems Represented - The need for providing/protecting unusual or sensitive ecosystems; proximity to similar protected ecosystems; uniqueness of ecosystem.

HIGH - Very limited as to extent or protectorate status; unique; very sensitive to disturbances by human activity.

Mod - Limited representation in protected status; unusual, but not unique; sensitive to disturbance, but manageable by other means.

L - Considerable similar systems protected; common to area.
0 - No defined need for protective status or special management.

Public Interest - The degree (extent and intensity) to which the public and other agencies have expressed interest in maintaining the area in either a roaded or unroaded condition.

HIGH - Significant involvement by many sectors; considered "sensitive."

Mod - Significant involvement or intensity by specific interest groups displayed over time.

L - Limited input or low intensity; issue not sensitive.
0 - Interest in area's management very limited.

Figure C-1a
RARE II AREA N/A
Grassy Knob Roadless Area

GRASSY KNOB

(5,428 Acres)

DESCRIPTION

STATUS OF ROADLESS AREA

The unroaded portion of the Grassy Knob area was studied for potential Wilderness in the Land Use Plan for the Mt. Butler-Dry Creek Planning Unit, Final Environmental Impact Statement (FEIS, 1976). The decision for this area resulted in a combination of management strategies, including timber management, Fisheries/ Wildlife, and Fisheries/Recreation areas. However, in the Oregon Wilderness Act of 1984, an area of 17,200 acres covered by the Mt. Butler-Dry Creek Planning Unit was designated as the Grassy Knob Wilderness.

The residual unroaded area, consisting of 5,428 acres, is divided by the Grassy Knob Wilderness. There is no private land within the unroaded area boundary. The western portion contains approximately 1,200 acres. The Mt. Butler-Dry Creek FEIS allocates the Anvil Creek watershed as a Fisheries/Wildlife area. Rock Creek is managed both for timber management and a Fisheries/Recreation area averaging 1/8 mile on either side of Rock Creek.

The eastern portion of the roadless area contains approximately 4,200 acres, of which only 1,000 acres is included in the Mt.Butler-Dry Creek Planning Unit. The remaining area is covered by the Powers Ranger District Multiple Use Plan of 1969. The eastern portion is allocated to timber management where full timber yield is consistent with land capabilities and appropriate constraints, along with coordination and multiple-use management of other resources. Refer to both the Mt. Butler-Dry Creek Planning Unit and Powers Ranger District Multiple Use Plan for more thorough descriptions and management direction.

Since the completion of the Mt. Butler-Dry Creek FEIS, all management activities in the area have conformed to the direction. Roads and area involved in the China Peak Timber Sale, located in the China Peak vicinity, have been removed from the unroaded area calculation. While quite unusual, the China Peak Timber Sale was specifically referenced in the Congressional Record by Senator Hatfield. Special provisions were added for temporary logging guylines and tailholds within the newly created Wilderness. This represented a compromise aimed at protecting both fishery and wilderness values while reducing the impact on the Forest's programmed timber harvest. Congress not only protected the integrity of the timber sale, but amended the proposed Wilderness boundary to allow for the activity.

CHANGES BETWEEN DRAFT AND FINAL

Between 1984 and 1988, only the China Peak Timber Sale remains active in the area. The upper part of North Fork Dry Creek was not excluded earlier from the inventoried area (Refer to Figure C-1a). This has been updated and the acres reduced from the 1984 figure of 6,009 to the current 5,428 acres. The remainder of the area is as previously described.

LOCATION AND ACCESS

The Grassy Knob area is in Curry County, approximately six miles east of the community of Port Orford, Oregon. The western portion is accessed by the Grassy Knob Road off of U.S. Highway 101, approximately four miles north of Port Orford. The eastern portion is accessed by the China Peak Road off the Sixes River.

PHYSIOGRAPHIC AND BIOLOGIC FEATURES

The physical location of the roadless area is on the western side of the coast range (Coast Range Geologic Province) in southwestern Oregon. The terrain is extremely steep and rugged, with deeply incised canyons. Elevation varies from near sea level to 2,900 feet on Mt. Butler. Ecosystems are mixed evergreen and western hemlock types Most of the area is heavily vegetated with stands of old-growth Douglas-fir and tanoak/madrone; the mature stands of Douglas-fir are the result of past fires

Annual precipitation averages over 100 inches per year, with most occurring in the form of rain during the fall, winter, and spring months. Average May through September precipitation for the dry season averages about 12 inches. Due to proximity to the ocean, the climate is heavily moderated by the coastal influence, with summer fog often extending inland to elevations near 1,500 feet.

The western portion of the roadless area drains into Anvil Creek and Rock Creek, both tributaries of Elk River Both streams are important sources of cool water for the lower reach of Elk River. Within the Forest boundary, the Elk River and many smaller tributaries contain a highly valuable anadromous fishery and are the source of water for the State Fish Hatchery.

The eastern portion of the roadless area drains into Butler Creek, Dry Creek and the South Fork Sixes River. Steelhead are found in the lower reaches of South Fork. The entire area is important to downstream fisheries as a supply of high quality, cool water during the summer months

On steep slopes, the surface soils are predominately rock mulch. Movement of this surface talus rock is often active beneath rock outcrops and in draw areas where it is concentrated. Where high precipitation intensities and oversteepened slopes combine with fractured and sheared geologic areas, mass soil movement has occurred. Refer to the Soils Resource Inventory for specific information by landtype.

Black-tailed deer, black bear and a variety of other animals occur in the Grassy Knob Roadless Area. No known threatened or endangered species inhabit the area. The Sixes River area contains possible nesting sites for the northern bald eagle. This potential is described in the Pacific Bald Eagle Recovery Plan (USDI Fish and Wildlife Service 1986). One sensitive species is present; the northern spotted owl, an old-growth dependent species, has been sighted in both portions of the area. Two nesting pairs are believed to be present in the South Fork Sixes River drainage. One site is being managed as a interim SOHA until the Forest Plan is implemented; this site encompasses approximately 1,000 acres. No sensitive plants are known within this area

RESOURCE USES

The South Fork Sixes River receives some of the heaviest mining use on the Powers Ranger District. Two cabins are occupied year round, and approximately 40 claims receive seasonal activity. No mineral claims are on file for the western portion.

Hunting is very limited due to steep, brushy terrain and the lack of roads and trails. For the same reasons, other recreational use is quite limited. There are no existing or planned trails. Anvil Creek is used as a domestic water source immediately downstream from National Forest land.

APPEARANCES, SURROUNDINGS AND ATTRACTIONS

The western portion of the roadless area consists of two steep, paralleling drainages flowing west into the Elk River. The north facing aspects of each is heavily timbered, while the south facing slopes are predominantly brush fields with scattered timber in the side drainages. To the north, south, and east of this portion of the roadless area lies the Grassy Knob Wilderness, which is similar in topography and vegetation. Private

land to the west is also similar, but most of the commercial timber has been logged from the slopes. The northern edge of the area borders the Grassy Knob Road.

The abandoned Grassy Knob Lookout site is on the east side of the western portion. Remnants of the lookout can still be seen. This site is historically significant; a Japanese bomber was sighted from this tower during World War II. Most of the Grassy Knob Trail was obliterated by the construction of the Grassy Knob Road. The only section left is from the end of the new road to the former lookout site.

The eastern portion of the roadless area is very steep, mountainous terrain with deeply incised canyons throughout. The area is heavily vegetated with a variety of cover types; few natural openings exist. The area consists of numerous fingers of undisturbed ground surrounded by roads and existing clearcuts in various states of revegetation. To the north of the area lies Mt. Avery and blocks of undisturbed BLM and State lands. These lands are similar, with Mt. Avery acting as a visual screen between the unroaded portion and harvested lands to the north. To the south and east, man's activities are evident in the form of roads and timber harvest units. To the west is Grassy Knob Wilderness.

Along the South Fork Sixes River is the site of a mining community that was occupied from 1857 until approximately 1900. This site is believed to be one of the first sites in the state where hydraulic mining was used. Remnants of old cabins and mining activity can still be found along the river.

CAPABILITY

MANAGEABILITY

The two portions are not in themselves easily manageable for wilderness characteristics, but their location adjacent to the Grassy Knob Wilderness provides for choices that would not otherwise be available. The western portion borders private land along its west boundary. This is a mid-slope property line with the roadless area on the uphill side. This situation increases the chances of fire entering the existing Wilderness from private land across the unroaded area. Though fire has historically been a major factor in creating and maintaining the present vegetative mosaic and ecology of the area, uncontrolled fire has the potential of destroying many of the area's desirable characteristics.

Except adjacent to the existing Wilderness, the boundaries and shape of the eastern portion are not readily manageable for roadless area qualities. The boundaries to the east, north, and west are defined by roads or timber harvest units. Much of the northern boundary is adjacent to the National Forest boundary, outside of which the Forest Service exerts little influence over activities which may impact or conflict with roadless area management objectives. The shape of the area is a series of fingers, generally one mile or less across, rather than one compact block. This situation will increase the chances of outside activities affecting management of roadless area values.

NATURAL INTEGRITY AND APPEARANCE

Other than the Grassy Knob Road (a portion is closed to vehicular traffic) and private timber harvest adjacent to the area, the western portion of the roadless area has not been measurably disturbed by human activity. Most evidence of human activity in the eastern portion of the roadless area is confined to the river bottom along the South Fork Sixes River. Most of the mining activity has healed over. Though evidence of past activity is still noticeable, its presence would not be perceived as particularly undesirable, i.e., the historical value often becoming an attraction rather than a detriment. The presence of occupied miners cabins in the area may detract from the experience desired by some users.

OPPORTUNITIES FOR SOLITUDE AND PRIMITIVE EXPERIENCE

With the steep, broken terrain and dense vegetation covering the western portion of the roadless area, the natural screening provides for localized solitude and a primitive experience. Sounds from the county road below, though, will be heard throughout the entire area. While the area is small, only the Grassy Knob Road separates it from the Wilderness Adding of the western portion to the Wilderness would effectively increase the size of the area available for a primitive experience.

The eastern portion of the roadless area offers the same opportunities as the western portion, being similar in topography, vegetation and proximity to the Wilderness. For some users, seeing timber harvest units in close proximity from inside the roadless area could detract from their experience. Periodic logging activity adjacent to the unroaded area may be an additional detraction. Finding occupied cabins in the roadless area may also reduce the feeling of solitude.

These areas offer a challenge for those seeking to test their outdoors skills. Due to the steep terrain, dense vegetation and lack of trails, cross country travel is difficult. The limited recreational use opportunities of these areas is primarily hiking and hunting. Most other uses are very incidental and quite secondary forms.

SPECIAL FEATURES

The primary attractions of this area are the old mining community, the abandoned Grassy Knob Lookout site, and the adjacent designated Grassy Knob Wilderness

AVAILABILITY

RESOURCE POTENTIALS

Use is presently well below its capacity. If the area remains roadless, use would not be expected to increase significantly unless trails were constructed and maintained.

Recreation

The potential for increased recreational use is greatest under roaded conditions where existing uses would continue along with the addition of motorized use. Much of the area would maintain its roadless character as road construction is not contemplated for much of the area due to the extremely rugged nature of the terrain, high costs, and resource impacts.

Wildlife

Under unroaded conditions, wildlife habitat will remain essentially unchanged Management practices, such as habitat improvement and prescribed burning, are not likely to be implemented due to the vegetative type and terrain features. Under roaded conditions, as timber is harvested and varying stages of vegetation become established, deer and elk herds can be expected to increase. Populations of old-growth dependent wildlife would decrease, but individual species would still be present due to land unsuitable for timber production and the adjacent Wilderness area. Sensitive species would be protected through applicable management standards.

Fisheries

Under unroaded conditions, fisheries habitat would not change. Under roaded conditions, the potential for adverse impact to the fisheries resource would increase, though mitigative measures and improved practices can reduce this potential to an acceptable level. The potential for fisheries enhancement projects would increase due to improved access.

Water

The greatest demand for water in these areas is for fisheries. Diversions and other on-site demands, such as for hydro-power, are currently absent. Downstream beneficial uses are primarily domestic, fish culture, and irrigation Quality aspects are of far greater importance than any other factors due to the extremely high value anadromous fishery.

Timber

Of the 1,200 acres in the western portion of the roadless area, approximately 800 acres are considered tentatively suitable for the production of timber. The 4,200 acre eastern portion has approximately 3,000 acres of land suitable for timber harvest. Standing volume is estimated to be 85 MMBF.

Road access is limited in two areas of the eastern portion. At the present time, it may not be feasible to access the area north of Mt. Butler in Section 20 by road. The second area is in Sections 18 and 19 in the Bee Creek drainage. Due to the Grassy Knob Wilderness, routes have not been located that would allow roads to reach harvestable areas without crossing a corner of the Wilderness. In both areas, the feasibility of helicopter logging is marginal due to distance to suitable log landing sites.

More recent timber harvest practices and road location, design, and construction techniques have substantially reduced the risks associated with steep and unstable landscapes. Older practices, as evidenced in one fork of Butler Creek, can result in unacceptable and irreversible damage to the soil and long-term impact on the fishery habitat. While current management practices demonstrate the ability to achieve utilization of the replenishable forest resources along with providing an acceptable environment for other elements, the sensitivity of activity in this area must always be balanced with extremely tight controls

Energy and Minerals

There are no plans for the exploration or development of energy sources in this area. The heaviest mineral use, primarily gold mining, has occurred on the South Fork Sixes River. If the area remained roadless, the level of mining activity would remain essentially constant. If road densities were increased, better access could result in an increase in mining activity, though such an increase is not expected to be great.

Cultural

Other than the sites and trails already noted, most probable occurrence of cultural evidence would be either along the stream benches or on the ridge lines. Few sites have been inventoried to date. Historical and prehistoric sites will be evaluated and provided for under the applicable laws and regulations for any proposed activity, whether under an unroaded or roaded scenario.

MANAGEMENT CONSIDERATIONS

The most critical consideration for management of this area is hazard and risks associated with fire. The potential for a major conflagration exists from the heavy fuels and dense brush. There have been a number of major fires within the area, the last being approximately 60 years ago. Additionally, the position of the area relative to private forested lands increases this threat. Fire severity is somewhat reduced, though, from the coastal marine air influence. The period of severe weather conditions is generally short.

Increased road access would allow for intensified treatment of activity fuels, which would lessen their concentration and continuity. Probability of major wildfire losses would thereby be reduced. Access, however, brings with it increased risk due to greater numbers and dispersion of people.

The potential for insect and disease outbreaks within the coniferous forest exist. Occurrences have been minor and localized. Tansy ragwort and gorse are two noxious weeds that have been introduced into the

area. Various treatments have been implemented to reduce their spread. With road development, the spread of *Phytophthora lateralis* root disease of Port-Orford-cedar may be increased where spores can be spread by machinery and water.

NEED

OTHER AREAS AND PUBLIC USE

Adjacent to the Grassy Knob Roadless Areas is the Grassy Knob Wilderness (17,200 acres). The Wild Rogue Wilderness (36,100 acres) and Kalmiopsis Wilderness (179,850 acres) lay 14 and 25 miles, respectively, southeast of Grassy Knob Numerous small unroaded areas occur throughout the vicinity.

Local users are more likely to utilize the Grassy Knob area than recreationists from major population centers, such as Portland and San Francisco. Some recreationalists may use the area incidental to visiting the Grassy Knob Wilderness. Most nonlocal use will occur with travelers leaving the nearby coastal U.S. Highway 101 during the summer period.

ECOSYSTEM REPRESENTATION

The Grassy Knob Roadless Area is well represented in terms of ecotypes, topography and vegetation by the Grassy Knob Wilderness.

PUBLIC INVOLVEMENT

During the development of the Mount Butler-Dry Creek Land Use Plan in the mid-1970's, public input into the process was extensive at both the local and state levels. The recommendations and opinions expressed varied from total preservation to total development. For a thorough review of public input and responses, refer to the Mt. Butler-Dry Creek Planning Unit FEIS. Earlier input derived from the Roadless Area Review and Evaluation (RARE) process (early 1970's) was also considered in this evaluation.

During 1981 and 1982, the Butler Sky, China Peak and Grassy Knob Timber Sales were appealed by an organization called Citizens for Grassy Knob. Their desire was to see the area remain roadless The Butler Sky and Grassy Knob sales were included in the present Grassy Knob Wilderness boundary and were not cut. The China Peak sale, on the periphery of the new Wilderness, has been roaded

When the Grassy Knob area was proposed for Wilderness status in 1984, local input was strong and highly polarized. Timber harvest interests and Coos and Curry County officials were opposed to the Wilderness because of the sizeable volume of commercial forest at stake; the impacts were expected to translate directly to fewer jobs in the forest products industry and less revenue to the counties Many local residents and representatives of the fishing industry, on the other hand, feared adverse impacts on fisheries resources in the Elk and Sixes Rivers from development activities.

Since the Grassy Knob Wilderness designation in 1984, public comment on the remaining area has been minimal. The only portions currently discussed are the two small western drainages, Anvil and Rock Creeks. A few local citizens still seek inclusion of these areas into the adjacent Wilderness. The two areas are also dealt with through special management areas (reference the Special Area Attributes list of "Supplemental Resource Areas" and inclusion of the two in various alternatives; Chapter II, FEIS).

ENVIRONMENTAL CONSEQUENCES

SIGNIFICANT EFFECTS

The inventoried Grassy Knob Roadless Area is known to contain historic and prehistoric sites, many of which need professional evaluation to determine their significance. Indians traveled the ridges and hunted the waterways during the pre-1856 cultural era. Mining played a strong role in the historical development of the Sixes River drainage; today it provides a living for a select few.

Cultural Resources

All alternatives, except E and M, would develop portions of the area which may disturb any existing cultural resources. Valuable sites will be protected via avoidance or conserved via data recovery. Alternatives E and M call for an unroaded regime which would minimize the need for cultural resource inventory.

Energy and Minerals

The following table is a tabular summary of the estimated mineral potential and access limitations for Grassy Knob Roadless Area. The acreages shown are subject to change due to the current withdrawal review by the Bureau of Land Management (BLM), and differences found for site specific needs included in any subsequent withdrawal applications to BLM.

	Mineral Potential (Acres)			
Access Restrictions	High	Moderate	Low	Total
Withdrawn	-	-		
High	-	-	-	-
Moderate	-	-	-	-
Low	-	1,100	4,300	5,400
Total	-	1,100	4,400	5,500

Improvements

The 3,813 acres of tentatively suitable land could generate about 18 miles of new road for timber harvest. However, since a portion of the eastern area between Bee Creek and the South Fork Sixes River may not be feasible to road due to Wilderness blocking the better access routes, the actual mileage would likely be lower. Roads for other purposes would be minor. Tie roads and loop road systems would be difficult and improbable due to steep terrain. No additional collector roads are planned and all local roads would most likely be dead-end systems following along or near ridges. Depending on the alternative, some mileage would remain open to passenger car use; other roads would be open to only high clearance vehicles or closed between projects. The following table shows the mileage of the area by alternative:

Alternative	Total Miles	Miles Open to Passenger Car	Miles Open to High Clearance	Miles Closed
NC and A	15	4	5	6
B	16	4	6	6
C	18	3	8	7
D	15	5	4	6
E and M	0	0	0	0
G	14	0	6	8
K	15	4	2	9
S	11	3	1	7

Alternatives E and M would have minimal effect on this area due to no roads being built. Alternative S would build the least miles of the roaded options, as it allocates an area to Backcountry Recreation and permits timber management on the remainder. Alternate G would build the next fewest miles of the roaded options and would not maintain roads open for passenger cars Alternatives NC, A, B, C, D, and K would be mostly roaded except for some stream Supplemental Resource areas. Alternative C, without Supplemental Resource areas, would have the highest mileage. Alternatives G, K, and S would close 60 percent of the roads

None of the roads would be expected to cross main streams or tributaries inhabited by fish Where roading requires full bench construction in steep terrain, excavated material would be hauled to stable disposal sites. Few new roads would be seen from the Grassy Knob Wilderness due to the heavy vegetative cover and topographic relief. New roads in the western portion would be seen from sections of U.S. Highway 101; some new roads in the eastern portion would be seen from parts of the Sixes River Road. Except for change in recreation experience from roading, the effects on other resources would be minor.

Wilderness Potential

All alternatives, except E, M, G and S assign most of the area to multiple resource management objectives. Under these, the area would be developed and Semi-primitive recreation opportunities currently available would shift to the motorized end of the opportunity spectrum. Wilderness potential would be lost.

Alternatives E and M would maintain the area in a roadless condition. The Wilderness potential would be maintained. Under alternatives G and S, the area allocated to Backcountry Recreation would be reduced (1,055 acres in G and 2,426 acres in S). Due to size of the allocations and the proximity of roads, the Wilderness potential would likely be lost. These alternatives provide additional capacity for Semi-primitive Non-motorized recreation opportunities and benefit the quality of recreation experience in the Grassy Knob Wilderness. The Wilderness potential would be maintained.

How much of the inventoried roadless area remains unroaded by alternative can be evaluated by either assessing a combination of Management Areas 1-9 (which retain essentially undeveloped conditions), or by viewing the spatial arrangement of blocks of undeveloped area at the end of a given period of time. Management Areas may or may not be contiguous, so the integrity of the roadless area as a whole may be compromised by management around them. The following table provides a spatial estimate of acres remaining unroaded at the end of specific decades; these figures differ from the Management Area 1-9 acres in that the minimum criteria is based on the area either (1) bordering designated Wilderness, or (2) being 5,000 acres or greater:

Alternative	Acres Remaining End of Decade 1/		
	1	2	5
A, A-Dep, and NC	500	500	500
B, C, D, and D1	500	500	500
E and M	5,400	5,400	5,400
G	1,100	1,100	1,100
K	500	500	500
S	500	0	0

1/ Minimum criteria is 5,000 unroaded contiguous acres or adjacent to designated Wilderness

Soil, Water, and Fish

There are no adverse soil, water, or fish habitat consequences associated with allocating the Grassy Knob area to Backcountry Recreation in Alternatives E and M because of the absence of development activities. All other alternatives allocate all or part of the area to development. Generally, the soils have a high hazard for accelerated sediment production, especially with activities associated with road building. The environmental effects of timber harvest and road construction are discussed in Chapter IV of the FEIS.

The risk of degrading these resources generally increases with more timber harvest and road building. Alternatives NC and C pose a higher risk of degradation than other alternatives because more activities are planned and area of soils with high hazard ratings for both road and regeneration are greater. All other alternatives have lesser risks (moderate) due to protection afforded by Supplemental Resource allocations.

Fire

In an undeveloped scenario (Alternatives E and M), natural fuel accumulations would increase and fuel continuity would remain the same or increase. These conditions lend themselves to large, high intensity fires. Adding to this is the increased response time for initial attack forces due to poor access. The result is larger fires, higher suppression costs, and increased resource losses. In a developed scenario (Alternatives NC, A, B, C, D, K, and S), the fire hazard increases at the time of timber harvest. As fuels are treated, the fire hazard is reduced. In the long-term, the continuity of the fuels are broken up, creating a mosaic of fuels and vegetative development. This mosaic, combined with improved access for initial attack forces, reduces the potential for large, high intensity fires. The result is smaller fires, lower suppression costs, and less resource loss due to fire.

In Alternatives E and M, all of the area would remain undeveloped, with fuels remaining continuous over the entire area. In Alternative G, 38 percent of the area would be developed, creating a mosaic of fuels over time. The remaining undeveloped area would be divided into 6 separate blocks. Alternatives A, B, C, D, K, and S would develop 52 to 62 percent of the area. The remaining undeveloped areas would be broken into 4 to 8 separate blocks. Alternative NC would develop 67 percent; the remaining undeveloped areas being in 5 separate blocks. All alternatives will treat some of the high priority natural fuels accumulations.

In undeveloped areas, the risk of ignition is low due to the low level of human use. As development occurs, risk increases with road construction, timber harvest, and treatment of activity slash from these operations. As access improves, level of dispersed recreation and other public uses increases, resulting in an increased risk of human-caused fires. Lightning fires have similar levels of risk for both developed and undeveloped areas

In Alternatives E and M, risk from human-caused ignition would be limited primarily to the area's periphery due to limited access. In Alternative G, industrial operations would result in increased risk, with risk from public use being increased along 14 miles of road. In Alternatives A, B, C, D, K, and S, industrial operations would result in increased risk over 52 to 62 percent of the area, and risk from public use would be increased along the 11 to 18 miles of road. In Alternative NC, industrial operations would result in increased risk over 67 percent of the area; risk from public use would be increased along 15 miles of road.

Vegetation

Effects on vegetation relative to diversity and age class distribution do not significantly differ from the effects on the Forest as a whole (See Chapter IV of the FEIS).

Sensitive Plants

No botanical sites are proposed in this roadless area. To date, no sensitive plants are known to exist in the area. There are no existing or proposed Research Natural Areas (RNA's).

Air Quality

The principle agent impacting air quality in the forest environment and surrounding areas is smoke from wildfire and prescribed burning To determine the impacts of each alternative, only the effects of prescribed burning will be considered. The effect of smoke is a temporary reduction in visibility in an area. Total suspended particulates (TSP) is used as the measurement of local and regional haze Alternatives E and M would contribute no TSP. All other alternatives would produce 12 to 18 tons of TSP per year.

The probability of a smoke intrusion from burning in the roadless area impacting Coos Bay or Roseburg, both designated areas for air quality, is very low based on past performance. The probability of impacting the Grassy Knob Wilderness is low to moderate.

Wildlife

Unless specifically mentioned below, effects of the alternatives on wildlife indicator species and wildlife habitat in this roadless area are the same as for the Forest as a whole.

Bald Eagle/Osprey. This area contains potential bald eagle and osprey habitat. Bald eagles may occasionally use the Sixes River as a flight corridor; this river system may also contain potential nesting habitat (USDI Fish and Wildlife Service 1986). Habitat would be slightly degraded in alternatives which do not allocate the unroaded management.

Spotted Owl/Pileated Woodpecker/Pine Marten. Under all alternatives except E and M, habitat for mature/old-growth indicator species would be considerably reduced over time. This is especially true for Alternative C which meets Management Requirements (MR's) for mature/old growth wildlife species, but otherwise allocates most of the area to development. At the extreme is Alternative NC, which contains no MR habitat. Except for Alternative NC, a mixture of habitat enclaves to meet MR's for mature/old-growth habitat is located within the roadless area: two for pileated woodpeckers and one for pine marten. At present, this area supports approximately three pairs of spotted owls; there would be no long-term change under Alternatives E and M, and moderate change under G. Mature/old growth habitat would ultimately be reduced to MR levels in all other alternatives, except Alternative NC which has no land assignments for wildlife species which use mature/old-growth forest.

Woodpeckers. Snag habitat would remain at or near 100 percent habitat capability for woodpeckers under Alternatives E and M.

Black-tailed Deer/Roosevelt Elk. Big game management opportunities would increase in all alternatives, except E and M, which open up much of the unroaded area to timber management. Opportunities for habitat improvement projects for game animals would also be greater.

Wildlife Habitats. No meadows have been identified in the area. Rock bluffs are present, particularly in the eastern portion. Among the alternatives which allocate all or part of the area to timber management and which utilize either a Riparian Prescription C or Supplemental Resource area designation, the highest level of riparian habitat protection for wildlife is provided.

Wildlife Recreation Use. Estimated Wildlife and Fish User Days (WFUD's) currently attributed to the area are low because human use is less in unroaded areas. Fewer hunters use unroaded areas and non-hunters generally stay on the few trails. Alternatives E and M, which leave the area in an unroaded condition, and G and S, which leave about 18 percent, would produce fewer WFUD's; other alternatives would generate more.

Visual Resource

The current VQO inventory indicates that Modification covers nearly the entire area, with exception of less than 100 acres of Retention. All alternatives, except E and M, manage the area under the Modification objective. Alternative S would allocate less than 200 acres to Retention and Partial Retention Visual Management Areas visible from the Elk Wild and Scenic River. A reduction in the natural appearance of the landscape character is expected under all alternatives except E and M. Alternatives E and M would maintain the area in a roadless condition, resulting in management for Preservation which would exceed the inventoried objective.

Recreation Settings

The Recreation Opportunity Spectrum (ROS) displays approximately 800 acres as suitable for Roaded Natural activities. Another 4,600 acres is inventoried as suitable for Semi-primitive Non-motorized and Motorized activities.

All alternatives, except E and M, would allocate most of the area to management for multiple resource objectives. Recreation opportunities would be motorized rather than non-motorized and, in that respect, would be enhanced as roads are constructed. The potential wilderness character and Semi-primitive recreation opportunities would be lost. Alternatives E and M would maintain the 5,400 acres in a roadless condition. Potential wilderness character and Semi-primitive recreation opportunities would be maintained over the planning period.

Alternatives A, B, and D would retain the essentially undeveloped character on approximately 2,000 acres due to assignments to Supplemental Resource and Designated Wildlife Habitat. Alternative NC and C would retain the essentially undeveloped character on 900 to 1,400 acres, respectively. Alternative K would retain undeveloped character on 2,400 acres due to Supplemental Resource and Designated Wildlife Habitat areas. Alternative G would retain the undeveloped character on 3,000 acres due to Backcountry Recreation, Supplemental Resource, and Designated Wildlife Habitat. Alternative S would retain essentially undeveloped character on 3,100 acres due to the above listed allocations.

Economic and Social

There are 3,813 acres of land identified as tentatively suitable for timber management in this unroaded area. The general effects on annual allowable sale quantity (ASQ) and long-term sustained yield (LTSY) of allocating these acres to uses that would include timber production are the same as those described in Chapter IV of the FEIS.

The estimated potential ASQ from the inventoried 5,428 acres of the Grassy Knob Roadless Area is 0.21 MMCF. The estimated LTSY would be 0.38 MMCF. Following are the estimates of the contribution to timber production (in MMCF) from this area under each alternative:

Alternative	ASQ	LTSY
NC	.17	.31
A and D	.13	.24
A-Dep and D1	.14	25
B and C	16	.28
E and M	.00	.00
G and S	09	.17
K	12	22

For projecting effects, the alternatives are divided into three groups: (1) Alternatives E and M leave the area in an unroaded condition; (2) Alternatives NC, A, A-Departure, B, C, D, D1, and K develop much of the area for timber production, and (3) Alternatives G and S develop approximately half the area.

The major direct economic effect is government expenditure for the timber and associated road construction program. Alternatives E and M have the biggest reduction in the timber and road expenditures. Alternatives G and S have a slight decrease. The last group of the alternatives have no significant change.

The indirect effects are associated with jobs, income, and payments to counties. Assuming no substitution of reduced timber harvest within the area of influence, Alternatives E and M have the biggest reduction while Alternatives G and S have a slight reduction in the level of employment, income, and payments to counties The other alternatives have insignificant changes; Alternatives NC, B, and C have a slight positive benefit.

The cumulative social effects of attitudes of people can be summarized by examining the different interests of the adjacent communities. Additional discussion is found in Chapters III and IV of the FEIS. The positive sign indicates a feeling by special interest groups of the Forest being responsive while a negative indicates a social feeling of the Forest not being responsive to particular interests as listed. For example, in Alternative E and M, fishing interests are predicted to feel positive about Forest management while timber interests as predicted to feel the Forest is ignoring their interests. An "0" indicates no change from current situation. Such gains and losses may create additional conflict.

	Alternatives		
Effects (Changes Compared to Alternative A)	E and M (Unroaded)	G and S (Partially Roaded)	NC, A, B, C, D and K (Roaded)
Direct Effects

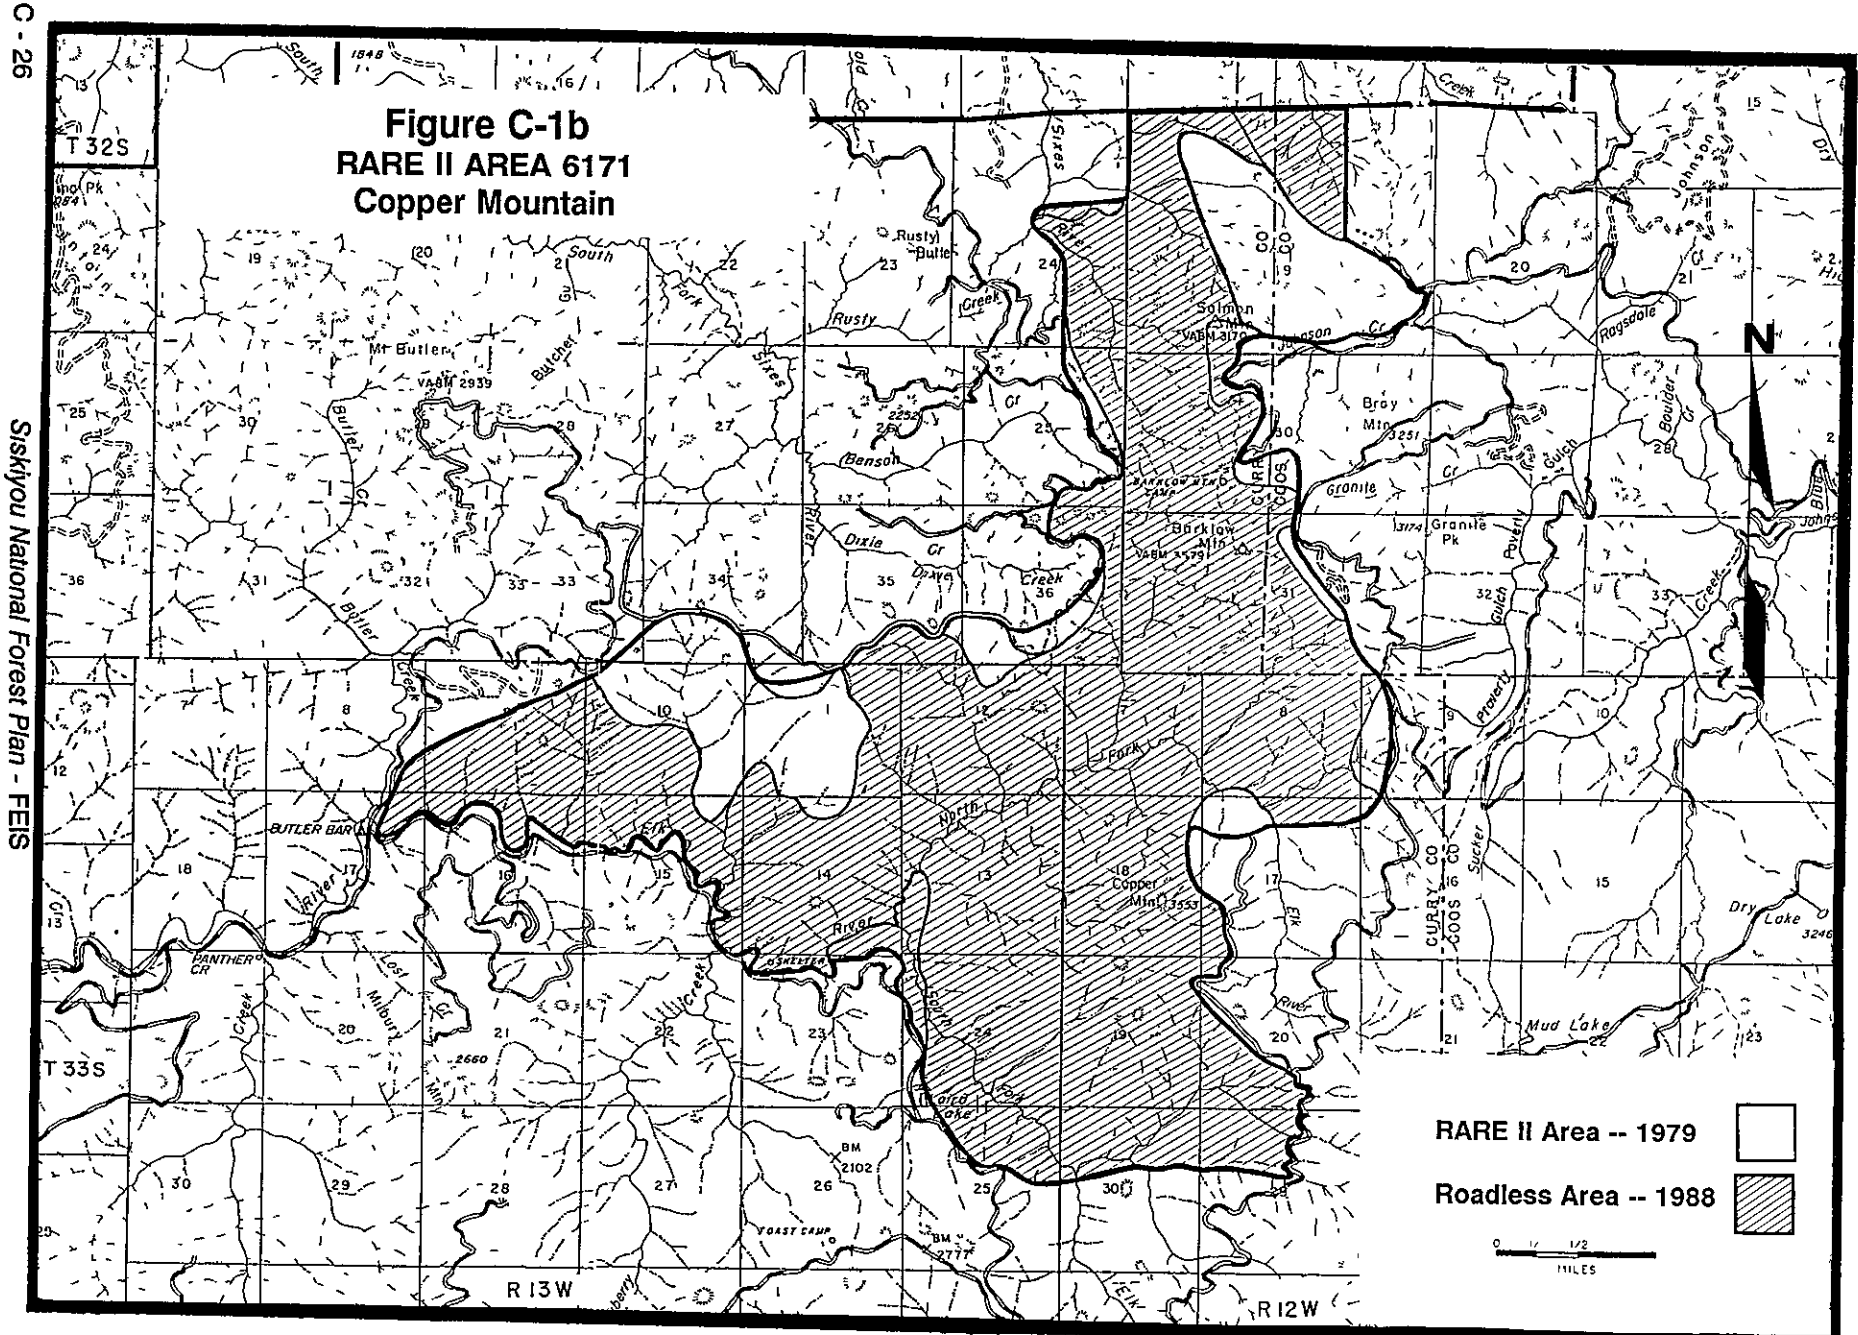
MITIGATION MEASURES



No additional mitigation measures have been identified beyond those already discussed in the above text and listed for each alternative through the application of the Standards and Guidelines.

POTENTIAL CONFLICTS WITH OTHER JURISDICTIONS

Conflict with adjacent landowners may occur over access.

COPPER MOUNTAIN No. 6171

(9,354 Acres)

DESCRIPTION

STATUS OF ROADLESS AREA

The Copper Mountain Roadless Area was studied as a potential Wilderness During the RARE II process. At that time it contained 10,884 acres and was allocated to non-Wilderness use by the RARE II decision in January of 1979. Since then, acres have been deleted by timber sales and acres added by the addition of two small areas. The new total for Copper Mountain area is 9,354 acres.

The unroaded area is covered by the Powers Ranger District Multiple Use Plan approved in 1969. The management direction and allocation is Principal Forest Resource Zone. In this nearly continuous forested zone, sustained production of timber is the primary goal. Other resources are to be managed for outputs or values consistent with this primary goal. Limited areas within this zone may be protected or managed for other purposes, e.g , watershed protection, recreation, wildlife and fisheries. Reference the Powers Ranger District Multiple Use Plan for management direction and coordinating requirements. Several management requirements have been updated by Forest policy and directives.

CHANGES BETWEEN DRAFT AND FINAL

Between 1984 and 1988, three timber sales and a refinement in the inventory have adjusted acreage of the unroaded area (Refer to Figure C-1a). In the northeast portion of the area, the Salmon Mountain Timber Sale has reduced the area by 600 acres and effectively severed a 1,000-acre block from the unroaded area. Another sale in that same area altered the boundary slightly. In the northwestern part, the North Shelter Timber Sale reduced the unroaded area by approximately 900 acres. Additional acreage was removed from the unroaded area due to the discovery of a portion of the area that was previously roaded in the 1940's and 50's.

As a result of the Omnibus Oregon Wild and Scenic Rivers Act of 1988, the main stem of the Elk and the North Fork for approximately two miles were added to the National Wild and Scenic Rivers System. The new designation affects the acreage array and, to a limited degree, discussion throughout the text. Elk River from the forks to Anvil Creek is classified as a Recreation segment; North Fork Elk River is classified Wild Due to the very recent passage of the Act, the Management Area acreages (Table C-5a) and analysis have not been updated to reflect the changes. Only Alternative S carries the adjustments for Management Areas 2 and 10. All alternatives would be treated the same relative to the Congressionally designated status. Management Area 2 (Wild River) would be 606 acres; Management Area 10 (Scenic/Recreation River) would vary due to the hierarchy of the land allocation scheme.

Also in late 1988 the Elk and both forks were added to the State Scenic Waterways system. The Scenic Waterway extends above the Wild River segment on the North Fork, and covers the South Fork which was not included in the National Wild and Scenic River System. For management, the State Scenic Waterway will increase the visual sensitivity as viewed from these streams. Where applicable, consideration should be made as to the added resource effects and tradeoffs in the following discussion. However, the expected impacts are deemed minor for all alternatives for management of this roadless area.

LOCATION AND ACCESS

The Copper Mountain area is located in Coos and Curry Counties, approximately 12 miles east of the coastal town of Port Orford and 12 miles southwest of the town of Powers. The east side of the roadless area can be accessed by the Mt. Butler Road from the east and Elk River Road from the west. The west side of the area can be accessed from the Sixes River Road 5201 which ties the Elk River and Sixes River transportation systems together.

PHYSIOGRAPHIC AND BIOLOGICAL FEATURES

The physical location of the roadless area is on the western side of the coast range (Klamath Mountain and Coast Range Geologic Provinces) in southwestern Oregon. The terrain is very steep and rugged, with deeply incised canyons Elevations vary from 800 feet to 3,579 feet at the top of Barklow Mountain The area is heavily vegetated with old-growth and second-growth Douglas-fir (a result of old wildfires). A variety of hardwood and brush species intermix with the conifer. The ecosystem is primarily mixed conifer with an intermingled mixed evergreen type.

Annual precipitation averages 115 inches per year, with most of it coming in the form of rain in the fall, winter and spring months An average 12 inches of rain occurs during the dry season (May through September). Summer coastal fog is limited to the lower elevations along Elk River.

A fault line runs through the roadless area along the southeast face of Copper Mountain. Naturally occurring slide activity is frequent along this line. Many of the drainages in the area have deep layers of deposited material, a result of old slide activity.

Soils in this area are quite variable. The steeper, highly dissected areas have shallow, rocky soils commonly with a surface layer of talus rock. A high incidence of debris slide activity occurs on this soil type on lower slope positions, along inner gorge areas, and in swales just above slope breaks. In sharp contrast, some deeper soils with more gently rolling topography are present in toe slope positions, the result of previous deep-seated landflow activity. Soil productivity is greatly increased on this soil type. Steeper pitches along drainages on this soil type have a high incidence of rotational slump failures.

Over 7,000 acres of the area drains into the Elk River drainage. Anadromous fisheries in the Elk River system are native. Steelhead and salmon run up the North Fork approximately 2.5 miles, and up the South Fork one mile from the confluence of both Forks of Elk River. The fisheries inventory crew from the Pacific Northwest Experiment Station, working in the area in May of 1985, found that the North Fork of the Elk River was producing tremendous numbers of fry steelhead and salmon. The crew described the area as being one of the most productive that had been found anywhere in the state. Similar results are expected to be found in the South Fork. The North and South Forks both support large populations of native trout which reach up stream 4 and 2.5 miles, respectively. This headwater area of the Elk River is an important source of water for the Elk River State Fish Hatchery, downstream approximately 10 river miles.

The remaining 2,000 acres contributes to the headwaters of the Sixes River, Johnson Creek, and Salmon Creek Though there are no fisheries in these upslope streams, they are important as sources of cool water during the summer months for downstream fisheries.

Populations of black-tailed deer and Roosevelt elk are present, but numbers are low due to limited forage in the area. A large population of black bear can be found, especially along the North Fork. No known threatened or endangered species inhabit the area. The northern spotted owl, a sensitive animal dependant on old-growth forest, undoubtedly resides in the roadless area; however, to date none have been sighted. No sensitive plants are known to occur in the roadless area, although *Darlingtonia californica*, a watch list plant, is found at a site east of Barklow Mountain. Given the close proximity of Iron Mountain,

an outstanding botanical area, it is probable that a thorough plant inventory of the Copper Mountain Roadless Area would result in the discovery of at least a few sensitive plant species.

RESOURCE USE

There are 10 active gold mining claims in the roadless area, with most activity on the North Fork Elk River. Several other claims are adjacent to the roadless area along Elk River downstream from the confluence of the North and South Forks.

Hunting is generally confined to the perimeter of the roadless area due to steep, densely vegetated terrain and minimal trail access. For the same reasons, other recreational use is limited.

The only maintained trail is 1/2 mile in length, running to the Barklow Mountain Lookout site from the end of a local road. From Barklow Mountain, the trail continues to Barklow Camp, then forks The west fork comes out on the Sixes River Road in Section 36. This piece was cleared and maintained until 1981, but is still in good shape. The east fork comes out near Johnson Creek in Section 30, while overgrown, the trail is in good shape.

APPEARANCES, SURROUNDINGS, AND ATTRACTIONS

The roadless area is long and narrow on its north-south axis. A long 4-mile finger juts westerly from the south end of the area. The north-south length is eight miles and the width is one to two miles. The main body of the roadless area surrounds Copper Mountain. The area is very steep, rugged and heavily vegetated with few natural openings. The south facing slopes are predominantly hardwood stands of tanoak, madrone and chinkapin, and brush fields. The entire area is surrounded by roads and harvest units. The southwest boundary is adjacent to Elk River. To the north of the area is private land. Southeast of the roadless area is the inventoried Iron Mountain Botanical Area.

In addition to Elk River, the principle attraction within the unroaded area is the Barklow Mountain trail and abandoned lookout site. A small pond, two to three acres in size, is located in the northwest corner of *Section 19 at the north end of the roadless area.*

CAPABILITY

MANAGEABILITY

The Copper Mountain Roadless Area boundaries do not follow natural topographic features for the most part, and are not easily discernible on the ground. Because of the shape and indistinct boundaries, protection and maintenance of roadless characteristics and values would be difficult. Potential for conflict with other management activities definitely exists.

NATURAL INTEGRITY AND APPEARANCE

Most of the roadless area has retained it's natural appearance, though past human and management activities are still evident throughout. Much healing has occurred and, while still apparent, does not disturb the area's natural balance.

The area north of Salmon Mountain has seen considerable human activity. Shaft mining has occurred along with access roads. The tipples of the mines were still standing in the late 1950's. Slides have closed the mineshafts, but mining evidence can be seen in the form of tailing piles, old timbers, and some abandoned equipment. About 250 acres was commercially thinned in the early 1970's. In addition, a large amount of Port-Orford-cedar was cut in this area between 1950 and 1970. The roads that access this area took off from Road 3353 near the line between Sections 19 and 20. The road forked and ran up into the

northeast and northwest corners of Section 19, with occasional spur roads along their length, to provide access for cedar logging These roads were waterbarred and grass seeded after the last commercial thinning in 1973, but are still evident on the ground.

The lookout tower at Barklow Mountain has been gone for years, but evidence of its presence is still apparent. North of the former lookout site is the Barklow Mountain trail camp. Remnants of the trail shelter remain. The old Zuber Cabin is still standing in Section 17 on the North Fork of Elk River. Remnants of another cabin have been reported on the North Fork in Section 13.

A portion of the old trail that ran from the Elk River north to Mount Butler Lookout and east to Barklow Mountain Lookout can still be found in Sections 11 and 14, though it has almost returned to a natural state. Remnants of a trail shelter can still be seen in Section 14.

An area in Section 14 north of the Elk River confluence was commercially thinned by a horse logging team, then helicopter yarded across the Elk River. Evidence of this operation can still be seen. Some of the landing piles were not burned.

Evidence of old activities such as the cabins, trail shelters, the lookout, and mining activity would be points of interest to many rather than distractions to their roadless experience. The logging and the roads are considered adverse impacts and would diminish the roadless experience. The trails are attributes that could be maintained for recreational and protection purposes.

OPPORTUNITIES FOR SOLITUDE AND PRIMITIVE EXPERIENCE

The mountainous topography with deep, heavily dissected river drainages and dense, continuous vegetation can provide localized conditions where a user would not be aware of presence of others nearby. These same features, however, tend to restrict cross-country travel whereby use would tend to be concentrated along river bottoms or ridgetops.

The key factor affecting the opportunity for solitude and primitive recreation is the physical size and shape of the roadless area. The core area, itself, is only one mile or so from a road at any point. Motorized activities outside the roadless area are very likely to be heard and possibly seen from within the area. Timber harvest units are visible from much of the area. These factors tend to reduce the opportunity for solitude and a quality primitive experience.

The Recreation Opportunity Spectrum (ROS) displays approximately 6,000 acres as suitable for Roaded Natural activities. Another 3,300 acres is inventoried as suitable for Semi-primitive Non-motorized activities.

SPECIAL FEATURES

The primary attraction of the Copper Mountain area is the Barklow Mountain trail and former lookout site. These provide a fine view of the surrounding area.

AVAILABILITY

RESOURCE POTENTIALS

Recreation

At present, the use of the area is well below capacity. If the area remains roadless, use would not be expected to increase unless the trail system was expanded. Potential for increased recreational use is greatest under roaded conditions where some of the existing roadless use would continue along with increased motorized forms. The area available for roadless uses, though, would greatly decrease.

Wildlife

Under unroaded conditions, wildlife populations would remain about the same unless habitat improvement projects were initiated. Under roaded conditions, as timber is harvested and varying stages of vegetation becomes established in the area, deer and elk herds can be expected to increase. Population of old-growth dependent wildlife would decrease in number, but individual species would not necessarily be eliminated, as considerable variety would remain in the area due to land unsuitable for timber management. Sensitive species would be protected through applicable management standards

Fisheries

This area contains high quality salmon, steelhead, and resident trout habitat. The North Fork of Elk River has been identified as especially important for production of salmon and steelhead. Under unroaded conditions, fisheries habitat would not change in the roadless area unless impacted by localized natural landslide activity. Under roaded conditions, the potential for increased risks to the fisheries would occur with timber harvest and associated roading. Current harvest practices, road location and construction techniques can greatly reduce this impact. Balancing activity with the landscape and fisheries is delicate, though. Past harvest activity heavily affected the headwaters of the North and South Forks of Elk River in the 1960's and early 1970's. The area is healing over time through vegetative regrowth along stream banks, and revegetation of landslides, road cuts and fills. With improved access, fisheries enhancement projects would be more efficiently implemented.

Water

The greatest demand for water is for the beneficial uses attributable to the high value fisheries of the Elk River and water used in the State Fish Hatchery operations. There are no existing or planned water developments. Quality aspects of the water resource remain most important relative to both the fishery and aesthetics of the river, itself.

Timber

Of the 9,354 acres in the roadless area, 7,802 acres are considered tentatively suitable for the production of timber. The area is moderately to highly productive. Standing volume is estimated to be 191 MMBF. The area northwest of Copper Mountain is primarily second-growth Douglas-fir. To harvest this area, special logging systems would be required. To the north, road access into the western half of Section 24 is not feasible at this time due to the low value of timber accessed.

Energy and Minerals

There are no plans for the exploration or development of energy sources in this area. The heaviest mineral use, although quite limited, is gold mining along the North Fork. If the area remained roadless, the level of mining activity would remain constant. With better access, increased mining activity could result, though such an increase is not expected to be appreciable.

Cultural

Other than those noted, historic and prehistoric sites will be evaluated and provided for under the applicable laws and regulations for any proposed activity. Sites in this locale have generally occurred on ridgelines and alongside the major streams.

MANAGEMENT CONSIDERATIONS

Fire is a critical consideration in management of this area. The potential for major conflagration exists with hazards posed by heavy fuels and dense vegetation. Conditions are somewhat lessened in severity due to the relatively short periods of extreme conditions largely attributable to coastal marine air influences.

With roading, access and intensified treatment of activity fuels would reduce fuel concentrations and continuity. Probability of major fire would be reduced. However, access also brings increased risks from the added numbers and dispersion of people and activities.

NEED

OTHER AREAS AND PUBLIC USE

The Grassy Knob Wilderness of 17,200 acres is adjacent to the westerly tip of the unroaded area. The Wild Rogue Wilderness (35,100 acres) is 9 miles southeast, while the Kalmiopsis Wilderness (179,850 acres) is 20 miles south Numerous small unroaded areas are dispersed throughout the Forest nearby. Immediately to the southeast is the inventoried Iron Mountain Botanical Area.

Local users are more likely to utilize the Copper Mountain area than recreationists from major population centers There are no specific attractions to draw much attention to the area, nor is the scenery particularly noteworthy. Users would primarily be drawn for the area's ruggedness and remoteness.

ECOSYSTEM REPRESENTATION

The area is well represented in terms of ecotypes and landform by the Grassy Knob Wilderness. While the proposed Iron Mountain Botanical Area is close, the ecosystems are quite different.

PUBLIC INVOLVEMENT

The area was allocated to non-Wilderness during the RARE II process. Over 60 percent of the 8,000 respondents preferred non-Wilderness due largely to no real drawing features and to the large amount of productive forest land. Reasons for inclusion as Wilderness were dominantly those related to old-growth and the quality salmon and steelhead fisheries of the Elk River. Recent input to the Forest planning process suggests that the same reasons hold true. The emphasis for maintaining the area in an unroaded condition is both light and localized.

Public input since RARE II on several of the inventoried roadless areas within the Siskiyou National Forest has been extensive. However, Copper Mountain has not received the same intensity of concern or advocation of protective status as several of the larger areas. Protection and enhancement of the fine anadromous fishery remains key to management of this area.

During recent environmental analysis of several proposed timber sales, input recommending that the Copper Mountain area be managed as a roadless area for protection of the area's visuals and fisheries resources was received from several local residents. Downstream residents and others in the Port Orford area most active in tracking management and contributing to proposed activities.

ENVIRONMENTAL CONSEQUENCES

The significant effects of each alternative are presented in Chapter IV of the FEIS. Additional site specific effects, mitigations, and potential conflicts are presented here. The Standards and Guidelines for each alternative were considered when evaluating the effects of implementation.

SIGNIFICANT EFFECTS

Cultural Resources

The Copper Mountain area contains archaeological potential along the Elk River drainage and the ridgelines where foot travel was facilitated by the relatively level terrain. Copper Mountain and Barklow Mountain are likely sites for Indian vision quest rites, although no such evidence has been discovered to date.

Historically, the area is noted for the Barklow Mountain trail and former lookout site. Mining occurred in the area in the 19th century and has continued into the present. Old cabins remain, as do trails and remnants of a trail shelter as reminders of the area's past use.

Alternatives NC, A, B, C, D, K, and S would road the area and possibly disturb unknown existing cultural resources Alternatives M, E, and G would not develop most or all of the area, thereby the potential for disturbance of cultural resources is greatly reduced.

Energy and Minerals

The following table is a tabular summary of the estimated mineral potential and accessibility limitations for Copper Mtn. The acreages shown are subject to change due to the current withdrawal review by the Bureau of Land Management (BLM), and differences found for site specific needs included in any subsequent withdrawal applications to BLM.

Access Restrictions	Mineral Potential (Acres)			
	High	Moderate	Low	Total
Withdrawn	-	-	<100	<100
High	-	-	-	-
Moderate	-	-	-	-
Low	<100	<100	9,200	9,300
Total	*<100*	*<100*	*<9,300*	*9,300*

Improvements

Depending on alternative, the 7,802 acres of tentatively suitable land could generate up to 40 miles of new road for timber harvest. Roads for other purposes would be minor. A new collector road would be planned with some of the roaded alternatives. All local roads would most likely be dead-end systems on or near ridges and off existing roads 5201 and 3353. Some mileage would remain open to passenger car use, depending on the alternative, and other roads would be open to only high clearance vehicles or closed between projects. The following table shows the mileage of the area by alternative:

Alternative	Total Miles	*Miles Open to* Passenger Car	*Miles Open to* High Clearance	Miles Closed
NC and A	40	10	14	16
B	36	9	13	14
C	40	6	18	16
D	36	11	11	14
E and M	0	0	0	0
G	7	0	3	4
K	37	9	6	22
S	29	7	5	17

Alternatives E and M would have minimal effect as no roads are built. Alternate G would have the least miles built of the roaded options and would not maintain any roads open for passenger cars. Alternatives NC, A, B, C, D, and K would be mostly roaded except for the Supplemental Resource areas in Alternatives B and D. Alternatives G and S allocate areas to Backcountry Recreation and permit timber harvest on the remaining areas. Alternatives G, K, and S would close approximately 60 percent of the roads.

None of the roads would be expected to cross main creeks or tributaries inhabited by fish. Several small tributaries to the North Fork and South Fork Elk River would be crossed in all roaded alternatives except

G All roaded alternatives would cross small tributaries of the Middle Fork Sixes River. Some decrease in water quality could be expected from construction and use of the new roads. Full bench ground would be crossed by roads with excess excavated material hauled to stable disposal sites.

A collector road would be planned in Alternatives NC, A, B, C, and D in the vicinity of Barklow Mountain. This road would provide a tie between two existing collector roads (3353 and 5201) and add about four miles to the collector system.

Wilderness Potential

All alternatives, except E, G, M and S, would allocate most of the area to multiple resource management objectives. Under these, the area would be developed and the Semi-primitive recreation opportunities currently available would shift to the motorized end of the opportunity spectrum. The change in the character of the landscape would result in the loss of Wilderness potential.

Alternative G would assign 7,700 acres to Backcountry Recreation and retain the essentially unroaded character on approximately 8,100 acres. Alternative S would assign 1,300 acres to Backcountry Recreation and retain an unroaded character on 2,700 acres. Some Wilderness potential may be retained in Alternative G, however Wilderness potential would be lost in Alternative S.

Alternatives E and M would maintain the Wilderness potential by retaining the area in a roadless condition. Additional capacity for Semi-primitive Non-motorized recreation opportunities would be provided.

How much of the inventoried roadless area remains unroaded by alternative can be evaluated by either assessing a combination of Management Areas 1-9 (which retain essentially undeveloped conditions), or by viewing the spatial arrangement of blocks of undeveloped area at the end of a given period of time. Management Areas may or may not be contiguous, so the integrity of the roadless area as a whole may be compromised by management around them. The following table provides a spatial estimate of acres remaining unroaded at the end of specific decades; these figures differ from the Management Area 1-9 acres in that the minimum criteria is based on the area either (1) bordering designated Wilderness, or (2) being 5,000 acres or greater:

Alternative	Acres Remaining End of Decade 1/		
	1	2	5
A, A-Dep, and NC	0	0	0
B, C, D, and D1	0	0	0
E and M	9,300	9,300	9,300
G	7,700	7,700	7,700
K	0	0	0
S	0	0	0

1/ Minimum criteria is 5,000 unroaded contiguous acres or adjacent to designated Wilderness.

Wild and Scenic Rivers

See **CHANGES BETWEEN DRAFT AND FINAL.**

Soil, Water, and Fish

For soil and water, no adverse consequences are associated with Alternatives E and M because no soil disturbing activities will occur. All other alternatives allocate all or part of the area to Management Areas which permit development A high percentage of the soils within this area have high hazard ratings for both regeneration and road related increases in accelerated sediment. The environmental effects of timber harvest and road building are discussed in Chapter IV of the FEIS.

The risk of degrading the soil and water resource increases with increasing timber harvest and road construction activity. Except for E, G, and M, all other alternatives pose a higher risk of degradation because more activity is planned with a corresponding increase in landslide frequency on the highly sensitive soils Alternative G greatly reduces the risk as most of the high risk soils are within Management Areas which remain undeveloped.

Fire

The effects of the alternatives from a fire standpoint are the increase or decrease that they will create in fire hazard and fire risk. Risk is defined as the probability that an ignition will occur. Hazard is a description of the fuels complex in terms of kind, volume, arrangement, condition and location of the fuels.

Fuels in the Copper Mountain area are moderate to heavy and are very continuous. The stands are predominantly old-growth Douglas-fir, with moderate to heavy understories of brush and hardwood. On some of the south slopes, brushfield conditions exist. In an undeveloped scenario (Alternatives E and M), natural fuel accumulations would increase and fuel continuity would remain the same or increase. These conditions lend themselves to large, high intensity fires. Adding to this is the increased response time for initial attack forces due to poor access. The result is larger fires, higher suppression costs and increased resource losses. In a developed scenario (all other alternatives), the fire hazard increases at the time of timber harvest. As fuels are treated, the fire hazard is reduced. In the long-term, the continuity of the fuels are broken up, creating a mosaic of fuels and vegetative development. This mosaic, combined with improved access for initial attack forces, reduces the potential for large, high intensity fires. The result is smaller fires, lower suppression costs and less resource damage.

In Alternatives E and M, with all the area remaining undeveloped, fuels would remain continuous over the entire area. Alternative G, where 11 percent of the area would be developed, a mosaic of fuels over created over time while the rest of the area would remain undeveloped. Alternatives B, D, K, and S would develop approximately 49 to 75 percent of the area. The remaining undeveloped areas would be broken into 4 to 7 separate blocks. Alternatives A and C develop 75 percent of the area. The entire area is developed over time in Alternative NC. The remaining undeveloped areas would be in 3 separate blocks. All alternatives treat some of the high priority natural fuels accumulations.

In undeveloped areas, the risk of ignition is low due to the low level of human use. As development occurs, risk increases with road construction, timber harvest, and treatment of activity slash from these operations. As access improves, the level of dispersed recreational and other public uses increases, resulting in an increase in risk of human-caused fires. Lightning fires will have similar risk levels for both developed and undeveloped areas.

In Alternatives E and M, the risk from human-caused ignition would be restricted primarily to the periphery of the area due to limited access. In Alternative G, industrial operations would result in increased risk over 11 percent of the area; risk from public use would increase along 7 miles of road. In Alternatives B, D, K, and S, industrial operations would result in increased risk over 49 to 75 percent of the area; risk from public use would be increased along 29 to 37 miles of road. In Alternatives NC, A and C, activities would result in increased risk over most of the area; risk from public use would be increased along 40 miles of road

Vegetation

The effects on vegetation relative to diversity and age class distribution do not differ from the Forest as a whole (See Chapter IV of the FEIS).

Sensitive Plants

No botanical sites are proposed in the Copper Mountain Roadless Area. The proposed Iron Mountain Botanical Area is just to the east. As yet, no sensitive plants are known from this roadless area, although a watch list plant (*Darlingtonia californica*) is present. Sensitive plants which may be in the roadless area would be best protected in Alternatives E, G, and M which allocate the area to Backcountry Recreation. Under all alternatives, sensitive plants would be protected through appropriate Standards and Guidelines. There are no proposed RNA's.

Air Quality

The principle agent impacting air quality in the forest environment and surrounding areas is smoke from wildfire and prescribed burning. To determine the impacts of each alternative, only the effects of prescribed burning are considered. Total suspended particulates (TSP) is used as a measurement of regional haze. Alternatives E and M would contribute no TSP to the annual total generated on the Siskiyou National Forest. Alternative G would produce 8 tons of TSP per year. Alternatives NC, A, B, C, D, K, and S would generate 46 to 50 tons of TSP per year.

The probability of a smoke intrusion from burning in the roadless area impacting Coos Bay, Roseburg or Grants Pass, all designated areas for air quality, is very low based on past performance. The probability of impacting the Grassy Knob or Wild Rogue Wilderness is low.

Wildlife

Unless specifically mentioned below, effects of the alternatives on wildlife indicator species and wildlife habitat in this roadless area are the same as for the Forest as a whole.

Spotted Owl/Pileated Woodpecker/Pine Marten. Under all alternatives except E, G, and M, habitat for mature/old-growth indicator species would be considerably reduced over time. This is especially true under Alternatives A, A-Departure, C, K, and S, which meet Management Requirements (MR's) for mature/old growth wildlife species, but otherwise allocates most of the area to development. No MR habitat is assigned in Alternative NC.

Except for Alternative NC, a mixture of habitat enclaves to meet MR's for mature/old-growth habitat is located within the roadless area: one for pileated woodpeckers and two for pine marten. At present, this unroaded area can support approximately three pairs of spotted owls; there would be little or no change under Alternatives E, G, and M. Mature/old-growth habitat would ultimately be reduced to MR levels (no spotted owls) in all other alternatives, except for Alternative S which allocates 14 percent of the area to Backcountry Recreation, and Alternative NC which has no allocation for this type of habitat.

Woodpeckers Snag habitat would remain at or near 100 percent habitat capability for woodpeckers under Alternatives E, G and M.

Black-tailed Deer/Roosevelt Elk. Big game management opportunities would increase in alternatives which open up much of the area to development (all alternatives except E, G, and M). Opportunities for habitat improvement projects for game animals would also be greater.

Wildlife Habitats. No meadows have been identified; a few rock bluffs are present. A small identified wildlife area (Special Wildlife Site) is allocated in all alternatives except B, C, D, and D1. The alternatives which assign all or part of the area to development, and utilize either a Riparian Prescription Cyor Supplemental Resource Area designation, provide the highest level of habitat protection in riparian areas for wildlife.

Wildlife Recreation Use. Estimated Wildlife and Fish User Days (WFUD's) currently attributed to the Copper Mountain area are low because use of the area is less than in roaded areas. Fewer hunters use unroaded areas and non-hunters generally stay on the few trails. Alternatives E and M, which leave the area in an unroaded condition, and G, which leaves 83 percent unroaded, produce the fewest WFUD's.

Visual Resource

The inventoried Visual Quality Objective (VQO) for the area includes 3,100 acres in Partial Retention and the balance of 6,200 acres in Modification.

Alternatives B, C, D, D1 and K develop most of the area and result in management under the Modification objective. Reduction in the natural appearance of the landscape, resulting in a modified forest setting, is expected Alternative G, which allocates 8,100 acres to an nonroaded management objectives, and Alternatives E and M, which allocate all the area to Backcountry Recreation, result in management under a Preservation VQO above the inventoried condition. The natural appearances of the area would be maintained.

Alternatives NC, A, and A-Departure would manage the area under the inventoried VQO's; approximately 2,700 acres are assigned to the Partial Retention Visual Management Area. Alternative S would allocate 1,600 acres to Backcountry Recreation and Partial Retention Visual. The natural/near natural appearance of the Forest would be retained in these areas.

Recreation Settings

All alternatives, except E, G, M and S, would allocate the roadless area to mostly General Forest management objectives. Under these alternatives, the area would be developed and the 3,300 acres capable of Semi-primitive recreation would shift rapidly to the motorized end of the opportunity spectrum. Access to the area and motorized opportunities would be enhanced as the area is roaded.

Alternatives NC, A, A-Departure, and C would retain very little undeveloped character throughout the area. Alternatives B, D, and D1 would retain the essentially undeveloped character on 1,800 acres due primarily to assignments to Supplemental Resource and Designated Wildlife Habitat. Alternative K would retain undeveloped character on 1,600 acres due primarily to assigned Designated Wildlife Habitat. The remaining unroaded areas are too small to provide for integrity of a roadless condition as they would be compromised by surrounding activities.

Alternative G emphasizes the maintenance of amenities and would maintain 8,100 acres in a roadless condition. The allocation would provide a link with the Grassy Knob Wilderness and increase the opportunity for "backcountry" types of recreation activities although, as noted, the area is very susceptible to the influence of management activities on adjacent lands. This alternative would provide a capacity for approximately 1,700 Semi-primitive Non-motorized recreation visitor days (RVD's) annually.

Alternatives E and M would maintain the area in its current unroaded condition. Recreation capacities would remain fixed since no new trail construction would be programmed. Alternative S would allocate 1,300 acres to Backcountry Recreation and retain the essentially undeveloped character on 2,700 acres. The area would be capable of providing Semi-primitive Motorized recreation opportunities in these areas.

Economic and Social

There are 7,802 acres of land identified as tentatively suitable for timber management in this unroaded area. The general effects on annual allowable sale quantity (ASQ) and long-term sustained yield (LTSY) of allocating these acres to uses that would include timber production are the same as those described in Chapter IV of the FEIS.

The estimated potential ASQ from the inventoried 9,354 acres of the Copper Mountain Roadless Area is 0.43 MMCF The estimated LTSY would be 0.78 MMCF. Following are the estimates of the contribution to timber production (in MMCF) from this area under each alternative:

Alternative	ASQ	LTSY
NC and A-Dep	.42	75
A and C	40	72
D and K	35	.63
D1	.38	.69
E and M	00	.00
G	06	10
S	30	55

For projecting effects, the alternatives are divided into five groups: (1) Alternatives E and M, which leave all of the area in an unroaded status; (2) Alternative G which leaves most of the area unroaded; (3) Alternative S which develops over two-thirds of the area; (4) Alternatives D and K which develop much of the area; and (4) Alternatives NC, A, B, and C which develop nearly all the area.

	Alternatives				
Effects (Changes Compared to Alternative A)	E and M (Unroaded)	G	S	K and D (Roaded)	NC, A, B, C
Direct Effects					
Timber and Road Expenditures	None	Largely Reduced	Moderate Reduction	Minor Change	No Change
Indirect Effects					
Jobs	-36	-31	-10	-5	0
Annual Income (MM $)	-0 84	-0 71	-0 21	-0 11	0
Annual Payments to Counties (MM $)	-0 20	-0 17	-0 05	-0.02	0
Cumulative Effects					
Attitudes of Communities in the Local Area					
Timber Related	-	-	-	-	0
Primitive Recreation	+	+	+	0	0
Fisheries	+	+	+	+	0
Wildlife Related					
Hunting	-	-	0	0	0
Old-Growth	+	+	+	+	0
Mining	-	-	0	0	0

The major direct economic effect is government expenditure for the timber and associated road construction program Alternatives E, G, and M have the biggest reduction in the timber and road expenditures. Alternative S has a moderate change, while the other alternatives have insignificant changes in budget expenditures.

Indirect effects are associated with jobs, income, and payments to counties. Assuming no substitution of reduced timber harvest within the area of influence, Alternatives E, G, and M have the biggest reduction. Alternative S has a moderate reduction. The other alternatives have slight decreases to slight increases when compared to Alternative A.

The cumulative social effects of attitudes of people can be summarized by examining the different interests of the adjacent communities. Previous documentation is found in Chapters III and IV of the FEIS. The positive sign indicates a feeling by special interest groups of the Forest being responsive to a particular interest while a negative sign indicates a social feeling of the Forest not being responsive to particular interests as listed. For example, in Alternative E, fishing interests are predicted to feel positive about forest management while timber interests as predicted to feel the Forest is ignoring their interests. Such gains and losses may create additional conflict.

MITIGATION MEASURES

No additional mitigation measures beyond those listed in the DEIS are required.

POTENTIAL CONFLICTS WITH OTHER JURISDICTIONS

No potential conflicts beyond those already recognized in the FEIS are identified.

MULE CREEK No. 6172

(352 Acres)

DESCRIPTION

STATUS OF ROADLESS AREA

The Mule Creek Roadless Area was inventoried for study as a potential addition to the Wild Rogue Wilderness during the RARE II process. The area, originally containing 250 acres, was recommended for non-Wilderness use in the RARE II decision of January 1979. Since then, boundaries have been changed to exclude features not conforming to the definition of wilderness, while some areas with low standard roads have been added. The area is now 352 acres and entirely National Forest System land.

The area is covered by the Powers Ranger District Multiple Use Plan of 1969. Management direction for this Principal Forest Resource Zone calls for optimum production of timber as the principal goal in concert with other resource values, outputs, and constraints Limited areas within this zone may have other primary goals such as watershed protection and recreation use

CHANGE BETWEEN DRAFT AND FINAL

During the period from 1984 to 1988 the size of the unroaded area was reduced due to mining activity and road construction in the northern portion of the unroaded area (Refer to Figure C-1c) The remainder of the area is as previously described.

LOCATION AND ACCESS

The Mule Creek area is in Coos County, approximately 13 miles southeast of the community of Powers, Oregon. The area is adjacent to the northern tip of the Wild Rogue Wilderness in the proximity of Mount Bolivar and Diamond Peak.

PHYSIOGRAPHIC AND BIOLOGIC FEATURES

The physical location of the area is in the coastal range (Klamath Mountain Geologic Province) in southwestern Oregon. The southern half of the area is very steep, mountainous terrain. The northern half is moderately steep and more rolling landform. Elevations vary from 2,300 feet to 4,116 feet at the top of Saddle Peaks The ecosystem is mixed evergreen, with heavily forested stands of old-growth Douglas-fir, minor amounts of hemlock, cedar and hardwoods, and a moderate to heavy understory of woody brush species Soils are moderately deep to deep, and generally moderately productive and relatively stable. Some inclusions of shallow, rocky soils are interspersed throughout the area.

Annual precipitation averages approximately 80 inches, most arriving in the winter. Rainfall in the dry season (May through September) averages seven inches Summer temperatures may reach into the 90's

The southern half of the area drains into Foggy Creek, a tributary of the South Fork Coquille River. The north half drains from Boliver Creek into the West Fork of Cow Creek, a tributary of the Umpqua River. There are no fisheries in the area, but native trout populations are found downstream in Foggy Creek and the West Fork of Cow Creek.

Populations of black-tailed deer, Roosevelt elk and black bear are found in the area. No threatened or endangered plant or animal species are known. The cliff faces on Saddle Peaks furnish potential nesting

habitat for various raptor species. Northern spotted owls, a sensitive species dependent on old-growth habitat, have been sighted within the northern portion of the area. No sensitive plant species are known from the roadless area

RESOURCE USES

There are numerous active gold mining claims in Section 10, both inside and adjacent to the roadless area. Recreational use in the area is primarily deer and elk hunting. There are no maintained trails, but many of the old roads in the area can be used for access through the northern half.

APPEARANCES, SURROUNDINGS AND ATTRACTIONS

The roadless area is pinched into three segments. It is long and narrow, being three miles in length and 1/2 mile at the widest point. The area is heavily forested with old-growth Douglas-fir stands Natural openings occur along the summit of Saddle Peaks.

Adjacent lands north and west are heavily roaded with numerous timber harvest units visible. South and east lays the Wild Rogue Wilderness. Within a mile of the roadless area are Diamond Peak and Mount Bolivar, both in the Wilderness Vegetative types in the roadless area do not vary greatly from the surrounding areas. The primary attraction in the vicinity is Mount Bolivar, affording a spectacular view of the Rogue River canyon and surroundings.

CAPABILITY

MANAGEABILITY

The boundaries on the north and west sides of the roadless area are defined by roads and timber harvest units Along the south and east, adjacent to the Wilderness, the boundaries follow natural topographic breaks. At present, the Wild Rogue Wilderness follows logical, easily defined natural boundaries in this locale. If the Mule Creek area was added, it would create a non-physiographic buffer where chance of management conflict would be increased.

NATURAL INTEGRITY AND APPEARANCE

The southern half is still in a natural state with little evidence of human activity. The northern half has been heavily impacted by historic mining activity. The Fuller Mine was located at the extreme north end of the roadless area. Numerous mining roads are still present throughout the area. Mine tailings in Section 10 cover approximately 10 acres and still are quite evident and devoid of vegetation. There is some evidence of timber harvest which probably was associated with use in the local mining activities.

OPPORTUNITIES FOR SOLITUDE AND PRIMITIVE EXPERIENCE

The opportunity for solitude and primitive experience in the Mule Creek area is poor. Roaded activities adjacent to the area would have a high probability of being seen and heard from inside the roadless area. Evidence of human activity is still very apparent in the north half of the area, and would detract from a roadless experience. Use of the north end of the Wilderness is very light; the ridgeline serving as the present boundary is an effective screen against outside intrusions.

AVAILABILITY

RESOURCE POTENTIALS

Present recreational use of the area is very light, the bulk of the use coming during hunting season. Future use is also expected to remain essentially unchanged. There are few features to draw use. The greatest

potential for increased use would occur under roaded conditions where, in addition to motorized use, access to the adjacent Wilderness for non-motorized recreation would be enhanced.

Wildlife

Under unroaded conditions, wildlife populations would remain about the same. Under roaded conditions, as units are harvested and varying stages of vegetation become established, deer and elk herds will increase. Populations of old-growth dependent wildlife would decrease over time; old-growth habitat is available in the adjacent Wilderness.

Fisheries

With development, the potential for impacts to the downstream fisheries would increased slightly. Current management practices would provide adequate protection for these fisheries.

Water

The greatest demand for water in this area relates to benefits to downstream fisheries.

Timber

Approximately 256 acres are inventoried as suitable for commercial timber production. Productivity is moderate Estimated standing volume is 6 MMBF.

Energy and Minerals

There are no plans for exploration or development of energy resources. The gold mining activity is not expected to increase even if the area became roaded.

Cultural

No inventoried sites. Historic and prehistoric sites will be evaluated and provided for under the applicable laws and regulations for any proposed activity, whether roaded or unroaded.

NEED

OTHER AREAS AND PUBLIC USE

Adjacent to the roadless area is the Wild Rogue Wilderness (36,100 acres). Local users are more likely to use this area than recreationists from major population centers. Little attraction is afforded by the area, nor is there developed access. Users would be more oriented to rugged cross-country travel.

ECOSYSTEM REPRESENTATION

The area is well represented in terms of ecotypes and landforms by the adjacent Wild Rogue Wilderness.

PUBLIC INVOLVEMENT

During the RARE II process, over 60 percent of the respondents favored non-Wilderness designation. General input was oriented to issues of local economic impact, reduction of the commercial forest land base, old-growth preservation, and Wilderness buffers. State and local agency input varied from moderate to strong opposition to Mule Creek being added to the National Wilderness System.

Public input since the RARE II decision has been keyed to specific roadless areas, however Mule Creek has received little or no input calling for it's protection or development. No input has been given to projects proposed either in or adjacent to the area.

ENVIRONMENTAL CONSEQUENCES

The significant effects of each alternative are presented in Chapter IV of the FEIS. Additional site specific effects, mitigations, and potential conflicts are presented here. The Standards and Guidelines for each alternative were considered when evaluating the effects of implementation

SIGNIFICANT EFFECTS

Cultural Resources

The area is rich in history and prehistory. Homesteading and mining played important roles. All alternatives, except E and M, call for a roaded regime which has the potential to disturb existing cultural resources. Alternatives E and M would minimize the potential for disturbance of cultural resources.

Energy and Minerals

The following table is a tabular summary of the estimated mineral potential and accessibility limitations for Mule Creek:

Access Restrictions	Mineral Potential (Acres)			
	High	Moderate	Low	Total
Withdrawn	-	-	-	-
High	-	-	-	-
Moderate	-	-	-	-
Low	-	<100	300	300
Total	-	<100	300	300

Improvements

The 256 acres of suitable land could generate about one mile of new road for timber harvest. Roads for mining could equal or exceed this amount, although such roads are not expected to be added to the existing system. All new roads would be dead-end local roads built when needed to access timber. All roads would be open to only high clearance vehicles, or closed between projects. All alternatives, except E and M, would road the area.

Roads on or near the north and west boundary would be extended, or local roads would be built off these roads for access. Some full bench ground would be crossed, especially on the south end, with excess excavated material hauled to stable disposal sites

Wilderness Potential

The maintenance of the roadless area would, in effect, expand the carrying capacity for the Wild Rogue Wilderness; however, the recreation experience would be influenced by adjacent motorized activities so that the quality of the experience is suspect. Access to the area is limited to existing roads within the area. No trails exist in the area; none are planned. Recreation demand projections indicate that levels of use will remain well within the carrying capacity over the planning period.

All alternatives, except E and M, would allocate the area to multiple resource management objectives. Under these alternatives, the area would be developed and the Roaded Natural recreation setting currently available would shift to a Modified setting. The change in character of the landscape would result in loss of Wilderness potential. Alternatives E and M would maintain the area in a roadless condition, thereby providing additional capacity for Semi-primitive wilderness recreation opportunities. The Wilderness potential of the area would be maintained.

How much of the inventoried roadless area remains unroaded by alternative can be evaluated by either assessing a combination of Management Areas 1-9 (which retain essentially undeveloped conditions), or by viewing the spatial arrangement of blocks of undeveloped area at the end of a given period of time. Management Areas may or may not be contiguous, so the integrity of the roadless area as a whole may be compromised by management around them. The following table provides a spatial estimate of acres remaining unroaded at the end of specific decades; these figures differ from the Management Area 1-9 acres in that the minimum criteria is based on the area either (1) bordering designated Wilderness, or (2) being 5,000 acres or greater:

Alternative	Acres Remaining End of Decade 1/		
	1	2	5
A, A-Dep, and NC	350	0	0
B, C, D, and D1	350	0	0
E and M	350	350	350
G	350	0	0
K	350	0	0
S	350	0	0

1/ Minimum criteria is 5,000 unroaded contiguous acres or adjacent to designated Wilderness.

Wild and Scenic Rivers

The roadless area is over the ridge line which forms the Wilderness boundary and is not visible from the Rogue Wild and Scenic River. None of the alternative allocations will effect the management of the Rogue Wild and Scenic River or the quality of the recreation experience of river users.

Soil, Water, and Fish

No consequences to soil, water, and fish are associated with Alternatives E and M as no soil disturbing activities would occur. All other alternatives allocate all or part of the area to Management Areas which permit development. In these alternatives, the risk of degrading the soil, fish, and water resources due to allocations to various levels of development is minimal. Acreages of activity are similar and limited in all alternatives; soil and water factors are not sensitive to management-induced impacts.

Fire

The effects of the alternatives from a fire standpoint are the increase or decrease that they will create in fire hazard and fire risk. In Alternatives E and M, all of the area would remain undeveloped, with fuels remaining continuous over the entire area. In all other alternatives, between 51 to 92 percent of the area would be developed, creating a mosaic of fuels over time. In all alternatives, some of the high priority natural fuels accumulations will be treated.

In undeveloped areas, the risk of ignition is low due to the low levels of human use. As development occurs, risk increases with road construction and timber harvest, and with the treatment of the activity slash from these operations. As access improves, the level of dispersed recreational and other public uses may increase, with an accompanying increase in the risk of human-caused fires. Both developed and undeveloped areas will have similar risk levels for lightning fires.

In Alternatives E and M, the risk from human-caused ignition would be limited primarily to the periphery of the area due to limited access. In all other alternatives, industrial operations would result in increased risk over 51 to 92 percent of the area and to the adjacent Wilderness; risk from public use would be increased along the 1 mile of road.

Vegetation

The effects on vegetation relative to diversity and age class distribution do not differ from the effects on the Forest as a whole (See Chapter IV of the FEIS).

Sensitive Plants

No Botanical areas or RNA's are proposed. No sensitive plants are known within the Mule Creek area.

Air Quality

The principle agent impacting air quality in this environment and surrounding areas is smoke from wildfire and prescribed burning. To determine the impacts of each alternative, only the effects of prescribed burning are considered. As an indicator of potential impacts, total suspended particulates (TSP) is used. Alternatives E and M would contribute no TSP. All other alternatives would produce three tons of TSP per year.

The probability of a smoke intrusion from burning in the roadless area impacting Coos Bay or Roseburg, both designated areas for air quality, is very low based on past performance. The probability of impacting the Wild Rogue Wilderness and Rogue River use is low to moderate.

Wildlife

Unless specifically mentioned below, wildlife indicator species and wildlife habitat are the same as for the Forest as a whole

Spotted Owl/Pileated Woodpecker/Pine Marten. Under all alternatives except E, M and S, habitat for mature/old-growth indicator species would be measurably reduced over time. At present, the area supports part of the habitat needs of one spotted owl pair; there would be no change under Alternatives E, M, and S. In all other alternatives, the area would not retain habitat capable of supporting any of the three indicator species.

Woodpeckers. Snag habitat would remain at or near 100 percent habitat capability for woodpeckers under Alternatives E, M, and S.

Black-tailed Deer/Roosevelt Elk. Big-game management opportunities would increase in all alternatives, except E, M and S, by creating timber harvest openings over much of the unroaded area. Opportunities for habitat improvement projects for game animals would be greater if the area was developed.

Wildlife Habitats. No meadows have been identified. Rock bluffs/cliffs on Saddle Mountain are allocated to wildlife use in Alternatives E thru S, but would probably remain unaffected in Alternatives A through D1.

Wildlife Recreation Use. Estimated Wildlife and Fish User Days (WFUD's) attributable to the area are low because fewer hunters use unroaded areas and non-hunters generally stay on maintained trails. Alternatives E, M and S produce the fewest WFUD's.

Visual Resource

All alternatives, except E and M, assign the area to management under the Modification objective, resulting in a modified Forest setting. Alternatives E and M assign the area to roadless objectives, resulting in management under the Preservation visual objective whereby the natural appearance of the landscape character would be retained.

Recreation Settings

Recreation use is very light and originates from local communities for the most part. The area is inventoried and capable of providing Roaded Natural ROS opportunities The estimated carrying capacity for the area is approximately 600 RVD's annually. Projected levels of recreation demand indicate that the use will remain well within the carrying capacity over the planning period.

All alternatives, except E and M, would shift the Roaded Natural recreation setting currently available to a Modified forest setting. Access and motorized opportunities would be enhanced as the area is roaded. The natural appearance of the landscape would be reduced to a modified forest setting. Alternatives E and M would maintain the current unroaded status. Recreation capacities would remain fixed since no new trail construction would be programmed.

Economic and Social

No significant social or economic effects associated with the roadless area have been identified.

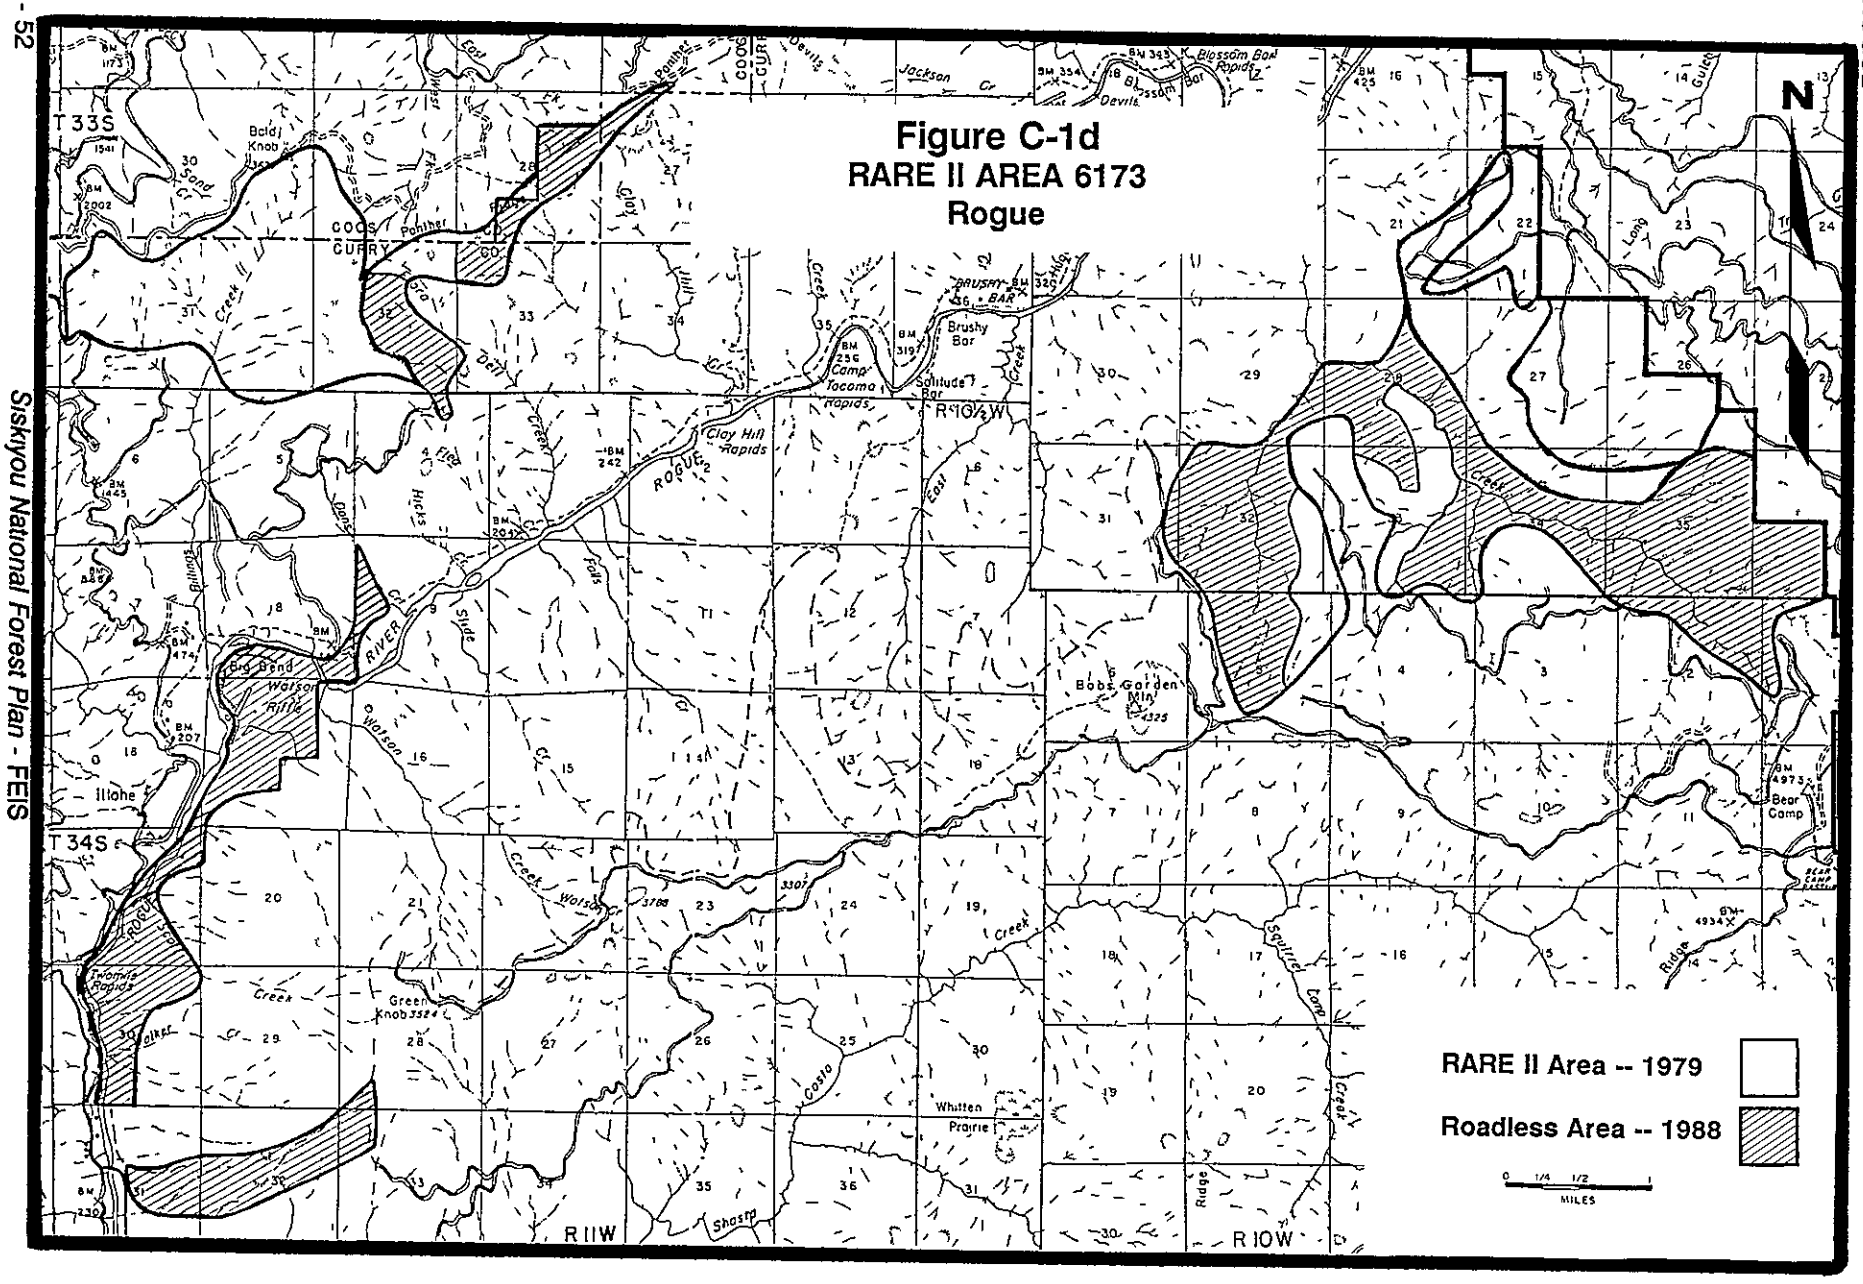
There are 256 acres of land identified as tentatively suitable for timber management in this unroaded area. The general effects on annual allowable sale quantity (ASQ) and long-term sustained yield (LTSY) of allocating these acres to uses that would include timber production are the same as those described in Chapter IV of the FEIS.

The estimated potential ASQ from the inventoried 352 acres of the Mule Creek Roadless Area is less than 0.02 MMCF. The estimated LTSY would be approximately 0.03 MMCF. Following are the estimates of the contribution to timber production (in MMCF) from this area under each alternative:

Alternative	ASQ	LTSY
NC and B	02	.04
A, A-Dep, C, D, G, and K	.01	.03
E and M	.00	00
S	.01	.02

MITIGATION MEASURES

No additional mitigation measures have been identified beyond those already listed for each alternative in the Standards and Guidelines.



POTENTIAL CONFLICTS WITH OTHER JURISDICTIONS

Conflicts with adjacent landowners may occur for access into the area. The Wild Rogue Wilderness bordering this area to the south is under jurisdiction of the BLM. However, this land is currently administered by the Forest Service under a cooperative agreement. No conflicts are anticipated.

ROGUE No. 6173

(3,839 Acres)

DESCRIPTION

STATUS OF ROADLESS AREA

The original inventoried area included most of the Wild Rogue Wilderness. The RARE II process included the balance for study as additions to the adjacent Wilderness. The RARE II inventory contained 6,744 acres and was allocated to non-Wilderness use by the RARE II decision in January, 1979 Since then, timber sale activities have reduced the area to 3,839 acres. The largest change occurred in the Billings Creek area where roading and timber harvest isolated an 1,100 acre tract of unroaded land. The inventoried area contains approximately 400 acres of private land; the balance is National Forest System land The area is actually five separate small parcels surrounding the Wild Rogue Wilderness

The Rogue Roadless Area is located within two Land Management Planning areas and the Powers Ranger District Multiple Use Plan of 1969. The Rogue Planning Unit (FEIS, 1975) generally divided the lands into those visible from the Wild section of the Rogue River and its paralleling trail with those lands outside the Wild and Scenic River Corridor which were not viewed Those areas not seen would be managed for timber production. In 1978, Congress passed legislation which designated all of the "seen" area and surrounding lands as the Wild Rogue Wilderness. The Rogue Roadless Area within the Rogue Planning Unit consists of three separate parcels designated for timber production.

The Rogue-Illinois Planning Unit (FEIS, 1979) allocated management of the two parcels of the Rogue Roadless Area south of the Wilderness to coordinated resource management, with the exception of a small piece of recreational river of the Wild and Scenic Rogue River. Coordinated resource management areas are managed to obtain full timber yield consistent with land capabilities and appropriate constraints, along with providing a high level of quality big-game habitat and protecting small areas containing exceptional features. The recreational river corridor is managed to: provide for a wide range of recreational activities which are oriented to the river and enhanced by its free-flowing condition; maintain or improve the quality of the water which enters the river; improve the fish and wildlife habitat; maintain or enhance the quality of the scenery; and utilize other resources and permit other activities to the extent that they do not significantly lower the quality of the wildlife or fisheries habitat, scenery, or recreation values.

Please reference these documents for a broad overview of the affected environment, evaluation of resources and management alternatives, and other requirements and constraints considered and currently implemented for the area. Since completion of the above unit plans, all project activities, e.g., timber harvest, fishery habitat improvements, etc., have been analyzed under their direction and NEPA requirements/process.

CHANGES BETWEEN DRAFT AND FINAL

During the period between 1984 and 1988, one timber sale northeast of Bob's Garden Mountain (Stair Creek drainage) has occurred. As a result of this activity, approximately 600 acres were removed from the area (Refer to Figure C-1d). The remainder of the area is as previously described.

LOCATION AND ACCESS

The Rogue area is located in Curry and Coos Counties, Oregon, and includes several small drainages tributary to the Rogue River. A small portion drains into the South Fork Coquille River watershed. The area is located approximately 18 miles from the coast and three miles from the community of Agness. Roads completely encircle the area. Primary access routes include Agness, Bear Camp, and Coquille River Roads These are multi-purpose routes, serving heavy recreation, timber, and administrative traffic.

PHYSIOGRAPHIC AND BIOLOGIC FEATURES

The physical location of the unroaded area is on the western side of the coast range (Klamath Mountain and Coast Range Geologic Provinces) in southwestern Oregon. Elevation ranges from 200 feet to 4,000 feet near Bobs Garden Mountain. Topography is very mountainous with steep slopes and deep canyons, with the exception of the river portion. The Big Bend area is a man-made prairie on a relatively flat river bench. Vegetation on the rest of the area is predominately Douglas-fir with a mix of hardwoods and other species. The forested areas have moderate variety due to some hardwood stands and brushfields. The ecosystem is mixed conifer. This zone is characterized by a mixed forest of evergreen needle-leaved trees in the upper strata and evergreen broad-leaved trees in the lower strata.

Soil conditions are highly variable within the proposed roadless area. In the western portion along the Rogue River, soils are generally moderately deep, moderately stable and productive. Some inclusions of rock talus and shallower soils occur in steep pitches along drainages. Broad, flat alluvial benches occur in the Big Bend area above the Rogue River, a rather uncommon landform feature in the Forest.

Along Stair Creek, soil and landform features also indicate a high degree of variability. Streams are generally deeply incised and show evidence of previous debris torrent activity. Streambank failures of various magnitudes are quite common to this drainage. The greatest amount of debris slide activity occurs where stream meanders have undercut toe slopes, creating oversteepened, unsupported blocks of soil material. Areas of water concentration and the presence of the siltstone member of the Dothan Formation are additional indicators of potential instability. On the more moderately sloping landforms, deep, clay rich soils occur. In some isolated toe slopes where massive amounts of water accumulate, deep-seated earthflows are present. These areas are characterized by a slow, large-scale gravitational movement of soil material downhill.

Average annual precipitation varies from 90 to 100 inches; dry season rainfall (May through September) averages 7 to 9 inches. Fog in the spring and summer often moves up the Rogue River corridor. Summer temperatures can exceed 100 degrees Fahrenheit in the lower river area.

Populations of black-tailed deer, Roosevelt elk, and black bear occur within the area. Large runs of anadromous fish utilize the Rogue River. The adjacent Wild Rogue Wilderness contains an active bald eagle nest (threatened species). The portion of the roadless area adjacent to the Rogue River is potential nesting habitat; bald eagles undoubtedly over-fly this zone and use perch trees here. Osprey are commonly observed along the Rogue River and may nest up to a mile or more from the river. Osprey have historically nested in the Big Bend area. Three sensitive plants, *Bensonilla oregana*, *Frasera umpquaensis*, and *Lewisia cotyledon* ssp. *howellii*, have been found in the Bear Camp/Bobs Garden vicinity and may exist within the roadless area. Sensitive animals found in the unroaded area also occur in the adjacent Wilderness and Rogue Wild and Scenic River corridor.

RESOURCE USES

While potential for mineral development exists, there is no current mining or leasing activity. There are no grazing allotments. Minor upland game and moderate big-game hunting on the fringes of the area occurs; interior hunting is very limited due to steep and brushy ground. Current recreation use for the area is

estimated to be 4,500 RVD's. Heaviest use takes place along the banks of the Rogue River bordered by the western unroaded portion (approximately 3,100 RVD's; 600 for tour boats and 2,500 for fishing and other river use). Away from the river, use is limited to some cross country hiking and minor hunting.

APPEARANCES, SURROUNDINGS, AND ATTRACTIONS

Four of the five parcels surrounding the Wild Rogue Wilderness are steep and heavily vegetated. For the lower elevation parcels, the major feature is the Rogue River. Stair Creek is the dominant feature of the eastern parcel. As the Stair Creek parcel protrudes from the Wilderness boundary, it appears to be part of the Wilderness.

The greatest influence upon the area is the heavily traveled roads. The Bear Camp Road is the major east-west road through the Siskiyou National Forest. Secondly, timber harvest activities and their associated roads abut most boundaries of the unroaded area. The Big Bend area is mostly private land. It currently has two existing residences, several farm buildings, fencing, cattle, old clearcuts, a power line rights-of-way, a tramway for access across the Rogue River, and an short landing strip for aircraft. This gives the appearance of a remote ranch where the natural setting has been altered.

The unroaded portions have no special features or scenic attractions except for the proximity to the Rogue Wild and Scenic River and Wild Rogue Wilderness. The Rogue River is a heavily utilized water resource. The western parcel can be accessed from the river while limited parts of the other unroaded parcels can be seen at a distance from the river.

Significant Indian cultural sites are present in the western unroaded portions due to prehistoric Indian use adjacent to the Rogue River. Petroglyphs are found at Twomile Creek. The Rogue River Trail location was probably used by prehistoric Indians.

CAPABILITY

MANAGEABILITY

The unroaded parcel along the Rogue River tends to straighten the Wilderness boundary, thereby making the boundary more manageable while permanently protecting the foreground view from the river. Leaving this narrow band of unroaded area between the Rogue River and the Wild Rogue Wilderness would affect nearly 600 acres of National Forest System land. While the strip could be managed for multiple resources, factors such as the limited amount of commercial timber, low intensity harvest requirements due to visuals, and problems of access combine to constrain development. The unroaded boundary could be adjusted to eliminate the private land in the Big Bend area. In effect, this would remove most of man's influence while consolidating the integrity of the unroaded area with that of the Wild Rogue Wilderness.

The two parcels on and near Panther Ridge are protrusions to the Wilderness boundary and do not provide good, manageable boundaries. The large parcel in Stair Creek is another protrusion of the Wilderness boundary. Boundaries of all three parcels would be difficult to locate on the ground.

NATURAL INTEGRITY AND APPEARANCE

All parcels, except around Big Bend, have a natural, unaltered appearance. An old road associated with the local residences borders the Rogue River between Big Bend and Illahe. The outer perimeter of the parcels is almost completely surrounded by roads and harvest units.

Fishing and boating are popular on the Rogue River. This use level is high and causes noise pollution impacts on the natural character of the area upslope of the river. And, private land in the Big Bend area

has several man-made features and livestock which have a significant impact on the area's appearance. The other parcels are not distinguishable from the Wild Rogue Wilderness.

OPPORTUNITIES FOR SOLITUDE AND PRIMITIVE EXPERIENCE

Due to the size of the parcels, external influences such as noise, roads, and harvest units are readily apparent. In all parcels except Big Bend, topography and dense vegetation provide screens. People could easily be within a quarter of a mile of each other and not be aware of one another. The same factors tend to negate cross-country travel so that recreation use is limited to principally the road corridors. The parcels, being almost completely surrounded by roads and timber harvest units (except for their boundary with the Wilderness) and quite small and narrow, do not provide a natural buffer of external influences. The parcels do provide a buffer for activities within the Wild Rogue Wilderness and help provide opportunities for solitude and primitive recreation there.

The opportunity for primitive recreation is limited. The Recreation Opportunity System (ROS) inventory indicates mostly Roaded Natural (3,400 acres); the remaining 400 acres is Semi-primitive Non-motorized.

SPECIAL FEATURES

The Rogue parcels have no special features other than their association with the Wilderness and Wild and Scenic River. Indian cultural sites are limited to specific spots along the Rogue River; they usually occur within the designated Wild and Scenic River corridor.

AVAILABILITY

RESOURCE POTENTIALS

Recreation

The opportunity for measurable change in unroaded recreation use is limited due to the area's size and topography. Use today is below capacity, and pressure for greater use is expected to increase very little in the future. The parcel of greatest existing and potential future use is the western piece bordering the Rogue River.

Potential for increased developed recreation use is greatest with a roaded condition. Access would be provided for hunting, dispersed camping, and other forms of motorized recreation.

Wildlife

Under unroaded conditions, wildlife would remain essentially unchanged. Over time, deer and elk populations will increase in response to the availability of forage. Varying stages of vegetation in harvest units and along roads, with adequate hiding cover, would promote expansion of existing herds. Populations of old-growth dependent wildlife would decrease, but still remain in old-growth forest along the river corridor, tributary streams, within the Wilderness, and on sites classified as unsuitable for timber production. Sensitive species would be protected through applicable standards.

Fisheries

The anadromous fisheries of the Rogue River are extremely important for recreation and commercial fishermen. The tributaries contribute cold clear water for the Rogue River fish However, most of these streams have gradients that are steep and have barriers to fish movement; they also have very limited potential for fisheries enhancement. Stair Creek is the primary stream associated with these parcels. Stair Creek provides a very important cooling effect at its mouth.

Water

There are no man-made impoundments or diversions either existing or proposed. Except for Stair Creek, the potential for small hydroelectric power development is very limited. A small increase in water yields would result as a consequence of timber harvesting. However, the greatest demand for water is directed toward maintenance or improvement of Rogue River water temperature in the summer and fall periods. *Quality aspects for the tributary streams are of far greater importance than water use or development due* to the high value fishery and recreational usage of the Rogue River.

Livestock

There is no livestock grazing on National Forest lands within the area now. Very little potential for livestock grazing exists. Some grazing use occurs on private lands in the Big Bend area.

Timber

The unroaded area contains approximately 3,520 acres of land suitable for the production of timber. Standing volume of timber is estimated at 92 MMBF. Site productivity is relatively high. The area is reasonably stable and could be logged using skyline cable systems that are in common use on the Forest. Additional roads would be required. Because of heavy vegetative competition and steep slopes, management for timber production would require various treatment methods to reduce brush competition for release of crop trees. Management along the Rogue River requires meeting the Visual Quality Objective of Retention.

Energy and Minerals

No exploration and development is known. While potential minerals may occur, development is highly improbable. There are no active mines or mineral leases in the roadless parcels.

Cultural

The area has had significant archeological and historical use along the Rogue River. The eastern part has low potential.

Land Use Authorization

Other than the private land and the various uses listed above, none exist. Few are expected whether roaded or undeveloped.

MANAGEMENT CONSIDERATIONS

Fire is the most serious management consideration. The potential for major conflagration does exist with the hazards posed by heavy fuels and dense brush. Conditions, however, are severe for a relatively short period of time due to coastal influence. With road development, access and intensified treatment of activity fuels would considerably lessen continuity and concentrations. The probability of major losses of resources by wildfire would be reduced. Access, however, also brings increased risks due to greater number and dispersion of people. The current risk of wildfire is greatest along and adjacent to the Rogue River *where concentration of recreational use is high.*

The potential for insect and disease outbreaks within the coniferous forest exist. However, actual occurrences have been minor and localized. With road development, the spread of *Phytophthora lateralis* root disease of Port-Orford-cedar will be increased where spores can be spread by machinery and water.

Private land in the Big Bend area has two existing residences and other man-made features. The Conservation Easement *for the private land within the Wild and Scenic River allows for 10 more residences.*

NEED

OTHER AREAS AND PUBLIC USE

Within 12 miles of Rogue exists three designated Wildernesses (Wild Rogue, Kalmiopsis, and Grassy Knob), and stretches of two Wild and Scenic Rivers (Rogue and Illinois). A portion of the Wild and Scenic Rogue River is located within the roadless area; the area is bordered by the Wild Rogue Wilderness.

Recreation use of the area and Wilderness is extremely light considering the acreage involved. The Wild Rogue Wilderness has many of the same attributes, but is generally far more rugged and diverse in geology and vegetation Use in the surrounding undeveloped areas is concentrated along rivers and trails.

Local users and residents are more likely to utilize the unroaded area than recreationalists from major population centers. Recreation oriented travelers from the metropolitan areas would normally seek areas closer and of higher quality in terms of views and experiences.

ECOSYSTEM REPRESENTATION

The major ecotypes of the unroaded area are well represented in the adjacent Wild Rogue Wilderness and Wild and Scenic River.

PUBLIC INVOLVEMENT

Public input on several of the inventoried roadless areas on the Siskiyou National Forest has been extensive, particularly the North Kalmiopsis. The Rogue parcels, however, have not received much attention or advocation of protective status. Of the 55 letters received during public review of the Rogue-Illinois Unit Plan in 1979, only two specifically stated that the Rogue should be designated as Wilderness. Several letters stated a Wilderness alternative (Alternative B) should have been selected as the preferred, however that alternative did not include the Rogue Roadless Area parcels as Wilderness.

Both the public and Forest managers have had considerable interest and concern for the existing and future management of the larger unroaded areas. During RARE II, units of local and state government responded to the potential inclusion of Rogue Roadless Area as Wilderness. They most often cited those impacts associated with local economy and community stability, loss of timber receipts, and multiple use opportunities foregone. Most respondents voiced similar reasons for opposition; the primary concern being the area's individual and cumulative effects on the critical timber supply of southwestern Oregon.

Since RARE II, the Rogue has been evaluated for timber management through site-specific project planning. Several projects have taken place and others have been planned within the unroaded portions that were inventoried. Little, if any, public input, concerns, or appeal of these activities has occurred.

In the current Forest Planning process, the roadless area question has remained a major issue. Public involvement, beginning with early public scoping in 1979 and continuing with public meetings, workshops, and other contacts in 1984 and later, had not surfaced additional concerns seeding unroaded status for this inventoried roadless area. Beginning in 1986, there was a movement to tie the Wild Rogue Wilderness and all contiguous unroaded areas to the south with the large Kalmiopsis Wilderness. This large block of land was promoted by several individuals and organizations as a potential National Park. As discussed in Chapter II of the FEIS, the proposal was not entertained as an alternative evaluated in detail.

ENVIRONMENTAL CONSEQUENCES

The significant effects of each alternative are presented in Chapter IV of the FEIS. Additional site specific effects, mitigations, and potential conflicts are presented here. The Standards and Guidelines for each alternative were considered when evaluating the effects of implementation.

SIGNIFICANT EFFECTS

Cultural Resources

All alternatives except E and M call for roading, which in turn may disturb existing cultural resources. Valuable sites can then be protected via avoidance or conserved via data recovery. Alternatives E and M call for an unroaded regime which would minimize the potential for disturbance of cultural resources.

Energy and Minerals

The following table is a tabular summary of the estimated mineral potential and accessibility limitations:

Access Restrictions	Mineral Potential (Acres)			
	High	Moderate	Low	Total
Withdrawn	-	100	200	300
High	-		200	200
Moderate	-	-	<100	<100
Low	300	-	3,000	3,300
Total	300	100	<3,500	3,800

Improvements

The 3,520 acres of suitable land could generate about 18 miles of new road for timber harvest. Roads for other purposes would be very minor. About two miles of collector road occurs in the Stair Creek drainage with Alternatives NC, A, B, C, and D. All other roads would be dead-end local roads built when needed to access timber harvest units. Some mileage would remain open to passenger car use, depending on the alternative; other roads would be open to only high clearance vehicles or closed between projects. The following table shows the mileage of the area by alternative:

Alternative	Total Miles	Miles Open to Passenger Car	Miles Open to High Clearance	Miles Closed
NC, A, B and D	18	5	6	7
C	18	3	8	7
E and M	0	0	0	0
G	15	0	6	9
K	15	4	2	9
S	14	4	2	8

Alternatives E and M would have minimal effect due to no roads being built. Alternative G would not maintain any roads open for passenger cars. Alternatives NC, A, B, C, D, K, and S would be essentially roaded. Alternatives G, K, and S would close approximately 60 percent of the roads.

The road system would be primarily extensions of existing roads. The new roads would cross small creeks and draws with the possibility of the lower parcels crossing some streams inhabited by fish. The new road construction could result in a temporary decrease in water quality. Some full bench ground would be

crossed by roads with excess excavated material hauled to stable disposal sites Some of the roads in the upper (eastern) parcel would be visible from viewpoints on the Bear Camp Road; parts of the lower parcels would be seen from sections of the Agness Road.

Wilderness Potential

The adjacent Wild Rogue Wilderness contains 36,100 acres and has an estimated carrying capacity of 18,700 RVD's. The maintenance of the roadless area would, in effect, expand the carrying capacity by another 5,600 RVD's Recreation demand projections indicate that levels of use will remain well within the carrying capacity over the course of the planning period.

All alternatives, except E and M, would allocate the area to multiple resource management objectives. The area would be entered for timber harvest and the Semi-primitive recreation opportunities currently available would shift to the Motorized end of the opportunity spectrum. The change in the character of the landscape would result in the loss of Wilderness potential.

Alternatives G, K, and S place the foreground of the Rogue River into a Supplemental Resource allocation that would not program timber harvest This assignment essentially eliminates development activities from the western portion of the Rogue Roadless Area. Wilderness potential would be maintained, thereby, between the Rogue River and the designated Wild Rogue Wilderness.

Alternatives E and M maintain the roadless condition and provide capacity for Roaded Natural and Semi-primitive Non-motorized recreation opportunities, along with adding to the quality of the recreation experience in the Wild Rogue Wilderness. Wilderness potential of the area would be maintained

How much of the inventoried roadless area remains unroaded by alternative can be evaluated by either assessing a combination of Management Areas 1-9 (which retain essentially undeveloped conditions), or by viewing the spatial arrangement of blocks of undeveloped area at the end of a given period of time. Management Areas may or may not be contiguous, so the integrity of the roadless area as a whole may be compromised by management around them. The following table provides a spatial estimate of acres remaining unroaded at the end of specific decades; these figures differ from the Management Area 1-9 acres in that the minimum criteria is based on the area either (1) bordering designated Wilderness, or (2) being 5,000 acres or greater:

Alternative	Acres Remaining End of Decade 1/		
	1	2	5
A, A-Dep, and NC	0	0	0
B, C, D, and D1	0	0	0
E and M	3,800	3,800	3,800
G	0	0	0
K	0	0	0
S	800	800	800

1/ Minimum criteria is 5,000 unroaded contiguous acres or adjacent to designated Wilderness.

Wild and Scenic Rivers

Alternatives NC, A, A-Departure, B, C, D, and D1 would not maintain the area in a roadless condition and would result in a modified forest setting as they are entered for timber harvest. The recreation setting for the Rogue River would be affected since harvest activities would be visible in the background in the Wild section of the river and in the near foreground in areas adjacent to the Recreation section.

Alternatives G, K, and S would not maintain the areas in a roadless condition. Under these alternatives, however, the foreground areas adjacent to the Rogue River would be removed from the timber base and

managed under the Preservation visual objective in response to the high levels recreation use on the river. The recreation setting would not be affected in these areas. Management activities would be visible in the background to river users in the Wild section. Alternatives E and M assign the area to Backcountry Recreation. The Preservation visual objective would be achieved.

Soil, Water, and Fish

The effects of assigning the area to various Management Area mixes is discussed by similar alternative groupings No adverse soil, water, and fish impacts are associated with Alternatives E and M because no soil disturbing activities will occur. All other alternatives would allow for development such as timber harvest and road building. The environmental effects of timber harvest and road building are discussed in Chapter IV of the FEIS.

The risk of degrading the soil, water, and fish resources generally increases with more timber harvest and road building. All alternatives, other than E and M, propose similar amounts of soil disturbing activities. Soils in the lower Stair Creek area are sensitive to accelerated mass soil movement due to management activities. Entry into these areas poses a moderate to high risk of degradation of the soil and water resource. Standards and Guidelines are crucial in the planning and implementation of activities here; in particular, preliminary geologic evaluations will be necessary to avoid the more unstable sites and adequately design for minimizing risks of mass failure. The western portion of the roadless area along the Rogue River poses a slight potential of adverse impacts.

Fire

The effects of the alternatives from a fire standpoint are the increase or decrease in fire hazard and risk that will be created. Risk is defined as the probability that an ignition will occur. Hazard is a description of the fuels complex in terms of kind, volume, arrangement, condition and location of the fuels.

The roadless area is broken into five sections; fuels vary greatly over these areas. The two sections in the Panther Ridge area have light fuel loadings with a large amount of hardwoods and brush, with a scattered overstory of Douglas-fir. Continuity is broken by natural openings. The two sections near Illahe are heavily timbered with light, continuous fuels. These areas are subject to strong local canyon winds. The section near Bobs Garden in Stair Creek is very steep with generally light fuel loadings. The stands are a mix of old-growth Douglas fir and hardwoods with numerous snags. In an undeveloped scenario, fuel accumulations would increase and fuel continuity would remain the same or increase. These conditions lend themselves to large, high intensity fires. Adding to this is the increased response time for initial attack forces due to poor access. This results in higher suppression costs and increased resource losses.

In a developed scenario, fire hazard is higher during the period of timber harvest. As fuels are treated, the hazard is reduced. Over time, the continuity of the fuels are broken up, creating a mosaic of fuels and vegetative development. This mosaic, combined with improved access for initial attack forces, reduces the potential for large, high intensity fires. The result is smaller fires, lower suppression costs and less resource loss due to fire.

In Alternatives E and M, all the area would remain undeveloped, with fuels remaining continuous over the entire area. In all other alternatives, 64 to 71 percent of the area would be developed, creating a mosaic of fuels over time. The remaining undeveloped areas would be broken into 2 to 4 separate blocks. Some of the high priority natural fuels accumulations will be treated in all alternatives.

In undeveloped areas, the risk of ignition is low due to the low levels of human use. As development occurs, risk increases with road construction, timber harvest, and treatment of activity slash. As access improves,

the level of dispersed recreational and other uses increase, resulting in an increase in the risk of human-caused fires. Lightning fires will have similar risk levels for both developed and undeveloped lands.

In Alternatives E and M, the risk from human-caused ignition would be limited primarily to the periphery of the area due to limited access In all other alternatives, industrial operations would result in increased risk over much of the area, and risk from public use would be increased along the 14 to 18 miles of road Another source of ignition in these areas could be the planned use of naturally occurring fire in the Wild Rogue Wilderness adjacent to these areas. If fires are allowed to burn, there is a chance of fire escaping from the Wilderness boundaries.

Vegetation

Effects on vegetation relative to diversity and age class distribution do not significantly differ from the effects on the Forest as a whole (see Chapter IV of the FEIS).

Sensitive Plants

No sensitive plants are known to occur in this area, and no botanical sites are proposed. Undiscovered sensitive plants which would be best protected in Alternatives E and M which allocate the area to Backcountry Recreation.

Air Quality

The principle agent impacting air quality in the forest environment and surrounding areas is smoke from wildfire and prescribed burning. To determine the impacts of each alternative, only the effects of prescribed burning will be considered. Total suspended particulates (TSP) is used as a measurement of the potential for regional haze. Alternatives E and M contribute no TSP. All other alternatives produce 26 to 29 tons of TSP per year.

The probability of a smoke intrusion from burning in the roadless area impacting Grants Pass, a designated area, is very low based on past performance. Because the area is in the Rogue drainage and adjacent to the Wild Rogue Wilderness, probability of impacting the Wilderness and Rogue River corridor is moderate.

Wildlife

Unless specifically mentioned below, effects of the alternatives on wildlife indicator species and wildlife habitat in this roadless area are the same as for the Forest as a whole.

Bald Eagle/Osprey. This area contains some of the Forest's prime bald eagle and osprey habitat. Habitat would be slightly degraded in Alternatives A through D1 as they do not allocate the area to Backcountry Recreation or include the Rogue River Visual Supplemental Resource area.

Spotted Owl/Pileated Woodpecker/Pine Marten. Under all alternatives except E and M, habitat for mature/old growth-indicator species would be reduced over time. Except for Alternative NC, a habitat enclave to meet Management Requirements (MR's) for pine marten is located within the area. At present, this area contains enough habitat to support approximately two pairs of spotted owls (and possibly parts of one or two other home ranges), there would be no change under Alternatives E and M. Mature/old-growth habitat would ultimately be reduced to MR levels (no spotted owls) in all other alternatives, except Alternative NC which does not contain MR's assigned to wildlife dependent on mature/old-growth habitat.

Woodpeckers. Snag habitat would remain at or near 100 percent habitat capability for woodpeckers under Alternatives E and M, which assigns the area to continued roadless status.

Black-tailed Deer/Roosevelt Elk. Big-game management opportunities would increase in alternatives which open up much of the unroaded area to timber management (all alternatives except E and M). Opportunities for habitat improvement projects for game animals would also be greater.

Wildlife Habitats. Three meadow areas are contained in the Rogue Roadless Area (approximately 100 acres); part of Foster Bar flat is located adjacent to the western boundary of the roadless area. This is one of the most valuable meadow areas on the Forest. Meadow habitat will be maintained under all alternatives, although meadow buffers area not allocated in Alternatives NC, A and A-Departure. Those alternatives (all except NC, A, A-Departure, B, C, D, and D1) which assign the Rogue River Visual Supplemental Resource area provide the highest level of habitat protection.

Wildlife Recreation Use. Estimated Wildlife and Fish User Days (WFUD's) currently attributed to this area are low (except on the western end), because human use of the area is less than in roaded areas. Fewer hunters use unroaded areas and non-hunters generally stay on the few trails. Alternatives E and M produce fewer WFUD's; other alternatives generate more.

Visual Resource

The current visual inventory indicates approximately 600 acres as Retention, 2,200 acres as Partial Retention, and the remaining 1,000 acres in Modification. Alternatives NC, A, and A-Departure would manage the area to meet inventoried objectives; roadless conditions would not be maintained. Management to meet visual objectives would maintain the quality of the landscape, particularly in foreground areas adjacent to the Rogue Wild and Scenic River, and in areas visible from Bear Camp Road

Alternatives B, C, D, and D1 also would not maintain the area in a roadless condition. Under these alternatives the areas would be managed to achieve visual objectives at a reduced level including the foreground area adjacent to the Rogue River. Areas inventoried for the Retention objective would be managed for Partial Retention, and areas inventoried for Partial Retention would be managed for Modification. These management objectives would result in a modified Forest setting throughout the area.

Alternatives K and S do not maintain the majority of the area in a roadless condition. The foreground area adjacent to the Rogue Wild and Scenic River would be removed from the timber base and managed to achieve the Preservation VQO which, in essence, maintains the roadless character of this portion of the area Most of the remaining area would be managed for the Modification objective, although 700 acres would be managed under the Partial Retention objective.

Alternative G does not maintain the roadless condition. The area would be managed to achieve inventoried visual objectives. The foreground area adjacent to the Rogue River would have no programmed timber harvest as a result of assignment to Preservation objective, thereby maintaining the roadless character of this portion. Alternatives E and M would maintain the roadless condition and achieve the Preservation objective.

Recreation Settings

The area has an estimated carrying capacity of 5,600 RVD's. Recreation use in the area is estimated at 3,500 RVDs annually. Most of the use is attributed to the two parcels adjacent to the Rogue Wild and Scenic River. Recreation use in the other parcels is limited by access. These are surrounded by roads, however. Except for the Rogue River Trail that crosses one parcel, there are no trails into any of the areas. Recreation use is not expected to increase beyond the estimated capacity over the planning period.

All alternatives, except E and M, would develop the area for multiple resource objectives. Recreation opportunities would be motorized rather than non-motorized and, in that respect, would be enhanced as roads are constructed which increase access. The two areas adjacent to the Rogue Wild and Scenic River will be managed to achieve the Retention VQO under these alternatives in response to the high levels of recreation use. The natural appearance of the landscape character is expected to be maintained The potential wilderness character and primitive recreation opportunities would be lost or reduced.

All alternatives, except E and M, would retain undeveloped character on only limited areas. These areas may or may not be contiguous to the adjacent Wilderness, so their integrity may be compromised by the close presence of motorized activities (See **Wilderness Potential**).

Alternatives E and M maintain the potential wilderness character and primitive recreation opportunities over the planning period. Maintenance of the natural character of the landscape is expected to contribute to the recreation setting within the Rogue River corridor.

Economic and Social

There are 3,520 acres of land identified as tentatively suitable for timber management in this unroaded area. The general effects on annual allowable sale quantity (ASQ) and long-term sustained yield (LTSY) of allocating these acres to uses that would include timber production are the same as those described in Chapter IV of the FEIS.

The estimated potential ASQ from the inventoried 3,839 acres of the Rogue Roadless Area is 0.19 MMCF. The estimated LTSY would be 0.35 MMCF. Following are the estimates of the contribution to timber production (in MMCF) from this area under each alternative:

Alternative	ASQ	LTSY
NC, A, C, and D	18	32
B	.21	39
E and M	00	00
G K, and S	15	28

For projecting effects, the alternatives are grouped into three categories: (1) Alternatives E and M which leave the area in an unroaded status; (2) Alternatives G, K, and S which develop much of the area; and (3) Alternatives NC, A, B, C, and D which develop the area.

The major direct economic effect is government expenditure for the timber and associated road construction program. Alternatives E and M have the biggest reduction in timber and road expenditures. The other alternatives have little or no differences.

Indirect effects are associated with jobs, income, and payments to counties. Assuming no substitution of reduced timber harvest within the area of influence, Alternatives E and M have a reduction while the other alternatives have little change compared to Alternative A. Alternative B would provide slightly more jobs and revenues in the first decade than under current direction.

The cumulative social effects of attitudes of people can be summarized by examining the different interests of the adjacent communities. Previous documentation is found in Chapters III and IV of the FEIS. The positive sign indicates a feeling by special interest groups of the Forest being responsive, while a negative indicates a social feeling of the Forest not being responsive to particular interests as listed. For example, in Alternative E, timber interests are predicted to feel negative about forest management while river

recreationists are predicted to see the Forest as responding to their needs. Such perceptions of gains and losses may create additional conflict.

Effects (Changes Compared to Alternative A)	Alternatives		
	E and M (Unroaded)	G, K, and S	NC, A, B, C, and D (Roaded)

MITIGATION MEASURES

No additional mitigation measures are identified for this area.

POTENTIAL CONFLICTS WITH OTHER JURISDICTIONS

Potential land management conflicts could occur between the Siskiyou Forest and Bureau of Land Management since the BLM Medford District manages upper fringes of the Stair Creek drainage. Through coordination of management plans, potential conflicts can be avoided.

POTATO MOUNTAIN No. 6174

(5,963 Acres)

DESCRIPTION

STATUS OF ROADLESS AREA

The Potato Mountain Roadless Area was inventoried for study as a potential Wilderness during the RARE II process. At that time, it contained 8,060 acres and was allocated to non-Wilderness use by the RARE II decision in January, 1979. Since then, timber sale activity has reduced the area to 5,963 acres. The entire area is National Forest System land.

The Rogue-Illinois Land Management Plan (FEIS, 1979) encompasses the Potato Mountain area. Management direction allocated most of the area to coordinated resource management to obtain full timber yield consistent with land capabilities and appropriate constraints, along with providing a high level of quality big game habitat and protecting small areas containing exceptional features.

The other management direction for the area provides scenic river status for a corridor along the Rogue River and is managed to: maintain or enhance the condition of the high quality scenery and the largely undeveloped character of its shoreline; provide opportunities for river-oriented recreation which is consistent with the area's largely undeveloped nature; and utilize other resources and permit other activities which maintain or enhance the quality of the wildlife habitat, river fishery, scenic attractions, and recreation values.

Complete descriptions of these management areas can be found in the Land Management Plan. Readers are directed to this document for a broad overview of the affected environment, evaluation of resources and management alternatives, and other requirements considered and currently implemented for the area. Since implementation of this Plan, all project activities, e.g , timber harvest and road construction, wildlife enhancement, etc , have been analyzed under it's direction and NEPA requirements/process.

CHANGES BETWEEN DRAFT AND FINAL

Between 1984 and 1988, timber sales have developed portions of the unroaded area. The most significant changes resulted from the Painted Picture and Waters Creek Timber Sales which essentially split the area into two portions (Refer to Figure C-1e). Another timber sale occurred along the northwest edge of the area. The remainder of the area is as previously discussed.

LOCATION AND ACCESS

The south and east facing Potato Mountain area is located in Curry County, Oregon, and includes portions of several small drainages tributary to the Rogue River. The area is located approximately 13 miles from the coast and is within a five mile radius of the community of Agness. The area is completely encircled by the Agness Road, Sawtooth-Foster Road, and Lake O' Woods Road.

PHYSIOGRAPHIC AND BIOLOGIC FEATURES

The physical location of the unroaded area is on the west side of the coast range and within the Klamath Mountain Geologic Province. Elevation varies from 200 to 3,419 feet near Lake O' Woods Lookout. Topography varies from rolling, hummocky terrain to steep slopes and deeply incised drainages. Most of the area is generally well timbered except for the river banks and bars and Adams Prairie. The forested

areas have much variety due to hardwood stands, brushfields, and various small open grassy sites. Douglas-fir is the primary conifer species with associated species being Port-Orford-cedar and sugar pine. Tanoak, madrone, and canyon live oak are important hardwoods with red alder, bigleaf maple, and myrtle found in drainages and wet areas. The ecosystem is predominately mixed-conifer and mixed evergreen type.

Soils are generally moderately deep to deep and productive. Shallow, rocky soils as inclusions occur in steeper headwall areas. Soil stability varies greatly; however, the great majority of the area is moderately stable. Some isolated mass movement activity has occurred on oversteepened slopes that have been undercut by stream channels and along geologic contacts.

Average annual precipitation varies from 100 to 110 inches; dry season rainfall (May through September) averages 9 to 11 inches. The climate is mild and heavily influenced by marine air. Fog in the spring and summer often lies in the Rogue River corridor to an elevation of 1,500 feet. Summer temperatures often exceed 90 degrees Fahrenheit in the Agness area.

Populations of black-tailed deer, Roosevelt elk, and black bear occur within the area. Large sea runs of salmon and steelhead use the Rogue River. The Federally listed threatened bald eagle has been observed in the area, but no nest sites have been found. Up to a half dozen osprey nests exist within the roadless area along the Rogue River. Northern spotted owls (sensitive species) have been observed in the roadless area. The area contains portions of two of the Forest's important meadow complexes and a large cliff site. A few sensitive plant species are found within the area: *Allium bolanderi* and *Erigeron cervinus*. A review list plant, *Arenaria howellii*, is also present.

RESOURCE USES

Little or no mineral development has occurred in the past and no activity other than occasional recreational exploration is present today. Livestock grazing occurs in Adams Prairie. Minor upland game and moderate big game hunting on the fringes of the unroaded area takes place; interior hunting is very limited due to steep and brushy ground. Fishing in the Rogue River is a major use.

Recreation along the Rogue River is the dominant use of the area. The Lower Rogue River Trail crosses the unroaded area along and near the north bank of the river and is well used The unmaintained Lake O' Woods Trail receives very little use. Hiking, fishing, and boating (including large commercial tour boats and other motorized craft) are popular along the river. The total annual recreation visitor days for this area is estimated to be 4,500, tour boats providing 3,000 visitor days and fishing and other river use 1,500 days.

The area just outside and upstream along the Rogue River is utilized for summer homes and private cabins. This use is well established and is very important to the people involved. Water is withdrawn from two streams; Waters Creek (domestic use) and from Morris Rodgers Creek (irrigation purposes).

APPEARANCES, SURROUNDINGS, AND ATTRACTIONS

The landform within the area has rounded, relatively flat ridges and sideslopes which average 60 percent. The area is covered by vegetative canopy of conifers, hardwoods, and brushfields. Prairies near and around Agness, Adams Prairie, and rock bluffs above Copper Canyon provide diversity. The most significant feature of the area is the Rogue River canyon.

The surrounding conditions do not vary greatly from within the unroaded portion. Vegetative type and landform is consistent. Man's activities have modified the environment on the ridgelines and along the Rogue River. Timber harvest entries have provided a mosaic of patch clearcuts where the vegetation varies a few decades in age.

Influences most predominate in this locale are heavily traveled roads. The Agness Road, the only east-west access to the community of Agness, is the western segment of the principal east-west road through the Siskiyou National Forest. Secondly, timber harvest activities and associated roads immediately border the area. Near the community of Agness, private lands which border the unroaded area have been altered through removal of much of the overstory vegetation and development.

Indians have occupied the Rogue River corridor in both historic and prehistoric times. Inventoried vision quest sites and a historic/aboriginal trail, which may follow a route used by native Americans prior to 1856, are located here.

CAPABILITY

MANAGEABILITY

The Potato Mountain unroaded area is well defined and management for protection and maintenance of unroaded characteristics and values in all or part would not pose any difficult or unreasonable situation. The location and size does not allow the complete screening from the sights and sounds of developments or activities However, the size and shape is adequate to reduce offsite intrusion from adjacent roads, timber harvesting, power tour boats, and associated human activity noises. The roadless area boundary is somewhat poorly defined as it crosses midslope along much of its length.

NATURAL INTEGRITY AND APPEARANCE

Human influences have had little impact on the natural appearance or long-term ecological processes of the roadless area, however, it does contain a number of man-made features along the Rogue River. The impact of the two trails, while low, will be evident for many years. Here, man's activities are noticeable, but would not be perceived by users as undesirable. Fishing and boating are popular on the Rogue River. This use level is high and causes considerable noise as well as visual impacts on the naturalness of the area.

Adams Prairie, along the southwestern edge, has been used many years for livestock grazing. This use has altered the natural processes of the area by retarding the invasion of forest trees and brush. Because of this use, fences have been added and non-native grass species have been introduced. A low standard road in Adams Prairie serves two summer homes along the Rogue River. Even if closed, it will affect the naturalness of the area for many years, although effecting only the fringe of the unroaded area. These summer homes are just outside the area's boundary. Power lines to the summer homes also have an effect on naturalness, but are not highly visible.

The Adams Prairie, Newhouse Cabin, and Painted Rock areas contain old orchards of planted fruit trees. While noticeable, they are not perceived as particularly undesirable; their historic value is an attraction rather than a detriment.

OPPORTUNITIES FOR SOLITUDE AND PRIMITIVE EXPERIENCE

The topographic and vegetative screening over most of the Potato Mountain area is sufficient to provide a sufficient opportunity for solitude. Due to the relatively small size, slope positioning, and narrowness of the unroaded area, however, there are many off-site intrusions on the opportunity for solitude. Frequent truck traffic and motorized boats are heard throughout area. The occupancies along the Rogue River also conflict with the naturalness of the area. Access roads, power lines, and other development on private ownership in the Agness vicinity provide a poor buffer for a primitive experience or solitude.

Use of the area for primitive recreation experiences is limited due to density of vegetation, steepness of slopes, and proximity to human activity and development. Few trails exist and in places the vegetation is so thick as to make cross country foot travel extremely difficult. Due to limited use and physical attributes,

entering the area a short distance would provide a feeling of solitude, adventure, and awareness of untrammeled conditions. The Recreation Opportunity Spectrum (ROS) of the area is split between Roaded Natural on the fringe and Semi-primitive Motorized upslope from the river.

SPECIAL FEATURES

The most significant feature is the classified Scenic segment of the Rogue Wild and Scenic River. The unroaded area encompasses over three miles of the designated river corridor. Previously noted are the native American cultural sites.

AVAILABILITY

RESOURCE POTENTIALS

Recreation

Undeveloped/unroaded. The opportunity for measurable change in type or use is limited even though there is some potential total use increases. Other than in the Rogue River corridor, there is little opportunity for increasing use. Use today is below capacity.

Developed. The potential for increased use is greatest with roaded development. The existing use on and along the Rogue River would not be impaired due to its designated status of Wild and Scenic River. Roads would provide greater access for hunting, dispersed camping, and other forms of motorized recreation.

Wildlife

Under unroaded conditions, game and nongame wildlife would remain constant unless specific management practices such as habitat improvement or prescribed fire were implemented. As development occurs over time, elk and deer populations would increase in response to increased forge. Varying stages of vegetation in harvest units and along roads with adequate hiding cover would promote expansion of existing herds. Populations of old-growth dependent wildlife species would decrease. They would not be eliminated, however, because considerable habitat would remain along the river corridor, tributary streams, and in areas unsuitable for commercial purposes. Sensitive species would be protected through applicable standards.

Fisheries

The anadromous steelhead and salmon fisheries of the Rogue River are extremely important for recreation and commercial fishermen. While the small tributary streams within the unroaded area do not provide spawning or rearing habitat, they do contribute clear, cool water to the Rogue River fishery. The stream gradients are steep and have very limited potential for fisheries enhancement. The fishery would be best protected under the existing condition where natural conditions prevail. Development poses only limited risk; that being principally related to land instability.

Water

There are no man-made impoundments or diversions either existing or proposed. The potential for small hydroelectric power exists on the steeper tributaries with development. A small increase in water yields would result as a consequence of timber harvesting. However, the greatest demand for water is directed toward maintaining the Rogue River water temperature in the summer and fall periods. Quality aspects for the tributary streams is far greater in importance than water use or development due to the high value fishery and recreational use of the Rogue River.

Livestock

The grazing of livestock at Adams Prairie is well established and is important to the permittee. The permit is for 30 AUM for the period of October 15 through May 31. There is little potential for increase with development. If the area were not available for grazing, the permittee would either have to severely reduce his herd or quit the livestock business.

Timber

The unroaded area contains approximately 5,147 acres of land suitable for producing timber. The standing volume of timber is estimated at 144 MMBF. Site productivity is relatively high. The area is reasonably stable and could be logged using skyline cable systems that are in common use on the Forest. Additional roads would be required. Because of heavy vegetative competition and steep slopes, management for timber production would utilize various methods, including use of herbicides, to reduce brush competition for release of crop trees Management of the area along the Rogue River has and will likely require meeting a Visual Quality Objective (VQO's) of Retention.

Energy and Minerals

Activity in the form of exploration and development is low to nonexistent. While potential minerals likely occur, development is remotely possible. There are no active mines or mineral leases in the area. Prior rights have potential for conflict.

Cultural

The inventoried sites and other historic and prehistoric sites that may be found will be evaluated and provided for under the applicable laws and regulations for any proposed activity, whether unroaded or developed. The potential for discovery of additional archeological evidence is good, especially in areas close to the river.

Land and Use Authorization

Only those uses already noted exist. Few are expected under either a roaded or undeveloped scenario.

MANAGEMENT CONSIDERATIONS

Fire is a major management consideration. The potential for major conflagration does exist with the heavy fuels and dense brush on the southerly slopes above the river. Severe conditions exist, however, for a relatively short period due to coastal influence. Road positioning is favorable; being generally above the fuels. The greatest threat of ignition is posed by dispersed recreation use along the Rogue River, and private ownership land uses and development in the Agness vicinity. While risk is low due to few users within the high hazard areas and heaviest use being on the river, fire ignition at the wrong time could have major consequences. With road development, access and intensified treatment of activity fuels would considerably lessen fuel continuity and concentrations. But, even though probability of major losses of resources by wildfire would be reduced, the improved access also brings with it increased risks due to greater numbers of people in the woods.

The potential for insect and disease outbreaks within the coniferous forest exists. However, actual occurrences have been minor and localized. With road development, the potential for spread of *Phytophthora lateralis* root disease of Port-Orford-cedar will be increased.

NEED

OTHER AREAS AND PUBLIC USE

Within eight miles of Potato Mountain exists the designated Wild Rogue and Kalmiopsis Wildernesses and stretches of the Wild and Scenic Rogue and Illinois Rivers. A segment of the Wild and Scenic Rogue River is within the unroaded area and the Wild Rogue Wilderness is only one-half mile to the east Several other special Management Areas and blocks of unsuitable land surround Potato Mountain.

Recreation use of the unroaded area and nearby Wilderness is extremely light in consideration of their size. They share many of the same attributes of Potato Mountain, but are somewhat more rugged and diverse in geology and vegetation. Use in the surrounding undeveloped areas is concentrated, much like Potato Mountain, along rivers and trails.

Local users are more likely to utilize Potato Mountain than recreationists from major population centers six to ten hours away via automobile. Recreation oriented travelers from the metropolitan areas would normally seek areas closer and of higher quality in terms of views and experiences.

ECOSYSTEM REPRESENTATION

The major ecotypes within Potato Mountain are well represented in other undeveloped areas in addition to the adjacent Wilderness and Wild and Scenic River areas. The designated Wild and Scenic River segment within this unroaded area, along with potential Supplemental Resource Area in the lower reaches of Morris Rodgers Creek (Copper Canyon), provide a permanent share of the more diverse ecosystems of this area.

PUBLIC INVOLVEMENT

Public input on a few selected roadless areas on the Forest has been extensive. Potato Mountain, however, has not received much attention or advocation for protective status. Substantive comments were received during public review of the Rogue-Illinois Land Management Plan in 1979. The majority of respondents supported the multiple use concepts, management prescriptions, and land use allocations proposed for this area Several letters stated a Wilderness preference (Alternative B); four respondents specifically called for the preservation of Potato Mountain to protect the quality of the Rogue River and its tributaries for fisheries, and to protect the unique Rogue River canyon.

Both the public and Forest managers have had considerable interest and concern for the existing and future management of the larger unroaded areas. During RARE II, units of local and state government responded to the potential inclusion of Potato Mountain Roadless Area as Wilderness. They most often cited impacts associated with local economy and community stability, loss of timber receipts, and multiple use opportunities foregone. Most reasons for opposition were similar; the primary concern being the area's individual and cumulative effects on the critical timber supply of southwestern Oregon.

Since RARE II, the Potato Mountain area has been evaluated for development activities through site-specific project planning. Several projects have taken place and others have been planned within the unroaded portions that were inventoried. Public involvement has occurred, but there has been little concern relative to the issue of leaving the area in an unroaded state.

In the current Forest planning process, the unroaded question has remained a major issue. Public involvement, beginning with early public scoping in 1979 and continuing with public meetings, workshops, and other contacts in 1984 and 1985, has not surfaced additional concern for unroaded status of this inventoried area. Public review and response of the DEIS for the Forest Plan also failed to focus heavily on this area The concensus for long-term management of the unroaded area generally was oriented to

maintenance of quality views from the Rogue River, protection of the river environs, and a special allocation for the Morris Rodgers Creek area, which includes the rock cliffs.

ENVIRONMENTAL CONSEQUENCES

The significant effects of each alternative are presented in Chapter IV of the FEIS. Additional site specific effects, mitigations, and potential conflicts are presented here. The Standards and Guidelines for each alternative were considered when evaluating the effects of implementation.

SIGNIFICANT EFFECTS

Cultural Resources

The Potato Mountain Roadless Area contains known and potential prehistoric and historic sites. Indian trails, vision quest sites and villages exist in the area along ridges and the Rogue River. Historic transportation routes include Lake O' Woods and Lower Rogue River Trails, both of which had prehistoric use.

All alternatives, except E and M, allow for development which requires intensive cultural resource inventory along any proposed activity area prior to approval. In this way, sites that may exist in the project area can be evaluated. Valuable sites can then be protected via avoidance or conserved via data recovery. Alternatives E and M, calling for an unroaded regime, minimize the need for cultural inventories

Energy and Minerals

The following table is a tabular summary of the estimated mineral potential and accessibility limitations for Potato Mountain. Acreages shown are subject to change due to current withdrawal review by the Bureau of Land Management (BLM), and differences found for site specific needs included in any subsequent withdrawal applications to BLM.

	Mineral Potential (Acres)			
Access Restrictions	High	Moderate	Low	Total
Withdrawn	-	-	1,100	1,100
High	-	-	700	700
Moderate	-	-	-	-
Low	-	-	4,100	4,100
Total	-	-	5,900	5,900

Improvements

Roads. The road system would follow ridge systems off the main roads on the boundary and would have midslope roads crossing the creeks and draws. Some full bench ground would be crossed by roads with much of the excavated material hauled to stable disposal sites. Many of the roads, especially those on ridges and in cut over units, would be visible from the Agness Road and the Rogue River. Access would be provided for timber management, roaded recreation, and fire suppression.

The 5,147 acres of land tentatively suitable for the production of timber could generate about 20 miles of new road for timber harvest. Roads for other purposes would be minor, if any All roads would be local roads built when needed to access timber harvest units. Most of these roads would be dead-end, but a possibility exists for a loop road, especially near the Rogue River corridor, which could provide access to portions of the north side of the river. Some mileage may be open to passenger cars, depending on the

alternative, but most of the roads would be open to only high clearance vehicles or closed between projects. The following chart shows the mileage of the area by alternative:

Alternative	Total Miles	Miles Open to Passenger Car	Miles Open to High Clearance	Miles Closed
NC, A and B	20	5	7	8
C	20	3	9	8
D	20	6	6	8
E and M	0	0	0	0
G	14	0	6	8
K	19	5	3	1
S	15	4	2	9

Trails. None of the alternatives would lead to construction of new trails within this area. The two existing trails are retained with some trail bridge replacements to provide for public safety; otherwise, no reconstruction is planned.

Developed Recreation Sites. One recreation site (Nail Keg Creek) is identified for construction under Alternatives B, D, D1, E, G, and M; the other alternatives construct none.

Wilderness Potential

The area has been inventoried according to ROS criteria and is in a natural appearing condition capable of providing approximately 3,000 acres each of Semi-primitive Motorized and Roaded Natural recreation opportunities. The carrying capacity for the area is estimated at approximately 8,700 RVD's. This figure is high since the coefficients used to calculate use from ROS categories was developed based on the assumption that roads were present. Current use is low (approximately 4,500 RVD's) and is attributed primarily to recreation activities on the Wild and Scenic Rogue River. The presence of motorized uses on the river and the surrounding road systems would preclude the ability of the area to provide a truly primitive recreation experience

Access into the area is limited to two trails. No new trails are programmed due to the low levels of use. Recreation demand projections indicate that levels of use will remain well within the carrying capacity over the planning period.

The area is isolated from other roadless areas and designated Wilderness. The Potato Mountain Roadless Area is not recommended for Wilderness designation in any of the alternatives.

All alternatives, except E and M, would assign the area to multiple resource management objectives Under these alternatives, the Semi-primitive recreation opportunities currently available would shift to the Roaded Natural end of the opportunity spectrum. The change in the character of the landscape would result in the loss of any Wilderness potential.

Alternatives E and M would maintain the area in a roadless condition, thereby providing additional capacity for Roaded Natural and Semi-primitive Motorized recreation opportunities. Wilderness potential of the area would be maintained.

How much of the inventoried roadless area remains unroaded by alternative can be evaluated by either assessing a combination of Management Areas 1-9 (which retain essentially undeveloped conditions), or by viewing the spatial arrangement of blocks of undeveloped area at the end of a given period of time.

Management Areas may or may not be contiguous, so the integrity of the roadless area as a whole may be compromised by management around them. The following table provides a spatial estimate of acres remaining unroaded at the end of specific decades; these figures differ from the Management Area 1-9 acres in that the minimum criteria is based on the area either (1) bordering designated Wilderness, or (2) being 5,000 acres or greater:

Alternative	Acres Remaining End of Decade 1/		
	1	2	5
E and M	6,000	6,000	6,000
All Other Alternatives	0	0	0

1/ Minimum criteria is 5,000 unroaded contiguous acres or adjacent to designated Wilderness

Wild and Scenic Rivers

The Potato Mountain area is located in and adjacent to the Wild and Scenic Rogue River, much of which is visible from the river or from the Agness Road paralleling the river corridor. Allocation of the area to roadless management objectives will not affect the management of the Wild and Scenic River, however, the allocation may effect the quality of the recreation setting near the river. The recreation setting is currently maintained through the use of VQO's which were assigned to the area in response to both the designation of the Rogue River as Wild and Scenic and to the high levels of recreation use that occur on the river. Area within the designated Wild and Scenic River corridor is currently managed to achieve the Retention objective. Variations on land allocations are discussed by alternative below

Alternatives A and A-Departure would manage the area to achieve inventoried Visual Quality Objectives. Some modifications would result as the area is developed. Alternatives B, C, D, and D1 would reduce visual objectives outside of the designated Wild and Scenic River corridor Areas outside the 1/4 mile corridor would be managed for Partial Retention, resulting in visible harvest activities.

Alternatives G, K, and S would allocate the foreground area adjacent to the Wild and Scenic River to Supplemental Resource and would retain the essentially undeveloped character of the area. Alternatives E and M would allocate the area to roadless management objectives. There would be no adverse visual impact.

Soil, Water, And Fish

The impacts of assigning the area to development or nondevelopment are discussed by alternative groups. No soil, water, and fish impacts are associated with Alternatives E and M as existing conditions are maintained. All other alternatives assign all or part of the area to some degree of development.

The majority of the soil, water, and fish resources within the Potato Roadless Area are not significantly affected by timber harvest related activities. All the alternatives, other than E and M, are similar in the amount of soil disturbing activities proposed. The allocations in these alternatives would have a minor to negligible potential impact on these resources.

Fire

The effects of the alternatives from a fire standpoint are the increase or decrease in fire hazard and risk that will be created. Risk is defined as the probability that an ignition will occur. Hazard is a description of the fuels complex in terms of kind, volume, arrangement, condition and location of the fuels.

The roadless area is a mixture of brushfields and old-growth Douglas-fir with a dense understory of brush. Though dead fuel loading is light over most of the area, the large amount of brush creates a high hazard. Fuels are continuous, with only a few natural breaks. These conditions lend themselves to large, high intensity fires. Adding to this is the increased response time for initial attack forces due to poor access. The result is larger fires, higher suppression costs and increased resource losses. In a developed scenario, fire hazard increases during timber harvest. As fuels are treated, the hazard is reduced. Over time, the continuity of the fuels are broken up, creating a mosaic of fuels and vegetative development. This mosaic, combined with improved access for initial attack forces, reduces the potential for large, high intensity fires. The result is smaller fires, lower suppression costs and less resource loss due to fire.

In Alternatives E and M, fuels would remain continuous over the entire area. In Alternatives G, K, and S, 45 to 49 percent of the area would be developed, creating a mosaic of fuels over time, while the remaining undeveloped area would be in 6-7 separate blocks. Alternatives A, B, C, and D would develop approximately 57 percent of the area. The remaining undeveloped areas would be broken into 3-5 separate blocks. Alternative NC would develop 63 percent of the area. In all alternatives, some of the high priority natural fuels accumulations will be treated.

In Alternatives E and M, the risk from human-caused ignition would be limited primarily to the periphery of the area due to limited access. In Alternatives G, K, and S, industrial operations would result in increased risk over 45 to 49 percent of the area, and risk from public use would be increased along the 14 to 19 miles of road. In Alternatives NC, A, B, C, and D, industrial operations would result in increased risk over 57 to 63 percent of the area, and risk from public use would be increased along 20 miles of road

Vegetation

Effects on vegetation relative to diversity and age class distribution do not significantly differ from the effects on the Forest as a whole (See Chapter IV, FEIS).

Sensitive Plants

No Botanical Areas or RNA's are proposed. A few sensitive plants are present and will be managed under appropriate Standards and Guidelines.

Air Quality

The principle agent impacting air quality in the forest environment and surrounding area is smoke from wildfire and prescribed burning. To determine the impacts of each alternative, only the effects of prescribed burning is considered. Total suspended particulates (TSP) is used as a measurement of the potential for regional haze. Alternatives E and M contribute no TSP. All other alternatives produce 32-40 tons of TSP per year.

The probability of a smoke intrusion from burning in the area impacting Roseburg or Grants Pass, both designated areas for air quality, is very low based on past performance. As the area is located in the Rogue River drainage, the probability of impacting the Wild Rogue Wilderness and Rogue corridor is moderate.

Wildlife

Unless specifically mentioned below, effects of the alternatives on wildlife indicator species and wildlife habitat in this roadless area are the same as for the Forest as a whole.

Bald Eagle/Osprey. This roadless area contains significant habitat for bald eagle and osprey, with the most important area being the corridor along the Rogue River. Within the area, bald eagles use the river as a flight corridor, they probably feed on fish resources here, and may have even nested here in the past, and may nest here in the future. In a given year, five or more osprey pairs normally nest within the roadless area along the Rogue River. In any alternative, management of eagle habitat would be governed by the Pacific Bald Eagle Recovery Plan (USDI-Fish and Wildlife Service 1986). Overall, prime habitat for eagle and osprey is maintained in alternatives which assign Potato Mountain to Backcountry Recreation (Alternatives E and M) or Supplemental Resource (Rogue River Visual--Alternatives E, G, K, and S).

Spotted Owl/Pileated Woodpecker/Pine Marten. Under all alternatives except E and M, habitat for mature/old-growth indicator species would be considerably reduced over time. This would be especially true under Alternatives A through D1, which meets Management Requirements (MR's) for wildlife species dependent on mature/old growth, but otherwise develops most of the area. Alternative NC does not meet MR's; it contains no habitat allocated for wildlife species using mature/old-growth forests.

Except for Alternative NC, a mixture of habitat enclaves to meet MR's for mature/old-growth habitat is located within the roadless area: portions of two spotted owl habitat areas, one pileated woodpecker area, and one pine marten area. At present this unroaded area supports approximately three to five pairs of spotted owls, there would be no change under Alternatives E and M. Mature/old-growth habitat would ultimately be reduced to MR levels in all other alternatives, except for Alternative NC.

Woodpeckers. Snag habitat would remain at or near 100 percent habitat capability for woodpeckers under Alternatives E and M. Snag habitat along the Rogue River would remain at or near 100 percent in all other alternatives which maintain the river corridor in a natural condition.

Black-tailed Deer/Roosevelt Elk. Big game opportunities would increase in alternatives which develop much of the area (all alternatives except E and M). Opportunities for habitat improvement projects for game animals would also be greater.

Wildlife Habitats. Five meadow areas are contained in the area (approximately 200 acres); Adams Prairie, located on the western boundary, is the most valuable meadow habitat on the Forest. The Morris Rodgers area, an important cliff/stream/forest habitat site along the Rogue River, is potential habitat for raptors. This site is specifically allocated as Supplemental Resource in Alternatives E through M, and as a Special Wildlife Site in Alternative S. General rock sites are allocated for wildlife use in Alternatives E through M, but would probably remain unaffected in Alternatives NC through D1. The potential for human disturbance of Special Wildlife Sites is reduced under Alternatives E and M. Among alternatives which assign all or part of the area to Management Areas which permit development, Alternative B, D, D1 and G, which utilize a Riparian Prescription C, provide the highest quality of riparian habitat protection for wildlife.

Wildlife Recreation Use. Estimated Wildlife/Fish User Days (WFUD's) are high on the River, and lower than average in the interior where hunters have poor access.

Visual Resource

The current inventory of Visual Quality Objectives (VQO's) is divided between the following three groups:

VQO	Acres
Retention	1,800
Partial Retention	3,300
Modification	800

The area is located within the Rogue-Illinois viewshed which is recognized for its high level of recreation use and attendant viewer concern for the scenery. Alternatives NC, A, and A-Departure would assign the area to management for inventoried VQO's, with maintenance of a natural/near natural landscape expected. Alternatives G, K, and S would also allocate the area to management for inventoried VQO's, but with the exception of the foreground area inventoried for Retention being removed from the programmed harvest in order to maintain the existing vegetative character of the river's shoreline.

Alternatives B, C, D, and D1 would assign the entire viewshed to management for a reduced level of visual objectives. Areas inventoried for Retention would be managed to achieve Partial Retention. Management activities would be evident to river users.

Alternatives E and M would maintain the roadless condition The area would be managed under the Preservation objective which exceeds the inventoried VQO's

Recreation Settings

Recreation use in the area is relatively light, most use being associated with the Wild and Scenic River. The area is heavily influenced by motorized use on surrounding road systems and the Rogue River. Projected levels of recreation demand indicate that the use will remain well within the carrying capacity over the planning period.

The isolated location will limit the ability of the area to provide a quality wilderness or primitive recreation experience. The significant value of the area with regard to the recreation resource is its beneficial effect on the recreation setting within the viewshed adjacent to the Wild and Scenic River corridor. The natural appearance of the landscape character will influence the quality of the recreation experiences available on the river.

All alternatives, except E and M, would allocate the roadless area to some degree of development. The area would be developed over time and the 3,000 acres capable of Semi-primitive Motorized recreation would shift to the Roaded Natural end of the opportunity spectrum. Access to the area and motorized opportunities would be enhanced as roads into the area are constructed. There would be a reduction in the natural appearance of the landscape character. A near natural/modified appearance is expected under Alternatives B, C, D, and D1. A natural/near natural appearance is expected in Alternatives NC, A, A-Departure, K, G, and S. In addition, Alternatives K, G, and S would remove the inventoried foreground from programmed timber harvest in order to protect the vegetative character and undeveloped river area through the roadless area.

Alternatives A, A-Departure, B, C, D, and D1 would retain the essentially undeveloped character on approximately 900 acres due to allocations to Designated Wildlife Habitat. Alternative NC would leave few acres in an undeveloped status. Alternative G, K, and S would retain undeveloped character on approxi-

mately 2,400 acres due to assignments to Supplemental Resource and Designated Wildlife Habitat These areas may or may not be contiguous, so the integrity of the unroaded areas may be compromised by the presence of motorized activities Alternatives E and M would maintain its current unroaded status. Recreation capacities would remain fixed since no new trail construction is programmed

Economic and Social

There are 5,147 acres of land identified as tentatively suitable for timber management in this unroaded area. The general effects on annual allowable sale quantity (ASQ) and long-term sustained yield (LTSY) of allocating these acres to uses that would include timber production are the same as those described in Chapter IV of the FEIS.

The estimated potential ASQ from the inventoried 5,963 acres of the Rogue Roadless Area is 0.28 MMCF. The estimated LTSY would be 0.51 MMCF. Following are the estimates of the contribution to timber production (in MMCF) from this area under each alternative:

Alternative	ASQ	LTSY
NC and D1	26	48
A, A-Dep, C, and D	24	.44
B	29	53
E and M	.00	.00
G and K	17	31
S	15	28

For projecting effects, the alternatives are grouped as: (1) Alternatives E and M which maintain unroaded status; (2) Alternatives G, K, and S which develop over half the area; and (3) Alternatives NC, A, B, C, and D which develop most of the area.

	Alternatives		
Effects (Changes Compared to Alternative A)	E and M (Unroaded)	G, K, and S	NC, A, B, C, and D (Roaded)
Direct Effects			
Timber and Road Expenditures	None	Minor Reduction	No Change
Indirect Effects			
Jobs	-22	-6	0
Annual Income (MM $)	-0 50	-0 15	0
Annual Payments to Counties (MM $)	-0.12	-0.04	0
Cumulative Effects			
Social Attitudes in Rural Communities			
Timber Related	-	-	0
Primitive Recreation	+	0	0
Fisheries	+	+	0
Wildlife Related			
Hunting	-	0	0
Old Growth	+	+	0
Mining	-	0	0

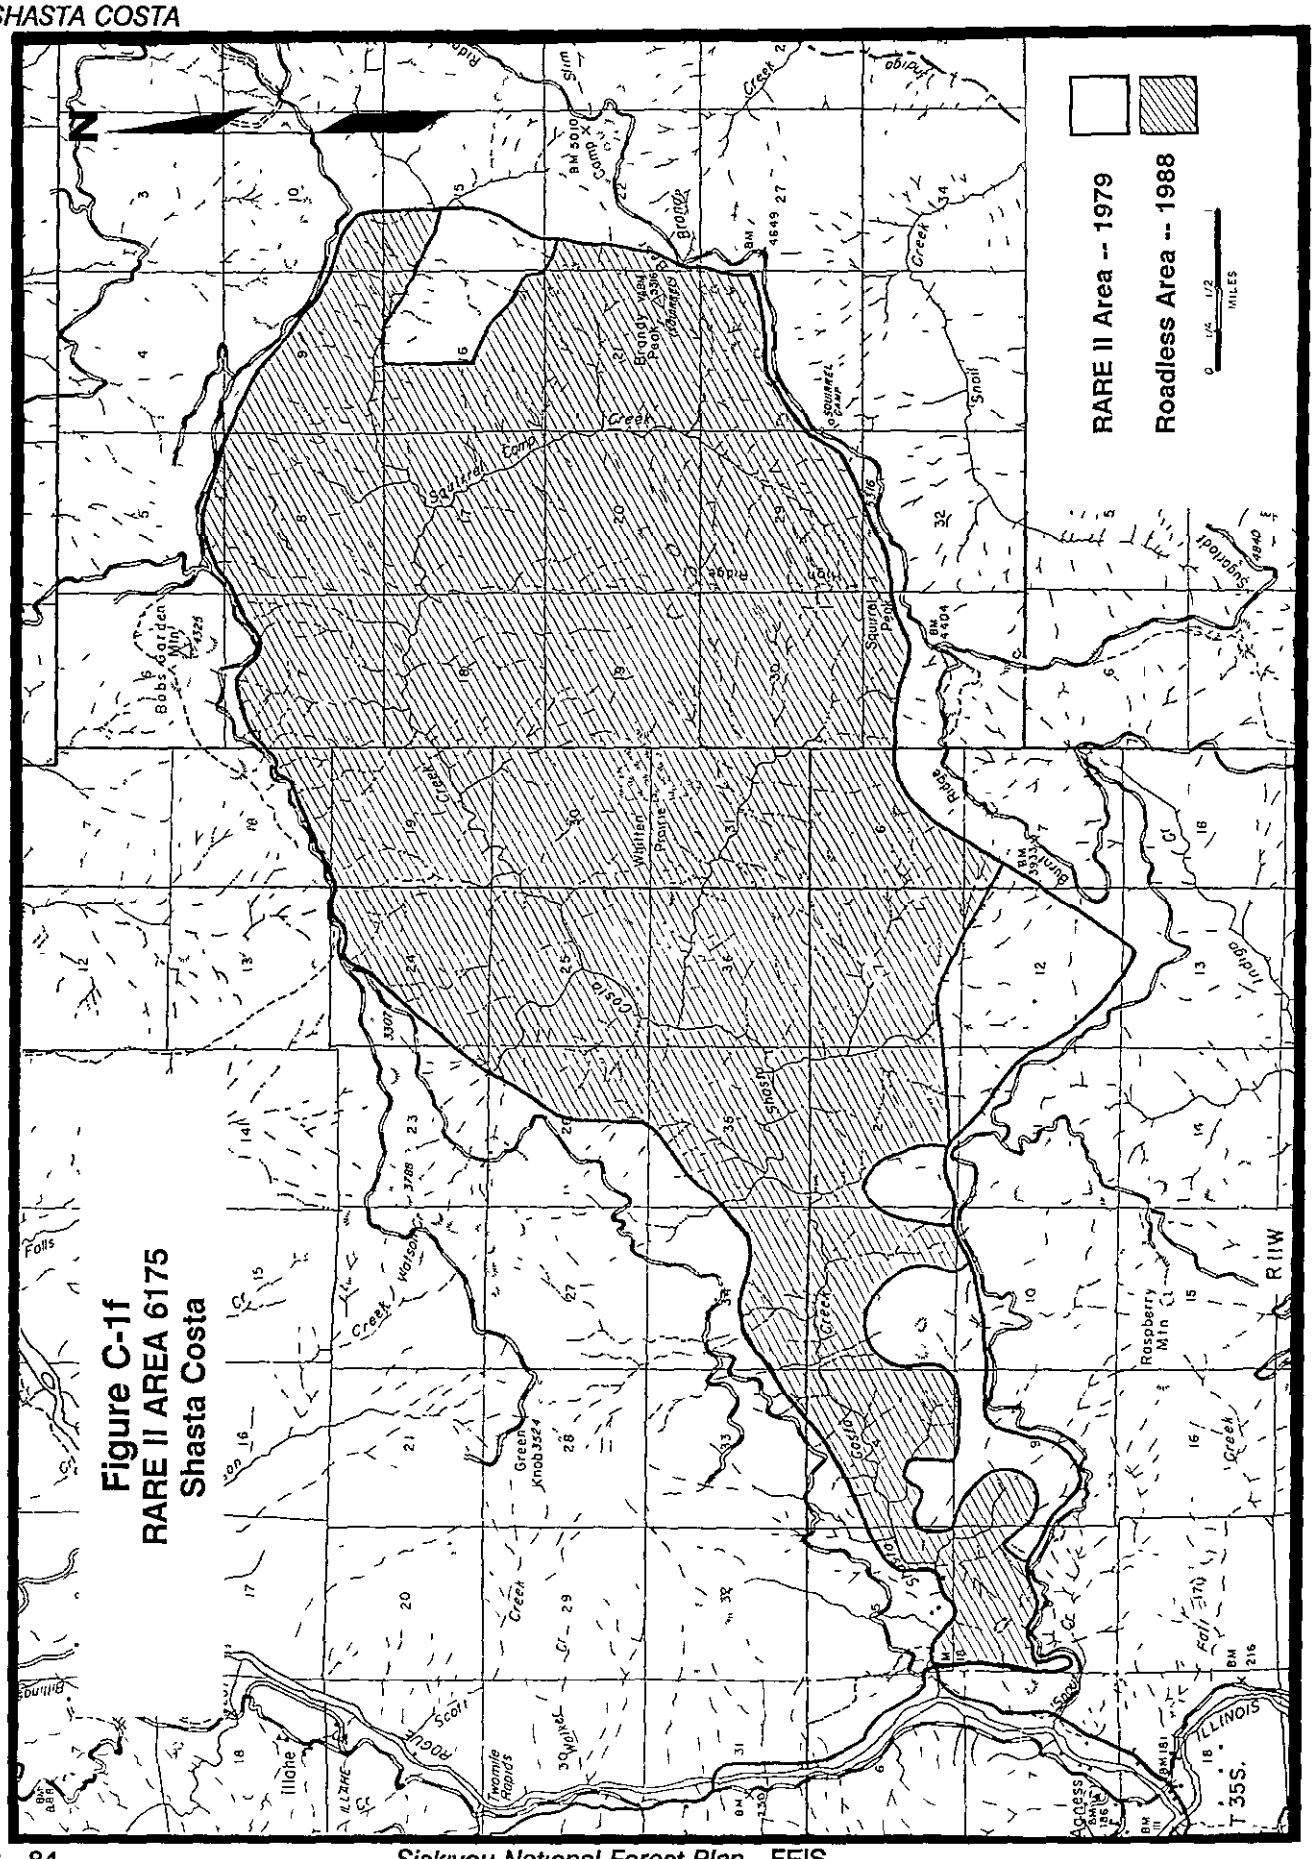
The major direct economic effect is government expenditure for the timber and associated road construction program Alternatives E and M have the biggest reduction in the timber and road expenditures The other alternatives have insignificant changes in budget expenditures.

Indirect effects are associated with jobs, income, and payments to counties. Assuming no substitution of reduced timber harvest within the area, Alternatives E and M have the biggest reduction while the other alternatives have little or no change in the number of jobs, amount of income, and payments to the counties Alternatives NC, B, and D1 have slightly greater benefits than Alternative A.

The cumulative social effects of attitudes of people can be summarized by examining the different interests of the adjacent communities Previous documentation is found in Chapters III and IV of the FEIS The positive sign indicates a feeling by special interest groups of the Forest being responsive while a negative indicates a social feeling of the Forest not being responsive to particular interests as listed. For example in Alternative E, fishing interests are predicted to feel positive about Forest management while timber interests would tend to feel the Forest is not listening to their needs. Such gains and losses may create additional conflict

MITIGATION MEASURE

No additional mitigation measures have been identified.



POTENTIAL CONFLICTS WITH OTHER JURISDICTIONS

No additional conflicts have been identified.

SHASTA COSTA No. 6175

(14,261 Acres)

DESCRIPTION

The Shasta Costa Roadless Area was inventoried for study as a potential Wilderness during the RARE II process. At that time, it contained 16,312 acres and was allocated to non-Wilderness use by the RARE II decision in January, 1979. Since then, timber sales, predominately on the south side along the lower portion of Burnt Ridge, have reduced the unroaded portion to 14,261 acres. The entire area is National Forest System land.

The Land Management Plan for the Rogue-Illinois Planning Unit (FEIS, 1979) encompasses the Shasta Costa area Management direction allocates most of the drainage to coordinated resource management to obtain full timber yield consistent with land capabilities and appropriate constraints, along with providing a high level of quality big game habitat and protecting small areas containing exceptional features. The only other management area within the drainage provides for a corridor on the main reach of Shasta Costa Creek to be managed in a near-natural condition.

Readers are directed to the Land Management Plan for a broad overview of the affected environment, evaluation of resources and management alternatives, and other requirements and constraints considered and currently implemented for the area All project activities have been analyzed under the the Plan's direction and NEPA requirements/process.

CHANGES BETWEEN DRAFT AND FINAL

Two timber sales were implemented between 1984 and 1988 that impacted the area The South Shasta Timber Sale along the southwest edge of the unroaded area, and the Squirrel Camp Timber Sale along the eastern portion of the area reduced the unroaded acres to approximately 14,261 (Refer to Figure C-1f). The remainder of the area remains as previously described.

LOCATION AND ACCESS

The Shasta Costa area is located in Curry County, Oregon, and includes most of Shasta Costa Creek drainage, which is tributary to the Rogue River one mile north of the community of Agness. Distance from the coast is approximately 20 miles. The unroaded portions of Shasta Costa Creek are completely encircled by roads. The two primary roads, Burnt Ridge and Bear Camp, are multi-purpose routes, serving heavy recreation, timber, and resource administration traffic.

PHYSIOGRAPHIC AND BIOLOGIC FEATURES

The physical location of the unroaded area spans the boundary between the Klamath Mountains and the southern extremity of the Coast Range physiographic provinces in southwestern Oregon. Elevation varies from near 100 feet above sea level to 5,318 feet at Brandy Peak. Topography is very mountainous with generally steep slopes and deeply incised canyons. Most of the area is generally well timbered, but considerable variety occurs through brushfields, hardwood stands, and a few small open grassy sites (shallow sedimentary bedrock). Douglas-fir is the primary conifer species while tanoak, madrone, and canyon live oak are important hardwoods. The ecosystem is predominately mixed evergreen with the mixed conifer type at the higher elevations.

Soil variability is great within the basin Soils are generally moderate in productivity In the western portion, soils are generally moderately deep and stable Some inclusions of unstable soils occur along contacts and along stream undercut slopes. Rocky soil surface layers are common along ridgetops and inner gorge areas In the eastern portion, natural debris slide activity has occurred frequently. Steep, incised drainages have experienced frequent debris torrents. Oversteepened streambanks are sites for continued small failures At higher elevations, soils are often shallow with a frequent surface layer of talus. Soil depth, rockiness and stability are highly variable at midslope positions. Steep, shallow and rocky soils predominate, however, deep, productive soil pockets occur frequently along benches. At midslope positions, breaks in slopes at headwalls of ephemeral drainages are often sites for soil mass failure

Average annual precipitation varies from 90 to 120 inches; dry season rainfall (May through September) averages around 8 to 10 inches. The climate is mild and heavily influenced by marine air Fog in the summer period often extends inland to elevations near 1,500 feet. Summer temperatures often exceed 90 degrees Fahrenheit.

Black-tailed deer and black bear occur within the area. Elk frequent the Burnt Ridge area Both anadromous and resident fish are present. Chinook salmon utilize the lower two miles of Shasta Costa Creek while steelhead move upstream about six miles. No known threatened or endangered species inhabit the area, although near the Rogue River the northern bald eagle may utilize a flight corridor through the unroaded area A few sensitive species do occupy the area, notably the northern spotted owl and the plant, Oregon bensonia (*Bensoniella oregana*). Oregon bensonia occupies the moist edges of Douglas-fir/true fir stands. Two other sensitive plants in the roadless area are *Allium bolanderi* and *Iliamna latibracteata*. Two watch list plants are also present: *Trillium kurabayashii*, and *Vancouveria chrysantha* Burnt Ridge, from Squirrel Peak east, is a fine Botanical area and is considered and evaluated in various Plan alternatives (see Bear Camp Botanical Area in Appendix F).

RESOURCE USES

Limited minerals development has occurred in the past, but little activity other than surficial exploration is present today. Livestock grazing occurs in the western portion for two to three months of the year. Minor upland game and moderate big game hunting takes place on the fringes of the area; interior hunting is quite limited due to steep and brushy ground. Trout fishing takes place in the lower reaches of the drainage; limited access in the upper reaches of the drainage restricts fisherman use.

The scenic attributes of the area are apparent to users of the Bear Camp and Burnt Ridge roads. Recreational use within the area is low and primarily restricted to cross-country travel. The few trails have been abandoned While use figures are not collected for the more random recreational activities, estimates of use are low at between 200 and 300 recreation visitor days (RVD's).

APPEARANCES, SURROUNDINGS, AND ATTRACTIONS

The look, or outward aspect, of the Shasta Costa watershed is that of a large "spoon-shaped" basin well clothed in conifers. Most of the east and northwest side of the watershed is developed. Distinguishing features are primarily those of heavily vegetated, steep, and highly dissected slopes with deep inner gorges. These physical details vary little with the exception of the lower reaches of Shasta Costa where open grassy areas with oak and other brush/conifer species intermix. The Squirrel Peak to Brandy Peak ridgeline (approximately two miles in length) is also open, rocky, and with widely differing vegetative types.

Conditions surrounding Shasta Costa do not vary greatly Vegetative type and landform is consistent. Man's activities have modified the environment on the ridgelines and local areas accessed for timber harvest and other purposes. The timber harvest entries have provided a mosaic of patch cuts where the new vegetation varies a few decades in age Large undeveloped areas exist a short distance to the north

and south. The upper portion of the watershed is moderately roaded and contains higher elevation true fir and a continuation of the rocky, open Burnt Ridge. Shasta Costa Creek empties into the Rogue River.

The predominant influences in this locale are heavily traveled roads. The Bear Camp Road, or Agness-Galice corridor, is the major east-west travelway through the Siskiyou. Secondly, timber harvest activities and their associated roads immediately border the unroaded area either on the same slope or immediately above along the ridgelines Fire, too, has played a major role over time in changing the vegetative mosaic of the area.

Primary attributes of Shasta Costa are proximity to the Rogue River and the community of Agness, contribution of high quality water to the Rogue, and the Burnt Ridge area. The Burnt Ridge area's scenic, floral, and geologic variety is easily accessible by good road. This higher elevation area contains sensitive and unusual plant life, open and rugged terrain, and interesting landforms The small basins just east of Brandy Peak in the Bear Camp area (outside the unroaded portions) appear to have been lightly glaciated Other than these, landscape variety is somewhat homogenous and generally reflects the features common to surrounding areas.

Shasta Costa Creek is important to the Rogue's salmonid fishery. The drainage contributes high quality water important to both onsite and offsite survival of juvenile salmon and steelhead

Elk frequent the Burnt Ridge area. Over the ridge a short distance to the north is the Wild Rogue Wilderness. The lower end of Shasta Costa is within the recreational segment of the designated Wild and Scenic Rogue River In this lower portion of Shasta Costa Creek a mile or so from the river is an early Forest Service Ranger Station site. Indians have occupied the lower reaches of Shasta Costa in both historic and prehistoric times.

CAPABILITY

MANAGEABILITY

The Shasta Costa area is so well defined and compact that there is no problem in maintaining or protecting the roadless character and values. The location does not allow complete screening from the sights and sounds of development activities. However, the size and shape of the basin is adequate to reduce off-site intrusion from adjacent roads, timber harvesting and associated noise of human activity The present boundary is suitable and recognizable on the ground. Terrain and vegetation along the boundary also provide some shielding of the interior environment from off-site sights and sounds.

NATURAL INTEGRITY AND APPEARANCE

Human influences have had little impact on the natural appearance or long-term ecological processes of Shasta Costa. The area is essentially free of disturbances. Natural balances, even where altered in the past, are intact and operating. These intangible values have been disrupted by past activity, but the activities were both minimal in extent and duration. Fire has been the factor with the greatest actual or potential for changing the area's character. Fire is the key to the long-term ecological changes and vegetative succession of the area Effects can vary by intensity and extent; duration would be limited to the period of vegetative recovery.

There are several mineral prospects located in the western portion of the area. There has been no current activity. Man's activities here are noticeable, but natural recovery has occurred on disturbed sites. An old, narrow mining road leading into the area has essentially been reduced to a trail by natural processes.

Several abandoned trails exist up Shasta Costa Creek to the falls, on High Ridge to Whitten Prairie, and along Bear Camp Ridge. None are maintained; most have nearly returned to a natural state.

The Shasta Costa Creek Falls, about a mile and a half upstream from the Rogue, presented a complete barrier to anadromous fish passage The falls are carved in bedrock and are quite scenic. In 1979, a fish ladder was constructed which allowed bypass of the falls by steelhead and fall chinook salmon.

Water quality and sedimentation from site specific sources, namely old road failures and poor drainage control, have had a minor effect on natural processes. These source areas are quite limited in extent Most have either been corrected or are returning to stable conditions.

OPPORTUNITIES FOR SOLITUDE AND PRIMITIVE EXPERIENCE

With highly broken topography and dense vegetation existing over most of the unroaded area, the natural screening provides ample opportunity for localized solitude and primitive experience The Recreation Opportunity Spectrum (ROS) inventory is split between Roaded Natural on the fringe (5,500 acres) and Semi-primitive Non-motorized (8,800 acres) in the heart of the drainage.

Size and the inferior position (physically lower) of the core of the unroaded area limits external, nonconforming sights and sounds. Conditions which constrain a totally primitive experience would be noise, dust, and minor views of activities on the borders of area Specifically, the Bear Camp Road and, to some degree, the Burnt Ridge Road compromise the area's overall naturalness.

Use of the area as a quality primitive setting is limited due to density of vegetation and steepness. Whereas few trails are maintained to promote access to the interior areas, sufficient openings exist to permit cross country foot travel. Most of the unique, interesting, or challenging features exist in the higher Burnt Ridge area and alongside Shasta Costa Creek. Due to limited recreation use and physical attributes, walking into the area a short distance would provide a feeling of solitude, adventure, and awareness of untrammeled conditions. However, the experience would not be unique as it is quite similar adjacent areas.

Recreational usage is highly dispersed. The unconfined types of recreation are camping, hunting, fishing, hiking, photography, swimming, nature study, and other miscellaneous forms. If the area remained unroaded, this type of recreational activity would remain essentially the same. Use would increase along with general trends for recreation, but would not exceed general trends A more beneficial aspect, though, is the availability of the area for recreation during the winter period.

SPECIAL FEATURES

The ridgeline of Burnt Ridge could contribute to outdoor education and/or scientific study and are is generally compatible with current activity and management direction for the locale

AVAILABILITY

RESOURCE POTENTIAL

Recreation Settings

Dispersed Other than what is provided above, the opportunity for measurable change in type or use is limited even though there is some potential for increase in total use. Trail construction, for example, could greatly increase RVD's. Capacity is not limiting.

Developed The potential for increased RVD's is greatest under a roaded environment where uses other than existing would occur. Even with motorized usage, capacity is not likely to be exceeded

Wildlife

Under unroaded conditions, wildlife numbers would remain constant unless specific management practices such as prescribed fire were implemented. As timber harvest occurs over time, elk and deer populations will increase in response to the development of forage areas Varying stages of vegetation in harvest units and along roads would promote expansion of existing herds. Populations of old-growth dependent wildlife would decrease. They would not be eliminated, however, because considerable habitat would remain along the river corridor, tributary streams, and in areas unsuitable for timber production.

Fisheries

The steelhead and salmon fisheries are extremely important to Rogue River recreational businesses and commercial fishermen Although few people actually fish Shasta Costa itself, the creek is a highly important contributor to downriver fisheries. Maintenance of the habitat through good resource management practices is essential. Enhancement of fish habitat has some potential to increase juvenile yields. This opportunity exists under either scenario, but has greater likelihood of implementation with improved access

Water

There are no man-made impoundments or diversions either existing or proposed. The fish ladder on Shasta Costa Creek provides an additional 3.5 miles of anadromous fish habitat. The potential for small hydroelectric power development may exist on the steeper tributaries of Shasta Costa Creek. There is no demand for augmenting flow. The greatest needs expressed have been for maintenance or improvement of water temperature in summer. Quality aspects for this drainage are of far greater importance than water use or development due to the high value fishery and recreational usage of the Rogue River.

Livestock

Grazing of livestock could be maintained, increased, or decreased. The small existing allotment is not critical to the permit holder's overall operations. The potential for increased use exists, but accessibility, range management, and roundup is extremely difficult. With improved access, greater utilization of transitory range would occur. Timber harvest would create temporary openings, providing increased forage.

Timber

The unroaded area contains approximately 11,370 acres of land tentatively suitable for the production of timber. The standing volume of timber is estimated at 262 MMBF. Site productivity is mostly moderate. The area is reasonably stable and can be harvested using presently available logging systems. Because of heavy vegetative competition and steep slopes, management for timber production would utilize various methods to reduce brush competition for release of crop trees.

Energy and Minerals

Activity in the form of exploration and development is low to nonexistent. An old coal mine is located outside the western boundary; it has been inactive since the 1930's. A thin layer of coal is suspected to extend into the western portion of the unroaded area. The limited extent, thinness of seam, and remoteness of markets reduces the commercial significance of this resource. Low percentage mineralizations of copper, silver, and gold are known to be present in some metavolcanic rocks within the area. The potential for other minerals exists. The area may warrant further investigation. Development of locatable minerals is unlikely in the near future. Keeping the area unroaded would limit exploration. Development of timber resources would improve road access, which could result in increased mineral activity.

Cultural

For any activity, sites will be evaluated and provided for under the applicable laws and regulations

Land Use Authorization

None existing; few expected.

MANAGEMENT CONSIDERATIONS

Ownership, including subsurface rights held by others, is not a problem. The potential for insects and disease outbreaks exists within the coniferous forest. However, actual occurrences have been minor and localized. Natural factors and management actions have substantially reduced this treat.

Fire, on the other hand, remains the most serious management consideration. The potential for major conflagrations definitely exists. If the Shasta Costa area is developed, access and intensified treatment of activity fuels would considerably lessen continuity and concentrations, reducing the probability of major resource losses. However, access also brings increased risks due to industrial activity and greater number of people in the woods. The area's dense fuels and heavy use of roads do present a management situation where considerable resource loss could occur and the character of the setting could be greatly altered. Favorable aspects are the climate, i.e., conditions are severe for a relatively short period due to coastal influences, and positioning - heavy use areas being generally above the fuels. The greatest threat, however, occurs from dispersed recreation use deep within the unroaded area. While risk is low due to few users, fire ignition at the wrong time could be disastrous.

NEED

OTHER AREAS AND PUBLIC USE

Within ten miles of Shasta Costa exist the Wild Rogue and Kalmiopsis Wildernesses, and stretches of the Wild and Scenic Rogue and Illinois Rivers. The Wild Rogue Wilderness lies immediately to the north, essentially bordering the watershed divide of Shasta Costa. To the south, the large unroaded area of the North Kalmiopsis (88,582 acres) adjoins the Kalmiopsis Wilderness (179,850 acres) and unroaded areas immediately to the south (another 142,000+ acres). The undeveloped areas south of Shasta Costa encompass an area approximately 15 miles in width and 40 miles deep. Shasta Costa connects these areas with the undeveloped and designated lands to the north. Only the two major roads which swing to both sides of Shasta Costa and associated timber harvest dissect this large unroaded land mass.

Recreation use of the unroaded areas and Wildernesses is extremely light considering the acreage involved. These areas share many of the same attributes of Shasta Costa, but are generally far more rugged and diverse in geology and vegetation (particularly areas to the south). Use in the surrounding unroaded areas is very much like Shasta Costa, most being concentrated in and along the rivers, trails, and more open and higher elevation sites.

Local users are more likely to utilize Shasta Costa than recreationists from major population centers, five to ten hours away by automobile. The coastal communities in Curry County and the interior Grants Pass and Medford areas are the most probable sources of frequent users of the area. In terms of views and experience, recreation-oriented travelers from the metropolitan areas would normally seek closer and higher quality areas.

ECOSYSTEM REPRESENTATION

The major ecotypes within Shasta Costa are well represented in other areas and the Kalmiopsis and Wild Rogue Wildernesses. The higher elevation true fir ecosystem along Burnt Ridge is not extensively repre-

sented in this locale While limited in area here, it is not unique as the ecosystem is widespread further east on the Forest and common in the western states.

PUBLIC INVOLVEMENT

Both the public and Forest managers have considerable interest and concern for the existing and future management of the larger unroaded tracts of land. For this specific area, involvement in evaluation of alternative management options for Shasta Costa began in the early 1970's. Between 1977 and 1979, the RARE II process was being finalized. Public preferences at that time indicated two-thirds of the respondents favored non-Wilderness allocation versus Wilderness; few requested the area be placed in a "further planning" status. Since RARE II, the area has been evaluated several times for development through site specific project planning and broad-area analyses (still project level).

All units of local and state governments responding have cited the effects on local economy and community stability, loss of timber receipts, and multiple uses that would be foregone if allocated to unroaded status. Most respondents voiced the same reasons for opposition. Few environmental groups have taken a hard position on this area based on it's unroaded attributes Not until the latter half of the 1980's have groups seriously suggested all inventoried roadless areas be carried in their undeveloped state; even then, Shasta Costa ranked relatively low in priority.

The Rogue-Illinois Land Management Plan again addressed the unroaded Shasta Costa area. Several responses from the public stated a Wilderness alternative preference; five specifically called for protecting the fishery and water quality values of Shasta Costa Creek through preservation The majority theme of input, though, was to direct management toward multiple use with a quality emphasis.

In the current Forest Planning process, the unroaded area question has remained a major issue. Beginning with "scoping" in 1979 to public meetings and workshops through 1985, public input about this specific area has been requested. Comments on several of the inventoried roadless areas on the Forest has been extensive. Shasta Costa, however, did not receive the same intensity of concern or advocation of protective status as several adjacent areas. This may have been due more to the early assessments and personal preferences of the area's characteristics than a thorough analysis of it's attributes.

Immediately before and after release of the Forest Plan DEIS, the roadless area question and potential for Wilderness moved to a new theatre. Beginning in 1986, there was a movement to tie the Wild Rogue Wilderness and all contiguous unroaded areas to the south (including Shasta Costa) with the large Kalmiopsis Wilderness. This large block of land was promoted by several individuals and organizations as a potential National Park As discussed in Chapter II of the FEIS, the proposal was not entertained as an alternative evaluated in detail.

ENVIRONMENTAL CONSEQUENCES

The significant effects of each alternative are presented in Chapter IV of the FEIS. Additional site specific effects, mitigations, and potential conflicts are presented here. The Standards and Guidelines for each alternative were considered when evaluating the effects of implementation.

SIGNIFICANT EFFECTS

Cultural Resources

The Shasta Costa Roadless Area has both historic and prehistoric sites within its boundaries, some requiring evaluation by an archaeologist. The area had prehistoric use by Indians along the Shasta Costa drainage. Hunting, gathering and fishing activities were pursued here. Historically, the area has been used by homesteaders. An abandoned homestead site is located in Whitten Prairie in the center of the area

Alternative NC has the greatest amount of roading, thereby the highest potential for disturbing cultural resources. Valuable sites, though, can then be protected via avoidance or conserved via data recovery. Alternative E and M calls for an unroaded regime which minimizes the need for cultural resource inventory

Energy and Minerals

The following table summarizes the estimated mineral potential and access limitations The acreages shown are subject to change due to the current withdrawal review by the Bureau of Land Management (BLM), and differences found for site specific needs included in any subsequent withdrawal applications·

	Mineral Potential (Acres)			
Access Restrictions	High	Moderate	Low	Total
Withdrawn	-	100	100	200
High	-	-	-	-
Moderate	-	-	-	-
Low	-	300	13,800	14,100
Total	-	400	13,900	14,300

Improvements

Roads The 11,370 acres tentatively suitable for timber production could generate about 51 miles of new road for timber harvest. Roads for other purposes would be minor, if any All the roads would be dead-end local roads built when needed to access timber harvest units. Some mileage would remain open to passenger car use, depending on the alternative, and other roads would be open to only high clearance vehicles or closed between projects. The following table shows road mileage in the area by alternative.

Alternative	Total Miles	Miles Open to Passenger Car	Miles Open to High Clearance	Miles Closed
NC and A	48	12	17	19
B	47	12	16	19
C	51	8	23	20
D	47	14	14	19
E and M	0	0	0	0
G	40	0	16	24
K and S	47	12	7	28

Alternatives E and M would have minimal effect as no roads are built. Alternate G would have the least miles built of the roaded options, but would not maintain any roads open for passenger cars Alternatives NC, A, B, C, D, K, and S would be mostly roaded Alternate C, with none of the Supplemental Resource areas, would have the highest mileage Alternatives G, K, and S have 60 percent of the roads closed

The road system would follow ridges off the main roads on the boundary or extend existing midslope roads. The ridge roads would change to midslope roads as the ridges steepen. The midslope roads would cross small creeks and draws None of the roads would be expected to cross the main Shasta Costa Creek nor the main laterals where inhabited by fish Some full bench ground would be crossed by roads with excess excavated material hauled to stable disposal sites. Many of the roads, especially those on ridges and in harvested units, would be visible from the Bear Camp Road.

Trails. No trail construction is programmed.

Developed Recreation Sites. No construction is programmed.

Wildlife and Fish Habitat Structural Improvements. All alternatives, except E and M, would facilitate the installation of structures by providing better access into the area.

Wilderness Potential

The Shasta Costa area has been inventoried according to ROS criteria and is capable of providing 8,800 acres of Semi-primitive Non-motorized recreation opportunities and 5,500 acres of Roaded Natural recreation opportunities The carrying capacity for the area is estimated at 10,600 RVD's. This figure is high since the coefficient developed for Roaded Natural is based on the assumption of presence of roads. Current use is very low and is attributed primarily to local users.

No trails are programmed for construction due to the low levels of use reported. Recreation demand projections indicate that levels of use will remain well within the carrying capacity over the planning period.

All alternatives, except E and M, would assign the area to multiple resource management objectives. Under these, the area would be developed over time and Semi-primitive recreation opportunities currently available would shift to the Roaded Natural end of the opportunity spectrum. The change would result in loss of Wilderness potential. Alternatives E and M would maintain the area in a roadless condition, providing additional capacity for the existing ROS recreation opportunities The Shasta Costa Roadless Area, however, is not recommended for Wilderness designation in any alternative.

How much of the inventoried roadless area remains unroaded by alternative can be evaluated by either assessing a combination of Management Areas 1-9 (which retain essentially undeveloped conditions), or by viewing the spatial arrangement of blocks of undeveloped area at the end of a given period of time Management Areas may or may not be contiguous, so the integrity of the roadless area as a whole may be compromised by management around them. The following table provides a spatial estimate of acres remaining unroaded at the end of specific decades; these figures differ from the Management Area 1-9 acres in that the minimum criteria is based on the area either (1) bordering designated Wilderness, or (2) being 5,000 acres or greater:

Alternative	Acres Remaining End of Decade 1/		
	1	2	5
A, A-Dep and NC	0	0	0
B, C, D and D1	0	0	0
E and M	14,300	14,300	14,300
G	5,200	5,200	5,200
K	0	0	0
S	0	0	0

1/ Minimum criteria is 5,000 unroaded contiguous acres or adjacent to designated Wilderness.

Wild and Scenic Rivers

Some of the area near the mouth of Shasta Costa Creek is visible to river users. The upper end of the area is visible to river users returning to Grants Pass via the Bear Camp Road. The assignment of the area to roaded or roadless management objectives will not effect the management of the Rogue Wild and Scenic River or recreation experience of river users The recreation setting is currently maintained through the use of VQO's which were assigned to the area in response to both the designation of the river as Wild and Scenic and to the high level of recreation use that occurs on the river.

Alternatives NC, A, A-Departure, and G would not maintain the area in a roadless condition, but would manage the area to achieve inventoried visual objectives, resulting in some modifications in the area which may be visible to river users Alternatives B, C, D, and D1 would assign the area to a reduced scheme of visual objectives. The lower end of the area would be managed to achieve Partial Retention in response to river use. The upper area would be managed to achieve the Modification visual objective, resulting in limited visible alterations to the landscape in the background as seen from the river

Alternatives K, and S provide for no programmed harvest of the foreground areas adjacent to the Rogue River. It would be managed under the Supplemental Resource area; the VQO is assigned in response to high levels of recreation use on the river The rest of the area would be managed to achieve the Partial Retention objective, resulting in some modifications to the Forest setting as the area is developed. Alternatives E and M would assign the area to roadless management objectives

Soil, Water, and Fish

No impacts are associated with Alternatives E and M because no soil disturbing activities will occur All other alternatives allocate all or part of the area to Management Areas which permit development. The environmental effects of timber harvest and road building are discussed in Chapter IV of the FEIS

The risk of degrading the soil, water, and fish resource increases with more timber harvest and road building The soils of the Shasta Costa area have a moderate to high hazard associated with road construction impacts Sensitive soils and difficult terrain indicate that there is a moderate risk to the soil, water, and fish resources from allocations found in Alternatives A, A-Departure, B, D, D1, K, and S. Alternatives NC and C have slightly more activity, thus a slightly higher potential for impact. Alternative G, with a reduced level of development, should result in a slightly lower potential impact.

Fire

The effects of the alternatives from a fire standpoint are the increase or decrease in fire hazard and risk that will be created. Risk is defined as the probability that an ignition will occur. Hazard is a description of the fuels complex in terms of kind, volume, arrangement, condition and location of the fuels

Fuel types in the Shasta Costa area quite variable due to aspect differences and a wide range of elevations. Fuels are continuous over the entire area, except for a few breaks on ridge tops. A large part of this area is old-growth Douglas fir with moderate to heavy understories of brush and hardwood. On more southerly slopes, stands of pure hardwood are numerous, with a large number of snags intermixed Fuel loadings are light to moderate

In an undeveloped scenario, fuel accumulations would increase and fuel continuity would remain the same or increase. These conditions lend themselves to large, high intensity fires. Adding to this is the increased response time for initial attack forces due to poor access. The result is higher suppression costs and increased resource losses. In a developed scenario, the fire hazard increases at the time of timber harvest. As fuels are treated, the fire hazard is reduced. Over time, the continuity of fuels is broken up, creating a mosaic of fuels and vegetative development. This mosaic, combined with improved access, reduces the potential for large, high intensity fires The result is lower suppression costs and less resource damage.

In Alternatives E and M, all of the area would remain undeveloped, with fuels remaining continuous over the entire area In Alternative G, 42 percent of the area would be developed, creating a mosaic of fuels over time, while the remaining undeveloped area would be in 5 separate blocks. Alternatives NC, A, B, C, D, K, and S would develop 66 to 79 percent of the area. The remaining undeveloped areas would be broken into 4-9 separate blocks.

In undeveloped areas, the risk of ignition is low due to the low levels of human use As development occurs, risk increases with road construction, timber harvest, and treatment of the activity slash. As access improves, the level of dispersed recreation and other public use increases, with an increased risk of human-caused fires Both developed and undeveloped areas will have similar risk levels for lightning fires.

In Alternatives E and M, the risk from human-caused ignition would be limited primarily to the periphery of the area due to limited access. In Alternative G, industrial operations would result in increased risk over 42 percent of the area, and risk from public use would be increased along the 40 miles of road. Alternatives NC, A, B, C, D, K, and S would result in increased risk over 66 to 79 percent of the area, and risk from public use would be increased along the 47 to 51 miles of road in the area.

Vegetation

Effects on vegetation relative to diversity and age class distribution do not significantly differ from the effects on the Forest as a whole (See Chapter IV, FEIS).

Sensitive Plants

Alternatives G and M include the Bear Camp Botanical Area, Option #4, most being included in the unroaded area Three sensitive plants and two monitor list plants are found in the Shasta Costa area. Sensitive plants are protected through application of appropriate Standards and Guidelines. For more detail on the proposed Bear Camp Botanical Area, see Appendix F.

Botanical Areas, by Alternative *1/* (Tentatively suitable for timber production)

Area Name	*Tentatively* Suitable (Acres)	Alternative (Acres) Priority Ranking	NC, A, B, C, D, E, K, and S	G and M
Bear Camp Option 4	1,539	10	-	2,314

1/ Total acres for Option 4 are shown Only a portion of Option 4 is actually within the Shasta Costa Roadless Area

Air Quality

The principle agent impacting air quality in the forest environment and surrounding areas is smoke from wildfire and prescribed burning. Only impacts on alternatives from prescribed burning are considered. The effect of smoke is a temporary reduction in visibility in an area. Total suspended particulates (TSP) is used as the measurement of local and regional haze. Alternatives E and M would contribute no TSP. Alternatives NC, A, B, C, D, G, K, and S would produce 46-60 tons of TSP per year.

The probability of a smoke intrusion from burning in the roadless area impacting Grants Pass, a designated area for air quality, is very low, based on past performance. The probability of impacting the Wild Rogue Wilderness or the Rogue corridor is low.

Wildlife

Unless specifically mentioned below, effects of the alternatives on wildlife indicator species and wildlife habitat in this roadless area are the same as for the Forest as a whole.

Bald Eagle/Osprey. Bald eagles and osprey may occasionally use the lower Shasta Costa drainage as a flight corridor In any alternative, management of eagle habitat would be governed by the Pacific Bald Eagle Recovery Plan (USDI-Fish and Wildlife Service 1986). Overall, alternatives which allocate the Shasta Costa Roadless Area to Backcountry Recreation (Alternatives E and M) or Supplemental Resource (all alternatives except C) would maintain current habitat values near the Rogue River.

Spotted Owl/Pileated Woodpecker/Pine Marten. Under all alternatives except E and M, habitat for mature/old-growth indicator species would be considerably reduced over time. This would be especially true under Alternative C, which meets Management Requirements (MR's) for mature/old-growth wildlife species, but otherwise allocates most of the area to timber management (no Supplemental Resource areas allocated). Alternative NC does not meet MR's; it contains no habitat allocations for wildlife species using mature/old-growth forests.

Except for Alternative NC, mature/old-growth habitat would remain at present levels under Alternatives E and M Wildlife species, which do best in secluded areas, such as cougar, would be best served by these alternatives, both alternatives also provide a corridor of mature/old-growth habitat linking the other roadless areas to the Kalmiopsis and Wild Rogue Wildernesses.

Except for Alternative NC, a mixture of habitat enclaves to meet MR's for mature/old-growth habitat are located within the roadless area: two for pileated woodpeckers and one for pine marten. This area presently supports approximately five pairs of spotted owls No change will occur under Alternatives E and M. Mature/old-growth habitat would ultimately be reduced to MR levels (no spotted owls) in other alternatives. In Alternative NC, habitat would be reduced below MR levels.

Woodpeckers. Snag habitat would remain at or near 100 percent habitat capability for woodpeckers under Alternatives E and M

Black-tailed Deer/Roosevelt Elk Big game management opportunities would increase under development (all alternatives except E and M). Opportunities for habitat improvement projects for game animals would also be greater. Meadow habitat in the western portion of the area is used extensively by deer and elk, and would be maintained under all alternatives, although meadow buffers are not protected in Alternatives NC, A, and A-Departure.

Wildlife Habitats. Six meadow areas, mostly on the western side, occur within the unroaded area (approximately 375 acres) A few cliff/rock sites area present in the area (165 acres). Meadow/cliff habitat will be maintained under all alternatives, although potential for human disturbance is reduced under Alternatives E and M, which maintain the unroaded status. Among the alternatives which allocate all or part of the area to Management Areas which permit development, Alternative B, D, D1, and G, which utilize a Riparian Prescription C, provide the highest quality of riparian habitat for wildlife. Alternatives B, D, D1, G, K, and S also allocate Shasta Costa Creek as a Supplemental Resource area

Wildlife Recreation Use. Estimated Wildlife/Fish User Days (WFUD's) currently attributed to the area are low because human use of the area is less than in roaded areas. Fewer hunters use unroaded areas and non-hunters generally stay on the few trails Alternatives E and M produce fewest WFUD's

Visual Resource

The following is the current Visual Quality Objective (VQO's) inventory based on visibility of the area from major recreation travel routes or use areas (specifically, the Rogue River and the Bear Camp Road):

VQO	Acres
Retention	5,600
Partial Retention	8,500
Modification	100

Alternatives NC, A, A-Departure, B, and G would assign the area to management for inventoried visual objectives and would impact the visuals less intensively than allocations to a reduced visual scheme. The area is in a natural appearing (undisturbed) condition. Under these management alternatives, the area would appear as slightly altered within the first decade. A near natural/modified appearance is expected in Alternatives NC, A, A-Departure, and G; a modified Forest setting is expected in Alternative B

Alternatives C, D, and D1 would assign the entire viewshed to management with a reduced level of visual objectives. Areas inventoried for Retention and Partial Retention would be managed to achieve the Visual Quality Objective of Modification. The viewshed would appear heavily altered within the first decade. Alternatives K, and S would also assign the area to management for a reduced level of Visual Management. However, the entire Bear Camp viewshed would be managed to achieve the Partial Retention objective in response to high levels of recreation traffic on the Bear Camp Road. The area would appear as slightly altered-altered at the end of the first decade.

Alternatives E and M would manage the area above the inventoried VQO's. The visual objective of Preservation would be achieved, the area retaining a natural appearing condition over the planning period.

Recreation Settings

Recreation use is very light. Projected levels of recreation demand indicate that the use will remain well within the carrying capacity over the planning period. The influence of management activities on adjacent lands limits the area's ability to provide a quality wilderness or primitive recreation experience.

Under Alternatives NC, A, A-Departure, B, and G, approximately 8,800 acres capable of Semi-primitive Non-motorized recreation would shift to the Roaded Natural end of the opportunity spectrum Access to the area and motorized opportunities would be enhanced as roads into the area are constructed.

Under Alternatives C, D, and D1, the inventoried Semi-primitive Non-motorized condition would shift to Roaded Modified by the end of the first decade. Alternatives K, and S would shift the inventoried Semi-primitive Non-motorized condition to the motorized end of the opportunity spectrum Roaded recreation opportunities would be enhanced as a result of timber-related road construction. Any Wilderness potential would be lost.

Alternatives A and A-Departure would retain the essentially undeveloped character on 1,900 acres, with Alternative NC retaining the least (900 acres). Alternatives K, and S would retain essentially undeveloped character on 2,800 and 3,000 acres, respectively. Approximately 2,400 acres in the D alternatives would remain undeveloped. Alternative G would retain an undeveloped character on 5,200 acres due to allocations to Botanical, Supplemental Resource, and Designated Wildlife Habitat. These areas may or may not be contiguous, so the integrity of the roadless area may be compromised by the presence of adjacent motorized activities (See **Wilderness Potential**). Alternative E and M would remain unchanged, no new trails would be constructed. Any wilderness character would be maintained.

Economic and Social

There are 11,370 acres of land identified as tentatively suitable for timber management in this unroaded area The general effects on annual allowable sale quantity (ASQ) and long-term sustained yield (LTSY) of allocating these acres to uses that would include timber production are the same as those described in Chapter IV of the FEIS.

The estimated potential ASQ from the entire inventoried 14,261 acres of the Shasta Costa Roadless Area is 0.63 MMCF. The estimated LTSY would be 1.14 MMCF. Following are the estimates of the contribution to timber production (in MMCF) from this area under each alternative:

Alternative	ASQ	LTSY
NC	59	1 10
A, A-Dep, C, and D1	.54	98
B	.63	1 23
D	.52	95
E and M	00	.00
G	40	73
K and S	50	.90

For projecting effects, the alternatives are grouped into three areas: (1) Alternatives E and M, as unroaded; (2) Alternatives G, which develops over half the area; (3) Alternatives K and S, which develop much of the area; and (4) Alternatives NC, A, B, C, and D, which develop most of the area.

Effects (Changes Compared to Alternative A)	Alternatives			
	E and M (Unroaded)	G	K and S	NC, A, B, C and D (Roaded)
Direct Effects				
Timber and Road Expenditures	None	Reduced	Minor Change	No Change
Indirect Effects				
Jobs	-49	-13	-4	0
Annual Income (MM $)	-1.13	-0.29	-0 08	0
Annual Payments to Counties (MM $)	-0 27	-0 07	-0 02	0
Cumulative Effects				
Attitudes of Communities in the Local Area				
Timber Related	-	-	-	0
Primitive Recreation	+	0	0	0
Fisheries	+	+	+	0
Wildlife Related				
Hunting	-	-	0	0
Old-Growth	+	+	0	0
Mining	-	-	0	0

The major direct economic effect on government expenditures of the alternatives is insignificant except for expenditures for the timber and associated road construction program. Alternatives E, G, and M have the biggest reduction in the timber and road expenditures. The other alternatives have insignificant changes in budget expenditures

The indirect effects are associated with jobs, income, and payments to counties. Assuming no substitution of reduced timber harvest within the area of influence, Alternatives E and M have the biggest reduction while the Alternatives G, K, and S have small decreases compared to Alternative A, while Alternative NC and B have slight benefits.

The cumulative social effects of attitudes of people can be summarized by examining the different interests of the adjacent communities Previous documentation is found in Chapters III and IV of the FEIS. The positive sign indicates a feeling by special interest groups of the Forest being responsive to a particular interest while a negative sign indicates a social feeling of the Forest not being responsive to the particular interests as listed. For example, in Alternative E, interests concerned with preserving old-growth are predicted to feel positive about forest management while timber interests are predicted to feel the Forest is ignoring their interests. Such gains and losses may create additional conflict.

MITIGATION MEASURES

No additional mitigation measures have been identified beyond those already listed for each alternative.

POTENTIAL CONFLICTS WITH OTHER JURISDICTIONS

No additional conflicts have been identified.

DESCRIPTION

STATUS OF ROADLESS AREAS

This narrative describes both the North Kalmiopsis and Kalmiopsis Addition Roadless Areas. Discussion of the North Kalmiopsis also pertains to the Kalmiopsis Addition, unless noted otherwise.

The North Kalmiopsis and Kalmiopsis Addition have similar characteristics and are located in close proximity to each other. They were inventoried for study as potential additions to the Kalmiopsis Wilderness during the RARE II process. Originally inventoried at 113,254 and 1,178 acres, respectively, they were allocated to non-Wilderness use by the RARE II decision in January, 1979. The North Kalmiopsis has been revised to 88,582 acres because of timber sales and associated roading. Most of the roadless area is National Forest System land; only the old homestead properties in the lower Illinois River area at Indian Flat, Conners Place, and Briggs Ranch are in private ownership (110 acres total) The Kalmiopsis Addition has not changed in size.

In the late 1970's, the Chetco-Grayback and Rogue-Illinois Land Management Plans were finalized (FEIS, 1979) Management direction from these documents allocated these areas to largely coordinated resource management (Management Area 1) to obtain full timber yield consistent with land capabilities and appropriate constraints, along with providing a high level of quality big game habitat and protecting small areas containing exceptional features The following Management Areas (2, 5, 6, 8, and 10) contain direction for other, more specialized land allocations:

Management Area 2 essentially covers the viewshed along the lower Wild section of the designated Wild and Scenic Illinois River just outside the Kalmiopsis Wilderness. Dispersed recreation is the primary theme, with other resource uses and development consistent with this goal. The area covers over 5,700 acres on both sides of the Illinois River for approximately 5 miles (to Oak Flat).

Management Area 5 was managed as a Wild River. In 1984, the Illinois River was designated as a National Wild and Scenic River; this reach remains classified and managed as a Wild River.

Management Area 6 contains stream corridors of an average 1/8 mile horizontal distance from each bank designed to protect or enhance fishery habitat, water quality, and old-growth forest characteristics These supplemental fisheries/watershed areas have been extended to stream reaches on Silver, Lawson, Briggs and Indigo Creeks, and along the Chetco River.

Management Area 8 of 400 acres is a scenic area containing Silver Creek Falls. Management is oriented to preserving the primitive character and outstanding scenic attractions for recreation.

Management Area 10, the Big Craggies Botanical Area (860 acres outside of the Wilderness), is managed to preserve the area's primitive character and outstanding botanical features.

Complete descriptions of these management areas can be found in the two Land Management Plans. Readers are directed to these documents for a broad overview of the affected environment, evaluation of resources and management alternatives, and other requirements and constraints considered and currently implemented for the area. Since implementation of the Land Management Plans in 1979, all project activities, e.g., timber harvest, fishery enhancement, etc , have been analyzed under their direction and NEPA requirements/process

CHANGES BETWEEN DRAFT AND FINAL

During the period from 1984 to 1988, the inventoried North Kalmiopsis Roadless Area was significantly impacted by the Silver Fire in 1987, and to a lesser extent by various timber sales (Refer to Figure C-1g) This reduced the unroaded area to approximately 88,600 acres. Approximately 2,000 acres of the difference is attributable to timber sales not associated with the 1987 fire. The balance of 19,000 acres was a direct result of the Silver Fire Recovery Project FEIS and Record of Decision (1988).

Preparation of a salvage project of fire-killed timber and other resource recovery projects followed a few months behind the 96,540 acre fire. The fire burned burned 41,100 acres in the unroaded North Kalmiopsis and 53,000 acres in the Kalmiopsis Wilderness. While proposed new roading was limited to 20 miles, a Congressional rider on the 1989 Appropriations Act reduced actual road construction to 13 miles (stopping construction from extending west and accessing the lower slopes of Bald Mountain). Whereas little roading is involved, mostly helicopter and some skyline salvage units created nonconforming features on the undeveloped landscape.

Tremendous efforts were taken to involve the public in that decision-making process. News media and public meetings continually kept the public informed. The final decision was a balance between the eight issues raised during the scoping process, and the rapid recovery of the area. The area's Wilderness potential and characteristics were evaluated in the project analysis.

Due to the important interaction between the Silver Fire and the inventoried North Kalmiopsis Roadless Area, a detailed description of the fire's impact to the unroaded areas character and resources, by alternative, was provided in the Silver Fire Recovery Project FEIS. This project FEIS is incorporated by reference here to complement the description and analysis of this area.

The impacts of the fire on the resources within the North Kalmiopsis and its unroaded character were discussed in the Silver Fire Recovery Project FEIS, and have been updated in this discussion of Alternatives NC through S. This approach will facilitate the comparison of alternatives in Appendix C. An analysis of the fire impacts to the Forest's unroaded areas is further discussed in the Siskiyou National Forest Land and Resource Management Plan FEIS (1988), of which this appendix is a part, and under the heading **1987 FIRES** in this section the appendix.

As a result of the Omnibus Oregon Wild and Scenic Rivers Act of 1988, Chetco River was added to the National Wild and Scenic Rivers System. The new designation affects the acreage array and, to a limited degree, discussion throughout the text. The reach of the Chetco River from the Wilderness boundary downstream to Mislatnah Creek lies within the inventoried roadless area This reach was Congressionally classified as a Wild segment from the Wilderness to Boulder Creek, and Scenic from there to Mislatnah. Due to the very recent passage of the Act, Management Area acreages (Table C-5a) and analysis have not been updated to reflect the changes. Alternative S is slightly different than the Congressional classification in that the entire reach is carried as a Wild River Management Area. Any alternative selected in the Record of Decision and displayed in the Forest Plan will display the new designation.

LOCATION AND ACCESS

The North Kalmiopsis is located in Josephine and Curry Counties, Oregon. The area is a large meandering area that is in five principal parts (See Figure C-1g). These five surround the north half of the Kalmiopsis Wilderness. The northern, and largest part, contains four important tributaries to the Illinois River: Silver, Indigo, Lawson, and Horse Sign Creeks. The western portion drains to the Chetco River; the eastern part faces into the middle Illinois River The Kalmiopsis Addition is on the west side of the Kalmiopsis Wilderness and slightly south of the Chetco River. It contains part of the headwaters of Boulder Creek which flows back into the Wilderness to join the Chetco River.

The North Kalmiopsis area is accessed from the west through the Oregon coastal towns of Gold Beach and Brookings, and from the Grants Pass and Cave Junction communities from the east Travel time by vehicle is about one to two hours from these local communities. Several roads within the Siskiyou National Forest provide access to the fringes of portions of the unroaded areas. Several trails also lead deep into the interior of the northern portion.

PHYSIOGRAPHIC AND BIOLOGIC FEATURES

Physical location of the area is on the western side of the coast range (Klamath Mountain Geologic Province) in southwestern Oregon. Elevation varies from about 200 feet at Oak Flat near Agness to slightly over 5,000 feet at Pearsoll and Fish Hook Peaks. The area is extremely mountainous and has steep, highly dissected slopes with large, deep canyons.

Vegetation varies from well-forested lands to brushfields, hardwood stands, grassy prairies, and sites with only scattered trees and sparse cover due to chemical imbalance of soils derived from ultramafic rock. The ecosystem is primarily mixed evergreen with small areas of mixed conifer at higher elevations. Tree species in the area include: Douglas-fir, sugar pine, Port-Orford-cedar, white fir, tanoak, Pacific madrone, canyon live oak, Jeffrey pine, knobcone pine, incense cedar, and western white pine.

Soil variability is pronounced within the North Kalmiopsis. Silver and Indigo Creek watersheds are dominated by soils derived from Dothan sandstone. Deep soil areas, primarily found in the upper slope positions, are extremely productive Shallower soils and steeper slopes become more prominent in middle and lower slope positions Rock outcrops and evidence of debris slide activity also increase downslope. Talus rock is often accumulated in swales and draws Areas just above stream channels are generally greatly oversteepened and consist of either rock bluffs or talus and slide material Much of this high risk site is currently within the supplementary fisheries/watershed area.

Upper portions of Silver Creek contain soils of intrusive-igneous origin which are less productive than the Dolthan soils. These soils are very unstable with very large slides occurring frequently along the lower inner-gorge stream channels Much of this land is classified as unsuitable for timber production

Soils west of the Illinois River and largely within the Lawson and Horse Sign Creek drainages are not as oversteepened and dissected as the Silver and Indigo watersheds. However, considerable mass movement activity is occurring along toe slope positions within the drainages, generally where stream meanders have undercut sensitive slopes. With the exception of serpentine and rock outcrop areas, the soils are moderately productive.

In contrast, the lower reaches of Panther Creek and Briggs Creek on the east side of the roadless area, and the Mislatnah portion on the west side, have soils of low to moderate productivity. Productivity is limited by the occurrence of ultramafic parent material or extremely shallow, rocky soils. In addition, a high percentage of the land area is actively unstable Much of these areas have been removed from the suitable land base.

Annual precipitation ranges from 90 to 120 inches, but reaches 140 inches in the southwestern portion An average 9 to 16 inches occurs during the dry season (May through September). Summer temperatures in the lower elevations get quite warm, occasionally attaining 100 degrees Fahrenheit along the lower Illinois River. For the most part, the climate is fairly mild and heavily influenced by marine air, the Pacific being only 15 to 30 miles west.

Populations of black-tailed deer, Roosevelt elk, and black bear occur within the area. Both anadromous and resident fish are present Steelhead and salmon utilize most of the area's major streams and many of their tributaries.

An active peregrine falcon nest is located within the roadless area. It is possible that bald eagles utilized potential habitat along the Illinois and Chetco Rivers. An active osprey nest is located on the Illinois River in the southeast corner of the area; other potential nesting sites exist along the Illinois and Chetco Rivers Old-growth forests provide habitat for dependent animals such as the northern spotted owl.

The following sensitive plants are known to occur in the North Kalmiopsis: *Arabis Koehleri var. stipitata*, *Arctostaphylos hispidula*, *Bensoniella oregana*, *Carex scabriuscula*, *Brodiaea ida-maia*, *Cypripedium californicum*, *Cypripedium fasciculatum*, *Erigeron cervinus*, *Monardella purpurea*, and *Sophora leachiana*. Uncommon plants in the area include: *Arabis aculeolata*, *Calypso bulbosa*, *Iris Innominata*, *Iris chrysophylla*, *Horkelia sericata*, *Lomatium howellii*, *Phacelia corymbosa*, *Saxifraga howellii*, *Trillium rivale*, *Vancouveria planipetala*, *Eburophyton austinae*, *Darlingtonia californica*, *Kalmiopsis leachiana*, and *Pellaea brachyptera*.

RESOURCE USES

Cultural background for the area indicates that Native Americans inhabiting the Illinois River basin occupied or had activities in numerous sites, particularly on the river and stream benches, and alongside natural prairie openings. Several vision quest sites also were used. Summer camps and use areas have been identified on high ridge areas. Sites along the creeks indicate that specialized activities of toolmaking and ritual sweating were carried out, rather than long-term habitation. Use of these sites were abandoned by 1856 following the Rogue River Indian wars. At that time, all of the surviving Indians of southwestern Oregon were removed to reservations at Siletz and Grand Ronde, Oregon.

Shortly after the Indian Wars, settlers began filtering into the area. The first records on the Nancy Creek Cabin and mine date back to early 1890's. Thereafter (primarily in the 1910-20 period), additional cabins were constructed. Only the Nancy Creek Cabin remains. This cabin is now occupied by a volunteer to provide needed maintenance, although former squatters have altered the historical integrity of the building The Briggs Ranch has been in continuous homestead from settlement to this day.

Mining has occurred in the past, but little activity other than surface exploration is present today. Mining activity is moderate in the eastern portion of the area and low to negligible in the western portion. Current claims are concentrated in Silver and Indigo Creeks, and southeastern drainages of the Illinois River.

Minor upland game and moderate big game hunting takes place, but is limited to the fringes of the area because of the steep, brushy terrain. Fishing is also quite limited due to tough access.

Recreation use is primarily dispersed recreation, most being associated with the Illinois River and with the adjacent Wilderness. Use consists primarily of fishing, backpacking, floating the Illinois, hiking, and swimming. There is camping on private land at Indian Flat. The Illinois River Trail and lesser trails receive various levels of use; most, though, is light. Use figures are not collected for the more dispersed recreational activities However, estimates of recreation visitor days (RVD's) are in a low range of 5,000 to 8,000 RVD's, the use being very low relative to the size of area. The Recreation Opportunity Spectrum (ROS) is split

between Roaded Natural on the fringe, Semi-primitive Non-motorized further in, and Primitive Non-motorized deep in the heart of the area (lower Silver Creek).

APPEARANCES, SURROUNDINGS, AND ATTRACTIONS

Except for the Silver Falls part, all of the unroaded area borders the Kalmiopsis Wilderness The Silver Falls portion is noteworthy for its extremely rugged terrain of knife ridges, white igneous cliffs, and deep inner gorges The primary attribute of the unroaded area is the relation to the Wilderness and Wild sections of the Illinois and Chetco Rivers. Other than these relationships and rivers, landscape variety is somewhat similar in surrounding areas The highly valuable fisheries and timber resources are also key

The northern portion is a large body of land approximately 10 to 15 miles wide and from 4 to 8 miles in depth Only on the fringes can man's activities be found. This larger area is bisected by the northerly-flowing Illinois River The large drainages of Indigo and Silver Creek flow into the Illinois from the east These two watersheds are characterized by heavily vegetated, steep, and highly dissected slopes with deep inner gorges Physical details vary little with the exception of some open meadows in the Silver Peak and Indian Flat areas, and some high open ridges of rock or low brush. The lower slopes of Indigo and Silver Creek contain sizeable areas of unstable soil which have been removed from the suitable land base Geology is very complex; features of extremely youthful landform are most pronounced in the inner gorges of Silver Creek near it's headwater. Man's activities, predominately timber harvest and associated roading, have occurred only on the northern and eastern edges, and predominately in the upper slope and ridge areas.

The area west of the Illinois River is largely within the Lawson and Horse Sign Creek drainages. It is vegetatively diverse with a mixture of openings, forest, and brush. Considerable geologic instability occurs throughout this portion, particularly in the lower slope position. Compared to Indigo and Silver Creek drainages, the terrain is not as steep nor relief as dramatic. Transportation systems and timber harvest units lie well within the Lawson Creek drainage and on all sides except those bordered by the Wilderness and Illinois River.

The east side contains the lower reaches of Briggs, Panther, and Labrador Creeks, and several other small streams which drain directly to the Illinois River. With the exception of Panther and Labrador Creek watersheds, this area is characterized by open and low brush. Past mining activity is noticeable on much of the area. Roads bordering the area are primarily for timber harvest, mining, and recreation.

The two portions on the west side of the Kalmiopsis Wilderness drain into the Chetco River This area is also highly dissected, with isolated stands of old-growth forest. Land instability and ultramafic rock (parent material for serpentine and peridotite-derived soils) measurably reduce the suitable land base in the Mislatnah portion These two narrow tracts are sandwiched between the Kalmiopsis Wilderness and roaded terrain to the west.

CAPABILITY

MANAGEABILITY

The North Kalmiopsis area is so irregular in shape as to make the boundaries difficult to manage as now drawn The large size of the area, though, inherently maintains or protects the roadless character and values of the interior environment and adjoining Wilderness. The location does not totally allow for the complete screening of the fringes from the sights and sounds of development activities on adjacent lands. The terrain and vegetation along the boundary does provide some shielding, though. The interior portions and portions adjacent to the Kalmiopsis Wilderness and Illinois River are generally well screened from off-site sights and sounds.

NATURAL INTEGRITY AND APPEARANCE

Human influences have had little impact on the natural appearance or long-term ecological processes of the North Kalmiopsis. The area is essentially free of disturbances, and natural balances, even where altered in the past, are intact and operating. Fire has been and most likely will continue to be the factor with the greatest potential for impacting the area's naturalness. Fire has, and will continue to play a major role in the long-term ecological changes of the area.

Mining activity has occurred in several portions of the roadless area. Some old mining roads can still be found in the vicinity of Horse Sign Butte, Nancy Creek, Red Dog Creek, Briggs Creek, around Salmon and Lightning Creek, and the headwaters of Silver Creek. These roads have had limited impact on the area's naturalness due to limited excavation when built. Lack of use in recent years has allowed them to return to near natural conditions.

Several maintained trails traverse the area; however, the extent and degree of disturbance is very limited. Old, abandoned trails exist, but many have nearly returned to natural conditions.

Man's activities outside the unroaded area have had little impact other than the aforementioned visual change. The area's natural processes are intact The most notable change, though, is attributable to water demands during the summer period. The Illinois River's natural low flow is measurably diminished by irrigation and domestic uses miles upstream in the Illinois and Deer Creek valleys.

OPPORTUNITIES FOR SOLITUDE AND PRIMITIVE EXPERIENCE

With topography highly broken and dense vegetation covering most slopes, natural screening provides ample opportunity for localized solitude and primitive experience. The overall opportunity is judged as moderate on the fringes not bordered by Wilderness, and high in the interior, particularly for the large northern portion. The lower half of Silver Creek drainage is totally screened from external sights and sounds

Use of much of the area is limited because of vegetative density and steepness of slope. Some open areas along the Illinois River provide opportunities for cross country hiking. Recreation use is mostly concentrated along the Illinois River and the main trail systems of the Kalmiopsis Wilderness A feeling of solitude, remoteness, and self-reliance is available to users leaving the established trails

If current unroaded conditions are maintained, dispersed forms of recreation activity would remain the same or increase along with the general trends for the adjacent Wilderness. Most of the parcels of the North Kalmiopsis can provide for primitive and unconfined types of recreation such as camping, hiking, fishing, hunting, nature study. The river areas can provide additional water-based recreation of a dispersed and primitive form; uses, though, will not vary from the current types, e.g., rafting, kayaking, swimming, etc.

SPECIAL FEATURES

Most notable features are the Congressionally designated lands within and adjacent to this unroaded area The Kalmiopsis Wilderness, along with the Wild segments of the Wild and Scenic Illinois and Chetco Rivers, focus considerable attention on these contiguous lands. Other special features may be those associated with both the size of the unroaded portion north of the Wilderness, and the extremely rugged nature of the mature/old-growth forested terrain.

Prehistoric use along the Illinois River adds to the archeological potential. Early homesteading and historic mining activities along the Illinois provide some of the richer cultural resources within the Forest. Several other mining locations, lookout sites, cabins, and trails contribute to the scattered evidence of earlier activities of man

AVAILABILITY

RESOURCE POTENTIAL

Recreation Settings

Undeveloped. Refer to previous discussion for present situation The opportunity for change in type of recreation is limited. Potential for total use should increase along the same trend as for the Kalmiopsis Wilderness and Illinois River. Trail construction could aid in increasing RVD's. Recreational use of the Illinois River is concentrated during the spring (March-May) when river flows are ideal for rafting and kayaking. While use of the river could substantially increase with its recent Wild and Scenic River designation and notoriety, the Illinois River Management Plan (1986) does establish use limitations to maintain the environment in accord with goals of the Wild and Scenic River Act. Use of the Illinois River Trail is normally split between motorbike use outside of the Wilderness (before mid-May and after mid-September) and other forms of trail use. Trail hikers constitute most of the use; they generally utilize this trail from April through October. Horseback riding is confined to trails and limited by availability of feed. Capacity is not limited during the planning period.

Develop. The potential for increased RVD's is greatest under a roaded environment where many of the existing uses would increase along with the added opportunities for motorized forms of recreation. Capacity is not likely to be exceeded.

Wildlife

Under unroaded conditions, wildlife would remain constant unless specific management practices such as habitat improvement or prescribed fire were implemented. As development occurs over time, elk and deer populations will increase in response to the development of forage areas. Varying stages of vegetation in harvest units and along roads with adequate hiding cover would promote expansion of existing herds Populations of old-growth dependent wildlife species would decrease. They would not be eliminated, however, because considerable habitat would remain along the river corridors, tributary streams, and in areas unsuitable for commercial purposes Endangered, threatened, and sensitive species would be protected through applicable Standards and Guidelines.

Fisheries

The anadromous steelhead and salmon fisheries are very important to the Rogue, Illinois, and Chetco River recreational businesses and sport and commercial fishermen. At least 30 miles of the Illinois and Chetco Rivers and their tributaries contribute to some of the most important native spawning and rearing habitat for anadromous fish in western Oregon.

The principal tributaries of the lower Illinois, namely Silver, Indigo, Horse Sign, and Lawson Creeks, provide over 20 miles of excellent habitat Also important is the offsite influence on the survival of salmonids in the lower reaches of the Illinois River system The contribution of water quantity and lower stream temperatures on the Illinois River, particularly at the confluence of these tributaries, greatly benefits the wild fish populations of this system Maintenance of this excellent habitat is essential. Enhancement of this habitat has potential to increase juvenile yields.

Water

There are no man-made impoundments or diversions existing or planned for the area. A small hydroelectric power development was proposed for the lower section of Briggs Creek, but has since been abandoned. There is no demand to augment flow. The greatest needs have been for maintenance or improvement of water temperature in the summer Water quantity and quality aspects for these drainages are of far greater

importance than water use or development due to the high value fishery and recreational usage of the Rogue, Illinois, and Chetco Rivers.

Livestock

A grazing allotment in the Indigo Ridge area does affect the area. There is limited potential for additional grazing allotments. Development would allow improved access for utilization of transitory range. Timber harvesting would create temporary openings where forage availability would be increased.

Timber

The unroaded area contains approximately 55,256 acres tentatively suitable for the production of timber Standing volume is estimated at 1,092 MMBF. Site productivity varies from low to high, but is mostly moderate. Areas that would be considered for timber harvest vary from stable to unstable, and most can be accessed and harvested using systems currently employed on the Forest today. Because of heavy vegetative competition and steep slopes, management of the area for timber production would utilize various treatment methods to reduce brush competition for release of crop trees

Energy and Minerals

Activity in the form of exploration and development is low at the present time. Mineral deposits are present, especially on the east side of the area. Chromite, nickel, gold and silver have been mined in the past. Keeping the area in an unroaded state would limit exploration; development of a road system would likely increase activity. Energy development is unlikely. The area has a large number of mining claims primarily concentrated in Silver Creek, Indigo Creek, and the southeastern drainages of the Illinois River.

Cultural

The potential for discovery of additional archeological sites is good. Sites will be evaluated and provided for under the applicable laws and regulations where activities are planned.

Land Use Authorization

Few are existing or expected Designation of the Wild and Scenic Rivers restricts many forms of withdrawals Outstanding mineral rights are most likely along streams and in the Silver Creek headwaters

MANAGEMENT CONSIDERATIONS

Ownership, including subsurface rights held by others, is not a problem. Several private ownerships in and around the roadless area are currently being occupied; these include camping at Indian Flat, the Briggs Ranch, Conners Place, and a parcel owned by Al Pierce Lumber Company at the mouth of Lawson Creek.

Fire remains the most serious management consideration. The potential for major conflagration definitely exists. Dispersed recreation use along the Illinois River and trails contributes to the greatest risk of fire. Increased use would contribute to higher probability of man-caused fires.

Development activities with improved access and intensified treatment of fuels would considerably lessen continuity and concentrations. Major loss of resources by wildfire would be reduced. However, improved access also brings increased risks due to greater activity and number of people in the woods.

Both the hazard and risk of wildfire ranges from moderate to high on portions of the area Natural fuel loadings range from 6-20 tons per acre. The areas of dense fuels present a management situation where considerable loss of resources could occur and the undisturbed setting could be greatly altered. The

greatest threat is from dispersed recreation use deep within the unroaded area. A reduction in treat is attributable to the climate, conditions are severe for a relatively short time due to ameliorating coastal influences. While risk is low due to few users, fire ignition at the wrong time could have dire consequences.

The potential for insects and disease outbreaks within the coniferous forest exists. Actual occurrences have been minor and localized. Natural factors and management actions have reduced this threat Areas adjacent to the Wilderness are at higher risk.

NEED

OTHER AREAS AND PUBLIC USE

Within 10 miles of the North Kalmiopsis exist two designated Wildernesses (Wild Rogue and the adjoining Kalmiopsis), stretches of four Wild and Scenic Rivers (Rogue, Illinois, Chetco, and North Fork Smith), and nine other inventoried roadless areas. The extent of unroaded/undeveloped areas surrounding or adjoining the North Kalmiopsis is impressive when viewed in total. Combined, the above unroaded areas total more than 278,000 acres; the designated Wilderness acres total over 210,000 acres The composite area covers the heart of the Forest, being approximately 40 miles in length from north to south (into California) by 15 miles in width from east to west.

Approximately 34,000 acres of the inventoried roadless area is unsuitable for timber production, thereby remaining predominately in an undisturbed condition. Except for the possibility of limited mineral exploration and development, activities on these lands would be either very light or nonexistent.

Recreation use is both light and concentrated along the Illinois River and trail. Major portions of interior areas receive little or no use. The same use patterns exist for the adjacent Kalmiopsis Wilderness; use is very light and mostly concentrated in a few areas, namely rivers, trails, and the more open and high elevation sites.

The Illinois Wild and Scenic River serves as a primary destination for visitors from major population centers such as Portland and San Francisco (6 to 10 hours away by car). Most frequent river use, though, comes from nearby communities. However, growing notoriety of the extremely rugged and wild nature of the Illinois River may attract river rafters from great distances during the spring period.

ECOSYSTEM REPRESENTATION

Major ecotypes within the North Kalmiopsis are well represented in the Kalmiopsis and Wild Rogue Wildernesses, and the Illinois and Chetco Wild and Scenic River corridors. Additionally, the large amount (34,000 acres) of area unsuitable for timber production is inherently protected. Other unique ecosystems or areas that are currently allocated, or are being evaluated for inclusion as special management areas within the various alternatives, should also complement the ecosystems coverage.

PUBLIC INVOLVEMENT

Both the public and Forest managers have an unusually strong interest and concern for the existing and future management of this large unroaded tract Involvement in evaluation of alternative management options began prior to the 1970's.

The northern slope of Bald Mountain and Silver Creek is thought by some to be Wilderness in its own right. The conflict posed by divergent views has persisted. Arguments were heated during the passage of the Endangered American Wilderness Act of 1978, but compromise was reached on the present boundaries of the Kalmiopsis Wilderness. As a result, the size of the Kalmiopsis Wilderness was increased from 76,000 acres to 179,850 acres. The northern boundary was drawn along Bald Mountain ridge.

Between 1977 and 1979, the Roadless Area Review and Evaluation RARE II process was being finalized RARE II (FEIS, 1979) recommended the area for neither Wilderness or further study; the North Kalmiopsis was allocated "non-Wilderness." Tremendous local involvement and specific input occurred during this formal study. Public preference was heavily in favor of allocating the area to a "multiple use" designation.

At the same time, the Forest released two FEIS's for Land Management Plans ("Unit Plans"). Public input and responses were documented. The issue of maintaining the existing wilderness character of the area was covered one of the Draft documents; however, direction followed which left the decisions for recommending unroaded areas for Wilderness to the RARE II process. In consideration of the area's values and characteristics, the Land Management Plan decisions allocated most of the area to coordinated resource management, i e , open to development activities of roading and timber harvest, among other things. Refer to the introductory discussion titled **STATUS OF ROADLESS AREAS**

In early 1981, the first major timber sale (Bald Mountain) in the North Kalmiopsis was approved; the project provided for road access into the area. A great deal of public interest was elicited from industry, environmental groups, local government, Congressmen, and others. Their input is a matter of record. Although numerous issues and concerns surfaced, the common denominator has been development of the unroaded area north of the Kalmiopsis Wilderness.

Following approval of the Bald Mountain Timber Sale as documented in the Environmental Assessment, the Bald Mountain road was designed, the construction contract awarded, and construction initiated. Shortly after beginning road construction, the project was taken to U.S. District Court by the Sierra Club, et al, and a temporary injunction was granted. In 1983, final judgement was made ruling against the plaintiff. The Environmental Assessment for the project was deemed adequate.

Shortly thereafter, Earth First, et al, reentered the U.S. District Court using inadequacies of the RARE II analysis (*California v Block*) as the basis for halting further activity on Bald Mountain. This was upheld and activity again ceased. Due to the changed circumstances in law brought about through the Oregon Wilderness Act of 1984, the judgement was vacated and the injunction preventing entry into the North Kalmiopsis dissolved.

Immediately before and after release of the Forest Plan DEIS, the roadless area issue and additions to the Wilderness System moved to a new arena. As a result of the release and sufficiency language contained in the Oregon Wilderness Act of 1984, the option for adding the remaining inventoried roadless areas to the Wilderness System was measurably thwarted. However, beginning in 1986 there was a movement to tie the Wild Rogue Wilderness, and all contiguous roaded unroaded areas in between (including the North Kalmiopsis), to the large Kalmiopsis Wilderness. At first, the idea was tied to the call for a "Wild Rivers National Park " When this failed, other creative options filled the void. This large block of undeveloped, mature and old-growth forest ecosystem was strongly promoted by several individuals and organizations as an ideal area for creation of a National Park. As discussed in Chapter II of the FEIS, the proposal was not entertained as an alternative evaluated in detail.

Tens of thousands of public comments as to the appropriate management for the North Kalmiopsis were received in response to the Forest Plan DEIS. After listening to the public and other agencies, the suggestions remained consistent with prior public involvement efforts The intensity of feelings was no less Notoriety of the area had blossomed.

Considerable documentation of issues, concerns, and recommendations relative to the North Kalmiopsis has been made through letters, public meetings and field trips, project planning and implementation, newspaper articles, the RARE II process, unit plans, and current Forest planning efforts. Primary concerns expressed to date span a broad range of subjects; the following are some of the more prevalent views:

- It is vital as a connector between the two designated Wildernesses in order to maintain their primitive character.
- The high quality water should be maintained in a pristine state; it's contribution to the quality of the rivers is essential to recreation and fishery values and interests.
- The importance of spiritual values and solitude offered.
- Timber resources are substantive and extremely important to community stability, dependent industries, and local governments.
- Old-growth habitat for dependent wildlife is critical.
- The ecosytem is well represented in adjacent Congressionally designated areas.
- The risk of wildfire may be increased.
- The pristine viewshed of the Wild and Scenic Illinois River may be impacted by sights of man's activity
- Activities might adversely effect wildlife and rare plants.
- Development adjacent to the Kalmiopsis Wilderness may adversely impact it's values and the Illinois River Trail.
- The location of the Kalmiopsis Wilderness boundary addition in 1978 was completely thrashed out by Congress; it was the intent of Congress to allow entry and development in this area north of the Wilderness - this notion being reinforced when Congress decided not to include the area in the Oregon Wilderness Act of 1984.
- Primitive recreational experiences in the area would be irreversibly lost by the construction of roads.
- The area should be managed on a multiple-use basis for recreation, timber, minerals, wildlife and fisheries.
- High cost roads and economic returns from investments are questioned.
- The area is very sensitive in terms of slope stability and soil erosion; with a potentially high risk for loss of site productivity and fishery damage.
- A high potential for minerals exists; restrictions on minerals exploration and development is probable if the area is allocated to unroaded management.
- Existence of huge tracts of adjacent Wilderness areas offer like experiences; no need for more.
- Very limited use of area by recreationists, nor does much use occur in the adjacent designated Wilderness having similar characteristics
- Not utilizing the area's forests would have a critical impact on local and State timber supplies.

The importance of this area to various interests has always been hotly contested. Viewpoints generally are very polarized. Environmental groups desire most or all of the North Kalmiopsis be left in an unroaded state; industry and local governments request that most of the area be developed for multiple uses. As a focal point of the Forest Plan, this area and issue becomes one of the toughest and most complex elements requiring resolution.

1987 SILVER FIRE

During the public review period for the Forest Plan DEIS, lightning ignited several major fires in southwestern Oregon. Beginning August 30, 1987, and continuing for weeks and even months later, these fires swept over 110,087 acres of Siskiyou National Forest land. During this period, several of the fires burned together to form the Silver Fire Complex.

Wide variation in burn intensity was characteristic throughout the area. Large areas within the fire perimeters were left unburned or merely underburned without killing the trees, leaving a mosaic of live and dead vegetation. The environmental components most affected included soil and water, vegetation, fish, wildlife, visual resources, and the recreation settings. The discussion presented here concentrates on elements of these environmental components that specifically relate to the unroaded North Kalmiopsis.

The most important resource changes relative to the planning analysis are changes in the land base tentatively suitable for timber production, the timber inventory, the potential for changes in fish habitat and water quality, and changes in wildlife habitat suitable for mature and old-growth dependent species. Other important considerations are the changes in other wildlife habitat and the recreation setting.

For a full disclosure of the affected areas, a description of the resources impacted, site-specific management options considered in treating the resources and salvage of fire-killed trees, please refer to the Silver Fire Recovery Project FEIS and ROD (1988); these documents are available in the Planning Records.

Vegetation

The perception of the importance of the changes created by the fires based on the total fire area is quite misleading in terms of change in the timber resource. Much of the area within the fire perimeter did not burn long or hot enough to kill the standing trees. In addition, many of the areas burned were not suitable for timber production.

In total, the Silver Fire covered 96,540 acres (all but 300 acres being lands of the Siskiyou National Forest). While a very large area was involved, only 22,400 acres of tentatively suitable lands were burned. The remainder was either unsuitable for the production of timber (20,500 acres), or unavailable within the Kalmiopsis Wilderness (53,340 acres). Most of the suitable lands are within the inventoried North Kalmiopsis Roadless Area.

The intensity of the burn and the degree of change in the vegetation are important when assessing impacts on the timber resource. Approximately 13,500 acres of tentatively suitable land burned at medium and high intensity. Of this, 9,300 acres are mature timber and 3,900 acres are immature stands and plantations. The following table displays the suitable acres within the fire perimeters by fire intensity, with a breakdown by vegetation class.

	Silver Fire		
Silver Fire.	High	Medium	Total
Old-Growth/Mature	1,800	7,500	9,300
Immature-Small Timber	100	100	200
Immature-Poles	700	1,800	2,500
Seeds and Saps	100	200	300
Hardwoods	300	1,000	1,300
TOTAL	3,000	10,600	13,600

Wildlife

The recent fires were an agent of positive change in wildlife habitat diversity. Although some areas were severely burned, many were not. The fires have created a mosaic of habitats which has markedly increased habitat diversity. Populations of species dependent on older forest stages are expected to decrease (spotted owls, hermit warblers, red tree voles). Populations of species that utilize younger forest habitat (bluebirds, brush rabbits, blacktail deer, elk) should increase. Resetting of the cycles in meadows and creation of more openings will benefit many species. Forage quantity and quality will increase in burned areas with deer and elk as the major beneficiaries. Overall, populations of wildlife species do not appear to be seriously affected, either positively or negatively by the fires.

Of particular concern in light of the planning issues are the changes in habitat suitable for wildlife dependent on mature and old-growth forest. As part of the Forest Planning process, a network of suitable habitats has been identified for spotted owls, pileated woodpeckers, and pine martens Where identified habitat areas within the network no longer contain suitable habitat as a result of the fires, opportunities for adjustment of areas within the network have been evaluated All necessary adjustments have been made and will have only minor effects on the alternatives considered. One Spotted Owl Habitat Area (SOHA) and four pileated areas within the North Kalmiopsis area are still suitable habitat.

Sensitive Plants

The fire did not eliminate any sensitive species or affect their viability. On the contrary, these plant communities evolved with fire and most of the sensitive species benefit from the reduction in competition from shrubs and trees. With many being pioneer species, the fire may in fact be beneficial to maintaining species diversity within given locations.

Fisheries/Watersheds

Much of the vegetative shade on perennial streams is still in place. Many small streams in the upper reaches of the watershed and a few principal tributaries to Silver and Indigo Creeks, however, were severely burned and the vegetative canopy lost. These changes will impact both stream temperatures and sedimentation as they affect the primary beneficial use, fish habitat. Critical summer stream temperatures are expected to increase by one to several degrees Fahrenheit in some stream reaches This will affect fish habitat capability to some extent since these streams currently reach temperatures exceeding 70 degrees The projected increase resulting from the fire may push temperatures to near critical thresholds. Regrowth of streamside vegetation has already begun; full recovery is expected in 10 to 20 years on smaller streams, with larger streams requiring more time.

Sediment delivered to some of the severely burned streams is expected to be as much as triple pre-fire base levels The significance of increased sedimentation was evaluated relative to characteristics of the specific watersheds involved. Silver and Indigo Creeks are steeper gradient systems with high flow energy capable of moving large amounts of material during winter storms. Even with the increase in sediment production, significant channel aggradation or siltation of anadromous fish spawning gravels is not expected to occur. Resident trout populations in upper reaches of some streams could be impacted, particularly where large areas of the watersheds are severely burned or local stream gradients are subject to sediment deposition. Most of these streams are quite remote and receive scant fishing use.

Cumulative effects analysis of the Silver Fire area estimates a first year post-fire reduction of approximately 6,500 steelhead smolt from the Silver and Indigo Creek drainages. The anticipated loss represents only a fraction of the area's fishery, further, the loss would be temporary as full recovery will occur within a decade.

Recreation Settings

Adjacent to the North Kalmiopsis, large areas of the Wilderness burned, changes in the vegetative character will be obvious to recreationists. However, these changes do not affect the primitive nature of the experience and may, over time, enhance the visual variety through creation of snags and openings, and rejuvenation of meadows. The view along the Wild segment of the Illinois River has changed slightly, but management options are essentially unaffected. The mosaic of vegetative changes in the North Kalmiopsis has also been changed, but again this will not have any appreciable long-term effect on the nature and type of recreation opportunity.

While the fires themselves did not appreciably change the recreation opportunities, the proposed salvage logging and associated road construction of the Silver Fire Recovery Project will affect the roadless area and unroaded recreation opportunities. The Selected Alternative of the Silver FEIS and Record of Decision, as amended by the 1989 Appropriations Act, schedules construction of approximately 13 miles of road in selected parts the 42,000 acres burned in the unroaded North Kalmiopsis. The decision affected change in the inventoried unroaded boundaries, with impacts on acres of Primitive and Semi-primitive Non-motorized recreation opportunities as noted in the table below.

With the roads having been built in the Bald Mountain and Indigo Creek areas, the inventoried North Kalmiopsis Roadless Area was reduced to 88,582 acres. The decision to road and salvage portions of the Silver Fire contributed approximately 19,000 acres to this reduction.

ROS Class	1984 Inventory (Acres)	1988 Inventory (Acres)
Primitive 1/	14,300	10,200
Semi-primitive Non-motorized	45,800	41,700
Semi-primitive Motorized	42,000	16,600
Roaded Natural	8,000	20,000
Total	110,100	88,500

1/ The 1988 inventory of Primitive ROS acres was based on the Silver Fire Recovery Project decision, but was adjusted through a Congressional rider to the 1989 Appropriations Act. With the restriction of the extending the Bald Mountain Road west, the inventoried area is considerably greater than 10,200 acres.

ENVIRONMENTAL CONSEQUENCES

The significant effects of each alternative are presented in Chapter IV of the FEIS. Additional site specific effects, mitigations, and potential conflicts are presented here. The Standards and Guidelines for each alternative were considered when evaluating the effects of implementation.

SIGNIFICANT EFFECTS

Cultural Resources

Alternatives NC, A, A-Departure, B, C, D, D1, and K provide for development of substantial portions of the area. Intensive cultural resource inventory will be required along any proposed road alignment prior to approval. Sites that may exist in the project area can thereby be evaluated. Valuable sites can then be protected via avoidance or conserved via data recovery.

Alternatives E, G, M, and S call for an unroaded regime minimizing the need for cultural resource inventory and limiting the potential for disturbance of existing cultural resources.

Energy and Minerals

The following table is a tabular summary of the estimated mineral potential and access limitations for the North Kalmiopsis and Addition. The acreages shown are subject to change due to the current withdrawal review by the Bureau of Land Management (BLM), and differences found for site specific needs included in any subsequent withdrawal applications to BLM.

Access Restrictions	Mineral Potential (Acres)			
	High	Moderate	Low	Total
Withdrawn	300	900	6,100	7,300
High	-	-	-	-
Moderate	-	<100	100	200
Low	2,700	23,800	55,700	82,200
Total	3,000	24,700	62,000	<89,700

Improvements

Roads. The 55,256 acres of tentatively suitable land could generate about 223 miles of new road for timber harvest. A few roads for other purposes could be expected, but the mileage would be minor. Included in this mileage would be four collector roads of 46 miles. All other roads would be dead-end local roads built when needed to access timber harvest units. Some mileage would remain open to passenger car use, depending on the alternative, and other roads would be open to only high clearance vehicles or closed between projects. The following table shows road mileage in the area by alternative:

Alternative	Total Miles	Miles Open to Passenger Car	Miles Open to High Clearance	Miles Closed
NC and A	201	50	71	80
B	217	54	76	87
C	223	33	101	89
D	217	65	65	87
E and M	0	0	0	0
G	68	0	27	41
K	176	44	26	106
S	131	33	19	79

With no roads being built, Alternatives E and M would have minimal effect on this area. Alternative G would have the least miles built of the roaded options, followed by Alternative S. Only Alternative G would not maintain any roads for passenger car use. Alternatives NC, A, B, C, D, K and S would be mostly roaded except for varying amounts of Wild River, Botanical, and Supplemental Resource areas and varying portions of the area remaining unroaded in Alternative K and S. Alternative C would have the highest mileage of the alternatives. Alternatives G, K, and S would close approximately 60 percent of the roads.

In some alternatives new construction would be primarily extensions of existing roads at the head of Lawson Creek, north of Indigo Creek, the Bald Mountain Road, and from the end of the Onion Camp Road. Lawson Creek would be crossed by a collector road to access the south side of Horse Sign Creek. Indigo Creek near the confluence of the North Fork would be crossed by a collector road to access Silver Peak Ridge. Other stream crossings would be minor and most likely not inhabited by fish where crossed Full bench ground (ground too steep for stable fills) would be encountered on most new construction. The excavated soil and rock would be hauled to a stable waste site or used where road fills are feasible.

Roads would not be visible from any arterial system nor from any highway, but could be visible from the Kalmiopsis Wilderness rim and, to a very limited degree, from the Wild and Scenic Illinois River. Access would be provided for timber management, roaded recreation, fire suppression, and miners

Trails. Alternative S would provide for construction of 30 additional trail miles. Five miles of trail construction is identified under Alternatives B, C, D, and D1; 10 miles under Alternative E; 11 miles under Alternatives NC, A, and A-Departure; and 16 miles under Alternatives G, K, M, and S. From 3 to 29 miles of trail reconstruction occurs under various alternatives.

Developed Recreation Sites. No recreation site construction is identified for this area under all alternatives

Wildlife and Fish Habitat Structural Improvements. Alternatives with various levels of roading would facilitate installation of any fish structures by providing better access into the area.

Wilderness Potential

There are 232,495 acres within five designated Wildernesses on the Siskiyou National Forest. Recreation demand projections indicate that the Forest has the capacity to sustain projected levels of use in these areas until approximately the fifth decade. There are no additions to the existing Wilderness System recommended under any of the alternatives.

The assignment of all or parts of the North Kalmiopsis to unroaded objectives can affect management in the Kalmiopsis Wilderness. Wilderness potential would be foregone in those alternatives that assign the area to development.

Alternatives NC, A, and A-Departure would assign the entire North Kalmiopsis to multi-resource management objectives. Current management policies will continue. Currently unroaded portions of Silver Creek will be entered for timber harvest, subjecting Wilderness users to the influence of road construction, harvest units, and motorized recreation. Quality of the wilderness recreation experience in the peripheral areas would be degraded as a result.

Alternatives G, K, and S allocate varying amounts of the North Kalmiopsis to Backcountry Recreation Management. Moderate levels of trail construction would expand the capacity for Non-motorized recreation opportunities in the adjacent Wilderness.

Alternatives B, C, D, and D1 would not assign any of the North Kalmiopsis to unroaded management objectives. To offset the impacts to non-motorized recreation opportunities that are foregone in the General Forest, the Forest would implement an aggressive trail construction program in the Kalmiopsis Wilderness, adding approximately 70 miles to the existing system.

Alternatives E, and M would assign essentially all of the North Kalmiopsis to unroaded objectives, thereby maintaining the quality of the recreation experience inside the Kalmiopsis Wilderness through peripheral buffers. The Kalmiopsis Wilderness would be maintained in its current condition since the Forest would have the capacity to sustain demand for non-motorized recreation activities in non-Wilderness areas.

How much of the inventoried roadless area remains unroaded by alternative can be evaluated by either assessing a combination of Management Areas 1-9 (which retain essentially undeveloped conditions), or by viewing the spatial arrangement of blocks of undeveloped area at the end of a given period of time Management Areas may or may not be contiguous, so the integrity of the roadless area as a whole may be compromised by management around them. The following table provides a spatial estimate of acres remaining unroaded at the end of specific decades; these figures differ from the Management Area 1-9 acres in that the minimum criteria is based on the area either (1) bordering designated Wilderness, or (2) being 5,000 acres or greater:

Alternative	Acres Remaining End of Decade 1/ 2/		
	1	2	5
NC, A, and A-Dep	14,200	13,000	13,000
B, C, D, and D1	4,200	3,000	3,000
E and M	89,700	89,700	89,700
G	64,200	63,000	63,000
K	23,200	22,000	22,000
S	43,400	42,300	42,300

1/ Minimum criteria is 5,000 unroaded contiguous acres or adjacent to designated Wilderness
2/ The acres shown include both the inventoried North Kalmiopsis and North Kalmiopsis Addition Roadless Areas

Wild and Scenic Rivers

The North Kalmiopsis includes the lower six miles and one mile of the upper Wild section of the Illinois Wild and Scenic River. A Wild segment and Scenic segment of the Chetco Wild and Scenic River is also within the North Kalmiopsis. Land allocations outside of the one-quarter mile boundary of the river corridor will not effect the management policy on the rivers nor the land within the designated Wild sections.

The lower Illinois River is considered to be one of the most pristine rivers in the western United States. The river canyon is essentially devoid of the influence of humans from Pine Flat to the end of the Wild section near Nancy Creek. Allocation of lands within the river viewshed to harvest activities could affect the quality of the Wild river experience currently available between the Kalmiopsis Wilderness boundary and Nancy Creek.

Alternative NC, A, and A-Departure would not effect the management of the Illinois River. Lands within the viewshed adjacent to the lower six miles of the Wild section of the Illinois River would be managed under the guidelines established for Management Area 2 in the Rogue-Illinois Land Management Plan Under these alternatives, management activities are permitted provided the Retention Visual Quality Objective is achieved in areas visible from the river.

Alternatives B, C, D, and D1 also would not effect the management of the Illinois River. However, lands within the viewshed adjacent to the last six miles of the Wild section would be managed under General Forest guidelines. Portions of the Rogue-Illinois and Upper Illinois viewsheds would be assigned to varying schemes of visual management Management activities within the river viewshed would be visible to river users in the middle and background distance zones. The pristine quality of this section of the river would be modified, thereby effecting the quality of the recreation experience.

Alternatives E, G, K, M and S would not effect the management of the Illinois River. Under these alternatives, the lands within the viewshed adjacent to the lower six miles of the Wild section of the Illinois River would be managed under Preservation guidelines, maintaining the pristine character of the river. Backcountry Recreation allocation of the viewshed adjacent to the River in the lower six miles affects approximately 5,400 acres

Approximately four miles of the Chetco River in the western portion of the North Kalmiopsis is included as Wild and Scenic River Alternatives B, D, and K provide similar management through the Supplemental Resource Management Area prescription. Alternative C provides no special Management Area assignment other than as Riparian Beside discussion and analysis in the FEIS, Appendix E of the DEIS has covered the management alternatives and attributes of the Chetco River in considerable detail.

Under Alternative S, the Chetco River is designated as a Wild and Scenic River, maintaining the area in a condition which meets the requirements of the Wild and Scenic Rivers Act. This alternative, however, carries the Wild segment of the Chetco to Mislatnah Creek confluence, or the portion mostly included in

the inventoried North Kalmiopsis Roadless Area. The Omnibus Wild and Scenic River Act of 1988 designates the Wild segment as extending from the Wilderness down to Boulder Creek; from Boulder Creek downstream the Chetco is classified as Scenic.

Soil, Water, and Fish

Allocating the North Kalmiopsis to any alternative has management consequences. The indirect effect upon salmonid fish habitat capability is especially critical as this area represents some of the most productive salmonid habitat on the Forest in terms of both on-site capability and contribution to off-site, downstream fish production

Management activities have the potential to adversely effect the soil and water resources in the form of increased turbidity and sedimentation, side slope failures, reforestation, and deposition of large rock material into streams. However, due to large areas having been removed from the suitable land base on the most hazardous soil types and landforms, coupled with Standards and Guidelines, best management practices, and project-specific management requirements and constraints, the success and quality of any development activity hinges on application of these in all phases of planning, design, implementation, and monitoring.

Negligible soil, water, and fish consequences are associated with Alternatives E, G, M, and S due to the limited management activities. Alternatives NC, A, B, C, D, and K assign all or part of the area to Management Areas which permit some degree of development. The effects of timber harvest and road construction are discussed in Chapter IV of the FEIS.

Alternatives NC, A, A-Departure, B, C, D, and D1 have a potential for moderate adverse risk. Large acreages of highly sensitive soils have been eliminated from the suitable land base and, thereby, will substantially reduce the potential impacts. Risks still exist, however, due to the complex and difficult nature of the terrain and the high hazard potential for road and forest regeneration impacts on some of the remaining suitable lands.

The magnitude of road-related activity is decreased in Alternative K and S. In addition, basin timber harvest constraints have been applied to these two alternatives. Alternative G further reduces activities, thereby greatly decreasing potential risks on unstable soil types.

Inclusion of over 8,300 acres as Supplemental Resource areas in Alternatives NC, A and K considerably lessens the potential for adverse impacts to the riparian habitat, particularly for the inner gorge areas. Application of the Riparian Prescription C to the smaller, non-fish bearing streams in Alternatives B, D, and G also lessens risks of degradation. Finally, control applied to the timing, spacing, and intensity of potential timber harvest operations and associated road construction would partially mitigate adverse impacts. Other mitigating measures that could be used in this area are discussed in Chapter IV of the FEIS.

Fire

The effects of the alternatives from a fire standpoint are the increase or decrease that will be created in the fire hazard and risks. Risk is defined as the probability that an ignition will occur Hazard is a description of the fuels complex in terms of kind, volume, arrangement, condition and location of the fuels

Fuels in the North Kalmiopsis are extremely variable. In the area east of the Illinois River, fuels are very continuous, with moderate fuel loadings. For the most part, this area is heavily timbered. In the area west ot the Illinois River, fuels are generally light and less continuous, with less timber and more pure brush stands. Fuels in the Kalmiopsis Addition are primarily light, with very continuous stands of hardwood and brush.

In an undeveloped scenario, fuel accumulations would increase and fuel continuity would remain the same or increase The conditions east of the Illinois River and in the Kalmiopsis Addition lend themselves to large, high intensity fires. The area west of the Illinois River would produce lower intensity fires Adding to this is the increased response time for initial attack forces due to poor access. The result is larger fires, higher suppression costs, and increased resource losses.

In a developed scenario, the hazard increases during timber harvest. As fuels are treated, the fire hazard is reduced. Over time, the continuity of fuels are broken up, creating a mosaic of fuels and vegetative development This mosaic, combined with improved access for initial attack forces, reduces the potential for large, high intensity fires. The result is smaller fires, lower suppression costs, and less resource loss due to fire

In Alternative E and M, nearly all the area remains undeveloped with fuels remaining continuous over the entire area. In Alternative G, 20 percent of the area would be developed, creating a mosaic of fuels over time; the remaining area would remain undeveloped. Alternative S would develop 37 percent of the area and Alternative K would develop approximately 54 percent of the area. The remaining undeveloped areas would be broken into 58 separate blocks. Alternative A would develop 66 percent of the area, while Alternative NC would develop 71 percent. The remaining undeveloped areas would be in 23 separate blocks. Alternatives B, C, and D would develop approximately 73 percent of the area, and the remaining undeveloped area would be broken into 23 separate blocks. In large parts of the North Kalmiopsis, development would be minimal due to a large areas unsuitable land. In all alternatives, some of the high priority natural fuels accumulations will be treated.

In undeveloped areas, the risk of ignition is low due to the low levels of human use. As development occurs, risk increases with road construction and timber harvest, and with the treatment of the activity slash from these operations. As access improves, the level of dispersed recreation and other public uses increase, with a corresponding increase in the risk of human-caused fires. Both scenarios have similar risk levels for lightning fires.

In Alternatives E and M, the risk from human-caused ignition would be limited primarily to the periphery of the area due to limited access. In Alternative G, industrial operations would result in increased risk over 20 percent of the area, and risk from public use would be increased along the 45 miles of road. In Alternative K, industrial operations would result in increased risk over 54 percent of the area; risk from public use would be increased along the 175 miles of road. In Alternative NC and A, activities would result in increased risk over 66 to 71 percent of the area; risk from public use would be increased along 199 miles of road. In Alternatives B, C, and D, industrial operations would result in increased risk over 73 percent of the area, and risk from public use would be increased over roughly 220 miles of road. In Alternative S, industrial operations would result in increased risk over 37 percent of the area; risk from public use would increase along 175 miles of road.

Another source of ignition in this area could be the planned use of naturally occurring fire in the Kalmiopsis Wilderness, adjacent to the area. If fires are allowed to burn, there is a chance of fire escaping from the Wilderness boundaries.

Vegetation

Effects on vegetation relative to diversity and age class distribution do not significantly differ from the effects on the Forest as a whole (See Chapter IV, FEIS).

Sensitive Plants

Research Natural Areas There are no existing or proposed RNA's within the North Kalmiopsis.

Botanical. The existing Big Craggies Botanical Area is partially within the roadless area (the major portion is part of the Kalmiopsis Wilderness). Portions of four of the Forest's 24 candidate Botanical areas for sensitive plants are also within the area (following Table). Alternatives E, G, K, M and S include many of the sensitive plant areas as Botanical areas (see Appendix F for more detail on individual sites).

A variety of sensitive and rare plants are present (See **PHYSIOGRAPHIC AND BIOLOGIC FEATURES** section); under all alternatives sensitive plants would be protected through application of appropriate standards and guidelines.

Botanical Areas, by Alternative *1/* (Tentatively suitable for timber production)

Area Name	Tentatively Suitable (Acres)	Priority Ranking	Alternative (Acres) NC/A	B/C/D	E	G/M	K	S
SENSITIVE PLANT AREAS								
Bear Camp Option 1	177	4	--	--	244	244	244	244
Bear Camp Option 3	2611	7	--	--	2,983	2,983	--	--

EXISTING BOTANICAL AREAS								
Big Craggies	0	-	3,803	3,803	3,803	3,803	3,803	3,803

1/ Total acres for Option 4 are shown Only a portion of Option 4 is actually within the Shasta Costa Roadless Area

Air Quality

The principle agent impacting air quality in the forest environment and surrounding areas is smoke from wildfire and prescribed burning. Only impacts on alternatives from prescribed burning are considered. The effect of smoke is a temporary reduction in visibility in an area Total suspended particulates (TSP) is used as the measurement of local and regional haze. Alternatives E and M would contribute no TSP. Alternative G would generate 78 tons; Alternative K, 271 tons. Alternatives NC, A, B, C, D, and S would produce 321-337 tons of TSP per year.

The probability of a smoke intrusion from burning in the roadless area impacting Grants Pass or Medford, both designated areas for air quality, is very low based on past performance. The probability of impacting the Rogue River corridor is low, and low to moderate for both the Illinois River canyon and Kalmiopsis Wilderness, a Class 1 area.

Wildlife

Unless specifically mentioned below, effects of the alternatives on wildlife indicator species and wildlife habitat in this roadless area are the same as for the Forest as a whole.

Bald Eagle/Osprey. One active osprey nest is located within the North Kalmiopsis The area contains potential habitat for both osprey and bald eagles along the Illinois and Chetco Rivers In any alternative, management of eagle habitat would be governed by the Pacific Bald Eagle Recovery Plan (USDI-Fish and

Wildlife Service 1986). Overall, existing or potential habitat for eagle and osprey is maintained if the river corridors are protected from disturbance.

Spotted Owl/Pileated Woodpecker/Pine Marten. Under Alternatives NC, A, A-Departure, B, C, D, D1, and K, habitat for mature/old-growth indicator species would be considerably reduced over time Mature/old-growth habitat would remain at present levels under Alternatives E and M; Alternatives G and S leave 64 and 42 percent of the area, respectively, unroaded and preserve much of this habitat type Wildlife species such as the cougar, which do best in secluded areas, would be best served by Alternatives E, G, M, and S. Except for S, these alternatives also provide a corridor of mature/old-growth habitat linking the Kalmiopsis and Wild Rogue Wilderness.

Except for Alternative NC, a mixture of habitat enclaves to meet MR's for mature/old-growth habitat are located within the roadless area· two for spotted owls, eight for pileated woodpeckers, and six for pine marten. This area presently supports approximately 15 pairs of spotted owls No change will occur under Alternatives E and M. Alternative G could probably support 10 to 12 owl pairs indefinitely, and five to six pairs under Alternative S. Mature/old-growth habitat would ultimately be reduced to MR levels in Alternatives A, B, C, and D. Habitat would eventually be reduced below MR levels in Alternative NC.

Woodpeckers. Snag habitat would remain at or near 100 percent habitat capability for woodpeckers under Alternatives E, G, and M. Snag habitat along the Chetco River would remain near 100 percent in Alternatives NC, A, and A-Departure; even though these alternatives assign a significant part of the area to General Forest, the river corridor is maintained in a natural condition.

Black-tailed Deer/Roosevelt Elk. Big game management opportunities would increase in Alternatives NC, A, A-Departure, B, C, D, D1, and K, which open up much of the area through timber management Opportunities for habitat improvement projects for game animals would also be greater.

Wildlife Habitats. Meadow habitat in the western portion of the area is used extensively by deer and elk This habitat would be maintained under all alternatives, although meadow buffers are not protected in Alternatives NC, A, and A-Departure.

Wildlife Habitats The North Kalmiopsis contains approximately 700 acres of meadow habitat (including buffers) concentrated mainly on the western half of the area. Some 15 separate meadow sites are included. Meadow habitat is allocated in all alternatives, although meadow buffers are not protected in Alternatives NC, A, and A-Departure. The North Kalmiopsis contains over 2,000 acres of rock bluffs and cliff sites Rock bluffs/cliffs are allocated for wildlife use in Alternatives E through S, but would probably remain unaffected in Alternatives NC through D1. The roadless area contains one active peregrine nest. The nest site is managed in accordance with an existing site management plan. Overall management of peregrine habitat on the Siskiyou National Forest will conform to direction in the Recovery Plan for Peregrine Falcon (USDI-Fish and Wildlife Service 1982). A 250-acre band-tailed pigeon area is located on the eastern boundary, and is allocated in Alternatives E through M.

More than half of the Fishhook Peak meadow/forest edge complex is within the North Kalmiopsis; this area is important for wildlife, especially elk. It is included in Alternatives E, G, and K as a Supplemental Resource area, and Alternative S as a Special Wildlife Site.

The potential for human disturbance of Special Wildlife Sites is reduced under alternatives which maintain most or all of the area as Backcountry Recreation (Alternatives E, G, M, and S) Among the alternatives which allocate all or part of the area to Management Areas which permit development, Alternative B, D, D1, and G which utilize a Riparian Prescription C would provide the highest quality of riparian habitat for wildlife.

Although a gray wolf was trapped on the Forest in the late 1970's, the species was most likely eliminated from this area many years ago The potential for reintroduction of this species in the Kalmiopsis Wilderness and the unroaded North Kalmiopsis has not been evaluated Alternatives A, B, C, D, and K, which assign a large portion of the area to development, provide a smaller land base for potential reintroduction.

Wildlife Recreation Use. Estimated Wildlife/Fish User Days (WFUD's) currently attributed to the area are low because human use of the area is less than in roaded areas Fewer hunters use unroaded areas and non-hunters generally stay on the few trails. Alternatives E and M produce fewest WFUD's.

Visual Resource

The following is the current Visual Quality Objective (VQO's) inventory based on visibility of the area from major recreation travel routes or use areas:

VQO	Acres
Retention	16,900
Partial Retention	31,300
Modification	39,500

Areas inventoried as Retention and Partial Retention respond to recreation use and attendant viewer sensitivity form the Wilderness access route to Game Lake, the Illinois Wild and Scenic River, and the Illinois River, Silver Peak, and Hobson Horn trail systems. Recreation use is occurring primarily on the river while use on the trail systems is low. Areas identified for visual objectives are primarily foreground and middle ground distance zones located adjacent to situations identified above.

Alternatives NC, A, and A-Departure manage the area for the current inventory throughout the roadless area, except for the area visible from the Illinois River Trail in the vicinity of Bald Mountain and Chinaman Hat peak The Illinois River Trail would be relocated to the south from its present locations so that areas formerly visible would be topographically screened from the view of recreation users. This would change the visual inventory, resulting in a reduction of the visual objectives in the Silver Creek drainage to Modification. Also, the Bald Mountain Road would be constructed and the Silver Creek drainage entered for harvest within the first planning decade. Management activities that are subordinate to the character of the landscape (Retention, Partial Retention) would be visible in the background from the last six miles of the Wild section of the Illinois River.

Alternatives B, C, D, and D1 emphasize development and, thereby, would assign most of the area to management under Modification objectives. Visual objectives would be allocated only to the unroaded areas within the Rogue-Illinois viewshed in response to recreation use on the Illinois River. Areas adjacent to Wilderness routes and trail systems would be allocated to Modification objectives.

Alternative K would allocate over 30,000 acres to roadless objectives. The area is comprised of the selected ground in the Silver Creek drainage and lands within the viewshed adjacent to the Wild section of the Illinois River. The inventoried VQO's are assigned to those areas adjacent to the Game Lake access road and to areas within the Upper Illinois viewshed The remaining area would be managed under the Modification objective.

Alternatives D, G, M, and S would maintain or exceed the current visual inventory under the Preservation objective in areas allocated to Backcountry Recreation management. Alternatives E and M would upgrade the inventory of all the area to Preservation. Alternative G and S would allocate approximately 57,000 acres and 37,500 acres, respectively, to Backcountry Recreation. In Alternative G, the area not allocated to Backcountry Recreation would be managed to achieve inventory VQO's. In Alternative S, the area not

allocated to Backcountry Recreation would be managed to achieve the Modification objective, although approximately 5,500 acres would be managed to achieve Retention and Partial Retention objectives.

Recreation Settings

Most of the roadless area is capable of offering Semi-primitive Non-motorized opportunities. the area identified as Semi-primitive Motorized falls in this category due to current management policy which provides for the use of trail bikes and motorcycles on trail systems within the area If motorized use is restricted, these areas would shift to the non-motorized end of the opportunity spectrum. Recreation use is light, the entire roadless area only has an estimated 6,000 RVD's. And, the majority of this recreation use is occurring within the Illinois River corridor between Silver Creek and Nancy Creek

The area inventoried as Primitive is located within the lower Silver Creek drainage, a small area of Primitive recreation opportunity also exists above Boulder Creek on the Chetco River. These are the only areas in non-Wilderness status on the Forest which offer Primitive recreation opportunities. Recreation use is light, being estimated at 700 RVD's. Use in the area is limited both in opportunity (it's hard to get to) and access (there are no trails within the large Silver Creek Primitive portion of the roadless area). projected levels of recreation demand indicate that the use will remain well within the carrying capacity over the planning period The influence of management activities on adjacent lands limits the area's ability to provide a quality wilderness or primitive recreation experience.

Alternatives NC, A, A-Departure, B, C, D, and D1 would not assign any of the area to Backcountry Recreation management. Under these alternative, the area would be developed and all inventoried Primitive and Semi-primitive Non-motorized recreation opportunities outside of designated Wilderness would be lost The area would lose its pristine character and present a roaded modified forest setting to the recreation user Portions of existing trail systems would also be lost as a result of road construction Except for alternative C, these alternatives would also retain over 12,600 acres in essentially undeveloped condition due to Wild River, Botanical, Supplemental Resource, and Designated Wildlife Habitat Management Areas. These areas are generally not contiguous, so the integrity of the roadless area is compromised by the presence of motorized activities around them.

Alternatives E, G, and M would allocate most or all of the area to unroaded management objectives, thereby maintaining all of the inventoried Primitive area. The alternatives would result in an expanded capacity for Semi-primitive Non-motorized opportunities as motorized use on trail systems would be restricted in favor of non-motorized recreation opportunities

Alternative S would allocate 37,500 acres to Backcountry Management. The allocation would include lands within the viewsheds adjacent to the last six miles of the Wild section of the Illinois River, and the area within the Silver Creek drainage that is capable of providing Primitive opportunities. The area would be managed to provide Primitive, Semi-primitive Non-motorized and Motorized recreation opportunities. Under this alternative, the essentially undeveloped character would be retained on approximately 50,100 acres of the roadless area due to allocations to Botanical, Supplemental Resource, and Designated Wildlife Habitat.

Alternative K would assign approximately 12,000 acres to Backcountry Recreation, and include lands within the viewshed adjacent to the last six miles of the Wild section of the Illinois River. The close proximity of harvest activities and associated road construction would result in the loss of Primitive opportunities. the reduction of Semi-primitive opportunities would be the same as those effects identified for Alternatives NC, A, B, C, and D. The essentially undeveloped character of the area would be maintained on an additional 17,000 acres. These areas may or may not be contiguous, so the integrity of the roadless area may be compromised by the presence of adjacent motorized activities (See **Wilderness Potential**).

Economic and Social

There are 55,256 acres of land identified as tentatively suitable for the production of timber in the two unroaded areas (54,233 acres in the North Kalmiopsis; 1,023 acres in the North Kalmiopsis Addition). The general effects on annual allowable sale quantity (ASQ) and long-term sustained yield (LTSY) of allocating these acres to uses that would include timber production are the same as those described in Chapter IV of the FEIS.

These above figures are based on the 1984 land base updated with the roadless area boundary changes to 1988. They do not account for the inventory changes resulting from the Silver Fire Recovery Project field survey. Incorporating these adjustments, the tentatively suitable land would be reduced 4,080 acres (North Kalmiopsis being 50,153 acres; the total for the two areas being 51,176). The outputs and effects in this section, therefore, are approximately eight percent greater than values adjusted for the Silver Fire area.

The estimated potential ASQ from the inventoried 89,748 acres of both roadless areas is 3.04 MMCF. The estimated LTSY would be 5.53 MMCF. Following are the estimates of the contribution to timber production (in MMCF) from these areas under each alternative:

Alternative	ASQ	LTSY
NC and D	2.61	4.77
A	2.44	4 44
A-Dep	2 34	4.61
B	3.19	5 80
C	2 71	4 92
D1	2.87	5 23
E and M	00	00
G	0.75	1 35
K	2 00	3 64
S	1.34	2 44

For projecting effects, the alternatives are separated into five groups: (1) Alternatives E and M, which leave the area as unroaded; (2) Alternatives G, which leaves much of the area unroaded; (3) Alternative S, which develops less than half the area; (4) Alternative K, which develops much of the area; and (5) Alternatives NC, A, B, C, and D, which develop most of the area.

The major direct economic effect is government expenditure for the timber and associated road construction program. Alternatives E, G, and M have the biggest reduction in the timber and road expenditures. Alternatives NC, B, C, and D have a slight increase in expenditures, while Alternative K and S have a small to moderate decrease. Alternative A has no change and provides the reference from which to gage other alternatives.

The indirect effects are associated with jobs, income, and payments to counties. Assuming no substitution of reduced timber harvest within the area of influence, Alternatives E, G, and M have the biggest reduction while Alternatives NC, B, C, and D have the highest level of employment, income, and payments to counties. Alternative K and S have intermediate effects.

The cumulative social effects of attitudes of people can be summarized by examining the different interests of the adjacent communities. Previous documentation is found in Chapters III and IV of the FEIS The positive sign indicates a feeling by special interest groups of the Forest being responsive while a negative indicates a social feeling of the Forest not being responsive to particular interests as listed For example, in Alternative E, people interested in old-growth habitat are predicted to feel positive about forest management while timber interests are predicted to feel the forest is not responsive to their interests. such gains and losses may create additional conflict.

	Alternatives				
Effects (Changes Compared to Alternative A)	E and M (Unroaded)	G	S	K and D (Roaded)	NC, A, B, C,

MITIGATION MEASURES

In general, mitigation measures are the same as for the Forest as a whole (See Chapter IV, FEIS). In some cases, individual management plans will be devised for specific species, such as *Bensoniella oregana*, a plant found within the roadless area, which could be affected by timber management activities.

POTENTIAL CONFLICTS WITH OTHER JURISDICTIONS

Timber harvest has occurred on BLM lands in the headwaters of the Silver Creek drainage The Forest Service and BLM will need to coordinate management plans to consider the potential for cumulative effects.

Figure C-1h
RARE II AREA 6177
Quosatana

QUOSATANA No. 6177

(5,097 Acres)

DESCRIPTION

STATUS OF ROADLESS AREA

The Quosatana Roadless Area was inventoried for study as a potential Wilderness during the RARE II process. At that time, it contained 5,514 acres and was allocated to non-Wilderness use by the RARE II decision in January, 1979. Since then, timber sale activities have reduced the area to 5,097 acres. The roadless area contains approximately 20 acres of private land; the rest is National Forest System land

The Rogue-Illinois Land Management Plan (FEIS, 1979) allocated the Quosatana Roadless Area to coordinated resource management, with the exception of a small part of the Recreation segment of the Rogue Wild and Scenic River. Direction for the coordinated resource management area is designed to obtain full timber yield consistent with land capabilities and appropriate constraints, along with providing a high level of quality big game habitat and protecting small areas containing exceptional features.

Management direction for the Recreational river corridor along the Wild and Scenic Rogue River is designed to: provide opportunities for a wide range of river-oriented recreational activities; maintain or improve the quality of the water which enters the river; improve the fish and wildlife habitat; maintain or enhance the quality of the scenery; and utilize other resources and permit other activities to the extent that they do not significantly lower the quality of the river's values.

Please reference the Land Management Plan for a broad overview of the affected environment, evaluation of resources and management alternatives, and other requirements and constraints considered and currently implemented for the area. Since completion of the Land Management Plan, all project activities have been analyzed under its direction and NEPA requirements/process.

CHANGES BETWEEN DRAFT AND FINAL

During the period between 1984 and 1988, three timber sales have reduced the inventoried roadless area An area in the northern portion and two small pieces in the Fritsche Cabin vicinity modified unroaded area (Refer to Figure C-1h). The remainder of the area is as described.

LOCATION AND ACCESS

The Quosatana area is located in Curry County, Oregon, and includes a large portion of Quosatana Creek drainage and portions of several small drainages tributary to the Rogue River. The area is approximately 10 miles from the coast and the community of Gold Beach. The area is completely encircled by roads; these include Agness, Quosatana Creek, Wildhorse, and Hunter Creek. They are multi-purpose routes, serving *heavy recreation, timber haul, and administrative traffic.*

PHYSIOGRAPHIC AND BIOLOGIC FEATURES

The physical location of the unroaded area is on the western side of the coast range (Klamath Mountain Geological Province) in southwestern Oregon. Elevation varies from 200 to 2,800 feet. Topography is very mountainous with steep slopes and deeply incised drainages Most of the area is generally well timbered except for Quosatana Creek bars and Skookumhouse Butte. The timbered areas have moderate variety

due to some hardwood stands and brushfields Douglas-fir is the primary conifer species with associated species being Port-Orford-cedar. Tanoak, Pacific madrone, and canyon live oak are important hardwoods components. The ecosystem is predominately mixed conifer and mixed evergreen types They are characterized by a mixed forest of evergreen needle-leaved trees in the upper strata and evergreen broad-leaved trees in the lower strata.

Highly variable soil conditions occur within the Quosatana area. Deep, clayey, moderately productive to very productive soils are common. The rolling, undulating topography which characterizes the area is a result of a series of large, deep-seated landflows which have occurred over geologic time Some landflow activity is still occurring, especially in the lower slope positions. Steep areas along drainages have experienced considerable mass movement activity, most notably in areas of water concentrations. Large blocks of soils are experiencing soil creep, particularly in the confluence of small tributaries Soils in the upper Quosatana area demonstrate less active landslide activity.

Average annual precipitation varies from 100 to 110 inches; dry season rainfall (May through September) averages 11 inches The climate is mild and heavily influenced by marine air. Fog in the spring and summer often lies in the Rogue River corridor. Summer temperatures can exceed 80 degrees Fahrenheit.

Populations of black-tailed deer, Roosevelt elk, black bear, and wild pigs occur within the area. Large runs of anadromous salmon and steelhead use Quosatana Creek as spawning and rearing habitat. Bald eagles frequent that portion of the Rogue River just north of the area. The roadless area contains potential nesting and roosting habitat for both bald eagle and osprey. A pair of northern spotted owls (sensitive species) were located in the extreme southwestern part of the unroaded area in 1983 One sensitive plant species (*Erigeron cervinus*) has been found in the area.

RESOURCE USES

No mineral development has occurred in the past and no activity is expected in the future. There are no grazing allotments in the area. Minor upland game and moderate big game hunting on the fringes of the unroaded area takes place; interior hunting is very limited due to steep and brushy ground.

Quosatana Creek is now, and is expected to continue to be, a popular dispersed use camping area for local residents. This is responsible for the relatively high level of recreation use (estimated to be 2,100 RVD's). Quosatana Campground is located adjacent to the north boundary.

APPEARANCES, SURROUNDINGS, AND ATTRACTIONS

An environmental analysis prepared for a Skookumhouse planning area in 1983 encompasses the majority of the roadless area This document describes the landforms within the area as composed of sharply dissected, angular ridges with slopes of 60 percent or greater. The dominant landform and focal point within the area is Skookumhouse Butte which rises to an elevation of 2,191 feet. The area is covered by an essentially unbroken vegetative canopy consisting of varying combinations of conifers, hardwoods, mixed stands of conifer and hardwoods, and brushfields. Old-growth Douglas-fir with a strong deciduous understory is very much in evidence in the immediate foreground within the river corridor The coniferous stands are consistent, though not truly continuous as they are broken intermittently by hardwood stands.

Several natural openings occur within the area, but are not readily visible from along the Agness Road Openings from past harvest activity are evident on adjacent private lands The most dominant of these is a long rectilinear opening on the east side near Bradford Creek. The opening is in sharp contrast to the surrounding landscape and is very evident to recreationists on the Rogue River. The Rogue River, bordering the area on the north, is another major landform affecting the area. The river and it's corridor are part of the National Wild and Scenic River System.

The greatest influence on the area is the heavily traveled Agness Road along the north fringe of the area. It is the primary east-west access to the community of Agness and is part of the principal east-west route through the Siskiyou National Forest. Secondly, timber harvest activities and their associated roads immediately border the area. Adjoining private lands have also been heavily logged in the recent past.

CAPABILITY

MANAGEABILITY

The location, shape, and size of the area makes it subject to the sights and sounds of activities outside the area The boundary is not easily definable nor recognizable on the ground. Terrain and vegetation provide some shielding of the interior from off-site sights and sounds

NATURAL INTEGRITY AND APPEARANCE

While the area is roadless, it is not easily recognized as such because of surrounding activities. Consequently, the area has the appearance of being managed for uses other than Wilderness.

An old trail leads from Fritsche Cabin site to the Rogue River. It is not maintained and has only minimal effects on naturalness. Boating on the Rogue River does cause noise. A power line right-of-way located beside the Agness Road is quite apparent. Periodic maintenance of the right-of-way is necessary. The boundary could be adjusted to exclude it and the private land without significant reduction in the area's size.

OPPORTUNITIES FOR SOLITUDE AND PRIMITIVE EXPERIENCE

The Quosatana area has been inventoried in the Recreation Opportunity Spectrum (ROS) as Roaded Natural, and would not change under any land allocation. The opportunity for a truly primitive recreation experience does not exist.

The area consists of a highly dissected drainage with extremely dense vegetation which promotes a degree of solitude However, the same factors tend to negate cross country travel so that recreation use is limited to Quosatana Creek itself; encounters with other people, thereby, are relatively common. The proximity of timber harvest activity, logging roads, Agness Road, and river use contribute as external sources to limiting solitude. Other activities are within close sight and sound.

SPECIAL FEATURES

The Recreation section of the Wild and Scenic Rogue River is the most notable feature. The bluffs of Skookumhouse Butte, quite noticeable from the roads and river, also provide some diversity in background scenery. The bluffs also provide excellent habitat for various wildlife species.

AVAILABILITY

RESOURCE POTENTIAL

Recreation Settings

Undeveloped/unroaded The opportunity for measurable change in type or use is limited due to its size and topography. Use today is below capacity, and pressure for more use is expected to increase very little in the future. Quosatana Creek bed receives a good share of the total use of the area; much of this is attributable to local area residents. The bluffs of Skookumhouse are seldom used for climbing, but are important to the visual quality of the river users experience.

Developed. Potential for increased use is greatest with roaded development. Roads would provide access for hunting, dispersed camping, and other forms of motorized recreation.

Wildlife

Under unroaded conditions, wildlife would remain essentially unchanged unless specific management practices such as habitat improvement and prescribed fire were implemented As development occurs over time, elk and deer population levels would increase. Varying stages of vegetation in harvest units and along roads with adequate hiding cover would promote expansion of existing herds Populations of wildlife dependent on old-growth habitat would decrease in number. They would not be eliminated, however, because considerable habitat would remain along the river corridor, Quosatana Creek, tributary streams, and in areas unsuitable for timber management purposes. Sensitive species will be protected through applicable Standards and Guidelines.

Fisheries

The anadromous fisheries of the Rogue River are extremely important for inland recreation plus offshore sport and commercial fishermen. Quosatana Creek provides excellent habitat for anadromous fish. Many smaller tributaries contribute cold, clear water to Quosatana Creek and the Rogue River salmonids, but are too steep for fish movement.

Water

There are no man-made impoundments or diversions either existing or proposed. The potential for small hydroelectric power development is very limited. A small increase in water yields would result as a consequence of timber harvesting. However, the greatest demand for water is directed toward maintenance of Rogue River water temperature in the summer and fall periods. Quality aspects for the tributary streams are of far greater importance than water use or development due to the high value fishery and recreation of the Rogue River and Quosatana Creek.

Livestock

There is no livestock grazing within the area now. Very little potential for livestock grazing exists.

Timber

The unroaded area contains approximately 3,844 acres of land tentatively suitable for the production of timber. Standing volume is estimated at 85 MMBF. Site productivity is relatively high. The suitable area is reasonably stable and could be logged using skyline cable systems that are in common use on the Forest. Because of heavy vegetative competition and steep slopes, management for timber production would utilize various methods to reduce brush competition for release of crop trees Management in view of the Rogue River requires meeting a Visual Quality Objective (VQO's) of Retention.

Energy and Minerals

Exploration and development is nonexistent. While potential minerals may occur, development is highly improbable. There are no active mines or mineral leases.

Cultural

No cultural sites have been inventoried Potential is low except for benches along Quosatana Creek

Land Use Authorization

Other than the power line right-of-way, none exist. Few are expected.

MANAGEMENT CONSIDERATIONS

Fire is the most serious management consideration. The potential for major conflagration does exist with the heavy fuels and dense brush. Conditions, however, are severe for a relatively short period of time due to coastal influence on climate. The greatest threat of ignition occurs from dispersed recreation use along Quosatana Creek While use is is concentrated on the creekbed, fire ignition at the wrong time could have major consequences

The potential for insect and disease outbreaks within the coniferous forest exists. Actual occurrences have been minor and localized. With road development, the spread of *Phytophthora lateralis* root disease of Port-Orford-cedar may be increased.

The private land parcel located in the northwest corner of the area was logged several years ago and the vegetation is well established. The vegetation along the Agness Road appears natural; restraints on maintenance activities for both the road and power line right-of-way provide for visual considerations.

NEED

OTHER AREAS OF PUBLIC USE

The Wild Rogue and Kalmiopsis Wildernesses and stretches of the Rogue and Illinois Wild and Scenic Rivers exist within 11 miles of this roadless area. A portion of the Wild and Scenic Rogue River is located within and along the north boundary.

Recreation use of the unroaded area and adjacent undeveloped areas is extremely light considering the acreage involved. The nearby designated Wilderness and Wild and Scenic River areas share many of the same attributes of Quosatana, but are generally more rugged and diverse. Use in the surrounding undeveloped areas is concentrated, much like Quosatana, along rivers and trails. Local people utilize Quosatana more than recreationists from major population centers hours away by automobile. Recreation oriented travelers from the metropolitan areas would normally seek areas closer and of higher quality in terms of views and experiences.

ECOSYSTEM REPRESENTATION

The major ecotypes within Quosatana are well represented in other undeveloped or designated areas.

PUBLIC INVOLVEMENT

Public input on several of the inventoried roadless areas on the Forest has been extensive. Quosatana, however, has not received much advocation for protective status. Of the 55 letters received during public review of the Rogue-Illinois Land Management Plan, only two specifically stated Quosatana should be designated as Wilderness. Reasons for designation were related to greater fisheries protection.

Both the public and Forest managers have had considerable interest and concern for the existing and future management of the larger unroaded areas During RARE II, local and state government units responded to the potential inclusion of Quosatana as Wilderness. Most often cited were the adverse

impacts associated with local economy and community stability, loss of timber receipts, and multiple use opportunities foregone Many individuals voiced similar concerns for the area's individual and cumulative effects on the critical timber supply of southwestern Oregon.

Since RARE II, Quosatana has been evaluated for development through site-specific project planning. Essentially no public concerns or input has been received.

In the current Forest Planning process, the unroaded area question has remained a major issue. Public involvement, beginning with early public scoping in 1979 and continuing with public meetings, workshops, and other contacts into 1985, has not surfaced any additional concern or movement to seek unroaded allocation of this inventoried roadless area Comments received on the Forest Plan DEIS in 1987 and 1988 also have not added any new insight or concerns as to management of this unroaded area

ENVIRONMENTAL CONSEQUENCES

The significant effects of each alternative are presented in Chapter IV of the FEIS Additional site specific effects, mitigations, and potential conflicts are presented here. The Standards and Guidelines for each alternative were considered when evaluating the effects of implementation.

SIGNIFICANT EFFECTS

Cultural Resources

The roadless area is known to contain prehistoric and historic sites, some of which require evaluation by a professional archaeologist. The area supported aboriginal hunting and fishing endeavors, while Skookumhouse Butte was the site of other Indian activities during pre-contact times. The area has moderate potential for yet undiscovered cultural resources

Alternatives which call for development requires intensive cultural resource inventory along proposed roads prior to approval. In this way, sites that may exist in the project area can be evaluated. Valuable sites can then be protected by avoidance or conserved through data recovery. Alternatives E and M, leaving the area unroaded, would minimize the need for cultural resource inventory.

Energy and Minerals

The following table is a tabular summary of the estimated mineral potential and accessibility limitations for the Quosatana area.

	Mineral Potential (Acres)			
Access Restrictions	High	Moderate	Low	Total
Withdrawn	-	-	200	200
High	-	-	100	100
Moderate	-	-	-	-
Low	-	-	4,800	4,800
Total	-	-	5,100	5,100

Improvements

Roads The 3,844 acres of tentatively suitable land could generate about 13 miles of new road for timber harvest Roads for other purposes would be minor, if any. All the new roads would be dead-end local roads built when needed to access timber harvest units. Some mileage would remain open to passenger car use, depending on the alternative, and other roads would be open to only high clearance vehicles or closed between projects. The following table shows road mileage in the area by alternative:

Alternative	Total Miles	Miles Open to Passenger Car	Miles Open to High Clearance	Miles Closed
NC, A and B	13	3	5	5
C	13	2	6	5
D	13	4	4	5
E and M	0	0	0	0
G	10	0	4	6
K and S	12	3	2	7

Alternatives E and M would have minimal effect on this area due to no roads being built. Alternate G would not maintain any roads open for passenger cars. Alternatives NC, A, B, C, and D would be completely roaded Alternatives G, K, and S would have a Supplemental Resource area which reduce mileage. Alternatives G, K, and S would close 60 percent of the roads.

The road system would follow on or near ridges where possible. Some roads would be on the midslopes once ridges became too steep or where shorter reaches for logging were needed. These midslope roads would cross small creeks and draws which could result in some decrease in water quality from the road construction and use. None of the roads would cross streams inhabited by fish. Some full-bench ground would be crossed by roads with excess excavated material hauled to stable disposal sites. Some of the roads would be visible from the Rogue River and parts may be seen from sections of the Agness Road. Access would be provided for timber management, roaded recreation, and fire suppression.

Trails. None of the alternatives schedule construction of trails within this area.

Developed Recreation Sites. No recreation site construction is identified under any alternative.

Wilderness Potential

The Quosatana Roadless Area has been inventoried according to ROS criteria and is capable of providing 5,100 acres of Roaded Natural recreation opportunities The carrying capacity for the area is estimated at approximately 8,200 RVD's. This figure is high since the it is based on coefficients which assume the presence of roads. Current use is low and is attributed primarily to dispersed motorized day use in the Quosatana Creek drainage. The presence of motorized uses on the Rogue River, on the surrounding road systems, and within the area itself would preclude the ability of the area to provide a truly primitive recreation experience. The roadless area is isolated from other roadless areas and designated Wilderness.

Access to the area is limited to surrounding road systems and the Quosatana creekbed. Cross country travel is difficult due to the prolific vegetative understory and steep terrain. Recreation demand projections indicate that levels of use will remain well within the carrying capacity throughout the planning period

All alternatives, except E and M, assign the area to multiple resource management objectives. Roaded Natural recreation opportunities currently available would be enhanced by timber-related road construction. The change in character of the landscape would result in loss of Wilderness potential Alternatives E and M would maintain the area in a roadless condition, thereby providing additional capacity for Roaded Natural recreation opportunities Wilderness potential of the area would be maintained

How much of the inventoried roadless area remains unroaded by alternative can be evaluated by either assessing a combination of Management Areas 1-9 (which retain essentially undeveloped conditions), or by viewing the spatial arrangement of blocks of undeveloped area at the end of a given period of time. Management Areas may or may not be contiguous, so the integrity of the roadless area as a whole may be compromised by management around them. The following table provides a spatial estimate of acres remaining unroaded at the end of specific decades; these figures differ from the Management Area 1-9 acres in that the minimum criteria is based on the area either (1) bordering designated Wilderness, or (2) being 5,000 acres or greater.

Alternative	Acres Remaining End of Decade 1/		
	1	2	5
A, A-Dep, and NC	0	0	0
B, C, D, and D1	0	0	0
E and M	5,100	5,100	5,100
G	0	0	0
K	0	0	0
S	0	0	0

1/ Minimum criteria is 5,000 unroaded contiguous acres or adjacent to designated Wilderness

Wild and Scenic Rivers

Approximately one half of the area is visible to river users. The allocation of the area to roadless management objectives will not effect the management of the Rogue Wild and Scenic River. However, the allocation could effect the quality of the recreation setting near the river. The recreation setting is currently maintained through the use of inventoried VQO's which were assigned to the area in response to both the designation of the river as Wild and Scenic and to the high levels of recreation use that occur on the river. Area within the designated Wild and Scenic River corridor is currently managed to achieve the Retention objective, which is the minimum. Alternatives NC, A and A-Departure would manage the area to achieve inventoried visual objectives, resulting in some modifications to the area as it is entered for timber harvest Alternatives E and M would maintain the current conditions.

Alternatives B, C, D, and D1 would allocate the area outside of the designated Wild and Scenic River corridor to a reduced scheme of visual objectives. Areas outside the 1/4 mile river corridor currently inventoried for Retention would be managed for Partial Retention and Modification visual objectives, resulting in visible harvest activities to river users. The quality of recreation settings is most impacted under these alternatives.

Alternatives G, K, and S would manage the foreground areas of the Rogue River for Preservation visual objective in response to the high levels recreation use on the river. There would be no programmed harvest in these foreground areas. The rest of the area would be managed to achieve the inventoried visual objectives, resulting in some modifications to the forest setting as the area is entered for harvest

Soil, Water, and Fish

No direct impacts on soil, water, and fish are associated with Alternative E and M as no soil disturbing activities will occur All other alternatives assign all or part of the area to Management Areas which permit development The environmental effects of timber harvest and road building are discussed in Chapter IV of the FEIS

Alternatives NC, A, B, C, and D have a moderate potential of adversely affecting the soil, water, and fish resources in the area Soils in the area have demonstrated a high potential hazard for impacts from both harvest and road-related increases in landslides. Harvest and road-related activities have been minimized on some more hazardous soils; however, because of the large extent and complex nature of the unstable areas in the lower area of Quosatana Creek, a moderate potential for significant adverse impact exists Alternatives G, K, and S reduce overall activities and, thereby, share less risk and impacts.

Fire

The effects of the alternatives from a fire standpoint are the increase or decrease in fire hazard and risk that will be created. Risk is defined as the probability that an ignition will occur. Hazard is a description of the fuels complex in terms of kind, volume, arrangement, condition and location of the fuels

Fuels in the area are generally light, though most of the area is hardwood stands and brush, creating a high hazard. Fuels are very continuous on steep terrain with few natural openings In an undeveloped scenario, fuel accumulations would increase and fuel continuity would remain the same or increase. These conditions lend themselves to large, high intensity fires. Adding to this is the increased response time for initial attack forces due to relatively poor access The result is larger fires, higher suppression costs and increased resource losses.

In a developed scenario, fire hazard increases during timber harvest. As fuels are treated, fire hazard is reduced. In the long term, continuity of fuels are broken up, creating a mosaic of fuels and vegetative development. This mosaic, combined with improved access for initial attack forces, reduces the potential for large, high intensity fires The result is smaller fires, lower suppression costs and less resource damage.

In Alternatives E and M, all of the area would remain undeveloped, with fuels remaining continuous over the entire area. In Alternatives G, 44 percent of the area would be developed, creating a mosaic of fuels over time while the remaining undeveloped area would be in 3-5 separate blocks. Alternative K would develop approximately 61 percent of the area. The remaining undeveloped areas would be broken into 9 separate blocks. Alternatives A, B, C, D, and S would develop approximately 60 to 67 percent of the area, while Alternative NC would develop 78 percent. The remaining undeveloped areas would be in 3-4 separate blocks. In all alternatives, some of the high priority natural fuels accumulations will be treated.

In undeveloped areas, the risk of ignition is low due to the low levels of human use. As development occurs, risk increases with road construction and timber harvest, and with the treatment of the activity slash from these operations. As access improves, the level of dispersed recreational and other public uses increases, with an increase in the risk of human-caused fires. Lightning fire risk levels are similar for scenarios.

In Alternatives E and M, risk from human-caused ignition would be limited primarily to the area's periphery due to limited access. In Alternatives G, industrial operations would result in increased risk over 44 percent of the area; risk from public use would be increased along 10 miles of road. In Alternative K, operations would result in increased risk over 61 percent of the area, and risk from public use would be increased along the 12 miles of road. Alternatives A, B, C, D, and S would result in increased risk over approximately 60 to 67 percent of the area, and Alternative NC would be over 78 percent; risk from public use would be increased along 12 to 13 miles of road.

Vegetation

Effects on vegetation relative to diversity and age class distribution do not significantly differ from the effects on the Forest as a whole (See Chapter IV, FEIS).

Sensitive Plants

No Botanical areas or RNA's are proposed. One sensitive plant species is present. Under all alternatives, sensitive plants will be protected through appropriate Standards and Guidelines

Air Quality

The principle agent impacting air quality in the forest environment and surrounding areas is smoke from wildfire and prescribed burning. Only the effects of prescribed burning are considered. The effect of smoke is a temporary reduction in visibility in an area. Total suspended particulates (TSP) is used as the measurement of local and regional haze. Alternatives E and M would contribute no TSP, all other alternatives would produce 17-26 tons of TSP per year.

The probability of a smoke intrusion from burning in this area impacting Grants Pass, a designated area for air quality, is very low based on past performance. Because the area is in the Rogue River drainage, the probability of impacting the Rogue River corridor is moderate.

Wildlife

Unless specifically mentioned below, effects of the alternatives on wildlife indicator species and wildlife habitat in this roadless area are the same as for the Forest as a whole.

Bald Eagle/Osprey The northern portion of the roadless area is potential roosting and nesting habitat for bald eagle and osprey An active osprey nest is located just outside of the roadless area and bald eagles sometimes roost near the mouth of Quosatana Creek (a feeding site). Both birds undoubtedly use the area as a flight corridor. In any alternative, management of eagle habitat would be governed by the Pacific Bald Eagle Recovery Plan (USDI-Fish and Wildlife Service 1986). Overall, habitat for eagle and osprey is maintained in Alternatives E and M which allocate Quosatana to Backcountry Recreation. Alternative G, which allocates Supplemental Resource areas, also helps maintain habitat.

Spotted Owl/Pileated Woodpecker/Pine Marten. Under all alternatives except E and M, habitat for mature/old-growth indicator species would be considerably reduced over time. This would be especially true under Alternatives A through D1 which meet Management Requirements (MR's) for mature/old-growth wildlife species, but otherwise allocate most of the area to development (no Supplemental Resource areas assigned) Alternative NC does not meet MR's; it contains no habitat assigned for wildlife species using mature/old-growth forest.

Except for Alternative NC, one habitat enclave for pileated woodpecker has been established in the area to meet MR's for mature forest habitat This area presently supports approximately two to three pairs of spotted owls (there is a specific sighting location in the northeast corner of the roadless area). There would be no change under Alternatives E and M. Mature/old-growth habitat would ultimately be reduced to MR levels in all other alternatives In Alternative NC, habitat would eventually be reduced below MR levels.

Woodpeckers. Snag habitat would remain at or near 100 percent habitat capability for woodpeckers under Alternatives E and M High snag levels would be maintained in Alternatives E through S.

Black-tailed Deer/Roosevelt Elk. Big game management opportunities would increase in all alternatives, except E and M, which open up much of the area to timber management. Opportunities for habitat improvement projects for game animals would also be greater.

Wildlife Habitats Five meadow areas are contained in the Quosatana area (approximately 200 acres) Meadow habitat is allocated in all alternatives, although meadow buffers are not protected in Alternatives NC, A and A-Departure. Potential for human disturbance of wildlife in meadow areas is minimized in Alternatives E and M which maintain the unroaded status The bluffs of Skookumhouse Butte provide excellent habitat for various wildlife species; the Butte and surrounding habitat would be maintained as at present in Alternatives E, G, and M. Alternatives B, D, D1, and G which utilize Riparian Prescription C provide the highest quality of riparian habitat.

Wildlife Recreation Use. Estimated Wildlife/Fish User Days (WFUD's) currently attributed to Quosatana are average to slightly less than average for the General Forest Management Area. Slightly fewer WFUD's would be produced in Alternatives E and M.

Visual Resource

The following three objectives are attributable to the current visual inventory based primarily on the river and highway usage·

VQO	Acres
Retention	900
Partial Retention	1,300
Modification	2,900

Alternatives NC, A and A-Departure assign the area to management for inventoried visual objectives Some management activities would be evident to viewers on the Agness Road and river. In general, the area visible from the road and river would present a slightly altered appearance, while those areas not visible would present a modified appearance to users on secondary road systems.

Alternatives B, C, D, and D1 would assign the area to management for a reduced level of visual objectives Areas inventoried for Retention would be managed to achieve Partial Retention. Management activities would be evident to river users in the foreground. In general, the area visible from the road and river would present a slightly altered-altered appearance, while those areas not visible would present a modified appearance to users on secondary road systems.

Alternatives G, K, and S would allocate the area to management for inventoried VQO's The exception is the foreground area adjacent to the Rogue Wild and Scenic River. Inventoried for Retention, it would be managed for Preservation; there would be no programmed timber harvest In general, the area visible from the road and river would present a natural appearing-slightly altered appearance, while areas not visible would present a modified appearance to users on secondary roads.

Alternatives E and M would be managed to achieve the Preservation objective. The entire area would remain in a natural appearing condition throughout the planning period.

Recreation Settings

The area is surrounded by Forest road systems and is heavily influenced by the sight and sound of motorized users. In addition, the Recreation section of the Wild and Scenic River borders the northern edge

of the roadless area. Motorized use, in the form of ORV's driving up the Quosatana Creek drainage for approximately 1-2 miles to utilize the stream bottom for swimming, picnicking, and other day use activities also occurs. The isolated location and existing patterns of motorized uses limits the ability of the area to provide a quality wilderness or primitive recreation experience.

All alternatives except E and M provide for some degree of development Roaded Natural recreation would be modified somewhat; however, not enough to cause any further shifts in the opportunity spectrum Access to the area and motorized opportunities would be enhanced as roading occurs over time. Management activities will be evident to river users, particularly toward the northern end of the area, and may effect the quality of the river recreation experiences. Alternatives E and M would maintain the area in its current status. Recreation capacities remain fixed

Alternatives A, A-Departure, C, D, and D1 would retain the essentially undeveloped character on 800 acres of Designated Wildlife Habitat. Alternative S would retain the essentially undeveloped character of the area on approximately 1,300 acres. Alternative NC would essentially develop the entire area Alternative G and K would retain the essentially undeveloped character on 2,400 acres and 1,300 acres, respectively, due to allocations to Supplemental Resource and Designated Wildlife Habitat. These areas may or may not be contiguous, so the integrity of the roadless area is mostly compromised by the presence of motorized activities.

Economic and Social

There are 3,844 acres of land identified as tentatively suitable for the production of timber in this unroaded area. The general effects on annual allowable sale quantity (ASQ) and long-term sustained yield (LTSY) of allocating these acres to uses that would include timber production are the same as those described in Chapter IV of the FEIS.

The estimated potential ASQ from the inventoried 5,097 acres of the Quosatana Roadless Area is 0.21 MMCF. The estimated LTSY would be 0 38 MMCF Following are the estimates of the contribution to timber production (in MMCF) from this area under each alternative:

Alternative	ASQ	LTSY
NC and B	.21	.37
A, C, and D	18	32
E and M	00	00
G	.11	21
K and S	.16	.29

The major direct economic effect is government expenditure for the timber and associated road construction program. Alternatives E and M have the biggest reduction in the timber and road expenditures. The other alternatives have insignificant changes in budget expenditures.

Indirect effects are associated with jobs, income, and payments to counties. Assuming no substitution of reduced timber harvest within the area of influence, Alternatives E and M have the biggest reduction while the other alternatives have little or no change in the number of jobs, amount of income, and size of payments to the counties. Compared to Alternative A, Alternatives NC and B have slightly positive effects.

The cumulative social effects of attitudes of people can be summarized by examining the different interests of the adjacent communities Previous documentation is found in Chapters III and IV of the FEIS. The positive sign indicates a feeling by special interest groups of the Forest being responsive while a negative

indicates a social feeling of the Forest not being responsive to particular interests as listed For example, in Alternative E, fishing interests are predicted to feel positive about forest management while timber interests would tend to feel the forest is not listening to their needs. Such gains and losses may create additional conflict.

	Alternatives		
Effects (Changes Compared to Alternative A)	E and M (Unroaded)	G	NC, A, B, C, D, K, and S (Roaded)
Direct Effects			
Timber and Reduced Road Expenditures	None	Reduced	No Change
Indirect Effects			
Jobs	-16	-6	0

Hunting	-	0	0
Old Growth	+	+	0
Mining	-	0	0

MITIGATION MEASURES

No additional mitigation measures have been identified beyond those already listed for each alternative through the application of the Standards and Guidelines.

POTENTIAL CONFLICTS WITH OTHER JURISDICTIONS

Conflicts with adjacent landowners may occur over access.

BRIGGS No. 6178

(5,544 Acres)

DESCRIPTION

STATUS OF ROADLESS AREA

The Briggs Roadless Area was inventoried for study as a potential Wilderness during the RARE II process At the time it contained 5,762 acres and was allocated to non-Wilderness use by the RARE II decision in January, 1979. Since that time it has been reinventoried to contain 5,544 acres. The entire area is National Forest System land

The Rogue-Illinois Land Management Plan (FEIS, 1979) encompasses the Briggs area. The entire Briggs area was allocated to Coordinated Resource Management to obtain full timber yield consistent with land capabilities and appropriate constraints, along with providing a high level of quality big game habitat and protecting small areas containing exceptional features.

Readers are directed to the Land Management Plan for a broad overview of the affected environment, evaluation of resources and management alternatives, and other requirements and constraints considered and currently implemented for the area. Since the completion of this Land Management Plan, all project activities have been analyzed under it's direction and NEPA requirements/process

CHANGES BETWEEN DRAFT AND FINAL

During the period from 1984 to 1988, the Onion Bowl Timber Sale in the southern portion of the area changed the inventoried status by approximately 200 acres (Refer to Figure C-1i). **Note:** Approximately 500 acres of the Chinaman Hat Timber Sale (1985) was not deleted from the unroaded portion west of Red Dog Creek during the 1988 inventory update. This adjustment would be applicable to all alternatives; the change is not shown on the map (Figure C-1i). The remainder of the area is as previously described.

LOCATION AND ACCESS

The Briggs area is located in Josephine County, Oregon, approximately 20 miles west of Grants Pass, and contains a portion of the Briggs Creek drainage which is tributary to the Illinois River. The Briggs area is accessed from the north by the Flat Top Road, from the east by the Onion Creek and Swede Basin roads, and from the south by the Six Mile Road. These roads are multi-purpose routes serving timber hauling, recreation, and administrative traffic.

PHYSIOGRAPHIC AND BIOLOGIC FEATURES

The physical location of the unroaded area is in the coast range mountains (Klamath Mountain Geologic Province) and is typical of the eastern portion of the Siskiyou National Forest. The ecosystem is predominately mixed conifer with an intermingled mixed evergreen type. The topography is characterized by steep slopes, sharp ridges, and numerous small drainages. Elevation varies from about 1,500 feet to 3,860 feet

Part of the area is well forested. Average annual precipitation varies from 70 to 100 inches. Douglas-fir, sugar pine, and tanoak occur on soils derived from diorite and metavolcanics. Unproductive and relatively barren serpentine derived soils also occur There are proven deposits of critical and non-critical minerals present in the area

Soil and landtype features are highly diverse. The Red Dog Creek area contains moderately deep, generally productive soils in midslope areas; however, much of the area is in the serpentinite-peridotite parent material which is either low in productivity or unsuitable for the production of timber. Toe slopes are oversteepened and show evidence of numerous debris slide activity, especially in areas of stream undercutting. The lower Briggs area contains very steep convex slopes and soils are generally very thin and extremely rocky. Large inputs of rock and talus are annually deposited into the stream system. The Granite Creek, Elkhorn Creek, Waterdog Creek, and Onion Creek drainages contain some productive deep soils along benches throughout these areas However, the majority of the soils have low to moderate productivity, a function of serpentine influence and high surface rock fragment contents. Contacts between serpentine and other geologic types, and abrupt changes vegetation and slopes nassociated with previous mass movement activity are common.

A variety of wildlife species utilize the area Briggs Creek is an important anadromous fish stream. While no known threatened or endangered species inhabit the area, a few sensitive species have been identified These are the northern spotted owl and western sophora (*Sophora leachiana*), a sensitive plant. The spotted owl is associated with the old-growth timber stands. Uncommon plants present are *Darlintonia californica* and *Lilium vollmeri* Other sensitive and uncommon plants are likely to be found in the area, the area has not been extensively inventoried.

RESOURCE USES

Mineral development has occurred over much of the area in past Small dredging and panning for gold are currently being operated in Briggs Creek and several tributaries. Big game hunting takes place primarily on the fringes of the area. Briggs Creek receives light fishing, but is limited by access. Recreational use is light. The Briggs Creek and Red Dog trail system is currently maintained and provides good access along the streams.

APPEARANCES, SURROUNDINGS, AND ATTRACTIONS

The appearance of the Briggs watershed is one of a steeply incised valley primarily covered with conifer vegetation. The western portion of the area does contain a broad ridge of serpentine soil with open or low brushy areas. The stream bottoms are generally more heavily timbered than the ridges

The area is surrounded by roaded areas and associated timber harvests on all sides but the southwest corner. The Kalmiopsis Wilderness is located approximately four miles west Briggs Valley and Big Pine Campground are two miles to the northeast.

Primary attributes of Briggs are the main streamcourse with the associated trails and fisheries. The serpentine bands contain unusual plant life and open, interesting landforms.

CAPABILITY

MANAGEABILITY

The area is irregular in shape and form. Much of area's character can be easily maintained and protected. The location does not allow for the complete screening from the sights and sounds of development activities of adjacent lands, however the interior portions of the area would be well screened.

Risk of wildfire is low to moderate from lighting Dense fuels and heavy use of roads on the boundary present a management situation where considerable loss of resources and character of the setting could be greatly altered The risk from miners and recreationists is moderate Control of a wildfire situation would be relatively easy due to adjacent excellent road access.

Mining activity may affect the character of the area. Claims have existed in the area for nearly a century and mineral examinations indicate that gold and chrome are available.

NATURAL INTEGRITY AND APPEARANCE

Human influences have had limited impact on the natural appearance or long-term ecological processes of the Briggs area. The area has considerable history of fire and mining activity Fire has been a key to the long-term ecological changes and vegetative succession. Mining has had an impact on the area's naturalness Examples of past hydraulic mining can be seen in most of the drainages. Old piping and other remnants of the activities can be seen today. Most of the streambanks have revegetated partially or totally since the original hydraulic activities Some mining roads are in the area, but are revegetating

OPPORTUNITIES FOR SOLITUDE AND PRIMITIVE EXPERIENCE

The broken topography and dense vegetation provide natural screening and the opportunity for localized solitude and primitive experience. Overall opportunity is judged as low to moderate because of the area's small size. Both size and the inferior position (physically lower) of the core of the unroaded area limits external sights and sounds. Detractions from a totally primitive experience would be noise, dust, mining activities, and some view of adjacent activities.

Use of the area as a quality primitive setting is limited due to the density of vegetation and steepness. Trails exist to promote access to the interior and sufficient openings exist on many of the ridges to permit cross country foot travel. Most of the unique, interesting or challenging features exist along the higher ridges and alongside Briggs Creek. Due to limited recreation use and physical attributes, entering the area a short distance would provide a feeling of solitude, adventure, and awareness of primitive conditions; however, the experience would not be unique or particularly memorable.

Recreational usage is highly dispersed. The unconfined types of recreation are camping, hunting, fishing, hiking, and other forms. If the established trends in recreational activity remain the same, use would be expected to increase. A greater increase is not expected because of the area's inherent characteristics.

SPECIAL FEATURES

The area is quite typical of many other places in southwest Oregon and contains no special features which would enhance its value.

AVAILABILITY

RESOURCE POTENTIAL

Recreation Settings

Undeveloped. The opportunity for measurable change in type or use is limited, although there is some potential for increase in total use. Increased trail maintenance and construction could increase visitor days.

Developed. The potential for increase in visitor use is greatest under a roaded environment where opportunities for both motorized and non-motorized forms of recreation are possible. Capacity is not likely to be exceeded.

Wildlife

Under unroaded conditions, wildlife would remain essentially unchanged unless specific management practices such as habitat improvement and prescribed fire were implemented. As development occurs, deer and elk populations will increase as a result of an increase in forage Populations of old-growth

dependent wildlife would likely decrease in number. Considerable vegetative variety and area would remain along streams and on land unsuitable for timber management to provide old-growth habitat. Sensitive species would be protected through applicable standards and guidelines.

Fisheries

The anadromous steelhead and salmon fisheries are extremely important to Rogue River recreation and commercial businesses Briggs Creek provides valuable spawning and rearing habitat for steelhead, resident trout, and a few salmon Enhancement of fishery habitat has considerable potential to increase juvenile yields. This opportunity would be enhanced by improved access

Water

Other than mining ditches and mine buildings, there are no man-made improvement or diversions. There have been two proposals in the last decade to create dams on Briggs Creek. These proposals were for hydroelectric power and recreation. Both proposals have been just outside the unroaded area, but would have had impacts on it. The greatest demand for water has been in maintaining the summer stream temperatures for fisheries.

Livestock

There are no grazing allotments; none are anticipated.

Timber

The area contains approximately 4,070 acres of land tentatively suitable for the production of timber. Standing volume is estimated at 61 MMBF. Productivity is moderate. The area is reasonably stable and can be harvested using logging systems in common use on the Forest without adverse consequences. Because of heavy vegetative competition and steep slopes, management for timber production would need to utilize various methods to reduce brush competition for release of crop trees.

Energy and Minerals

There has been extensive mineral exploration for gold, and to a lesser extent chromite. Energy exploration has been low or nonexistent. If the area is developed, mineral development would increase, especially on the stream benches.

Cultural

Most activity has centered on historical mining activity, which includes Chinese mining. There are remnants of an old tramway which which crossed the area Historic and prehistoric sites will be evaluated and provided for under applicable laws and regulations. The archeological potential is moderate.

Land Use Authorization

None are existing or expected.

MANAGEMENT CONSIDERATIONS

Ownership, including subsurface rights held by others, is not considered a problem. Fire remains the most serious management consideration. The potential for major conflagrations definitely exists The potential for insects and disease outbreaks within the coniferous forest exists. However, actual occurrences have been minor and localized. Natural factors and management actions have substantially reduced this threat.

NEEDS

OTHER AREAS AND PUBLIC USE

Within ten miles of the Briggs area exists the Kalmiopsis Wilderness and the Wild and Scenic Illinois River Recreation use of the unroaded areas and Wilderness is light considering the acreage involved The major use of these areas is concentrated along the trails and waterways. Major population areas are six to ten hours away by automobile. Local users from Grants Pass and Medford are about one to two hours away and are the more likely users of the area due to limited outstanding or high quality features.

ECOSYSTEM REPRESENTATION

The major ecotypes within the Briggs area are well represented in the nearby Kalmiopsis Wilderness.

PUBLIC INVOLVEMENT

Both the public and the Forest managers have had considerable interest and concern for the existing and future management of these larger unroaded tracts of land. For this specific area, involvement in evaluation of alternative management options for Briggs began in the early 1970's. Between 1977 and 1979, the RARE II process was being finalized. Since RARE II, the area has been reevaluated several times through site specific project planning and broader area analyses. In the current Forest Planning process, the unroaded area question has remained a major issue. The analysis included herein is a compilation of information beginning with early public scoping in 1979 to public meetings and workshops through 1985.

Public input on several of the Forest's inventoried roadless areas has been extensive Briggs, however, has not received the same intensity of concern or advocation of protective status as several adjacent areas. Local and State governments that responded have cited effects on the local economy and community stability, loss of timber receipts, and multiple uses that would be foregone if the area remains undeveloped. The majority of respondents voiced the same reasons. Local citizens have not suggested Briggs as an area to be maintained as roadless or recommended for Wilderness inclusion. Few environmental groups have taken any position on this area for selection based on its unroaded attributes.

Since 1986, public and other agency input has not surfaced any additional substantive concern or desire for an unroaded allocation of this inventoried area. Comments received on the Forest Plan DEIS in 1987 and 1988 also have not added any new insight or concerns as to management of this unroaded area.

ENVIRONMENTAL CONSEQUENCES

The Briggs Roadless Area has abundant mining activity dating from historic times to the present. Evidence of Chinese mining from the late 19th century exists. The potential for archaeological resources is moderate, with the higher probability being along the Briggs Creek drainage.

SIGNIFICANT EFFECTS

Cultural Resources

Alternatives which development all or part of the area require intensive cultural resource inventory along any proposed road prior to approval. In this way, sites that may exist in the project area can be evaluated Valuable sites can then be protected by avoidance or conserved through data recovery. Alternatives E and M call for an unroaded regime which would minimize the need for cultural resource inventory.

Energy and Minerals

The following table is summarizes the estimated mineral potential and accessibility limitations for Briggs The acreages shown are subject to change due to the current withdrawal review by the Bureau of Land Management (BLM), and differences found for site specific needs included in any subsequent withdrawal applications to BLM.

Access Restrictions	Mineral Potential (Acres) High	Moderate	Low	Total
Withdrawn	-	-	-	-
High	-	-	-	-
Moderate	-	-	-	-
Low	2,000	3,500	-	5,500
Total	2,000	3,500	-	5,500

Improvements

Roads The 4,070 acres of tentatively suitable land could generate about 17 miles of new road for timber harvest All would be dead-end local roads built when needed to access timber harvest units. Some mileage would remain open to passenger car use depending on alternative; other roads would be open to only high clearance vehicles or closed between projects. Roads for other purposes would be minor, but some mining roads could be expected. The following table shows road mileage by alternative.

Alternative	Total Miles	Miles Open to Passenger Car	Miles Open to High Clearance	Miles Closed
NC, A and B	17	4	6	7
C	17	3	7	7
D	17	5	5	7
E and M	0	0	0	0
G	15	0	6	9
K and S	17	4	3	10

Alternatives E and M would have minimal effect on this area as no roads are built. All other alternatives would be mostly roaded, except for some Supplemental Resource areas in Alternative G. Alternatives G, K, and S would close 60 percent of the roads.

The road system would follow ridges off the main roads on the boundary and build midslope roads as the ridges steepen to reach timber units. The midslope roads would cross small creeks and draws, but none of these are inhabited by fish where crossed. None of the roads would be expected to cross Briggs Creek, but the crossing would be possible if ties to other system roads are needed Some full bench ground would be crossed by roads with excess excavated material hauled to stable disposal sites New roads would not have a visual impact from the Illinois River nor from Briggs Valley, but logging and associated roads would be seen from portions of the Briggs Valley Road to the east, a distance of five miles or more Access would be provided for timber management, roaded recreation, and fire suppression

Trails None of the alternatives provide for construction of trails. Existing trails are retained.

Developed Recreation Sites. No recreation sites proposed.

Wildlife and Fish Habitat Structural Improvements. No sites are specifically identified for structural improvements Alternatives that provide development would facilitate access for installations and maintenance Alternatives E and M retain the existing access limitations.

Wilderness Potential

This area and the Kalmiopsis Wilderness are similar in character and recreation opportunities The area has been inventoried according to ROS criteria and is capable of providing a Roaded Natural recreation experience on approximately 3,200 acres, and a Semi-primitive Motorized experience on the remaining 2,300 acres Carrying capacity for the area is estimated at approximately 8,200 RVD's. This figure is high since Roaded Natural and Semi-primitive Motorized coefficients were developed based on the assumption of presence of roads Current use is low (300 RVD's annually) and is expected to remain low over the planning period.

The roadless area is near the Kalmiopsis Wilderness, but is not contiguous Maintenance of the roadless area would expand the carrying capacity for Semi-primitive recreation opportunities However, the quality of the experience is suspect due to the close proximity of roads and management activities and the likelihood of similar activities in the future.

Access is limited to trails adjacent to the streams. No new trails are programmed for construction due to the low levels of use reported in the area. Recreation demand projections indicate that levels of use will remain well within the carrying capacity over the planning period.

All alternatives, except E and M, provide for development. Semi-primitive recreation opportunities currently available would shift to the motorized end of the opportunity spectrum. The change in the character of the landscape would result in the loss of Wilderness potential in the area. Alternatives E and M allocate the area to roadless management objectives and maintain the availability of roadless recreation opportunities. Wilderness potential is maintained

How much of the inventoried roadless area remains unroaded by alternative can be evaluated by either assessing a combination of Management Areas 1-9 (which retain essentially undeveloped conditions), or by viewing the spatial arrangement of blocks of undeveloped area at the end of a given period of time. Management Areas may or may not be contiguous, so the integrity of the roadless area as a whole may be compromised by management around them. The following table provides a spatial estimate of acres remaining unroaded at the end of specific decades; these figures differ from the Management Area 1-9 acres in that the minimum criteria is based on the area either (1) bordering designated Wilderness, or (2) being 5,000 acres or greater:

Alternative	Acres Remaining End of Decade 1/		
	1	2	5
A, A-Dep, and NC	0	0	0
B, C, D, and D1	0	0	0
E and M	5,500	5,500	5,500
G	0	0	0
K	0	0	0
S	0	0	0

1/ Minimum criteria is 5,000 unroaded contiguous acres or adjacent to designated Wilderness

Wild and Scenic Rivers

The area is located within the viewshed adjacent to the Illinois Wild and Scenic River, however, it is not readily seen from the river and therefore has little effect on the area's visuals. Briggs Creek flows into the Illinois River and is considered important with regard to contribution of high quality water to the beneficial uses of the Illinois Wild and Scenic River. Allocation of the area to roaded or unroaded management will have no effect on the management of the designated Wild and Scenic River, but will have a very limited effect on the recreation settings in the adjacent viewshed and quality of the recreation experiences.

Soil, Water, and Fish

No consequences to soil, water, and fish are associated with Alternatives E and M because no soil disturbing activities will occur All other alternatives assign all or part of the area to Management Areas which permit timber harvest and road building. The environmental effects of timber harvest and road building are discussed in Chapter IV of the FEIS.

A large proportion of the soils in the roadless area have a high hazard potential for road-related impacts and are less sensitive to regeneration-related impacts Some of the most severe hazards related to roads are located within areas inventoried as unsuitable for the production of timber; thereby, the need for road access is eliminated Alternatives NC, A, A-Departure, B, C, D, D1, K, and S have a slight to moderate risk of impacting the soil, water, and fish resource, especially where activities may be planned on the lower one-third of the slope. Alternative G poses slightly less risk because road construction is reduced.

Fire

The effects of the alternatives from a fire standpoint are the increase or decrease in fire hazard and risk that will be created. Risk is defined as the probability that an ignition will occur. Hazard is a description of the fuels complex in terms of kind, volume, arrangement, condition and location of the fuels.

In the Briggs Creek area, fuels are light to moderate with a large amount of continuous brushfields Timber is scattered in pockets throughout the area. In the serpentine areas, fuel and brush loadings are lighter and less continuous In an undeveloped scenario, fuel accumulations would increase and fuel continuity would remain the same or increase. These conditions lend themselves to large, high intensity fires. The result is higher suppression costs and increased resource losses. In a developed scenario, the fire hazard increases at the time of timber harvest. As fuels are treated, the fire hazard is reduced Over time, the continuity of the fuels are broken up, creating a mosaic of fuels and vegetative development This mosaic, combined with improved access for initial attack forces, reduces the potential for large, high intensity fires The result is smaller fires, lower suppression costs and less resource loss due to fire.

In Alternatives E and M, all of the area would remain undeveloped with fuels remaining continuous over the entire area In Alternative G, 55 percent of the area would be developed creating a mosaic of fuels over time, while the remaining undeveloped area would be in three separate blocks Alternatives NC, A, B, C, D, K, and S would develop approximately 65 to 78 percent of the area. Remaining undeveloped areas would be in one block In all alternatives, some of the high priority natural fuels accumulations will be treated

In undeveloped areas, the risk of ignition is low due to the low levels of human use As development occurs, risk increases with road construction and timber harvest, and with the treatment of the activity slash from these operations. As access improves, the level of dispersed recreational and other public uses increases with an increase in the risk of human-caused fires. Both developed and undeveloped areas will have similar risk levels for lightning fires

In Alternatives E and M, the risk from human-caused ignition would be limited primarily to the periphery of the area due to limited access In Alternative G, industrial operations would result in increased risk over 55 percent of the area, and risk from public use would be increased along the 15 miles of road. In Alternatives NC, A, B, C, D, K, and S, industrial operations would result in increased risk over 65 to 78 percent of the area, and risk from public use would be increased along the 17 miles of road.

Vegetation

Effects on vegetation relative to diversity and age class distribution do not significantly differ from the effects on the Forest as a whole (See Chapter IV, FEIS).

Sensitive Plants

No Botanical areas or RNA's are proposed. At least one sensitive plant is known to exist in the area. Under all alternatives, sensitive plants will be protected through application of appropriate Standards and Guidelines.

Air Quality

The principle agent impacting air quality in the forest environment and surrounding areas is smoke from wildfire and prescribed burning To determine the impacts of each alternative, only the effects of prescribed burning is considered The effect of smoke is a temporary reduction in visibility in an area. The total suspended particulates (TSP) is used as the measurement of local and regional haze. Alternatives E and M would contribute no TSP. All other alternatives would produce 15-19 tons of TSP per year.

Based on past performance, the probability of a smoke intrusion from burning in the area impacting Grants Pass or Medford, both designated areas for air quality, is very low. The probability of impacting the Kalmiopsis Wilderness, a Class I area, is very low.

Wildlife

Unless specifically mentioned below, effects of the alternatives on wildlife indicator species and wildlife habitat in this roadless area are the same as for the Forest as a whole.

Bald Eagle/Osprey. The area is not considered habitat for bald eagle or osprey. These birds may occasionally overfly the area near the mouth of Briggs Creek (an active osprey nest is in this general area of the Illinois River).

Spotted Owl/Pileated Woodpecker/Pine Marten. Under all alternatives except E and M, habitat for mature/old-growth indicator species would be considerably reduced over time. This would be especially true under Alternatives A through D1, K, and S which meets Management Requirements (MR's) for mature/old-growth dependent wildlife species, but otherwise assigns most of the area to development Alternative NC does not meet MR's; it contains no habitat allocated for wildlife species using mature/old-growth forests.

Except for Alternative NC, one habitat enclave for spotted owl has been established in the Onion Creek area to meet MR's for old-growth forest habitat (this is one of the best habitat sites on the Forest--data has been gathered here continuously since 1974). At present this area supports approximately two or three pairs of spotted owls; there would be no change under Alternatives E and M. Mature/old-growth habitat would ultimately be reduced to MR levels in all other alternatives In Alternative NC, habitat would eventually be reduced below MR levels.

Woodpeckers. Snag habitat would remain at or near 100 percent under Alternatives E and M.

Black-tailed Deer/Roosevelt Elk. Big game management opportunities would increase in alternatives which open up much of the unroaded area to development (all alternatives except E and M). Opportunities for habitat improvement projects for game animals would also be greater.

Wildlife Habitats. No meadows are known; 70 acres of rock bluffs are identified. Rock areas are allocated to wildlife use in Alternatives E through S, but would probably remain unaffected in Alternatives NC through D1. Riparian areas would continue to serve as valuable habitat. Alternative G, which manages the area under a Riparian Prescription C and assigns Briggs Creek to Supplemental Resource, comes close to maintaining natural conditions

Wildlife Recreation Use. Estimated Wildlife/Fish User Days (WFUD's) currently attributed to the roadless area are somewhat below average. Fewer hunters use unroaded areas and non-hunters generally stay on the few trails. Alternatives E and M produce fewest WFUD's; other alternatives generate more.

Visual Resource

The current inventory indicates that the area is located where it is not visible to major recreation travel routes or use areas. The area consists of approximately 300 acres of Partial Retention and 5,200 acres of Modification The Partial Retention objective was assigned in response to recreation use on the Flattop Road and the unique variety in the character of the landscape relative to the rest of the Forest. Viewer sensitivity is low, as indicated by the low levels of recreation use attributed to the area.

Alternatives NC, A, and A-Departure would assign the area to management under inventoried visual objectives. Since the majority of the area is inventoried as Modification, this would change the existing natural appearing character to a modified (altered) forest setting within the first two decades.

Alternatives B, C, D, D1, and K assign the area to management under the modification visual objective Alternative S would allocate nearly all of the unroaded area to the Modification objective. The existing natural appearing character would become a modified (altered) setting within the first two decades.

Alternatives E and M would be managed to achieve the Preservation objective. The natural appearance of the area would be maintained over the planning period.

Recreation Settings

The area is influenced by the sight and sound of motorized users. Recreation use in the area is very light and originates from local communities for the most part. The isolated location will limit the ability of the area to provide a quality non-motorized recreation experience whether the area is maintained in a roadless condition or not. The area could provide 2,200 acres of Semi-primitive Non-motorized opportunities if the existing trail system were closed to motorized uses

All alternatives, except E and M, would allocate the area to development, resulting in the shift of Semi-primitive recreation opportunities to the motorized end of the opportunity spectrum. Access to the area and motorized opportunities would be enhanced as roads into the area are constructed

Alternatives A, A-Departure, B, C, D, and D1 would retain the essentially undeveloped character on 800 acres, and Alternatives K and S on 1,100 acres due to allocation to Designated Wildlife Habitat. Alternative NC would essentially develop the entire area Alternatives G would retain the undeveloped character on 2,000 acres due to allocation to Supplemental Resource and Designated Wildlife Habitat areas These

areas may or may not be contiguous, so the integrity of the area would be compromised by the presence of motorized activities (See **Wilderness Potential**).

Alternatives E and M would maintain the area in its current status with recreation capacities fixed since no new trail construction is programmed.

Economic and Social

There are 4,070 acres of land identified as tentatively suitable for the production of timber in this unroaded area. The general effects on annual allowable sale quantity (ASQ) and long-term sustained yield (LTSY) of allocating these acres to uses that would include timber production are the same as those described in Chapter IV of the FEIS.

The estimated potential ASQ from the inventoried 5,544 acres of the Briggs Roadless Area is 0.22 MMCF. The estimated LTSY would be 0.41 MMCF. Following are the estimates of the contribution to timber production (in MMCF) from this area under each alternative:

Alternative	ASQ	LTSY
NC and D1	21	39
A, A-Dep, C, D, K, and S	.19	35
B	.23	.42
E and M	00	00
G	.14	26

The major direct economic effect is government expenditure for the timber and associated road construction program. Alternatives E and M have a reduction in the timber and road expenditures. The other alternatives have insignificant changes in budget expenditures.

Indirect effects are associated with jobs, income, and payments to counties. Assuming no substitution of reduced timber harvest within the area of influence, Alternatives E and M have the biggest reduction while the other alternatives have little or no change in the number of jobs, amount of income, and size of payments to the counties Alternatives NC, B, and D1 have slightly greater benefits than Alternative A.

The cumulative social effects of attitudes of people can be summarized by examining the different interests of the adjacent communities (See FEIS Chapters III and IV). The positive sign indicates a feeling by special interest groups of the Forest being responsive while a negative indicates a social feeling of the Forest not being responsive to particular interests as listed. For example, in Alternative E, fishing interests are predicted to feel positive about forest management while mining interests would tend to feel the forest is not listening to their needs. Such gains and losses may create additional conflict.

Effects (Changes Compared to Alternative A)	Alternatives		
	E and M (Unroaded)	G	NC, A, B, C, D, K, and S (Roaded)
Direct Effects			
Timber and Road Expenditures	None	Little Change	No Change
Indirect Effects			
Jobs	-17	-5	0

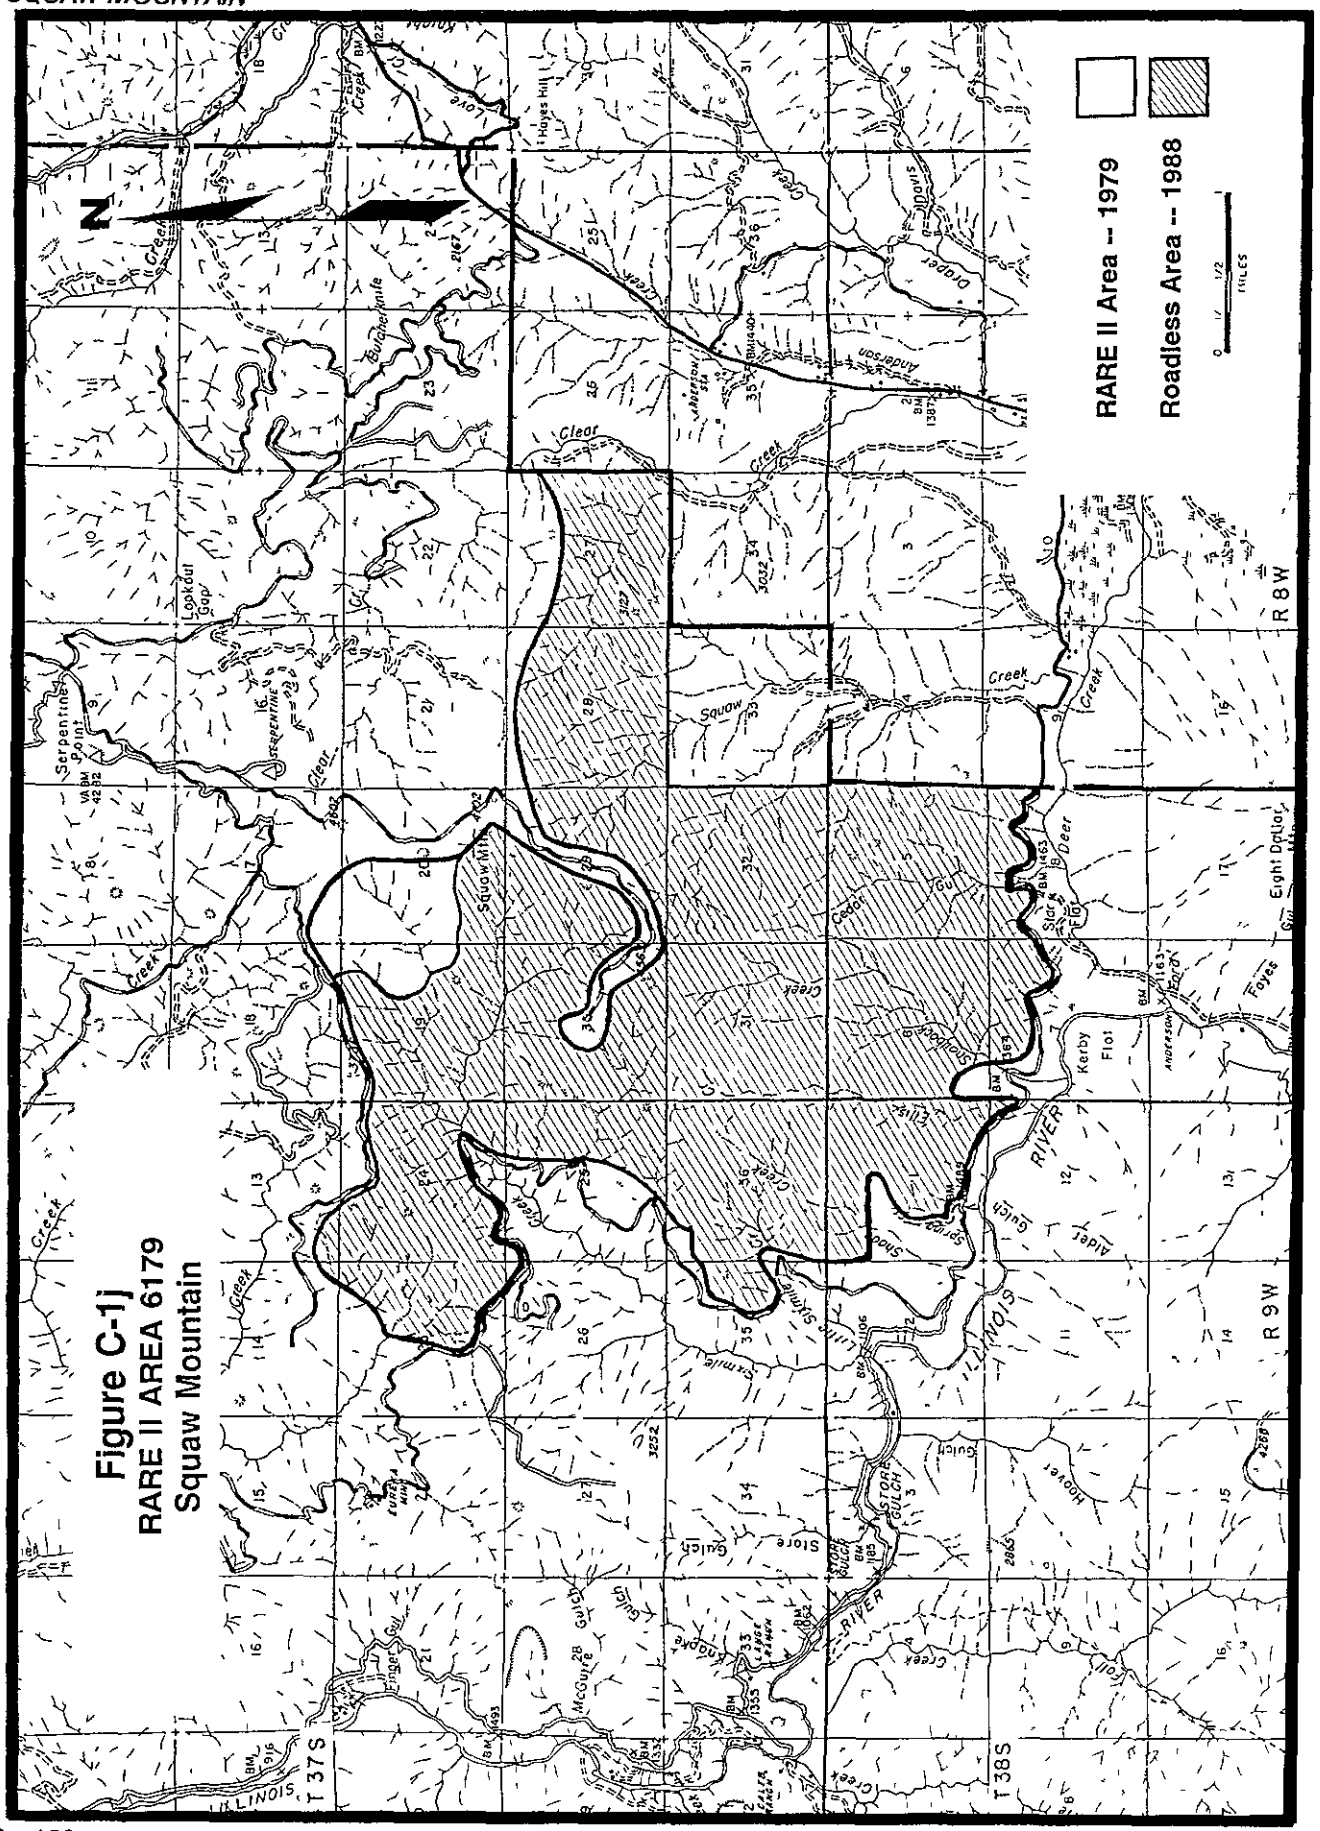
MITIGATION MEASURES

No additional mitigation measures have been identified.



POTENTIAL CONFLICTS WITH OTHER JURISDICTIONS

No additional conflicts with other jurisdictions have been identified.

SQUAW MOUNTAIN No. 6179

(7,704 Acres)

DESCRIPTION

STATUS OF ROADLESS AREA

The Squaw Mountain Roadless Area was inventoried for study as a potential Wilderness during the RARE II process The original inventoried area contained 8,064 acres and was allocated to non-Wilderness use by the RARE II decision in January, 1979. Since then, timber sale activity has reduced the unroaded portion to 7,704 acres. The entire area is National Forest System land

The Land Management Plan for the Chetco-Grayback Planning Unit (FEIS, 1979) encompasses the Squaw Mountain area Management direction allocated most of the area to Coordinated Resource Management to obtain full timber yield consistent with land capabilities and appropriate constraints, along with providing a high level of quality big game habitat and protecting small areas containing exceptional features.

Other management direction provides for a Scenic River corridor on the Illinois River to be generally managed to meet Scenic River objectives. This part is now under the River Management Plan direction for the designated Illinois Wild and Scenic River (1984).

Readers are directed to the Land Management Plan for a broad overview of the affected environment, evaluation of resources and management alternatives, and other requirements and constraints considered and currently implemented for the area. Since the completion of this Land Management Plan, all project activities have been analyzed under it's direction and NEPA requirements/process

CHANGES BETWEEN DRAFT AND FINAL

Between 1984 and 1988, the inventoried area was reduced as a result of timber sale activity north of Squaw Mountain.

LOCATION AND ACCESS

The Squaw Mountain area is located in Josephine County, Oregon, and includes several small drainages of the Illinois River adjacent to the Forest boundary in the Illinois Valley. It lies approximately four miles northwest of Selma, Oregon The area is bordered by the Illinois River Road on the south, the Six Mile Road on the west, the Snailback and Spalding Mill Roads on the north, and the National Forest boundary on the east The Illinois River Road is a multi-purpose route, serving heavy recreation, timber hauling, administrative and some residential traffic.

PHYSIOGRAPHIC AND BIOLOGIC FEATURES

The physical location of the unroaded area is on the northwestern side of the Illinois Valley in southwestern Oregon. Elevation varies from about 1,500 feet near the Illinois River Road to 4,702 feet on Squaw Mountain. Topography is very mountainous with steep slopes and deeply incised canyons

There is a major geologic contact that bisects the area into two major bedrock types. The northwest half of the roadless area is of the Jurassic-Galice formation; the southeast half is from a serpentine and peridotite intrusion. The vegetation strongly reflects differences in geology. On the Galice Formation,

Douglas-fir is the primary conifer species, but incense-cedar, Port-Orford-cedar, sugar pine, Jeffery pine and some knobcone pine can be found. Tanoak, Pacific madrone, and canyon live oak are major hardwood species. On serpentine-peridotite derived soils, Jeffery pine is the primary conifer; major hardwood species are white oak and canyon live oak.

The serpentine area contains extremely clayey soils that are often poorly drained Some deep-seated soil creep is evident on the lower one-third of the slope. High intensity storms often result in heavy runoff and the occurrence of numerous springs at the soil surface. The location of these springs is often variable from year to year. Soils derived from the Galice Formation have better drainage and productivity Inclusions of extremely rocky soils are present in some locations and have decreased productivity and a higher occurrence of brush species. Landslide activity levels are not particularly high in the roadless area, although some evidence of debris slide activity does occur along the contact between serpentine and metavolcanic parent materials.

Average annual precipitation varies from 50 to 70 inches; dry season rainfall (May through September) averages around 7-8 inches Summer temperatures often exceed 100 degrees Fahrenheit.

A variety of wildlife species utilize the area, including of black-tailed deer. The lower elevations are important winter range. The serpentine areas contain large numbers of Jeffery pine snags; pileated woodpeckers are frequently sighted here.

No known threatened or endangered species of animals or plants are known to inhabit the area; however, there are a number of sensitive and uncommon plants growing on the serpentine soils. Serpentine drainages, such as Snailback Creek and Cedar Gulch, are dotted with seeps and wet spots which harbor a variety of rare plants

RESOURCE USES

The geologic contact zone is mineralized and there has been mining activity in the past. Limited exploration and assessment work is continuing today. Although some mineralization does occur, it does not appear that the deposits are of commercial value.

Permitted livestock grazing has occurred in the past. There has not been a demand for this allotment in the past 15 years.

Recreational use is, at best, occasional and of a "cross country" type. The one nonsystem trail is low standard and has not been maintained for many years. While use figures are not collected for the more random recreational activities, estimates would place Recreation Visitor Days (RVD) in the low range.

APPEARANCE, SURROUNDINGS, AND ATTRACTIONS

The look, or outward aspect, of the Squaw Mountain area is that of a series of six small drainages facing into the Illinois River. It lies north of the junction of Deer Creek and the River. Distinguishing features are primarily those of heavily vegetated, steep, and highly dissected upper slopes. Lower slopes are sparsely vegetated, typical of the serpentine areas.

Conditions surrounding Squaw Mountain do not vary greatly. Vegetative type and landform is consistent Man's activities have modified the environment to the southwest near Selma; local areas have been accessed for mining, timber harvest, and other purposes.

Influences most predominate in this area are activities and development in the Selma area, the Illinois River, and Eight Dollar Mountain to the south The southwestern edge of the area overlaps (for two miles) the Scenic segment of the Illinois River.

The area does not contain any unique or special features that set it apart from the surrounding area It does contain several small perennial streams and one waterfall in the headwaters of Snailback Creek that is quite spectacular during high water.

CAPABILITY

MANAGEABILITY

The Squaw Mountain area is bounded by roads, private land, the National Forest Boundary, and a ridge. To effectively manage and protect the unroaded characteristics, the following would have to be resolved: Several access points to the area through private land are not controlled by the Forest Service; existing roads and trails would have to be closed to motorized vehicles; plans exist for a timber sale in the northern portion and roads have been constructed; and off road motorbikes could enter the area in several places.

NATURAL INTEGRITY AND APPEARANCE

Human influences have not had a noticeable impact on the natural appearance or the long-term ecological processes of the disturbances. Past fire and grazing have undoubtedly altered the species composition on the area, but natural balances have been re-established and are operating.

The evidence of old mining roads, waste dumps, adits, and equipment is recognizable, but not obtrusive, to the roadless character. Although small scale, there are fresh tailings dumps, new excavations and motorbikes being used within the area.

OPPORTUNITIES FOR SOLITUDE AND PRIMITIVE EXPERIENCE

Solitude can be found in the canyons and other areas that limit vision and hearing to the immediate surroundings. When on the ridges or hillsides, the sparse vegetation allows frequent views of roads, developed residential areas and agricultural activities. The center of the area is only four miles from the community of Selma and U.S. Highway 199, so noises are obvious unless in a locally protected environment Recreationists seeking solitude would probably not utilize the Squaw Mountain area because other nearby areas offer much greater opportunities for both solitude and a wilderness experience. Present recreation use is very light and limited to a few hearty hikers, hunters, prospectors or those involved in nature study.

SPECIAL FEATURES

The area is quite typical of many other places in southwest Oregon and contains no special features which would enhance its value.

AVAILABILITY

RESOURCE POTENTIALS

Recreation Settings

Characteristics of the area are low to moderate in quality for recreation. There is virtually no use of the area for recreation purposes at this time. An unroaded designation would provide less than 200 RVD's (current use); expected increase in use would be less than the trends due to the inherent nature of the area Roaded, there would be increased use in motorized forms of recreation, particularly in fall hunting

Wildlife

Under unroaded conditions, wildlife would remain essentially unchanged. With development, the greatest change would be in increased numbers of deer. Varying stages of vegetative habitat over time would promote expansion of existing herds. Populations of old-growth dependent wildlife would decrease They would not be eliminated, however, because considerable undisturbed habitat will remain in areas determined unsuitable for timber management, in stream gorges, and within much of the Illinois River corridor.

Sensitive Plants

The area offers the casual visitor or botanist a unique experience. There are a number of sensitive and uncommon plants growing on the serpentine soils. Pitcher plants (*Darlingtonia*) are common The following list is a beginning; future inventories will undoubtedly bring new discoveries:

Sensitive Plants	Uncommon Plants
Allium bolanderi	*Arabis aculeolata*
Arabis koehleri var. stipitata	*Castilleja elata*
Balsamorhiza sericea	*Castilleja brevilobata*
Cypripedium californicum	*Darlingtonia californica*
Gentiana bisetaea	*Dicentra formosa ssp. organa*
Lewisia leana	*Horkelia sericata*
Lewisia oppositifolia	*Lilium vollmeri*
Thlaspi montanum var. siskiyouense	*Lomatium howellii*
	Phacelia corymbosa
	Sarcodes sanguinea
	Sidalcea malveflora ssp. elegans

Fisheries

The anadromous fisheries of the Illinois River are extremely important. The tributary streams are generally blocked to fish passage by steep gradients and do not support a fishery; they are also quite small and dry up in the late summer period Their incremental contribution of cool, clear water, though, is beneficial. Roaded or unroaded, there would be little impact.

Water

There are no impoundments or diversions either existing or proposed The potential for small hydroelectric power development does exist on the small tributaries for the periods of flow Water quality aspects are important to the fisheries and recreation use of the Wild and Scenic Illinois River

Livestock

The grazing season is very short and forage has low nutrient value Future demand for grazing is not expected.

Timber

The Squaw Mountain area contains 3,533 acres of land tentatively suitable for the production of timber. Standing timber volume is estimated at 63 MMBF. Site productivity is low to moderate. The area is reasonably stable and could be harvested using logging systems and road construction methods in

common use on the Forest The area is in a portion of the Forest that usually requires release treatments to maintain the growth of crop trees. If managed for timber production, a full range of treatment methods should be available.

Energy and Minerals

The roadless area does contain some mineral deposits. However, the chance that any commercial mining will take place in this area in the near future is quite remote.

MANAGEMENT CONSIDERATIONS

Land ownership around the perimeter of the area poses some interesting management situations should it be managed as a Wilderness or quality unroaded area. The mining claims may also pose some conflicting situations should development continue.

Heavily used roads and private land around much of the perimeter present a fire risk situation that may require special management attention to retain the unroaded character. While fire is a threat, fuels are generally light next to the roads. But, the potential for a major fire presents itself annually.

NEED

OTHER AREAS AND PUBLIC USE

The Kalmiopsis Wilderness is within 10 miles and the Wild and Scenic Illinois River lies at the foot of the area; both offer similar recreation opportunities, but in much greater quantity and quality.

ECOSYSTEM REPRESENTATION

The ecosystems represented in this area are also represented in surrounding undeveloped areas as well as in the nearby Wilderness.

PUBLIC INVOLVEMENT

Both the public and Forest managers have had considerable interest and concern for the existing and future management of these unroaded tracts of land. For this specific area, involvement in evaluation of alternative management options for Squaw Mountain began in the early 1970's. Between 1977 and 1979, the RARE II process was being finalized. Since RARE II, the area's unroaded attributes have been reevaluated several times through site specific project planning and broader area analyses

Public input on several of the inventoried roadless areas on the Siskiyou National Forest has been extensive. Squaw Mountain, though, has not received the same intensity of concern or advocation of protective status as several adjacent areas. In the current Forest Planning process, the unroaded area question has remained a major issue. Public involvement, beginning with early public scoping in 1979 and continuing with public meetings, workshops, and other contacts into 1985, has not surfaced any additional concern or movement to seek unroaded allocation of this inventoried roadless area. Comments received on the Forest Plan DEIS in 1987 and 1988 also have not added any new insight or concerns as to management of this unroaded area.

ENVIRONMENTAL CONSEQUENCES

The significant effects of each alternative are presented in Chapter IV of the FEIS. Additional site specific effects, mitigations, and potential conflicts are presented here. The Standards and Guidelines for each alternative were considered when evaluating the effects of implementation.

SIGNIFICANT EFFECTS

Cultural Resources

The Squaw Mountain area is known to have prehistoric and historic sites along the Illinois River. Hunting, gathering and fishing activities by local Indians in pre-contact times in the area have left archaeological remains, most of which require evaluation by a professional archaeologist Historically, mining was the predominant activity in the area

All alternatives, except E and M, call for development which requires intensive cultural resource inventory and site evaluation along any proposed road prior to approval. Valuable sites can then be protected by avoidance or conserved through data recovery. Alternatives E and M call for an unroaded regime which would minimize the need for cultural resource inventory.

Energy and Minerals

The following table is a tabular summary of the estimated mineral potential and accessibility limitations for Squaw Mountain The acreages shown are subject to change due to the current withdrawal review by the Bureau of Land Management.

	Mineral Potential (Acres)			
Access Restrictions	High	Moderate	Low	Total
Withdrawn	-	<100	-	<100
High	-	-	-	-
Moderate	-	<100	-	<100
Low	-	7,600	-	7,600
Total	-	7,700	-	7,700

Improvements

Roads. The 3,533 acres of tentatively suitable land could generate about 16 miles of new road for timber harvest. All would be dead-end local roads built when needed to access timber harvest units. Roads for other purposes would be minor, but some mining roads could be expected. Some mileage would remain open to passenger car use, depending on the alternative, and other roads would be open to only high clearance vehicles or closed between projects. The following table shows the expected road mileage.

Alternative	Total Miles	Miles Open to Passenger Car	Miles Open to High Clearance	Miles Closed
NC, A and B	16	5	5	6
C	16	3	7	6
D	16	6	4	6
E and M	0	0	0	0
G	16	0	6	10
K and S	16	4	2	10

Alternatives E and M would have minimal effect as no roads are built. All other alternatives would be roaded. However, Alternative G would not maintain any roads open for passenger car use Alternatives G, K, and S would close approximately 60 percent of the roads.

Roads would be located on or near ridges where possible as accessed from the upper road system Some roads would be in midslope positions once ridges became too steep or where shorter reaches for logging

were needed These midslope roads would cross small creeks and draws Some full-bench ground would be crossed with excess excavated material hauled to stable disposal sites. Some of the roads would be visible from the Illinois River; parts may be seen from sections of U.S. Highway 199 and the community of Selma. Access would be provided for timber management, recreation, and fire suppression.

Trails. No trails are planned.

Developed Recreation Sites. None are planned.

Wilderness Potential

The area has been inventoried according to ROS criteria and is capable of providing 2,500 acres of Semi-primitive Non-motorized recreation opportunities and 5,200 acres of Roaded Natural recreation opportunities. The carrying capacity for the area is estimated at approximately 9,000 RVD's This figure is high since the numbers are based on the assumption of the presence of roads. Current use is low (approximately 100-200 RVD's) and is attributed primarily to recreation activities such as hunting The presence of motorized uses on the river and the surrounding road systems would preclude the ability of the area to provide a truly primitive recreation experience. The roadless area is isolated from other roadless areas and designated Wilderness

Access within the area is limited to one unmaintained trail. No new trails are programmed due to the low levels of use. Recreation demand projections indicate that use levels will remain well within the carrying capacity over the planning period.

All alternatives, except E and M, would assign the area to multiple resource management objectives; Semi-primitive recreation opportunities currently available would shift to the Roaded Natural end of the opportunity spectrum The change in landscape character would result in the loss of any Wilderness potential. Alternatives E and M would provide additional capacity for Roaded Natural and Semi-primitive Motorized recreation opportunities. Wilderness potential would be maintained.

How much of the inventoried roadless area remains unroaded by alternative can be evaluated by either assessing a combination of Management Areas 1-9 (which retain essentially undeveloped conditions), or by viewing the spatial arrangement of blocks of undeveloped area at the end of a given period of time Management Areas may or may not be contiguous, so the integrity of the roadless area as a whole may be compromised by management around them. The following table provides a spatial estimate of acres remaining unroaded at the end of specific decades; these figures differ from the Management Area 1-9 acres in that the minimum criteria is based on the area either (1) bordering designated Wilderness, or (2) being 5,000 acres or greater:

Alternative	Acres Remaining End of Decade 1/		
	1	2	5
A, A-Dep, and NC	0	0	0
B, C, D, and D1	0	0	0
E and M	7,700	7,700	7,700
G	0	0	0
K	0	0	0
S	0	0	0

1/ Minimum criteria is 5,000 unroaded contiguous acres or adjacent to designated Wilderness

Wild and Scenic Rivers

As the Squaw Mountain area is located adjacent to the Illinois Wild and Scenic River, much of the area is visible to river users The assignment of the area to roadless management objectives will not effect the management of the Illinois Wild and Scenic River. However, this allocation could have an effect on the quality of the recreation setting near the river. The recreation setting is currently maintained through the use of VQO's which were assigned to the area in response to both the designation of the river as Wild and Scenic and to the high levels of recreation use that occur on the river. Area within the designated Wild and Scenic River corridor is managed to achieve the Retention objective.

All alternatives, except C, would manage the area to achieve inventoried visual objectives, resulting in some modifications in the area as they are entered for timber harvest. The quality of the recreation experience of the river users would be maintained. Alternative C would assign the area outside of the designated Wild and Scenic River corridor to a reduced scheme of visual objectives. This area, inventoried for Retention, would be managed for Partial Retention resulting in visible harvest activities in proximity to river users The quality of the recreation experience of river users would be affected minimally because so little of the area is inventoried for Retention.

Alternatives E and M would be managed under the Preservation objective. This would maintain the natural appearance and the Wilderness potential over the planning period.

Soil, Water, and Fish

No consequences to the soil, water, or fisheries are expected under Alternatives E and M because no soil disturbing activities are planned. All other alternatives assign all or part of the area to Management Areas which permit development. The environmental effects of timber harvest and road building are discussed in Chapter IV of the FEIS.

The risk of degrading the soil and water resource increases with more timber harvest and road building. The sediment potential for road and regeneration related increases is low. Development alternatives are similar in the amount of soil disturbing activities proposed. Alternatives NC, A, B, C, and D, would have potential for slightly greater sediment outputs. The assignment of acres to development in this area would have slight to negligible effect on the soil, water, and fisheries resources.

Fire

The effects of the alternatives from a fire standpoint are the increase or decrease in fire hazard and risk that will be created. Risk is defined as the probability that an ignition will occur. Hazard is a description of the fuels complex in terms of kind, volume, arrangement, condition and location of the fuels

The Squaw Mountain area is a patchwork of dense timbered stands, grassy areas, and brushfields. In the timbered sites, fuel loadings are light to moderate, and continuous. The areas of brush vary from sparse to dense, with dead fuel loadings generally light. In an undeveloped scenario, fuel accumulations would increase and fuel continuity would remain the same or increase. These conditions lend themselves to large, high intensity fires Adding to this is the increased response time for initial attack forces due to poor access The result is larger fires, higher suppression costs and increased resource losses In a developed scenario, the fire hazard increases during timber harvest As fuels are treated, the fire hazard is reduced Over time, the continuity of fuels are broken up, creating a mosaic of fuels and vegetative development. This mosaic, combined with improved access for initial attack forces, reduces the potential for large, high intensity fires. The result is smaller fires, lower suppression costs and less resource loss due to fire.

In Alternatives E and M, all of the area would remain undeveloped with fuels remaining continuous over the entire area. In Alternatives G, K, and S, approximately 62 to 71 percent of the area would be developed, creating a mosaic of fuels over time while the remaining undeveloped area would be in 10-13 separate blocks. Alternatives A, B, C, and D would develop approximately 82 percent of the area. The remaining undeveloped areas would be broken into two separate blocks. Alternative NC would develop 86 percent of the area. In all alternatives, some of the high priority natural fuels accumulations will be treated.

In undeveloped areas, risk of ignition is low due to low levels of human use. As development occurs, risk increases with road construction, timber harvest, and with treatment of activity slash from these operations. As access improves, the level of dispersed recreational and other public uses increases with an increase in the risk of human-caused fires. Risk level for lightning fires is similar for both developed and undeveloped scenarios.

In Alternatives E and M, the risk from human-caused ignition would be limited primarily to the periphery of the area due to limited access. In Alternatives G, K, and S, industrial operations would result in increased risk over 62 to 71 percent of the area, and risk from public use would be increased along the 16 miles of road. In Alternatives NC, A, B, C, and D, industrial operations would result in increased risk over 82 to 86 percent of the area, risk from public use would be increased along 16 miles of road

Vegetation

Effects on vegetation relative to diversity and age class distribution do not significantly differ from the effects on the Forest as a whole (See Chapter IV, FEIS).

Sensitive Plants

Portions of two of the Forest's 24 candidate Botanical areas for sensitive plants are within the area: one-half of Squaw Mountain and the "Addition" section of Eight Dollar Mountain. These two sites are allocated as Botanical areas in Alternatives G and M (see Appendix F for more detail on individual sites).

A significant group of sensitive and rare plants are present. Less than 50 percent of the area is tentatively suitable for timber production Most of the sensitive and uncommon plants are restricted to serpentine or peridotite derived soils. These areas are generally not suitable for timber harvest, and other than mining activities by private individuals, will remain relatively untouched between now and the next revision of the Forest Plan. There are no existing or proposed RNA's. Under all alternatives, sensitive plants will be protected by the use of appropriate Standards and Guidelines.

Air Quality

The principle agent impacting air quality in the forest environment and surrounding areas is smoke from wildfire and prescribed burning. To determine the impacts of each alternative, only the effects of prescribed burning will be considered. The effect of smoke is a temporary reduction in visibility in an area. Total suspended particulates (TSP) is used as the measurement of local and regional haze. Alternatives E, L, and M would contribute no TSP to the annual total generated on the Siskiyou National Forest. All other alternatives would produce 23-25 tons of TSP per year.

Based on past performance, the probability of a smoke intrusion from burning in the area impacting Grants Pass air quality is very low. The probability of impacting the Kalmiopsis Wilderness, a Class 1 area, is also very low.

Wildlife

Unless specifically mentioned below, effects of the alternatives on wildlife indicator species and wildlife habitat in this roadless area are the same as for the Forest as a whole.

Bald Eagle/Osprey. The area is not considered habitat for bald eagle or osprey. These birds may occasionally overfly that part of the roadless area near the Illinois River.

Spotted Owl/Pileated Woodpecker/Pine Marten. Under all alternatives except E and M, habitat for mature/old-growth indicator species would be considerably reduced over time. This would be especially true under Alternatives A through D1, K, and S, which meets Management Requirements (MR's) for mature/old-growth wildlife species, but otherwise allocate most of the area to development. Alternative NC does not meet MR's; it contains no habitat allocations for wildlife species using mature/old-growth forests.

Except for Alternative NC, one habitat enclave for pileated woodpecker has been established in the area to meet MR's for old-growth forest habitat. At present, this area probably supports one or two pairs of spotted owls; there would be no change under Alternatives E and M. Mature/old-growth habitat would ultimately be reduced to MR levels in all other alternatives. In Alternative NC, however, habitat would reduced below MR levels.

Woodpeckers. Snag habitat would remain at or near 100 percent under Alternatives E and M which maintain roadless status.

Black-tailed Deer/Roosevelt Elk Big game management opportunities would increase in alternatives which open up much of the unroaded area to timber management (all alternatives except E and M). Opportunities for habitat improvement projects for game animals would also be greater.

Wildlife Habitats No meadows are known, however, almost 500 acres of rock-type habitat are located within the area Rock areas are allocated to wildlife use in Alternatives E through S, but would probably remain unaffected in Alternatives NC, A through D. Alternative G, which manages the area under a Riparian Prescription C, comes close to maintaining natural conditions

Wildlife Recreation Use Estimated Wildlife/Fish User Days (WFUD's) currently attributed to the area are somewhat below average Fewer hunters use unroaded areas and non-hunters generally stay on trails Alternatives E and M, which leave the area in an unroaded condition, produce fewest WFUD's.

Visual Resource

The area has been inventoried based on visibility to major recreation travel routes or use areas. The visual resource inventory is shown as:
888888

VQO	Acres
Retention	650
Partial Retention	3,700
Modification	3,350

All alternatives, except E and M, would assign the area to management for inventoried VQO's. The natural appearance would be modified over time so that feature vistas would present a slightly altered appearance. Alternatives E and M would manage the area to achieve the Preservation objective; natural appearance is maintained

Alternative C would assign the area to a reduced level of visual objectives. Areas inventoried for Retention would be managed to achieve Partial Retention Management activities would be evident to river users in the foreground The natural appearance of the area would shift to a slightly altered-altered appearance as a result of management activities within the first two decades.

Recreation Settings

The area is surrounded by roads, thereby greatly influenced by the sight and sound of motorized users A portion of the Illinois Wild and Scenic River runs through the southern fringe of the area. The physical position of the area might limit it's ability to provide a quality wilderness or primitive experience.

All alternatives, except E and M, which would allow for development create a shift of Semi-primitive Non-motorized recreation to the Roaded Natural end of the opportunity spectrum. Access to the area and motorized opportunities would be enhanced as the area is roaded. Alternatives E and M would maintain the area as unroaded; any Wilderness potential would be maintained.

Alternatives A, A-Departure, B, C, D, and D1 would retain the essentially undeveloped character of the area on 400 acres, and Alternatives K and S on 800 acres due to Designated Wildlife Habitat. The entire area would be developed under Alternative NC. Alternative G would retain the undeveloped character on 1,300 acres due to assignments to Botanical and Designated Wildlife Habitat Management Areas. These areas may or may not be contiguous, so the integrity of the roadless area may be compromised by the presence of motorized activities.

Economic and Social

There are 3,533 acres of land identified as tentatively suitable for the production of timber in this unroaded area The general effects on annual allowable sale quantity (ASQ) and long-term sustained yield (LTSY) of allocating these acres to uses that would include timber production are the same as those described in Chapter IV of the FEIS.

The estimated potential ASQ from the inventoried 7,704 acres of the Squaw Mountain Roadless Area is 0.19 MMCF. The estimated LTSY would be 0.35 MMCF. Following are the estimates of the contribution to timber production (in MMCF) from this area under each alternative:

Alternative	ASQ	LTSY
NC, A, A-Dep, C, D, and D1	18	.33
B	22	41
E and M	00	.00
G, K, and S	.16	29

For projecting effects, the alternatives are grouped: (1) Alternatives E and M, which leave the area in an unroaded condition; (2) Alternatives G, K, and S, which develop much of the area; and (3) Alternatives NC, A, B, C, and D, which develop most of the area.

The major direct economic effect is government expenditure for the timber and associated road construction program Alternatives E and M have a reduction in the timber and road expenditures. The other

other alternatives have insignificant changes in budget expenditures. Alternative B has a minor benefit as compared to Alternative A

The indirect effects are associated with jobs, income, and payments to counties Assuming no substitution of reduced timber harvest within the area of influence, Alternatives E and M reduce outputs while the other alternatives have little or no change in the number of jobs, amount of income, and size of payments to the counties.

The cumulative social effects of attitudes of people is summarized by examining the different interests of the adjacent communities. Previous documentation is found in Chapters III and IV of the FEIS. The positive sign indicates a feeling by special interest groups of the Forest being responsive while a negative indicates a social feeling of the Forest not being responsive to particular interests.

	Alternatives		
Effects (Changes Compared to Alternative A)	E and M (Unroaded)	NC, A, B, C and D G, K, and S	G, K, S NC, A, B, C, and D (Roaded)

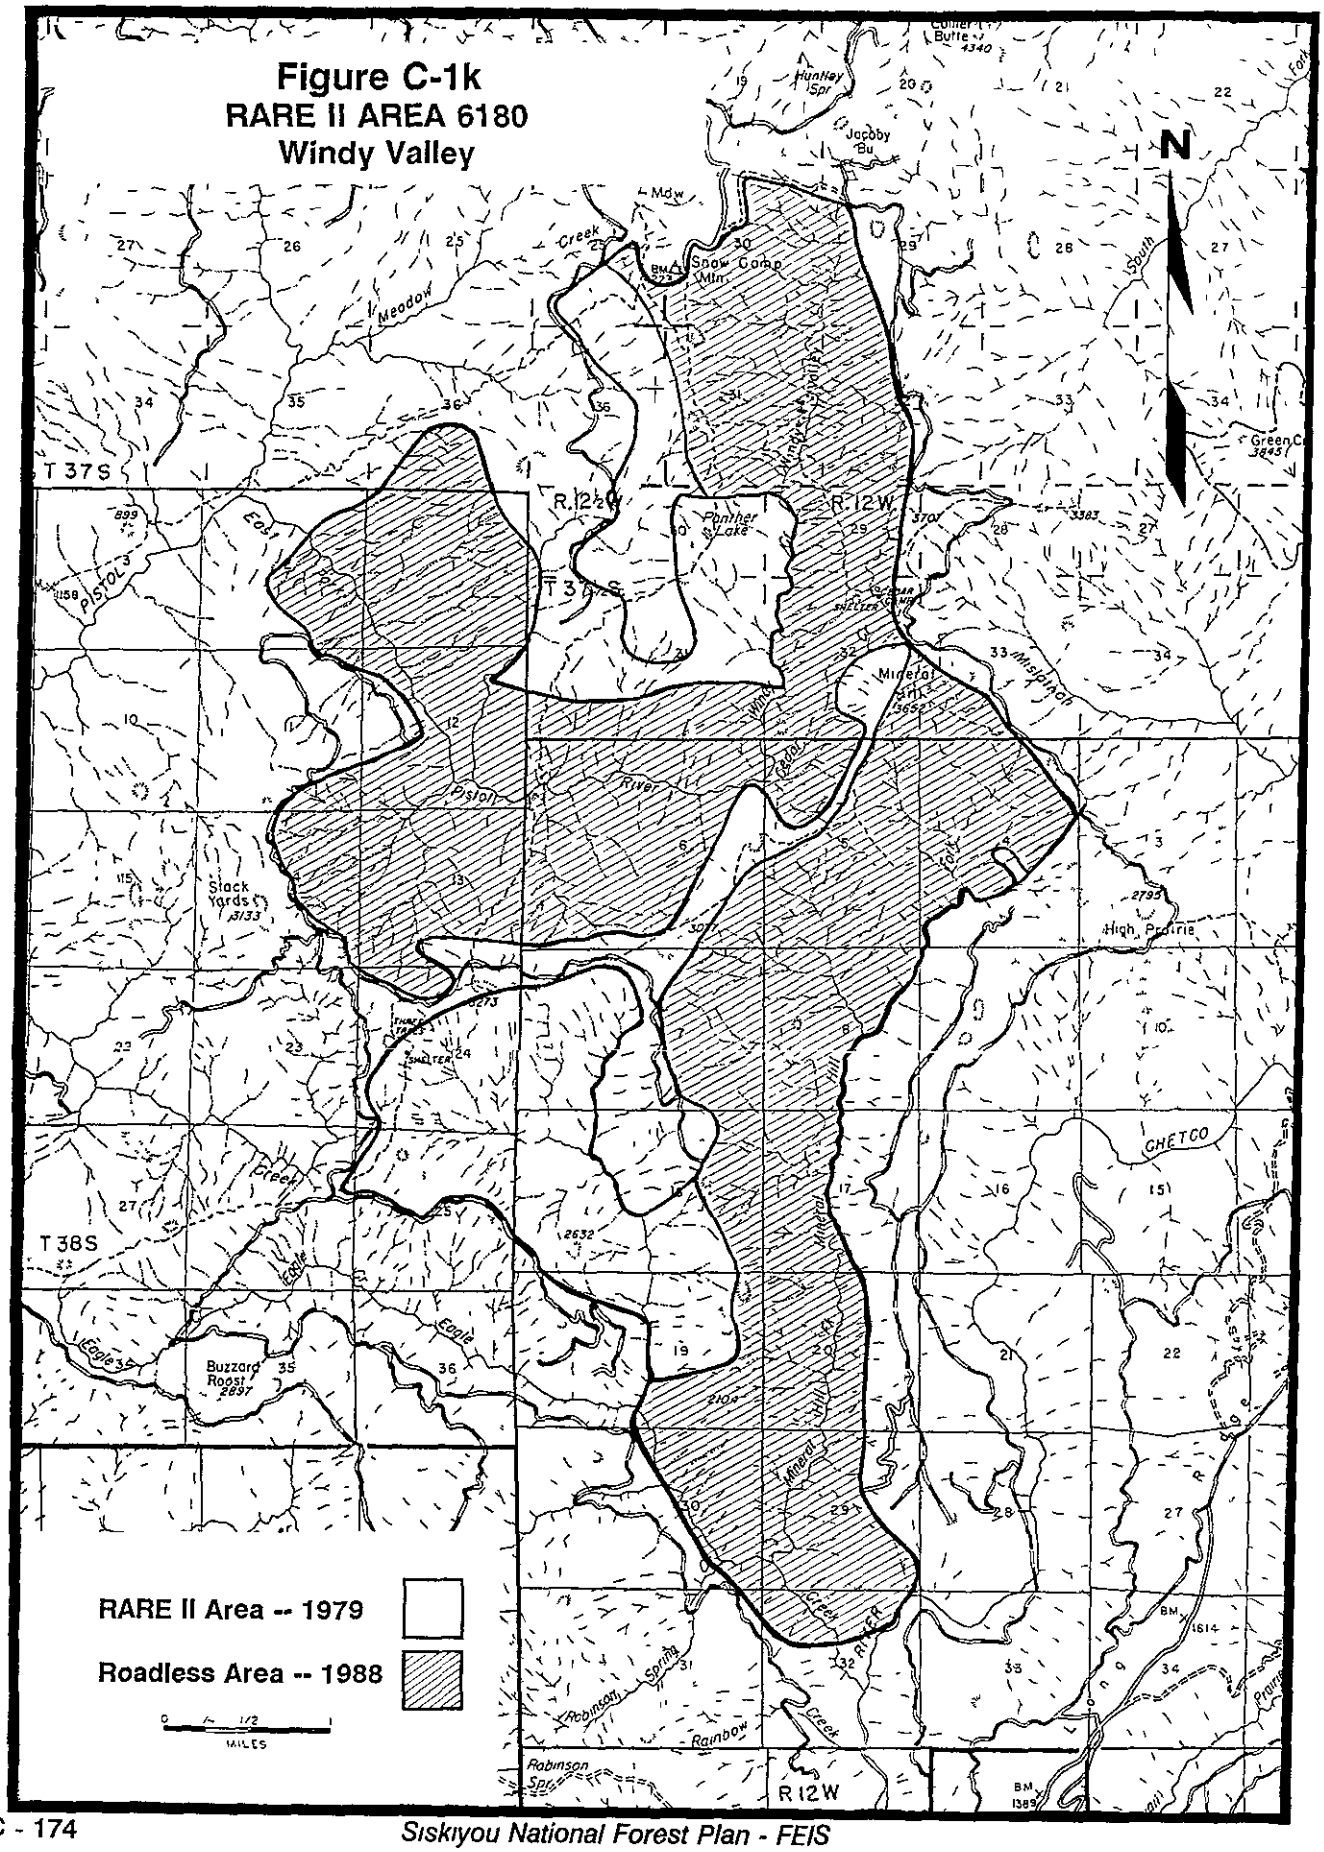
MITIGATION MEASURES



No additional mitigation measures have been identified.

POTENTIAL CONFLICTS WITH OTHER JURISDICTIONS

No potential conflicts have been identified.

WINDY VALLEY No. 6180

(10,214 Acres)

DESCRIPTION

STATUS OF ROADLESS AREA

Windy Valley Roadless Area was inventoried for study as a potential Wilderness during the RARE II process It contained 13,491 acres at that time and was allocated to non-Wilderness use by the RARE II decision in January 1979. Since that time, road construction and timber sales have reduced the area to 10,214 acres. This activity also cut the roadless area into two parts. The entire roadless area is National Forest System land.

The Chetco-Grayback Land Management Plan (FEIS, 1979) encompasses the Windy Valley area This document allocated 2,413 acres of Windy Valley to dispersed recreation. Management direction for this portion of the inventoried roadless area states that the area will be managed to protect and retain the existing natural qualities, protect and preserve small areas which have exceptional features, to provide opportunities for primitive and semi-primitive recreational experiences and to protect other resources The remaining area adjacent (mostly south in Mineral Hill Fork and west in the East Fork Pistol River) to Windy Valley is allocated to Coordinated Resource Management designed to obtain full timber yield consistent with land capabilities and appropriate constraints, along with providing a high level of quality big game habitat and protecting small areas containing exceptional features.

A small section of the roadless area within 1/8 mile horizontal distance from the Chetco River is allocated to a Recreation/Fisheries area (synonymous with the Supplemental Resource Management Area) Land within this area will be managed to provide opportunities for a wide range of recreational activities which are river oriented and enhanced by its free-flowing condition NOTE· Because this section is quite small relative to the overall inventoried Windy Valley Roadless Area, specific discussion will be limited Information and discussion of alternative management strategies are provided for in the FEIS.

Readers are directed to the Land Management Plan for a broad overview of the affected environment, evaluation of resources and management alternatives, and other requirements and constraints considered and currently implemented for the area. Since the completion of the Land Management Plan, all project activities have been analyzed under it's direction and NEPA requirements/process

CHANGES BETWEEN DRAFT AND FINAL

The area remains as previously described No activity has occurred between 1984 and 1988 which reduced the inventoried roadless area (Refer to Figure C-1k).

The small portion of the southernmost tip of the roadless area that borders the Chetco River became classified as a Recreation segment under the Omnibus Oregon Wild and Scenic Rivers Act of 1988. Any alternative selected in the Record of Decision and disclosed in the Land and Resource Management Plan will treat this portion alike for its Congressionally designated values.

LOCATION AND ACCESS

The Windy Valley area is located approximately 20 miles northeast of the town of Brookings in southwest Oregon The area lays in the Chetco River and Pistol River drainages The area is surrounded by many

multi-purpose roads used for timber hauling, administration and recreation. The primary roads include the Chetco River, Panther Lake, Eagle Creek, and the Chetco Pistol roads The Cedar Ridge Road bisects the unroaded area.

PHYSIOGRAPHIC AND BIOLOGIC FEATURES

The physical location of the unroaded area is on the western side of the coast range (Klamath Mountain Geologic Province) in southwestern Oregon Elevation ranges from about 1,000 feet to 4,200 feet on Snow Camp Mountain,;and between 300 and 3,650 feet in the southern part. Topography is mountainous with steep slopes and deeply incised canyons.

The area is well timbered with a mixed evergreen forest. Douglas-fir is the primary conifer species with Port-Orford-cedar, knobcone pine and white pine making up secondary components. Associated hardwood species include tanoak and Pacific madrone intermixed with the conifers. A dense understory of brush species is also present over most of the area.

Soil conditions, productivity, and hazards are highly variable within the area Soils in the area above Windy Valley are generally low in productivity, extremely cobbly, and derived from serpentine and peridotite parent materials. In contrast, coluvial soils derived from sedimentary rocks and alluvial soils at the valley floor are quite productive. No significant slide activity is occurring in this portion of the area.

Soils in the Pistol River portion of the area are generally deep and productive, formed by ancient landflow activity. Although some channel instability is evident along the Pistol River, the rate of activity has not been great The Mineral Hill portion, on the other hand, has experienced frequent, massive debris slide activity. Slopes are unstable with areas undercut by stream meanders and areas of water concentration receiving the most mass movement Much of this area has been removed from lands suitable for timber production due to the high mass instability hazard.

Average annual precipitation ranges from 130-150 inches per year. All but 12-15 inches of precipitation falls between October and April. The climate is mild and heavily influenced by marine air. Summer temperatures often exceed 80-90 degrees Fahrenheit.

A variety of wildlife species utilize the area. Populations of black-tailed deer and black bear are present. An elk herd frequents the Windy Valley and East Fork Pistol River areas. While no known threatened or endangered species inhabit the area, the bald eagle may utilize a flight corridor in the extreme southeast portion of the area in the Mineral Hill Fork and Chetco River drainages A northern spotted owl was heard in the area on one occasion but no nest were discovered.

Botanically, the Snow Camp and Windy Valley area is quite interesting Several sensitive plant species occupy the area· California lady's slipper (*Cypripedium californicum*), cascade sedge (*Carex scabriuscula*), Howells' streptanthus (*Streptanthus howellii*), Koehler's rock cress (*Arabis Koehleri* var. *stipitata*), Piper's bluegrass (*Poa piperi*) and long-stalked eriogonum (*Eriogonum pendulum*). Howell's streptanthus, Koehler's rock cress, Piper's bluegrass and long-stalked eriogonum occupy serpentine areas. California lady's slipper can be found in serpentine bogs and moist rocky places; Cascade sedge occupies open meadows and moist rocky areas A number of uncommon plants inhabit the area, such as Vollmer's lily (*Lilium vollmeri*), snow plant (*Sarcodes sanguinea*), California pitcher plant (*Darlingtonia californica*), and Siskiyou everlasting (*Antennaria suffrutescens*) Future inventories will likely result in the discovery of additional sensitive and uncommon plants.

Major streams in the area are Windy Creek, East Fork Pistol River, Mineral Hill Fork and Eagle Creek. Both anadromous and resident fish are present. Chinook salmon and steelhead can be found in Eagle Creek, while steelhead inhabit the lower East Fork Pistol River and Mineral Hill Fork. Trout can be found in all the

major creeks within the area, including Windy Creek. Most creeks containing salmonid populations are not easily accessible.

RESOURCE USES

The roadless area contains several chrome claims but little activity other than surface exploration is present today The Pistol River Range Allotment exists in the Snow Camp portion of the area but it is not currently being used.

Big game hunting occurs along the fringes of the area Hunting within the interior is limited to Windy Valley; in other areas, a heavy brush cover and steep ground discourages use. Use by fisherman is quite sparse.

Recreational use is highest within the Windy Valley portion, and consists of day hikers, overnight campers, horseback riders, and motorbike riders. Use is presently classified as Semi-primitive Motorized Other portions of the area get little recreation use

APPEARANCES, SURROUNDINGS, AND ATTRACTIONS

The roadless area has been divided into two areas by new road construction; a long section of the Mineral Hill Fork drainage and the J-shaped East Fork Pistol/Windy Valley area. Distinguishing features of the Mineral Hill Fork and East Fork Pistol areas are heavily vegetated, steep, and highly dissected slopes with deep inner gorges, and rocky creek beds. The Windy Valley area is characterized by slopes lightly vegetated with knobcone pine and Port-Orford-cedar. The lower slopes and creeks are similar to the rest of the roadless area. A small meadow exists along Windy Creek. Snow Camp Mountain is a dominant rock point and the highest feature in (just outside) the area.

Conditions surrounding the roadless area do not vary greatly. Vegetative type and land form are consistent. Man's activities have modified the environment on the ridgelines and local areas accessed for timber harvesting and other purposes. Timber harvest entries have provided a mosaic of patch cuts where the vegetation varies in age.

Influences which predominate in this locale are primary and secondary roads which receive moderate use. Timber harvest activities and their associated roads immediately border the unroaded area either on the same slope or immediately above on the ridgelines. Fires, too, have played a major role in the past in changing the vegetative mosaic of the area.

The primary attribute of the roadless area is Windy Valley. The attractiveness of Windy Valley is in it's scenic, floral and geologic variety which is easily accessible by good road and maintained trails. This higher elevation area contains sensitive and unusual plant life, open and rugged terrain and interesting landforms. The landscape is homogenous over the rest of the area and generally reflects the features common to surrounding areas.

CAPABILITY

MANAGEABILITY

Portions of the Windy Valley area follow well defined topographic boundaries, however, much of the boundary is located on midslopes below recent road construction or timber harvest units. Poor boundary definition may complicate management efforts to maintain and protect the unroaded characteristics and values of the area. The principal concern would be escape fires from the disposal of logging slash Light recreation, along with hunting and very limited fishing, poses little risk of fire starts; however, fire ignition within the interior at the wrong time could result in a major conflagration. Favorable aspects from a fire

perspective are weather conditions ameliorated by coastal marine influences, and positioning - heaviest use being generally above the fuels.

The area would be difficult to manage due to its unconsolidated, narrow, and highly dissected nature. Conflicts could arise between existing or potential public uses outside which could result in a disturbance of the natural settings and values within the area. The boundary, in some cases, is not easily definable and recognizable on the ground As all locations are within 3/4 mile of the edge, few physical features or terrain exist to adequately shield the interior from the sights and sounds of civilization outside There is ample opportunity for access to nearly all the perimeter.

NATURAL INTEGRITY AND APPEARANCE

Although humans may have used fire to change vegetative patterns within the area in the past, today, long-term ecological processes are intact and operating. Fires may continue to be a factor in successional changes within the area. The area contains several features which effect its natural appearance. The Windy Valley portion contains the remnants of an old historical trail shelter and an old homestead where two buildings stood. Otherwise, little evidence remains to indicate man's presence.

Several maintained trails that are currently used by both backpackers, horseback riders, and motorbike riders. Some portions of these trails have been abandoned and have nearly returned to natural conditions

There is a range allotment in the Snow Camp/Windy Valley portion of the area which has been retained, but is not being used. There is little or no evidence of past grazing.

A small part of the area has been treated with herbicides in the past to retard the growth of hardwoods and encourage the growth of conifers. This treatment has altered the natural processes in favor of conifer growth, but is barely evident today.

The area contains several chrome claims. Pit holes were dug to uncover ore deposits and can still be seen today. Although they are present, their impact is negligible.

OPPORTUNITIES FOR SOLITUDE AND PRIMITIVE EXPERIENCE

Highly dissected topography, deep valleys and dense vegetation over most of the unroaded area provides natural screening and opportunities for localized solitude. Encounters with other people would be few within the interior of each portion of the roadless area Chances for solitude is rather limited due to narrow shape of the roadless area, noise, dust, and views of activities on the borders could be seen or heard.

Use of the area as a quality primitive setting is limited due to dense vegetation and steep terrain. Along with the few trails, sufficient openings exist to permit cross country foot travel to the interior area Opportunities for a quality primitive experience would be very limited due to the area's narrow shape and the high density of perimeter roads.

The Windy Valley portion of the area covers a good quality semi-primitive experience The meadow is the principle feature; it is surrounded by a natural vegetation screen and offers a good chance for solitude.

SPECIAL FEATURES

The Snow Camp/Windy Valley area is an interesting botanic and geologic area which could contribute to outdoor education and/or scientific study Educational use is generally compatible with current activity and management direction. Much of this area has been classed as unsuitable for timber production.

Snow Camp Lookout is a historic site located on the top of Snow Camp Mountain, just outside the roadless area boundary. The lookout was rebuilt on the 1950's and is operated during periods of high fire danger.

AVAILABILITY

RESOURCE POTENTIALS

Recreation Settings

Undeveloped/unroaded. The opportunity for measurable change in type or use is limited even though there is some potential total use increases. New trail construction and trail improvements could increase RVD's. Capacity of use is great and is not likely to be exceeded.

Developed. There would be only slight increases in RVD's if development were allowed since there are few development opportunities. Windy Valley has the greatest potential for recreational development. Increased roading could increase use by hunters. The capacity is not likely to be exceeded.

Wildlife

Under unroaded conditions, wildlife populations would fluctuate with the natural changes in vegetative succession unless special habitat improvements were implemented. Under a roaded condition with timber harvesting, deer and elk populations would increase. The effect of timber harvesting on old-growth dependent species would be lessened by the habitat provided in the proposed pileated woodpecker and pine marten areas. Additional habitat variety would be provided by unsuitable areas.

Fisheries

The anadromous steelhead and salmon fisheries are extremely important to the local community. While this area contributes little to on-site catchables, maintenance of downstream rearing and spawning habitat is essential.

Water

There are no impoundments or diversions either existing or proposed. There is little potential for power development in the area. Management emphasis has been placed on protecting and maintaining water quality for fish habitat. An increase in water yields would result from timber harvesting activity.

Livestock

Grazing under the existing allotment could resume if new forage area were opened up by timber harvest activities or range improvement projects. Demand on this area for grazing is low. The potential for grazing outside the existing allotment is also low due to the lack of available forage.

Timber

The area contains 7,907 acres of land tentatively suitable for timber production. Standing timber volume is estimated at 130 MMBF. Site productivity is moderate. Soils in the some areas are unstable and will require harvest methods which minimize impacts. Some additional roads will be required. The area has a dense undergrowth of brushy type species, and reforestation after timber harvest operations will likely require vegetative release. Approximately 1,200 acres within the area has been placed in a proposed *special harvest site (separate suitability component) with a long rotation; the site productivity is generally* very low.

Energy and Minerals

Several mining claims exist within the area, although no mining activities are currently taking place. The potential for commercially valuable deposits of both critical (chrome) and non-critical minerals exists, but is low. These minerals are currently in low demand and the deposits are not of a particularly high grade. Mining is not expected to occur in the near future.

Cultural

Other than those noted, historic and prehistoric sites will be evaluated and provided for under applicable laws and regulations for any proposed activity.

Land Use Authorizations

None existing, few expected.

MANAGEMENT CONSIDERATIONS

Ownership, including subsurface rights held by others, is not considered a problem. The potential for insects and disease outbreaks with the coniferous forest exists. However, actual occurrences have been minor and localized Fire is the most serious management consideration The potential for major conflagrations exists.

NEED

OTHER AREAS AND PUBLIC USE

The Kalmiopsis Wilderness is approximately five miles east of the Windy Valley Roadless Area The Wilderness and adjacent unroaded/undeveloped areas are very different from Windy Valley and are discussed in separate documents. The Big Craggies Botanical Area, which contains many rare plants is located four miles east of Windy Valley.

Recreation use of this unroaded area is very light. Most of the use is by local people rather than by recreationalists from major population centers.

ECOSYSTEM REPRESENTATION

The major ecotypes within the Windy Valley area also occur in the Kalmiopsis Wilderness.

PUBLIC INVOLVEMENT

Both the public and Forest managers have had considerable interest and concern for the existing and future management of these larger unroaded areas For this area, involvement in evaluation of alternative management options for Windy Valley began in the early 1970's. Between 1977 and 1979, the RARE II process was being finalized. Since RARE II, the area's unroaded attributes have been reevaluated several times through site specific project planning. The analysis included herein is a compilation of information beginning with early public scoping in 1979 to public meetings and workshops through 1985

Public input on several of the inventoried roadless areas on the Siskiyou National Forest has been extensive. Windy Valley, though, has not received the same intensity of concern or advocation of protective status as several adjacent areas. Input by the public on the advisability of designating this area as either Wilderness, back country or some form of non-commodity management was divided between extremes. Local government and the timber industry were opposed while many individuals supported removing the area from timber production. Those opposed site economic needs of the local community and their belief

that other resources could be protected. Those desiring Wilderness designation generally believed that all other resources would be severely and adversely impacted by timber harvest activities. The most specific input and desire, though, were requests by individuals and some State personnel for the protection of Windy Valley, itself, and the immediate surrounding environs.

In the current Forest Planning process, the unroaded area question has remained a major issue. Since 1985, comments received on the Forest Plan DEIS have not surfaced any additional concern or movement to seek unroaded allocation of this area, with the exception of the Windy Valley/Snow Camp portion

ENVIRONMENTAL CONSEQUENCES

SIGNIFICANT EFFECTS

The significant effects of each alternative are presented in Chapter IV of the FEIS. Additional site specific effects, mitigations, and potential conflicts are presented here. The Standards and Guidelines for each alternative were considered when evaluating the effects of implementation.

Cultural Resources

The Windy Valley area has some known prehistoric use, much of which requires evaluation by a professional archaeologist. Overall, its archaeological potential is low. Historic sites within the area are quite limited and are not significant All alternatives, except E and M, call for development which would require intensive cultural resource inventory and site evaluations along any proposed road prior to approval. Valuable sites can then be protected by avoidance or conserved through data recovery. Alternatives E and M call for an unroaded regime which would minimize the need for an inventory.

Energy and Minerals

The following table is a tabular summary of the estimated mineral potential and accessibility limitations for Windy Valley. The acreages shown are subject to change due to the current withdrawal review by the Bureau of Land Management (BLM), and differences found for site specific needs included in any subsequent withdrawal applications to BLM.

	Mineral Potential (Acres)			
Access Restrictions	High	Moderate	Low	Total
Withdrawn	<100	<100	-	<100
High	-	-	-	-
Moderate	-	-	-	-
Low	1,300	8,900	-	10,200
Total	1,300	8,900	-	10,200

Improvements

Roads. The 7,907 acres of tentatively suitable land could generate about 27 miles of new road for timber harvest. Roads for other purposes would be minor. All would be dead-end local roads built when needed to access timber harvest units. Some mileage would remain open to passenger car use, depending on the alternative; other roads would be open to only high clearance vehicles or closed between projects. The following table shows road mileage in the area by alternative.

Alternative	Total Miles	Miles Open to Passenger Car	Miles Open to High Clearance	Miles Closed
NC and A	20	6	6	8
B	27	8	8	11
C	27	5	11	11
D	27	9	7	11
E and M	0	0	0	0
G	19	0	8	11
K and S	20	6	3	11

Alternatives E and M would have minimal effect as no roads are built. Of the roaded options, Alternatives NC, A, G, K, and S would have fewer miles built due to a Supplemental Resource allocation for Windy Valley, the Backcountry Recreation allocation in Alternative S, and a Botanical area in Alternative G. Alternatives B, C, and D would be completely roaded. Alternatives G, K, and S, would close nearly 60 percent of the roads.

The road system would follow ridges off the main roads on the boundary or extend existing midslope roads. Midslope roads would cross small creeks and draws, but none would be expected to cross the principal streams or other primary tributaries inhabited by fish. Some full bench ground would be crossed by roads with excess excavated material hauled to stable disposal sites.

Trails. Alternatives NC, A, A-Departure, E, G, K, M, and S would provide for reconstruction of five miles of trail. Alternatives B, C, D, and D1 provide no additional improvements.

Developed Recreation Sites. None are programmed.

Wildlife and Fish Habitat Structural Improvements. The East Fork Pistol River, Eagle Creek and Mineral Hill Fork are excellent candidates for improvements applied on a Forest-wide basis

Wilderness Potential

The roadless area has a landscape character that is unique relative to the rest of the Forest and offers a wide array of recreation opportunities. The area has been inventoried according to ROS criteria and is capable of providing a Roaded Natural recreation experience on approximately 7,200 acres, and a Semi-primitive Motorized experience on the remaining 3,000 acres The carrying capacity for the area is estimated at 15,200 RVD's. This figure is high since Roaded Natural coefficients were developed based on the assumption of the presence of roads. Current use is low but consistent (500-1,000 RVD's annually) and is expected to remain low over the planning period.

The roadless area is near the Kalmiopsis Wilderness, but is not contiguous. Maintenance of the area would in effect expand the carrying capacity for Roaded Natural and Semi-primitive Motorized recreation opportunities. However, quality of the experience is suspect due to the proximity of roads and management activities. Alternatives E and M would provide additional capacity for Semi-primitive Motorized recreation opportunities. Wilderness potential of the area would be maintained

All alternatives, except E and M, assign the area to multiple resource management objectives; Semi-primitive recreation opportunities currently available would shift to the Roaded Natural end of the opportunity spectrum. The change in character of the landscape would result in the loss of Wilderness potential. Alternatives A, A-Departure, G, K and S would maintain 3,000 to 4,000 acres in a roadless condition as a result of assignments to Supplemental Resource and Designated Wildlife Habitat Management Areas. The

Supplemental Resource assignment is in response to the consistent level and type of recreation use reported in Windy Valley; no programmed harvest is planned here.

How much of the inventoried roadless area remains unroaded by alternative can be evaluated by either assessing a combination of Management Areas 1-9 (which retain essentially undeveloped conditions), or by viewing the spatial arrangement of blocks of undeveloped area at the end of a given period of time. Management Areas may or may not be contiguous, so the integrity of the roadless area as a whole may be compromised by management around them. The following table provides a spatial estimate of acres remaining unroaded at the end of specific decades; these figures differ from the Management Area 1-9 acres in that the minimum criteria is based on the area either (1) bordering designated Wilderness, or (2) being 5,000 acres or greater:

Alternative	Acres Remaining End of Decade 1/		
	1	2	5
A, A-Dep, and NC	0	0	0
B, C, D, and D1	0	0	0
E and M	10,200	10,200	10,200
G	0	0	0
K	0	0	0
S	0	0	0

1/ Minimum criteria is 5,000 unroaded contiguous acres or adjacent to designated Wilderness.

Wild and Scenic Rivers

A small portion of the southernmost tip of the roadless area borders the Chetco River. In several alternatives, this area is treated as a Recreation segment of the National Wild and Scenic River System. With passage of the Omnibus Wild and Scenic River Act of 1988, the Chetco was designated Wild and Scenic and this section classified as Recreation. Protection of its values will be provided under all alternatives per recent Congressional designation.

Soil, Water, and Fish

No consequences to soil, water, and fish are associated with Alternatives E and M because no soil disturbing activities will occur. All other alternatives assign all or part of the area to Management Areas which permit development The environmental effects of timber harvest and road building are discussed in Chapter IV of the FEIS.

A low risk of degrading the water, soil, and fisheries resources in the Pistol and Windy Creek areas exists for all roaded alternatives. Soils in these areas do not display the potential for significant impacts as a result of management activities. The Mineral Creek area, however, has a moderate to high potential risk of impact to the soil resource These soils are highly sensitive to both harvest and road related impacts. Alternatives NC, B, C, and D propose roughly double the amount of soil disturbing activity over Alternatives A, G, K, and S. All alternatives, though, have eliminated extremely sensitive soils in the area, and particularly along the streamcourses, from the lands suitable for timber production. This mitigation greatly minimizes the potential for major adverse watershed impacts.

Fire

The effects of the alternatives from a fire standpoint are the increase or decrease in fire hazard and risk that will be created. Risk is defined as the probability that an ignition will occur. Hazard is a description of the fuels complex in terms of kind, volume, arrangement, condition and location of the fuels.

The Windy Valley area is predominantly dense brush and hardwoods with a conifer overstory. Fuels are continuous over the entire area, and though dead fuel loadings are light, the large amount of brush creates a high hazard. In an undeveloped scenario, fuel accumulations would increase and fuel continuity would remain the same or increase These conditions lend themselves to large, moderate to high intensity fires Adding to this is the increased response time for initial attack forces due to poor access. The result is larger fires, higher suppression costs and increased resource losses. In a developed scenario, fire hazard increases during timber harvest. As fuels are treated, the hazard is reduced. Over time, continuity of the fuels are broken up, creating a mosaic of fuels and vegetative development. This mosaic, combined with improved access for initial attack forces, reduces the potential for large, high intensity fires. The result is smaller fires, lower suppression costs and less resource loss.

In Alternatives E and M, all of the area would remain undeveloped, with fuels remaining continuous over the entire area In Alternative G, 49 percent of the area would be developed, creating a mosaic of fuels over time, while the remaining undeveloped area would be in 11 separate blocks. Alternatives NC, A, K, and S would develop 51 to 61 percent of the area. The remaining undeveloped areas would be broken into six to seven separate blocks Alternatives B, C, and D would develop 68 percent of the area. The remaining undeveloped areas would be in two separate blocks.

In undeveloped areas, the risk of ignition is low due to the low levels of human use. As development occurs, risk increases with road construction, timber harvest, and with treatment of activity slash from these operations. As access improves, the level of dispersed recreational and other public uses increases, with an increase in risk of human-caused fires. The risks of lightning fire is similar in both developed and undeveloped areas.

In Alternatives E and M, risk from human-caused ignition would be limited primarily to the periphery of the area due to limited access. In Alternative G, industrial operations would result in increased risk over 49 percent of the area, and risk from public use would be increased along the 19 miles of road Alternatives NC, A, K, and S would result in increased risk over 51 to 61 percent of the area; risk from public use would be increased along the 20 miles of road. In Alternatives B, C, and D, industrial operations would result in increased risk over 68 percent of the area, with increased risk from public use along 27 miles of road.

Vegetation

Effects on vegetation relative to diversity and age class distribution do not significantly differ from the effects on the Forest as a whole (See Chapter IV, FEIS).

Sensitive Plants

Approximately 100 acres of the proposed Snow Camp Botanical Area is within the northern tip of the roadless area The Botanical area is allocated in Alternatives E, G, M and S (See Appendix F for more detail on the Snow Camp site). A significant number of sensitive and rare plants are present Under all alternatives sensitive plants would be protected through application of appropriate Standards and Guidelines There are no existing or proposed RNA's.

Air Quality

The principle agent impacting air quality in the forest environment and surrounding areas is smoke from wildfire and prescribed burning. To determine the impacts of each alternative, only the effects of prescribed burning is considered. The effect of smoke is a temporary reduction in visibility in an area. Total suspended particulates (TSP) is used as the measurement of local and regional haze. Alternatives E and M would contribute no TSP. All other alternatives produce 34-50 tons of TSP per year.

The probability of a smoke intrusion from burning within the unroaded area impacting Grants Pass, a designated area for air quality, is very low. The probability of impacting the Kalmiopsis Wilderness, a Class 1 area, is low.

Wildlife

Unless specifically mentioned below, effects of the alternatives on wildlife indicator species and wildlife habitat in this roadless area are the same as for the Forest as a whole.

Bald Eagle/Osprey. No bald eagle or osprey are known to inhabit the Windy Valley area. Bald eagle and osprey may use a flight corridor on the extreme southeast portion of Mineral Hill Fork and Chetco River drainages. Under any alternative, management of eagle habitat would be governed by the Pacific Bald Eagle Recovery Plan.

Spotted Owl/Pileated Woodpecker/Pine Marten. Under Alternatives B, C, D, and D1, habitat for mature/old-growth indicator species would be considerably reduced over time. In Alternatives NC, A, A-Departure, G, K, and S significant mature/old-growth habitat would be protected in the Windy Valley Supplemental Resource area, and Backcountry Recreation in the case of Alternative S Mature/old-growth habitat would remain at present levels under Alternatives E and M.

Except for Alternative NC, a mixture of habitat enclaves to meet Management Requirements (MR's) for mature/old-growth habitat are located within the roadless area: three for pileated woodpeckers, and three for pine marten (one of the marten areas is only partially within the area). This area presently supports approximately two pairs of spotted owls. There would be no change from present conditions under Alternatives E and M. Mature/old-growth habitat would ultimately be reduced to MR levels in all other alternatives. In Alternative NC, habitat would eventually be reduced below MR levels.

Woodpeckers. Snag habitat would remain at or near 100 percent habitat capability for woodpeckers under Alternatives E and M. In areas not suitable for timber production, snag levels will remain high. Snag habitat would remain at high levels in alternatives which allocate the Windy Valley area as a Supplemental Resource area, or as Backcountry Recreation in the case of Alternative S.

Black-tailed Deer/Roosevelt Elk. Big game management opportunities would increase somewhat in all alternatives except E and M. All of these alternative would open up significant areas tentatively suitable for timber production. Opportunities for habitat improvement projects for game animals would also be greater in these alternatives.

Wildlife Habitats. The area contains approximately 55 acres of meadow habitat (including buffers) at two separate sites (one is Windy Valley). Meadow habitat is allocated in all alternatives, although meadow buffers are not protected in Alternatives NC, A, and A-Departure. Among the alternatives which allocate much of the area to General Forest, Alternatives C, D, D1, and S utilize a Riparian Prescription C which provides a higher quality riparian habitat for wildlife.

Wildlife Recreation Use. Estimated Wildlife/Fish User Days (WFUD's) currently attributed to the roadless area are lower than average on the eastern portion of the area (away from roads and the Illinois River). User-days on the western portion of the area are assumed to be equal to or slightly less than the General Forest. Fewer hunters use unroaded areas and non-hunters generally stay on the trail system. Alternatives E, G and M produce fewer WFUDs; other alternatives would generate more

Visual Resource

The current visual inventory indicates that the area is in a location visible to recreation travel routes. The area consists of approximately 500 acres of Retention, approximately 5,300 acres of Partial Retention, and approximately 4,400 acres of Modification The Partial Retention objective was assigned in response to the recreation use on the Snow Camp Lookout Road, and the variety in the landscape that is unique relative to the rest of the Forest Viewer sensitivity is moderate as indicated by the consistent levels of recreation use attributed to the area.

Alternatives A, A-Departure, and G would assign the area to management under the inventoried visual objectives. Approximately 3,000 to 4,200 acres would be assigned as Supplemental Resource and Designated Wildlife Habitat Management Areas; no timber harvest would be programmed. The natural appearance of this portion of the roadless area would be maintained over the course of the planning period. The natural appearance of the remaining area would shift to a slightly altered-altered appearance depending on the visual objective.

Alternatives NC, B, C, D, and D1 assign the area to management under a reduced scheme of visual objectives. With the exception of 1,400 to 1,900 acres assign to Designated Wildlife Habitat, the remainder of the area would be managed under the Modification visual objective. The existing natural appearance of the area would shift to an altered-heavily altered appearance within the first two decades.

Alternatives E and M manage the area to achieve the Preservation objective. The natural appearance of the entire area would be maintained over the planning period.

Alternatives K and S would assign the area to management under a reduced scheme of visual objectives. Under these alternatives, all areas inventoried for Partial Retention would be managed to achieve the Modification visual objective. In addition, approximately 3,300 acres would be managed as Designated Wildlife Habitat and Supplemental Resource areas; timber harvest would not be programmed. The natural appearance of this area would be maintained while the remaining acres would shift to an altered-heavily altered appearance as a result of activities.

Recreation Settings

The Windy Valley area is accessed by several trails and is heavily influenced by Forest road systems surrounding the area. The isolated location will limit the ability of the area to provide a quality non-motorized recreation experience whether the area is maintained in a roadless condition or not.

All alternatives, except E and M, assign the area to development. Semi-primitive recreation would shift rapidly to the motorized end of the opportunity spectrum. Access to the area and motorized opportunities would be enhanced as the area is roaded over time. Alternatives E and M would maintain the area in its current status. Recreation capacities would remain fixed since no new trail construction is programmed.

Alternatives A and A-Departure would retain the essentially undeveloped character on 3,000 acres due to Supplemental Resource and Designated Wildlife Habitat areas. Alternatives NC, B, C, D, and D1 would retain undeveloped character on less than 2,000 acres. Alternative G would retain the undeveloped character on 4,200 acres due to assignments to Botanical, Supplemental Resource, and Designated Wildlife Habitat areas Alternatives K and S would retain the essentially undeveloped character on 3,000 acres (3,600 acres due to allocations to Supplemental Resource and Designated Wildlife Habitat areas). These areas may or may not be contiguous so that the integrity of the roadless area would be compromised by the presence of motorized activities (See **Wilderness Potential**).

Economic and Social

There are 7,907 acres of land identified as tentatively suitable for the production of timber in this unroaded area. The general effects on annual allowable sale quantity (ASQ) and long-term sustained yield (LTSY) of allocating these acres to uses that would include timber production are the same as those described in Chapter IV of the FEIS.

The estimated potential ASQ from the inventoried 10,214 acres of the Windy Valley Roadless Area is 0.43 MMCF. The estimated LTSY would be 0.79 MMCF. Following are the estimates of the contribution to timber production (in MMCF) from this area under each alternative:

Alternative	ASQ	LTSY
NC, C, and D	37	68
A and A-Dep	.30	.56
B	45	82
D1	40	74
E and M	00	00
G	25	47
K and S	.28	.51

For projecting effects, the alternatives are grouped: (1) Alternatives E and M maintain the area in an unroaded status; (2) Alternatives A, G, K, and S, which develop approximately one-third of the area, and (3) Alternatives NC, B, C, and D which develop much of the area.

	Alternatives		
Effects (Changes Compared to Alternative A)	E and M (Unroaded)	A, G, K, & S	NC, B, C, & D (Roaded)
Direct Effects			
Timber and Road Expenditures	*None*	*Minor Change*	*No Change*
Indirect Effects			
Jobs	-27	0	+6
Annual Income (MM $)	-0 63	0	+0.15
Annual Payments to Counties (MM $)	-0.15	0	+0 04
Cumulative Effects			
Social Attitudes of Local Communities			
Timber Related	-	0	+
Primitive Recreation	+	0	-
Fisheries	+	0	0
Wildlife Related			
Hunting	-	0	0
Old-Growth	+	0	-
Mining	-	0	0

The major direct economic effect is government expenditures for the timber and associated road construction program. Alternatives E and M have the biggest reduction in the timber and road expenditures The other alternatives have insignificant changes in budget expenditures.

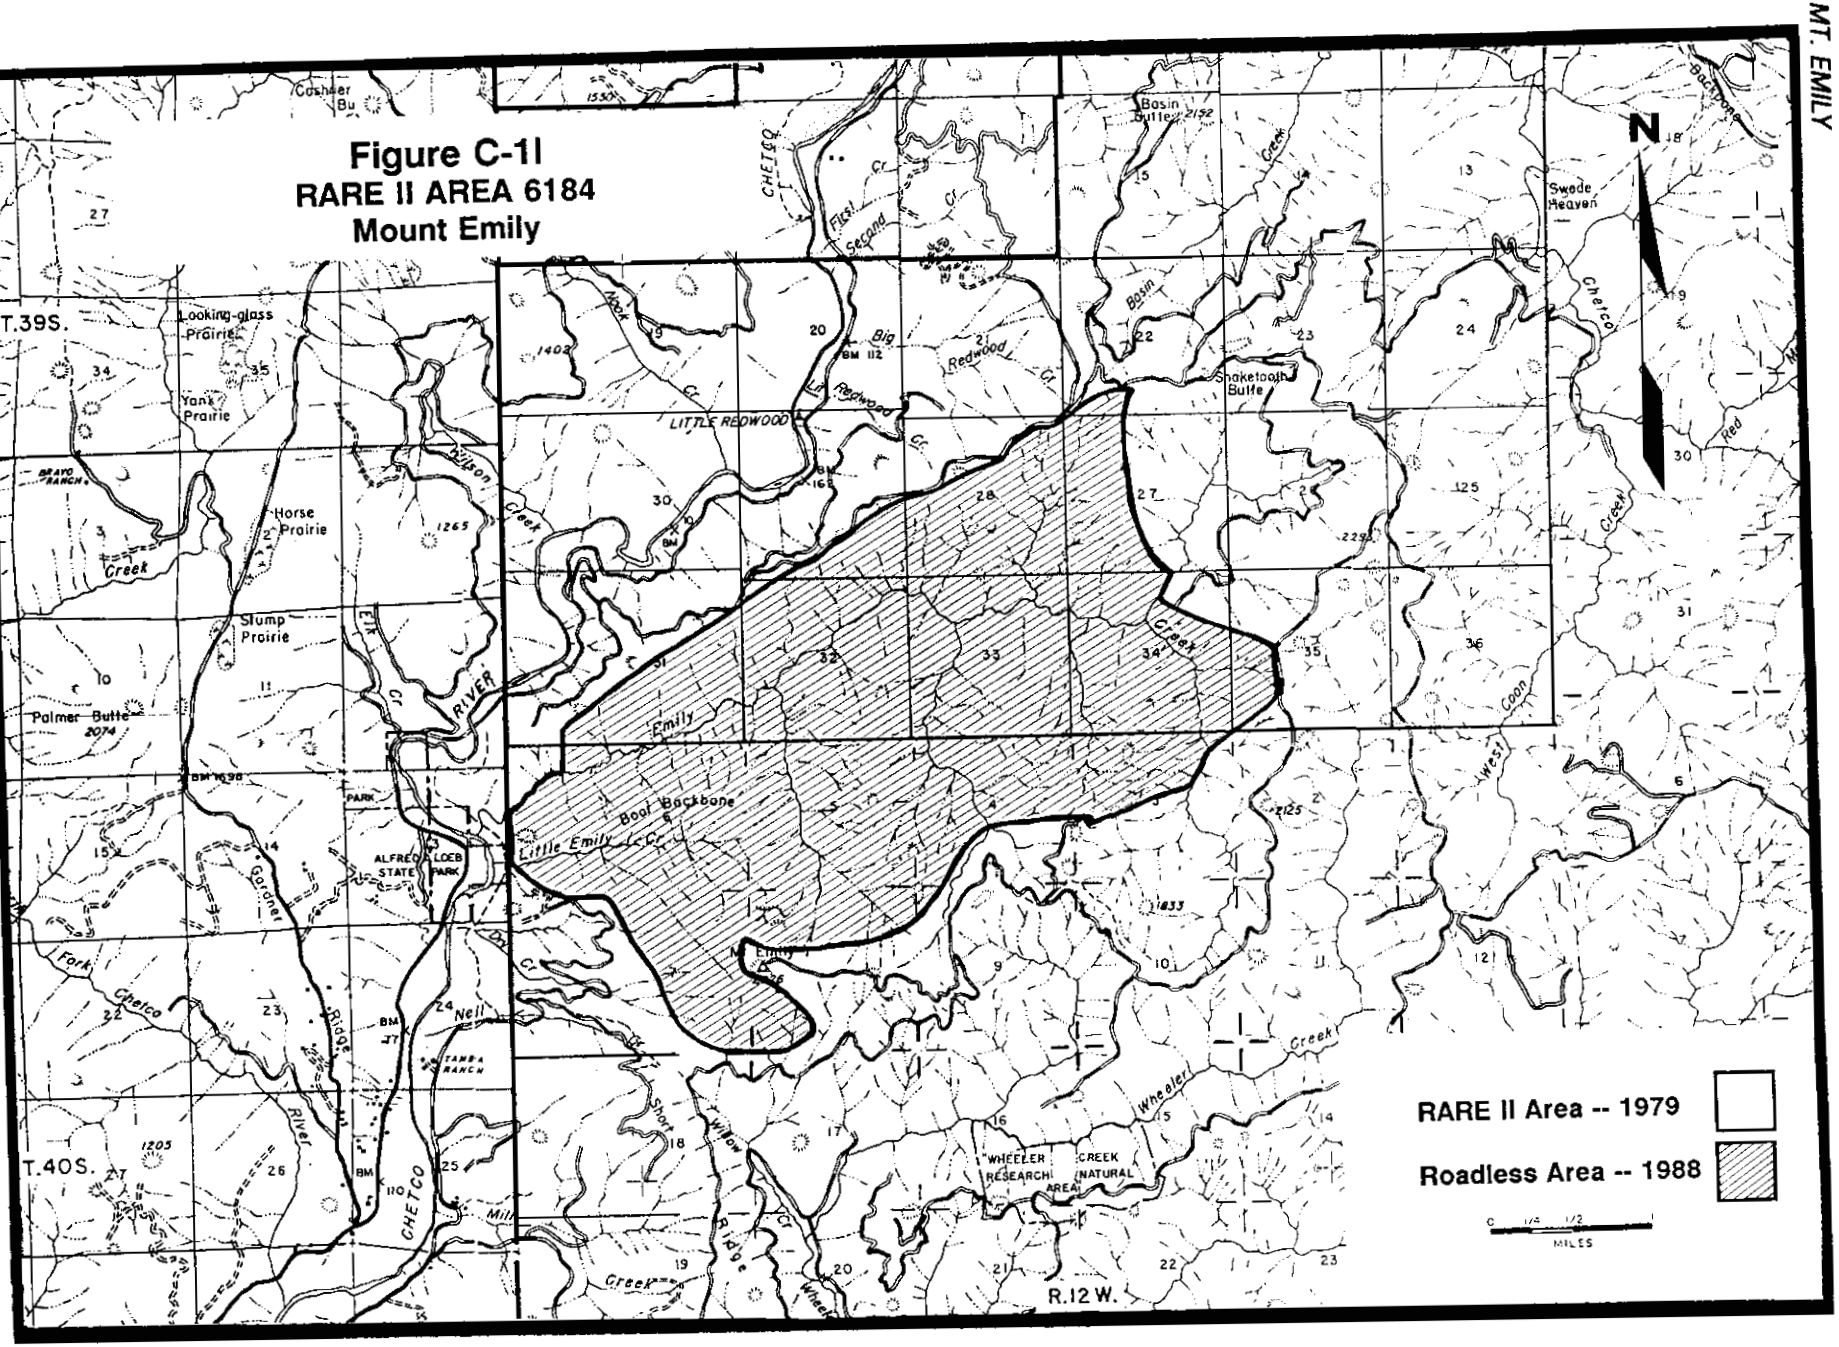
Indirect effects are associated with jobs, income, and payments to counties. Assuming no substitution of reduced timber harvest within the area of influence, Alternatives E and M have the biggest reduction while the other alternatives have a small reduction or change in the number of jobs, amount of income, and size of payments to the counties. Slightly greater benefits than provided by Alternative A are achieved under Alternatives NC, B, C, and D.

The cumulative social effects of attitudes of people can be summarized by examining the different interests of the adjacent communities. Previous documentation is found in Chapters III and IV of the FEIS The positive sign indicates a feeling by special interest groups of the Forest being responsive while a negative indicates a social feeling of the Forest not being responsive to particular interests as listed. For example, in Alternative E, fishing interests are predicted to feel positive about forest management while timber interests would tend to feel the forest is not listening to their needs. Such gains and losses may create additional conflict.

MITIGATION MEASURES

No additional mitigation measures have been identified.

POTENTIAL CONFLICTS WITH OTHER JURISDICTIONS



No additional conflicts with other jurisdictions have been identified

Figure C-1l
RARE II AREA 6184
Mount Emily

MT. EMILY No. 6184

(5,945 Acres)

DESCRIPTION

STATUS OF ROADLESS AREA

The Mt. Emily Roadless Area was inventoried for study as a potential Wilderness during the RARE II process. It was allocated to non-Wilderness use by the RARE II decision in January 1979 No activities have taken place since that decision which have changed the area's wilderness characteristics The entire 5,945 acres is National Forest System land.

The Chetco-Grayback Land Management Plan (FEIS, 1979) includes the Mt. Emily area Management direction allocates most of the area to Coordinated Resource Management to obtain full timber yield consistent with land capabilities, while giving full considerations to other resource values. The area within one-eighth mile horizontal distance on each side of Emily Creek is allocated to Fisheries/Watershed *(synonymous with the Supplemental Resource Management Area). It is managed to maintain or improve* water quality, to maintain old-growth forest characteristics, and to protect or enhance spawning and rearing habitat for anadromous fish. Fisheries/Watershed areas are managed in a near natural condition, though management activities designed to improve water quality or fisheries habitat may be undertaken where appropriate.

Readers are directed to the Land Management Plan for a description of the affected environment, evaluation of resources, management alternatives, and other requirements and constraints. Since completion of the Land Management Plan, all project activities have been analyzed under it's direction and NEPA requirements/process.

CHANGES BETWEEN DRAFT AND FINAL

During the period between 1984 and 1988, no activity has occurred that would impact the area (Refer to *Figure C-1l). The area remains as previously described*

LOCATION AND ACCESS

The Mt. Emily Roadless Area is approximately nine miles northeast of the coastal community of Brookings, Oregon. It includes the lower four miles of the Emily Creek drainage and the Little Emily Creek drainage, both of which are tributaries to the Chetco River. The area covers most of the north and west slopes of Mt Emily. The roadless area is surrounded by ridge-top roads. These roads are used for timber hauling, administration and recreation. An old abandoned road enters the lower portion of the area and follows Little Emily Creek for about one mile. In its present state, it is little more than a trail.

PHYSIOGRAPHIC AND BIOLOGIC FEATURES

The Mt Emily area is located on the western side of the coast range (Klamath Mountain Geologic Province) in southwestern Oregon. Elevation varies from near sea level to almost 3,000 feet. The topography is mountainous with steep slopes and deeply dissected canyons. Most of the area is covered by a mixed evergreen forest. Douglas-fir is the principle conifer species in association with tanoak and Pacific madrone hardwoods. The southern portion of the area contains many brushfields and rock outcrops.

Soil conditions are quite variable. Shallow soils with abundant surface rock and talus movement dominate ridgetop areas. Deeper, more productive soils are common along the mid to lower slopes. Evidence of streambank failures are not uncommon, especially on oversteepened slopes and in the contact area of dacite and sandstone parent materials. The majority of the area is relatively stable, however

Average annual precipitation is 110 to 120 inches per year. All but 10 to 15 inches falls between October and April. The climate is mild and heavily influenced by marine air. Fog is common during the summer.

Black-tailed deer, black bear, coyotes and many small animals common to the Forest occur within the area. Bald Eagles have been seen along the Chetco River but are not known to use the roadless area. Spotted Owls are present and two Spotted Owl Habitat Areas (SOHA's) are located within the roadless area A sensitive plant species, Howell's manzanita (*Arctostaphylos hispidula*), has been found in the southern portion of the area, near the summit of Mt. Emily. Another sensitive plant, Golden fleece (*Happlopappus arborescens*), is located in the Snaketooth Butte area.

Emily Creek has important runs of fall chinook salmon and winter steelhead. Resident trout and a small number of coho salmon also use the stream.

RESOURCE USES

There is an old mining site near the top of Mt Emily and a pit on the west slope. This mine has not been worked since the early part of this century. Recent mining activity (road construction and trench excavation) has occurred just south of the roadless area boundary.

Recreational use is low at approximately 100 RVD's. Some hunting and fishing take place People occasionally hike to the old lookout site at the top of Mt. Emily, just outside the roadless area boundary.

APPEARANCES, SURROUNDINGS, AND ATTRACTIONS

The Mt Emily area has highly dissected topography and is covered by a mixture of old growth, and second growth conifers, hardwood stands and brushfields. Rock outcrops also occur. The Chetco River, at the mouth of Emily Creek, and Mt Emily are the most prominent features. The view from within the roadless area is dominated by the high bluffs on the north side of Mt. Emily or by the forest itself, depending on the viewers position The Kalmiopsis Wilderness is approximately four miles east of the roadless area. The Snaketooth Road, near the northwestern boundary, and the Mt. Emily Road south of area, are major access routes within the Chetco Ranger District Trout fishing in Emily Creek and hunting along fringes of the area are the major attractions for recreationists.

CAPABILITY

MANAGEABILITY

The Mt Emily Roadless Area boundaries are well defined and follow topographic features It includes much of the Emily Creek drainage and could be managed in a roadless condition. Management as a roadless area would be compatible with management of the planned designated wildlife habitat Management Requirement (MR's) areas and with protection the valuable salmon and steelhead runs on Emily Creek.

Dense fuel loads and heavy use of roads near the boundaries create a situation where the potential for considerable loss of resources and the existing character of the area is high. While climate is favorable for minimizing wildfires, severe fire conditions do occur for relatively short periods. Ignition during one of these periods could be disastrous.

The ability to manage the area for its potential for Wilderness and accompanying values is limited by the area's size and proximity to roads. Though the nature of the drainage limits views to the natural conditions found within most of the area, motorized vehicles and equipment can often be heard.

NATURAL INTEGRITY AND APPEARANCE

The area is generally in a natural appearing condition. The old mining site near the top of Mount Emily has essentially returned to a forested condition. What little impact still exists is on the perimeter of the roadless area and could be removed from the area by a minor boundary adjustment.

Approximately 900 acres within the area was treated with herbicides during the 1950's and 1960's to reduce hardwood competition. This treatment altered the natural processes to favor the growth of conifers on the treated sites. Hardwoods have been reduced in number and size, but were not eliminated The effects of this treatment are no longer visible; the forest in the treated area appears to have developed naturally.

An old abandoned road enters the lower portion of the area and follows Little Emily Creek for about one mile It was no longer visible on aerial photographs taken 20 years ago. Its present state is a brushy trail.

OPPORTUNITIES FOR SOLITUDE AND PRIMITIVE EXPERIENCE

The Mt. Emily area's steep, rugged topography and dense vegetation result in natural screening. People using the area are not to be aware of each other's presence. The major intrusion solitude is from the sound of activities outside the area.

Use of the area for primitive recreation is limited by the dense vegetation and steep terrain. Few trails exist to promote access to the interior areas, but sufficient openings exist to permit some cross country travel on foot. The most unique and physically challenging terrain exists on the north slopes of Mt. Emily. High rocky bluffs and deeply incised canyons make traversing that portion of the roadless area hazardous.

Large portions of Mt. Emily are covered by mining claims, though no mining activity is currently taking place within the area. If mining were to begin, it could have a significant impact on the roadless characteristics. Noise from the mining activities would impinge upon the feeling of solitude. Hiking near the summit of Mt. Emily would also be impeded. This section could be removed from the roadless area without destroying its integrity, however, noise generated within the drainage would have greater impacts than noise generated on the other side of the mountain

SPECIAL FEATURES

Mt Emily is the predominant feature. An old mine, lookout and archeological site exist on Mt. Emily. The other primary feature is the highly prized anadromous fishery of Emily Creek.

AVAILABILITY

RESOURCE POTENTIALS

Recreation Settings

Present use is low and likely to remain so under unroaded conditions. Trail construction could increase use since it provide access to a roadless area close to town. The capacity the area for dispersed recreation is large and not likely to be exceeded. Under a roaded condition, hunting and other forms of dispersed recreation would increase significantly.

Wildlife

Since almost all of the old-growth in the roadless area is included in the designated wildlife MR areas, roading would have little effect on old-growth habitat. Some hardwood stands may be available for harvest under the roaded alternatives for several years. These openings would provide improved habitat for deer and other species requiring early successional stages for several years after harvest. The only effects on wildlife under the unroaded alternatives would be from the gradual successional changes which occur over decades or centuries. Fire would interrupt this successional pattern and improve habitat for early successional species These changes will gradually degrade habitat for old-growth dependent species as mature tanoak stands succeed Douglas-fir.

Fisheries

Emily Creek has important runs of fall chinook salmon and winter steelhead. It is one of the most valuable streams on the Forest for spawning adult salmonids and rearing of juveniles. Opportunities for enhancement exist under either scenario.

Water

The area contributes indirectly to the Brookings community water supply, but has little bearing on the delivered water quality or quantity. There are no impoundments or diversions either existing or proposed. Maintaining high water quality is a primary goal of the beneficial uses associated with Emily Creek and Chetco River.

Timber

Only 300 acres are classified as non-reforestable. The remaining 5,625 acres of land tentatively suitable for timber production contains approximately 104 MMBF. Much of the area is included in the designated wildlife MR areas. Land outside of wildlife areas is generally of low site productivity. Because of the dense undergrowth and the presence of sprouting hardwoods in existing stands, release treatments to establish and maintain conifer trees would likely be necessary in new plantations.

Minerals

Large portions of Mt. Emily are covered by mining claims. Exploration work has recently been done in the southwest portion of the area Road construction and trench excavation was done in the early 1980's on a claim which extends into the roadless area. The operation site is just outside the boundary, on the south side of the old lookout. Significant amounts of gold were removed from Mt. Emily in historic mining operations and the possibility of renewed mining activity within the drainage cannot be discounted.

Cultural

Historic sites in the vicinity include the old mine, as evidenced by 1930's era machinery and equipment, and Mt. Emily lookout just outside the boundary. Prehistoric use included a vision quest site near the summit of Mt. Emily. No other prehistoric sites have been found. If any are found, they will be evaluated and provided for under the applicable laws and regulations.

MANAGEMENT CONSIDERATIONS

The potential for insects and disease outbreaks within the coniferous forest exists. However, actual occurrences have minor and localized. Fire is the most serious management consideration. The potential for major conflagrations definitely exists. Under a developed scenario, access and intensified treatment of fuels would considerably lessen continuity and concentrations. The probability of major losses of resource by wildfire would be reduced. However, access also brings increased risks due to greater numbers of people in the woods.

NEED

OTHER AREAS AND PUBLIC USE

The Kalmiopsis Wilderness is approximately four miles east of the Mt. Emily Roadless Area. The Mt Emily area is very different in character from the adjacent unroaded areas and Wilderness. Recreation use of both Mt. Emily and the adjacent unroaded areas is extremely light. Most of the recreation use is by local people rather than by recreationalists from major population centers.

ECOSYSTEM REPRESENTATION

The major ecotypes within the Mt. Emily area also in the Kalmiopsis Wilderness.

PUBLIC INVOLVEMENT

Both the public and Forest managers have had considerable interest and concern for the management of the unroaded areas. For this specific area, involvement in evaluation of alternative management options for Mt. Emily began in the early 1970's. Between 1977 and 1979, the RARE II process was being finalized. Since RARE II, the area has been reevaluated several times through site specific project planning and broader area analysis. The analysis included herein is a compilation of information beginning with early public scoping in 1979 to public meetings and workshops through 1985.

Public input on several of the inventoried roadless areas on the Siskiyou National Forest has been extensive. Mt. Emily, though, has not received the same intensity of concern or advocation of protective status as several adjacent areas. Most input was prepared by State of Oregon agencies. Their suggestions centered on protection of the valuable fisheries, leaving productive areas in the timber base, and retaining the area in non-Wilderness status due to the known mineral deposits.

Input by the public on the advisability of designating this area as either Wilderness, back country or some other form of non-commodity management was divided between both extremes. Local government and the timber industry were opposed while many individuals supported removing the area from timber production. Those opposed site economic needs of the local community and their belief that other resources could be protected by proper multiple use management. Those favoring protection generally believed that all other resources would be severely and adversely impacted by timber harvest activities.

In the current Forest Planning process, the unroaded area question has remained a major issue. Comments received on the Forest Plan DEIS in 1987 and 1988 also have not surfaced any additional insight or concerns as to management of this unroaded area.

ENVIRONMENTAL CONSEQUENCES

The significant effects of each alternative are presented in Chapter IV of the DEIS. Additional site specific effects, mitigations, and potential conflicts are presented here. The Standards and Guidelines for each alternative were considered when evaluating the effects of implementation.

SIGNIFICANT EFFECTS

Cultural Resources

The Mount Emily area has known prehistoric and sites. The area has moderate potential for finding additional archaeological sites.

All Alternatives, except E and M, call for development which requires intensive cultural resource inventory along any proposed road prior to approval. In this way, sites that may exist in the project area can be evaluated. Valuable sites can then be protected by avoidance or conserved through data recovery. Alternatives E and M call for an unroaded regime which would minimize the need for cultural resource inventory.

Energy and Minerals

The following table is a tabular summary of the estimated potential and accessibility limitations for Mt. Emily. The acreages shown are subject to change due to the current withdrawal review by the Bureau of Land Management (BLM), and differences found for site specific needs included in any subsequent withdrawal applications to BLM.

	Mineral Potential (Acres)			
Access Restrictions	High	Moderate	Low	Total
Withdrawn	-	-	-	-
High	-	-	-	-
Moderate	-	-	-	-
Low	-	-	5,900	5,900
Total	-	-	5,900	5,900

Improvements

Roads. The 5,625 acres of tentatively suitable land could generate about 19 miles of new road for timber harvest. However, the Emily Creek Supplemental Resource area is included in all alternatives This would reduce the possible new roading to 16 miles. Roads for other purposes would be minor, with some possibility of mining activity in the vicinity of Mt. Emily. All would be dead-end local roads built when needed to access timber harvest units Some mileage would remain open to passenger car use, depending on the alternative, and other roads would be open to only high clearance vehicles or closed between projects. The following table shows road mileage in the area by alternative.

Alternative	Total Miles	Miles Open to Passenger Car	Miles Open to High Clearance	Miles Closed
NC,A,B,C	16	5	5	6
D	16	3	7	6
E and M	0	0	0	0
G	16	0	6	10
K and S	16	4	2	10

Alternatives E and M would have minimal effect due to no roads being built. Alternative G would not maintain any roads open for passenger cars. All other alternatives would be roaded except for the Supplemental Resource area. Alternatives G, K, and S will close 63 percent of the roads.

The road system would follow ridges off the main roads on the boundary and would change to midslope roads as the ridges steepen The midslope roads would cross small creeks and draws. None of the roads would be expected to cross Emily Creek nor the main tributaries inhabited by fish Some full bench ground would be crossed by roads with excess excavated material hauled to stable disposal sites. Some of the roads may be visible from a short stretch of the Chetco River Road, otherwise the roads would be largely hidden from high use routes.

Trails None are programmed.

Developed Recreation Sites. No construction is programmed.

Wildlife and Fish Habitat Structural Improvements. Emily and Little Emily Creeks are excellent candidates for improvements. Alternatives which provide for roading would facilitate implementation of structures by providing better access

Wilderness Potential

The roadless area has a landscape character that is steep, vegetated, and without exceptional features. The area has been inventoried according to ROS criteria and is capable of providing a Roaded Natural recreation experience on approximately 5,900 acres. The carrying capacity for the area is estimated at approximately 9,700 RVD's. This figure is high since Roaded Natural coefficients were developed based on the assumption of the presence of roads. Current use is low (100 RVD's annually) and is expected to remain low over the planning period.

The roadless area is near the Kalmiopsis Wilderness but is not contiguous. The maintenance of the roadless area would in effect expand the carrying capacity for Roaded Natural recreation opportunities. No trails are programmed for construction due to the low levels of use reported in the area. Recreation demand projections indicate that levels of use will remain well within the carrying capacity over the planning period.

How much of the inventoried roadless area remains unroaded by alternative can be evaluated by either assessing a combination of Management Areas 1-9 (which retain essentially undeveloped conditions), or by viewing the spatial arrangement of blocks of undeveloped area at the end of a given period of time. Management Areas may or may not be contiguous, so the integrity of the roadless area as a whole may be compromised by management around them. The following table provides a spatial estimate of acres remaining unroaded at the end of specific decades; these figures differ from the Management Area 1-9 acres in that the minimum criteria is based on the area either (1) bordering designated Wilderness, or (2) being 5,000 acres or greater:

Alternative	Acres Remaining End of Decade 1/		
	1	2	5
A, A-Dep, and NC	0	0	0
B, C, D, and D1	0	0	0
E and M	5,900	5,900	5,900
G	0	0	0
K	0	0	0
S	0	0	0

1/ Minimum criteria is 5,000 unroaded contiguous acres or adjacent to designated Wilderness

All alternatives, except E and M, assign the area to multiple resource management objectives. The Roaded Natural recreation opportunities would remain available in a modified Forest environment. The change in character of the landscape would result in the loss of Wilderness potential. Motorized recreation opportunities would be enhanced as the area is roaded.

Except for Alternatives E and M, all alternatives, except NC, would maintain at least 2,200 acres in a roadless condition as a result of assignments to Supplemental Resource and Designated Wildlife Habitat Management Areas Timber harvest would not be programmed in these two areas Alternatives E and M would provide additional capacity for Semi-primitive Motorized recreation opportunities. The Wilderness potential of the area would be maintained.

Wild and Scenic Rivers

A portion of the area is located immediately adjacent to the Chetco River corridor with some portions being visible in the backround Alternatives NC, A, A-Departure, B, C, D and D1 would manage lands under varying levels of visual objectives. Alternatives K and S would manage the majority of the area for Modification and Partial Retention; some some limited effect on the quality of recreation settings may occur within or as viewed from the river corridor. Alternatives E and M would have no effect on the existing quality of the river experience.

Soil, Water, and Fish

No consequences to soil, water, and fish resources are with Alternatives E and M because no soil disturbing activities will occur. All other alternatives allocate all or part of the area to Management Areas which permit development. The environmental effects of timber harvest and road building are discussed in Chapter IV of the FEIS

The risk of degrading the soil, water, and fisheries resource increases with more timber harvest and road building All roaded alternatives slightly increase the potential for adverse impacts. Of these, Alternative NC would result in greatest potential for watershed impacts. The majority of the area, however, does not contain soils highly sensitive to management-related impacts. Inclusions of some soil conditions that have demonstrated hazards due to road construction activities are interspersed in the area as suitable lands. Therefore, some increased risk of adverse impacts does occur.

Fire

The effects of the alternatives from a fire standpoint are the increase or decrease in fire hazard and risk that will be created. Risk is defined as the probability that an ignition will occur. Hazard is a description of the fuels complex in terms of kind, volume, arrangement, condition and location of the fuels

The Mt. Emily area is primarily second-growth Douglas-fir with moderate fuel loadings and a light brush understory. Pockets of brushfield are intermixed with the timber. Fuels are generally continuous over the entire area. In an undeveloped scenario, fuel accumulations would increase and fuel continuity would remain the same or increase. These conditions lend themselves to large, high intensity fires. Adding to this is the increased response time for initial attack forces due to poor access. The result is larger fires, higher suppression costs and increased resource losses In a developed scenario, the hazard increases during timber harvest. As fuels are treated, fire hazard is reduced. Over time, continuity of the fuels are broken up, creating a mosaic of fuels and vegetative development. This mosaic, combined with improved access for initial attack forces, reduces the potential for large, high intensity fires The result is smaller fires, lower suppression costs and less resource loss due to fire.

All the area in Alternatives E and M would remain undeveloped, with fuels remaining continuous over the entire area. In Alternatives G, K, and S, 39 percent of the area would be developed, creating a mosaic of fuels over time; the remaining undeveloped area would be in one to two separate blocks. Alternatives A, B, C, and D develop approximately 55 percent of the area, while Alternative NC would develop 71 percent; the remaining undeveloped area being one block.

In undeveloped areas, risk of ignition is low due to the low levels of human use. As development occurs, risk increases with road construction, timber harvest, and with treatment of activity slash from these operations. As access improves, the level of dispersed recreational and other public uses increases, with an increase in risk of human-caused fires Risk levels for lightning fires is similar in both developed and undeveloped areas.

In Alternatives E and M, risk from human-caused ignition would be limited primarily to the periphery of the area due to limited access. In Alternative G, K, and S, industrial operations would result in increased risk over 39 percent of the area, and risk from public use would be increase along the 16 miles of road. In Alternatives NC, A, B, C, and D, industrial operations would result in increased risk over 55 to 71 percent of the area; risk from public use would be increased along the 16 miles of road.

Vegetation

Effects on vegetation relative to diversity and age class distribution do not significantly differ from the effects on the Forest as a whole (See Chapter IV, FEIS).

Sensitive Plants

No Botanical Areas or RNA's are proposed. Two sensitive plants are present. Sensitive plants will be protected through appropriate Standards and Guidelines in all alternatives.

Air Quality

The principle agent impacting air quality in the forest environment and surrounding areas is smoke from wildfire and prescribed burning. Only impacts of prescribed burning are considered. The effect of smoke is a temporary reduction in visibility in an area. Total suspended particulates (TSP) is used as the measurement of local and regional haze. Alternatives E and M would contribute no TSP. All other alternatives would produce 19-26 tons of TSP per year.

The probability of a smoke intrusion from burning in the area impacting Medford, a designated area for air quality, or the Redwood National Park and Kalmiopsis Wilderness, both Class 1 areas, is very low based on past performance.

Wildlife

Unless specifically mentioned below, effects of the alternatives on wildlife indicator species and wildlife habitat in this roadless area are the same as for the Forest as a whole.

Bald Eagle/Osprey. Bald Eagles and osprey have been seen along the Chetco River but are not known to use the Mt. Emily area. Under any alternative, management of eagle habitat would be governed by the Pacific Bald Eagle Recovery Plan (USDI-Fish and Wildlife Service 1986).

Spotted Owl/Pileated Woodpecker/Pine Marten. Except for Alternative NC, almost all of the old growth in the area is included as Designated Wildlife Habitat to meet Management Requirements (MR's). Under Alternative NC, however, no mature/old-growth forest is assigned to wildlife; the area would not contribute to the MR network. Two Spotted Owl Habitat Areas (SOHA's) are within the area; owls were found in both SOHA's in 1988. In Alternatives K and S, blocks of hardwood stands interspersed among the old-growth stands are included as Special Wildlife Sites.

Woodpeckers. Snag habitat would remain near 100 percent habitat capability for woodpeckers under Alternatives E through S. Even in Alternatives A through D1, snag levels for the area would remain above average because of the allocations to Designated Wildlife Habitat and Supplemental Resource.

Black-tailed Deer/Roosevelt Elk Big game management opportunities would increase somewhat in Alternatives NC, A, A-Departure, B, C, D, and D1, which allocate a portion of the area to development. Opportunities for habitat improvement projects for game animals would also be somewhat greater.

Wildlife Habitats. The area contains 20 acres of rock habitat and no meadows. Rock bluffs/cliffs are allocated for wildlife use in Alternatives E through S, but would probably remain unaffected in Alternatives NC, A through D1. Among the alternatives which allocate a portion of the area to General Forest, C, D, and D1 are the only alternatives to utilize a Riparian Prescription C which provides a higher quality of riparian habitat for wildlife.

Wildlife Recreation Use. Estimated Wildlife/Fish User Days (WFUD's) currently attributed to the area are lower than average because of the difficulty in traversing the steep, trailless terrain Fewer hunters use unroaded areas and non-hunters generally stay on trails. Alternatives E, K, M and S produce fewest WFUD's; other alternatives would generate more.

Visual Resource

The visual inventory consists of approximately 400 acres of Retention, 3,200 acres of Partial Retention, and 2,300 acres of Modification. The Partial Retention objective was assigned in response to the recreation use on the Chetco River Road and the variety in the landscape that is somewhat unique relative to the rest of the Forest. Viewer sensitivity is moderate, as indicated by the consistent levels of recreation use attributed to the area

Alternatives NC, A, A-Departure, and G assign the area to management under the inventoried visual objectives. The natural appearance of the Supplemental Resource area of 700 acres would be maintained over the planning period The remaining area would shift to a slightly altered-altered appearance

Alternatives B, C, D, and D1 allocate the area to management under a reduced scheme of visual objectives. The entire area would be managed under the Modification visual objective. The existing natural appearance of the area would shift to an altered-heavily altered appearance within the first two decades.

Alternatives E and M would manage the area to achieve the Preservation objective. The natural appearance of the entire area would be maintained over the planning period.

Alternatives K and S assign the area to management under a reduced scheme of visual objectives. Areas inventoried for Retention would be managed for Partial Retention; areas inventoried as Partial Retention would be managed to achieve the Modification visual objective. Approximately 700 acres would be managed as a Supplemental Resource area to protect Emily Creek, maintaining the natural appearance of the inner gorge area. The remaining area would shift to an altered-heavily altered appearance.

Recreation Settings

The area is heavily influenced by the sight and sound of users from adjacent activities. Recreation use in the area is very light. The isolated location and the influences of surrounding road systems and attendant activities will preclude the area from providing a quality primitive or semi-primitive recreation experience whether the area is maintained in a roadless condition or not.

All alternatives, except E and M, would assign all or part of the area to Management Areas which permit development. Roaded Natural recreation opportunities would shift rapidly to the motorized end of the opportunity spectrum. Motorized opportunities would be enhanced as the area is roaded over time.

Alternatives E and M would maintain current status Recreation capacities would remain fixed since no new trail construction is programmed. Wilderness potential would be maintained

Alternatives A, A-Departure, B, C, D, and D1 would retain the essentially undeveloped character on 2,200 acres, and Alternatives K and S on 3,300 acres due to allocations to Supplemental Resource and Designated Wildlife Habitat areas Alternative NC provides for only 1,000 acres. These areas may or may not be contiguous, so the integrity of the area would be compromised by the presence of motorized activities (See **Wilderness Potential**).

Economic and Social

There are 5,635 acres of land identified as tentatively suitable for the production of timber in this unroaded area. The general effects on annual allowable sale quantity (ASQ) and long-term sustained yield (LTSY) of allocating these acres to uses that would include timber production are the same as those described in Chapter IV of the FEIS.

The estimated potential ASQ from the inventoried 5,945 acres of the Mt. Emily Roadless Area is 0.31 MMCF. The estimated LTSY would be 0.56 MMCF. Following are the estimates of the contribution to timber production (in MMCF) from this area under each alternative:

Alternative	ASQ	LTSY
NC and B	.24	42
A, A-Dep, C, D, and D1	20	35
E and M	.00	00
G, K, and S	.14	24

For projecting effects, the alternatives are grouped: (1) Alternatives E and M maintain the area in an unroaded status; (2) Alternatives G, K, and S develop less than one-half the area; and (3) Alternatives NC, A, B, C, and D develop much of the area.

The major direct economic effect is government expenditure for the timber and associated road construction program. Alternatives E and M have the biggest reduction in the timber and road expenditures. The other alternatives have minor to insignificant changes in budget expenditures.

Indirect effects are associated with jobs, income, and payments to counties Assuming no substitution of reduced timber harvest within the area of influence, Alternatives E and M have the biggest reduction while the other alternatives have minor or no change in the number of jobs, amount of income, and size of payments to the counties. Alternatives NC and B have a slight benefit when compared to Alternative A.

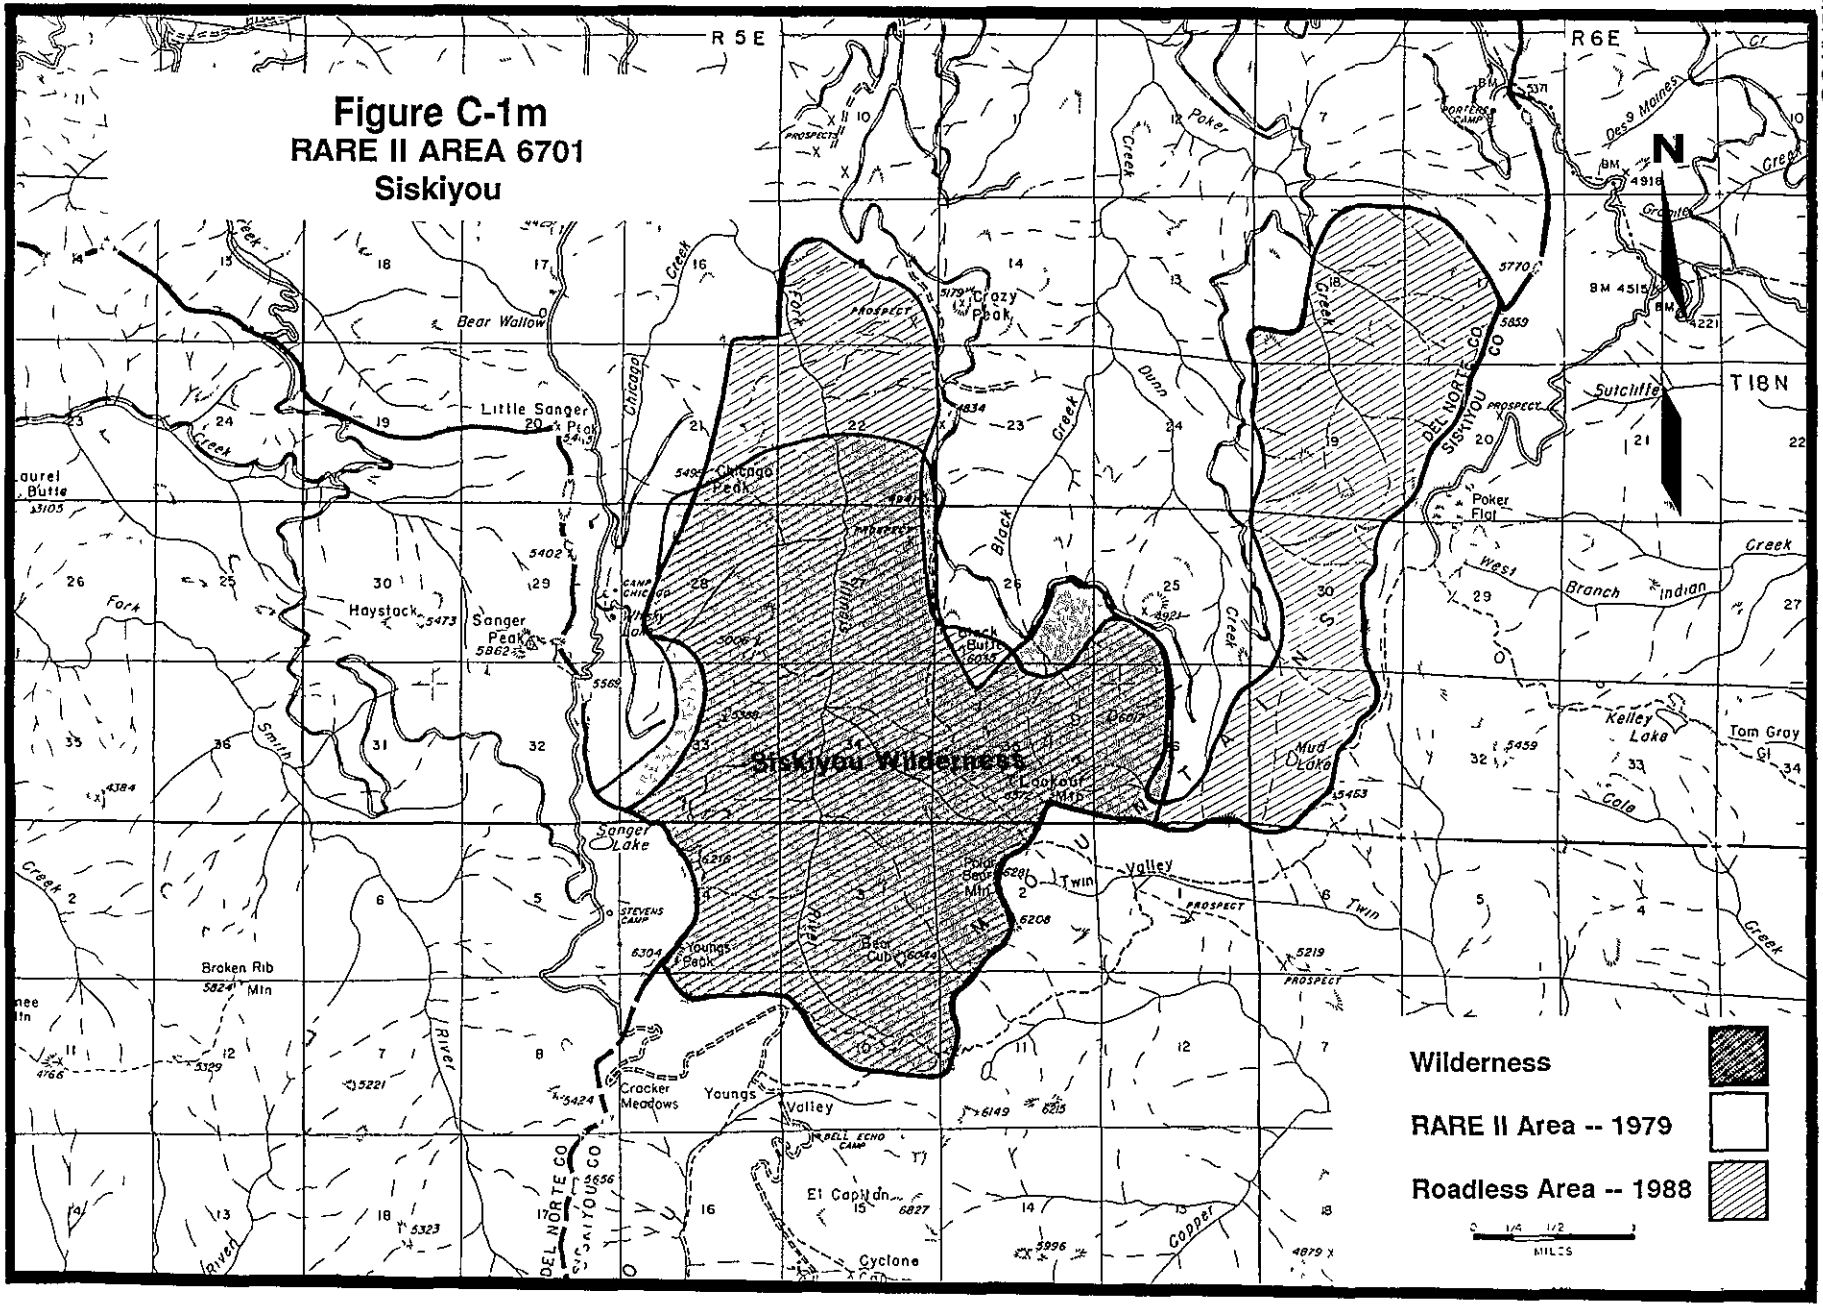
The cumulative social effects of attitudes of people can be summarized by examining the different interests of the adjacent communities. Previous documentation is found in Chapters III and IV of the FEIS. The positive sign indicates a feeling by special interest groups of the Forest being responsive while a negative indicates a social feeling of the Forest not being responsive to particular interests as listed For example in Alternative E, fishing interests are predicted to feel positive about forest management while timber interests would tend to feel the forest is not listening to their needs. Such gains and losses may create additional conflict.

Effects (Changes Compared to Alternative A)	Alternatives		
	E and M (Unroaded)	G, K and S	NC, A, B, C, and D (Roaded)
Direct Effects			
Timber and Road Expenditures	None	Minor Change	No Change
Indirect Effects			
Jobs	-18	-5	0
Annual Income (MM $)	-0 42	-0 13	0
Annual Payments to Counties (MM $)	-0 10	-0 03	0
Cumulative Effects			
Social Attitudes of Local and Westside Rural Communities			
Timber Related	-	-	0
Primitive Recreation	+	0	0
Fisheries	+	+	0
Wildlife Related			
Hunting	-	0	0
Old-Growth	+	+	0
Mining	-	0	0

MITIGATION MEASURES

No additional mitigation measures have been identified.

POTENTIAL CONFLICTS WITH OTHER JURISDICTION



No additional conflicts with other jurisdictions have been identified.

Figure C-1m
RARE II AREA 6701
Siskiyou

SISKIYOU No. 6701B

(3,284 Acres)

DESCRIPTION

STATUS OF ROADLESS AREAS

The Siskiyou Roadless Area was inventoried for study as a potential Wilderness during the RARE II process. As a result of the California Wilderness Act of 1984, the area is now adjacent to the large Siskiyou Wilderness. The eastern portion on the Siskiyou National Forest also abuts the north end of the residual inventoried Siskiyou Roadless Area on the Klamath National Forest to the south.

These contiguous roadless portions were studied for Wilderness as a whole The Siskiyou National Forest portion was divided during the study into an "A" area of 4,950 acres and a "B" area of 3,284 acres The "A" area was allocated to recommended Wilderness by the RARE II decision in January 1979, and in 1984 it was designated as a Wilderness by the California Wilderness Act The "B" area was allocated to recommended non-Wilderness use by the RARE II decision in January, 1979 The "B" area was included in the California v. Block lawsuit which challenged the RARE II FEIS. No activities have taken place in any portion of the roadless area which would alter the wilderness characteristics covered by the judgment

The Chetco-Grayback Land Management Plan (FEIS, 1979) allocated the roadless area to dispersed recreation. Management direction emphasizes the protection and retention of existing natural qualities, including visual qualities; the protection of unique areas within; the protection of all resources, and development and utilization of recreation, timber, and the minerals resource potentials as consistent with the goals of essentially maintaining the existing natural values of the ecosystems.

This roadless area is surrounded totally by National Forest System lands The Siskiyou Wilderness divides the inventoried roadless area into two portions. Past management activities have been minimal, this is primarily due to the lack of commercial timber The area has not been roaded. Several trails exist within the area, but maintenance has been limited because of low recreation use.

There are several mining claims in the areas, however none have been developed to a noticeable extent. The area is within a livestock grazing allotment. The range condition and trend has been improving since 1976 as a result of a deferred rotation grazing system and fewer cows than the carrying capacity.

CHANGES BETWEEN DRAFT AND FINAL

During the period from 1984 to 1988, no activities occurred that impacted the unroaded area. The area is as previously described (Refer to Figure C-1m).

LOCATION AND ACCESS

The Siskiyou Roadless Area is located in Del Norte County, California. It is approximately 19 air miles south of the town of Cave Junction, Oregon, and approximately 6 air miles south of the Oregon-California state line The area contains the upper reaches of the East Fork Illinois River and Dunn Creek, a tributary of the East Fork.

PHYSIOGRAPHIC AND BIOLOGIC FEATURES

Prominent topographic features of the Siskiyou Mountains that surround the area include Black Butte, Crazy Peak, Mud Lake, and Chicago Peak Plant communities are diverse and interesting With the exception of drainage bottoms and lower slopes, most of the area is poorly forested Ridge tops are typically barren, being best described as subalpine in character

The area is part of the Siskiyou Mountain portion of the Klamath Mountain Geologic Province This geologic province is a steep, highly dissected mountainous area extending from northern California across southwestern Oregon. Elevations vary from about 3,000 feet in the East Fork Illinois River gorge to over 5,800 feet on the peaks.

Average annual precipitation averages approximately 60 inches, most coming in the form of snow in the elevations above 4,000 feet. In excess of 75 percent of the annual precipitation occurs during the months of November through March. Summer temperatures often exceed 80 and 90 degrees Fahrenheit.

Soils are of glacial origin and are typically shallow and mixed with rock outcrop. Soil productivity is low, a function of the shallow, rocky soil conditions and cold soil temperatures which shorten the growing season. Soils in the area along the East Fork Illinois River are also generally unproductive due primarily to influence by unfertile serpentine bedrock. Some previous mass soil movement is evident in this area

The ecosystem is predominately mixed conifer. The primary conifer species include Douglas-fir, Shasta red fir, and white fir, with only shrub forms of hardwood species.

A variety of fish and wildlife species utilize the area The lower half mile of the East Fork Illinois adjacent to the area is habitat for steelhead spawning and rearing. Black-tailed deer are present, but numbers are low due to limited forage in the area. No known threatened or endangered species inhabit the area The area contains a number of sensitive and uncommon plants.

RESOURCE USES

An old trail crosses the area, but use is light. Recreational activities in the area include hiking, fishing, and hunting. The management objective is directed to maintaining a high quality recreation experience. Approximately 50 RVD's can be attributed to the roadless area, itself. Water from the area is important to downstream domestic and irrigation interests.

APPEARANCES, SURROUNDINGS, AND ATTRACTIONS

This high elevation area is scenic and adjoins one of the most scenic locations on the Forest, the Siskiyou Wilderness. When combined with the existing Wilderness, this area does provide the opportunity for a high quality recreation experience. The roadless area is in a near-natural condition It contains attractions that are not common to the rest of the Forest, those being primarily open and subalpine characteristics.

CAPABILITY

MANAGEABILITY

Retention of this roadless area adjacent to the Siskiyou Wilderness could play an important role in the protection and management of both areas. The western portion, in particular, could serve as a logical topographic extension of the Wilderness which could aid in retaining the primitive character of both areas. The area may also serve as a natural screening tool.

OPPORTUNITIES FOR SOLITUDE AND PRIMITIVE EXPERIENCE

The roadless area offers an opportunity for solitude because of the large undeveloped area to the south. The major intrusions are from highly visible activities outside the area The topographic and vegetative screening are relatively limited within the area, but it's open nature and subalpine peaks provide the feeling of solitude common to Wilderness. The area does not contain many features that are considered challenging to the primitive recreationalist, but the opportunity for a limited primitive recreation experience is present.

SPECIAL FEATURES

The area offers opportunities similar to those present in the adjacent Siskiyou Wilderness

AVAILABILITY

RESOURCE POTENTIALS

Recreation Settings

The greatest resource potential that exists for this area is the fact that it could enhance the protection and management of the Siskiyou Wilderness The area can serve as a transition between the Wilderness and development activities. The setting is very conducive to high country dispersed recreation activities.

Wildlife

Under unroaded conditions, wildlife populations would remain about the same unless habitat improvement projects were initiated. Under roaded conditions, as units are harvested in the third of the area (mostly in the eastern portion) tentatively suitable for timber production, more forage will be available to deer in snow-free months of the year. Considerable habitat variety would remain under all alternatives because two thirds of the ground is unsuitable for development.

Sensitive Plants

The plant resources in the area contain several unusual species which provide a unique experience for both the casual visitor and botanist. The existing inventory indicates occurrence of the following species:

Sensitive Plants	Uncommon Plants
Eriogonum hirtellum	*Darlingtonia californica (nearby)*
Lewisia leana	*Dicentra formosa ssp oregana*
Pedicularis howellii (nearby)	*Erigeron bloomeri var nudatus*
	Lilium bolanderi
	Lilium washingtonianum
	Sidalcea malveflora ssp. elegans

Timber

Site productivity is low. Approximately 997 acres is tentatively suitable for timber production Standing volume is estimated at 16 MMBF

Minerals

The area has a moderate potential for both critical and non-critical minerals. Deposits do not appear to exist in quantities that will become commercially profitable in the foreseeable future

Livestock

The area is under a livestock grazing permit. Although actual use and forage capacity is low, these areas are important as travelways between pastures.

Cultural Resources

The area has some known historic mining sites and some prehistoric use, both of which need evaluation by an archaeologist. The ridgeline running through the area was likely an Indian trail, and subsequently, an historic transportation route. Overall, the area has low archaeological potential

MANAGEMENT CONSIDERATIONS

Fire occurrence has been low Fuel loadings range from low to moderate, with occasional heavy accumulations of natural fuels There are no known infestations of insects in the area, however the common and most significant disease is mistletoe.

NEED

OTHER AREAS AND PUBLIC USE

The area is bordered by the Siskiyou Wilderness Other large Wildernesses are within view (Red Buttes and Kalmiopsis). The extent of unroaded/undeveloped area adjoining the inventoried Siskiyou Roadless Area is significant. With the exception of the potential for minerals, management activities would be either very limited or nonexistent The current recreation use would continue as the dominate activity

The Siskiyou Mountains are an attraction for both vacationers and residents of nearby communities. The major population centers, such as Portland and San Francisco, are from six to ten hours away by car. However, summer recreation traffic between the coast and inland areas using U.S. Highway 199 pass very close to the area. Access from this major travel route is good.

ECOSYSTEM REPRESENTATION

The major ecotype is well represented in the adjacent Siskiyou Wilderness and other undeveloped or unsuitable lands nearby

PUBLIC INVOLVEMENT

Public input on this area and adjacent roadless areas has been substantial. For the Siskiyou Roadless Area and the portion that is now Wilderness, involvement in evaluation of management options began prior to 1970 In early 1970, RARE initiated a proposal for Wilderness RARE II followed closely in its tracks. With this "B" section of the roadless area being relegated to non-Wilderness, public input continued. The California Wilderness Act of 1984 created the adjoining Siskiyou Wilderness and released this area from further study through this round of Forest planning

The area was also evaluated in the Chetco-Grayback Land Management Plan However, this evaluation did not consider the area for Wilderness, but relied instead on RARE II outcome. As a result, the "B" portion was given a de-facto "backcountry" or "scenic" status After passage of the Wilderness Act, the residual unroaded portion has been only moderately sought after for inclusion into the Wilderness system Much

of the area is inherently protected due to the high percentage of nonforested land Public involvement has continued with meetings, workshops, and other contacts into 1985, and formal comments to the Forest Plan DEIS in 1987 and 1988. This input has not surfaced any new or additional concerns relative to allocation of this area as roadless. It is likely that the 1984 Wilderness Act resolved many of the concerns.

ENVIRONMENTAL CONSEQUENCES

The significant effects of each alternative are presented Chapter IV of the FEIS. Additional site specific effects, mitigations, and potential conflicts are presented here. The Standards and Guidelines for each alternative were considered when evaluating the effects of implementation.

SIGNIFICANT EFFECTS

Cultural Resources

Alternatives B, C, D, K, and S require some degree of which will require intensive cultural resource inventories along any proposed road prior to approval. Sites that may exist in the project area can be evaluated. Valuable sites can then be protected by avoidance or conserved through data recovery Alternatives NC, A, E, G, and M call for an unroaded regime which would minimize the need for cultural resource inventory.

Energy and Minerals

The following table is a summary of the estimated mineral potential and accessibility limitations Acreages shown are subject to change due to the current withdrawal review by the Bureau of Land Management.

	Mineral Potential (Acres)			
Access Restrictions	High	Moderate	Low	Total
Withdrawn	-	-	-	-
High	-	<100	-	<100
Moderate	-	-	-	-
Low	-	3,300	-	3,300
Total	-	3,300	-	3,300

Improvements

Roads. The 997 acres of tentatively suitable land could generate about four miles of new road for timber harvest. Other roads for mining are possible, but would be minimal. All would be dead-end local roads built when needed to access timber harvest units. All roads would be open to only high clearance vehicles or closed between projects. Alternatives B, C, D, K, and S would road part of the area; Alternatives NC, A, E, G, and M would not. That portion of Alternative S allocated to Backcountry Recreation has an insignificant affect on roading needs for timber harvest activities.

Existing roads on the boundary are local roads except for Road 4803 near the western boundary. This section of collector Road 4803 is maintained only for high clearance vehicles. The local roads are also high clearance vehicle roads. The road system would follow ridges or be midslope roads off the existing local system. Midslope roads would cross only small creeks and draws. Some full bench ground would be crossed with excess excavated material hauled to stable disposal sites.

Trails. No new trails are programed under any alternative.

Recreation Site Development. No construction is programed.

Wilderness Potential

The roadless area and the Siskiyou Wilderness are similar in character and recreation opportunities, however the roadless area is influenced by management activities on adjacent lands The area has been inventoried according to ROS criteria and is capable of providing a Roaded Natural recreation experience on approximately 3,300 acres. The carrying capacity for the area is estimated at approximately 5,300 RVD's. This figure is high since the Roaded Natural coefficients were developed based on the assumption of the presence of roads

Current use is low and is expected to remain low over the planning period. Maintaining the roadless area would expand the carrying capacity for the Siskiyou Wilderness. However, the recreation experience would be influenced by adjacent motorized activities so that the quality of the experience is suspect The area could be managed in a roadless condition under Semi-primitive objectives and provide some recreation opportunities, helping to insure the quality of experience in the adjacent Wilderness

Access is provided on several existing trails. The trails have not been maintained due to low levels of use and constrained budgets and are in various stages of deterioration. Recreation demand projections *indicate that levels of use will remain well within the carrying capacity over the planning period.*

Alternatives B, C, D, K, and S assign the area to multiple resource management objectives; the Roaded Natural recreation setting currently available would shift to a modified setting as a result The change in the character of the landscape would result in the loss of Wilderness potential.

Alternatives NC and A assign the area to Supplemental Resource management objectives; in essence, maintaining the area in a roadless condition Alternatives E, G, and M maintain the area in a roadless condition. The area would provide additional capacity for some Semi-primitive recreation opportunities. Wilderness potential would be maintained.

How much of the inventoried roadless area remains unroaded by alternative can be evaluated by either assessing a combination of Management Areas 1-9 (which retain essentially undeveloped conditions), or by viewing the spatial arrangement of blocks of undeveloped area at the end of a given period of time Management Areas may or may not be contiguous, so the integrity of the roadless area as a whole may be compromised by management around them. The following table provides a spatial estimate of acres remaining unroaded at the end of specific decades; these figures differ from the Management Area 1-9 acres in that the minimum criteria is based on the area either (1) bordering designated Wilderness, or (2) being 5,000 acres or greater.

Alternative	Acres Remaining End of Decade 1/		
	1	2	5
A, A-Dep, and NC	3,300	3,300	3,300
B, C, D, and D1	1,000	0	0
E and M	3,300	3,300	3,300
G	3,300	3,300	3,300
K	1,000	0	0
S	1,000	600	600

1/ Minimum criteria is 5,000 unroaded contiguous acres or adjacent to designated Wilderness

Wild and Scenic River

The area is far removed from any designated Wild and Scenic River Allocation of the area will have no effect on the downstream management of the designated Illinois Wild and Scenic River.

Soil, Water, and Fish

No consequences to soil, water, and fish are associated with Alternatives NC, A, E, G, and M because no soil disturbing activities will occur. All other alternatives allocate part of the area to Management Areas which permit development. The environmental effects of timber harvest and road building are discussed in the Chapter IV of the FEIS.

The risk of degrading the soil, water, and fish resources in all roaded alternatives is negligible. The acreages proposed for road construction and timber harvest are limited in all alternatives. Areas in which these disturbing activities would occur do not demonstrate high risk for increased mass movement activity.

Fire

The effects of the alternatives from a fire standpoint are the increase or decrease in fire hazard and risk that will be created. Risk is defined as the probability that an ignition will occur. Hazard is a description of the fuels complex in terms of kind, volume, arrangement, condition and location of the fuels.

Fuels in the Siskiyou area are quite variable. The lower elevations are dense, continuous stands of brush. At the higher elevations, brush areas are interspersed with open timber stands. Numerous natural openings are present at the higher elevations. In an undeveloped scenario, fuel accumulations would increase and fuel continuity would remain the same or increase. The conditions at the lower elevations lend themselves to large, high intensity fires; at the higher elevations, lower intensity fires. Adding to this is the increased response time for initial attack forces due to poor access. The result is larger fires, higher suppression costs and increased resource losses. In a developed scenario, the hazard increases during timber harvest. As fuels are treated, fire hazard is reduced. Over time, continuity of the fuels are broken up, creating a mosaic of fuels and vegetative development. This mosaic, combined with improved access for initial attack forces, reduces the potential for large, high intensity fires. The result is smaller fires, lower suppression costs and less resource loss due to fire.

In Alternatives NC, A, E, G, and M, all of the area would remain undeveloped or have only very limited development, with fuels remaining continuous over the entire area. Alternatives B, C, D, K, and S develop between 55 and 81 percent of the area. The remaining undeveloped areas would be broken into two to six separate blocks. In all alternatives, some of the high priority natural fuels accumulations will be treated.

In undeveloped areas, the risk of ignition is low due to the low levels of human use. As development occurs, risk increases with road construction, timber harvest, and treatment of activity slash. As access improves, the level of dispersed recreation and other public uses increase, with an increase in the risk of human-caused fires. Both developed and undeveloped areas will have similar risk levels for lightning fires.

In Alternatives NC, A, E, G, and M, the risk from human-caused ignition would be limited primarily to the periphery of the area due to limited access. In Alternatives B, C, D, K, and S, industrial operations would result in increased risk over 55 to 81 percent of the area, and risk from public use would be increased along the four miles of road.

Vegetation

Effects on vegetation relative to diversity and age class distribution do not significantly differ from the effects on the Forest as a whole (See Chapter IV, FEIS).

Sensitive Plants

No Botanical Areas or RNA's are proposed. A significant number sensitive and rare plants are present; others will likely be discovered. Sensitive plants will be protected through application of appropriate Standards and Guidelines.

Air Quality

The principle agent impacting air quality in the forest environment and surrounding areas is smoke from wildfire and prescribed burning Only impacts of prescribed burning are considered. The effect of smoke is a temporary reduction in visibility in an area. Total suspended particulates (TSP) is used as the measurement of local and regional haze. Alternatives NC, A, E, G, and M would contribute no TSP. Alternatives B, C, D, K, and S would produce six tons of TSP per year.

The probability of a smoke intrusion from burning in the roadless area impacting Cave Junction or Grants Pass, a designated area for air quality, is very low based on past performance. The probability of impacting the Oregon Caves National Monument or the Marble Mountains Wilderness, a Class 1 area, is very low The probability of impacting the Siskiyou Wilderness is moderate.

Wildlife

Unless specifically mentioned below, effects of the alternatives on wildlife indicator species and wildlife habitat in this roadless area are the same as for the Forest as a whole.

Bald Eagle/Osprey. The area does not contain suitable habitat for bald eagle or osprey.

Spotted Owl/Pileated Woodpecker/Pine Marten. About a third of the roadless area is tentatively suitable for timber production. Under all alternatives, most of the area would maintained in its current condition, barring natural changes. Alternatives NC, A, E, G, and M would allocate the entire area to land classifications with no programmed timber harvest In all alternatives except NC, two habitat enclaves to meet Management Requirements (MR's) for mature/old-growth habitat are located within the area one for pileated woodpecker, and one for pine marten (the pileated's area is only partially within the roadless area) Because of the high elevation, it is questionable whether the area supports any spotted owls.

Woodpeckers. Snag habitat would remain at or near 100 percent habitat capability for woodpeckers under Alternatives NC, A, E, G, and M. In areas unsuitable for timber production, snag levels will remain high

Black-tailed Deer/Roosevelt Elk Elk are not present in the area. Management opportunities for deer would be increased in alternatives which open up areas suitable for timber production

Wildlife Habitats The area contains 200 acres of rock habitat and no meadows Rock bluffs/cliffs are allocated for wildlife use in Alternatives E through S, but would probably remain unaffected in Alternatives NC through D1.

Wildlife Recreation Use. Total estimated Wildlife/Fish User Days (WFUD's) currently attributed to the roadless area are lower than average Non-consumptive use may not be much less than average, but this is offset by low hunter use Hunting is not as prevalent due to the higher elevation and geographic fact that the area is in California (most the hunting use being from local hunters, and these hunters living and being licensed in Oregon). Alternatives NC, A, E, G, and M produce fewest WFUD's.

Visual Resource

The current visual inventory indicates that the area is in a location where it is visible to recreational users. The area is distinctly different in landscape character from the rest of the Forest, and offers some of finest scenery found on the Forest. The area inventory is listed below.

VQO	Acres
Retention	400
Partial Retention	1,600
Modification	1,300

Viewer sensitivity or concern for the visual quality of the area is high. However, recreation use in the area is extremely low. Retention and Partial Retention objectives were assigned in response to the high quality of scenic values. Alternatives E, G, and M would result in upgrading of the area to management under the Preservation visual objective. The natural appearance of the area would remain essentially unchanged Similarly, Alternative NC and A emphasizes management for inventoried visual objectives. The Supplemental Resource area assignment would preclude harvest and, in effect, upgrade visual objectives to management under the Preservation objectives.

Alternatives B, C, and D would assign the area to management under the Modification visual objective, resulting in a modified forest environment where management activities would be readily apparent. The existing natural appearance would appear slightly altered-altered since less than 1,000 acres of the area is considered tentatively suitable for timber harvest.

Alternatives K and S assign the area to management under a reduced scheme of visual objectives. Areas inventoried for the Retention would be managed under the Partial Retention objective. Management activities would be apparent but subordinate (less obvious) to the existing character of the landscape. The area's natural appearance would be modified somewhat so that some area would appear as slightly altered, with the exception of the 600 acres of the western portion assigned to Backcountry Recreation in Alternative S.

Recreation Settings

The area is surrounded on three sides by lands that have been modified by past activities, and thereby makes the area very susceptible to sight and sound of motorized users. The south half is contiguous to the Siskiyou Wilderness. The area could be managed in a roadless condition with Semi-primitive objectives and provide some recreational opportunities.

Alternatives B, C, D, K, and S currently provide a Roaded Natural recreation setting which would be retained in a near natural setting. Access to the area and motorized opportunities would be enhanced as the area is roaded over time. They also would retain the essentially undeveloped character on 400 to 500 acres due to assignments to Designated Wildlife Habitat. Alternative S allocates an additional 600 acres under Backcountry Recreation, thereby maintaining the western portion in an unroaded setting adjacent to the Wilderness.

Alternatives NC, A, E, G, and M would maintain current status. Recreation capacities remain fixed since no new trail construction would occur. Natural appearance of the area would be maintained.

Economic and Social

There are 997 acres of land identified as tentatively suitable for the production of timber in this unroaded area The general effects on annual allowable sale quantity (ASQ) and long-term sustained yield (LTSY) of allocating these acres to uses that would include timber production are the same as those described in Chapter IV of the FEIS

The estimated potential ASQ from the inventoried 3,284 acres of the Siskiyou Roadless Area is 0.05 MMCF The estimated LTSY would be 0.10 MMCF. Following are the estimates of the contribution to timber production (in MMCF) from this area under each alternative:

Alternative	ASQ	LTSY
NC, A, E, G, and M	00	.00
B	.05	11
C, D, and K	04	.09
S	.03	06

For projecting effects, the alternatives are grouped: (1) Alternatives NC, A, E, G, and M leave the area unroaded; (2) Alternative S which develops much of the area; and (3) Alternatives B, C, D, and K develop most of the area.

	Alternatives		
Effects (Changes Compared to Alternative A)	NC, A, E, G and M (Unroaded)	S	B, C, D, and K (Roaded)
Direct Effects			
Timber and Road Expenditures	None	Minor Increase	Increased
Indirect Effects			
Jobs	0	+1	+4
Annual Income (MM $)	0	+0.02	+0.08
Annual Payments to Counties (MM $)	0	+0.00	+0.02
Cumulative Effects			
Westside Rural Communities			
Timber Related	0	+	+
Primitive Recreation	0	-	-
Fisheries	0	0	0
Wildlife Related			
Hunting	0	0	0
Old-Growth	0	0	-
Mining	0	0	+

All economic and social effects for all alternatives are insignificant because of the small amount of resources involved The amount of these resources indicate substitution of other resources could occur fairly easily resulting in little if any impact on the social and economic environment.

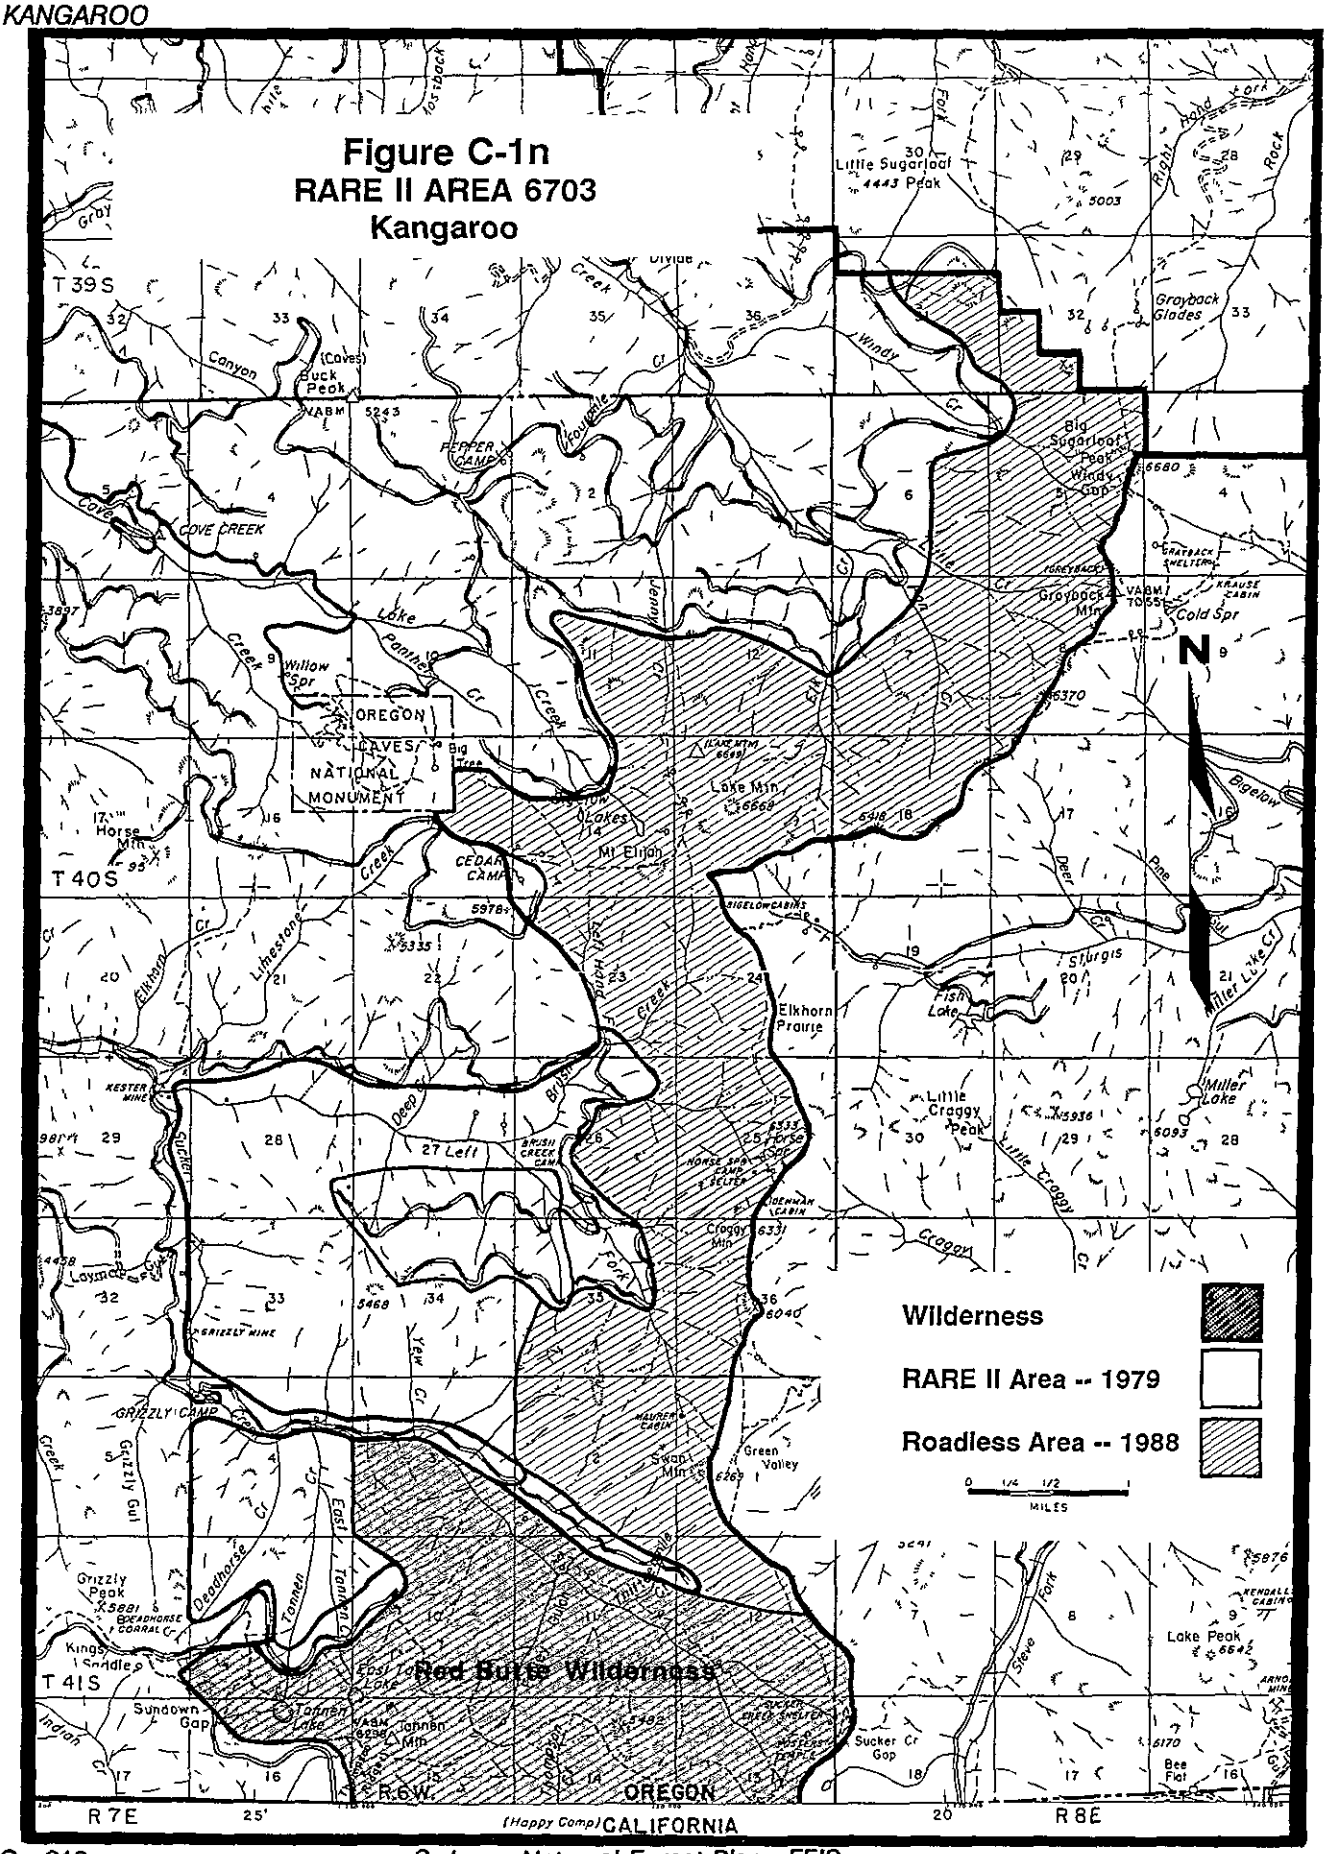
The direct economic effect is government expenditure for the timber and associated road construction program. Alternatives B, C, D, K, and S create a slight increase in timber and road expenditures over Alternative A. The other alternatives maintain the current condition.

Indirect effects are associated with jobs, income, and payments to counties. Assuming no substitution of reduced timber harvest within the area of influence, Alternatives B, C, D, K, and S slightly increase the levels of employment, income, and payments to counties.

The cumulative social effects of attitudes of people can be summarized by examining the different interests of the adjacent communities. Additional discussion is found in Chapters III and IV of the FEIS. The positive sign indicates a feeling by special interest groups of the Forest being responsive while a negative indicates a social feeling of the Forest not being responsive to particular interests as listed. For example, in Alternative E and M, fishing interests are predicted to feel positive about Forest management while timber interests as predicted to feel the Forest is ignoring their interests. An "0" indicates no change from current situation. Such gains and losses may create additional conflict.

MITIGATION MEASURES

No additional mitigation measures have been identified.



POTENTIAL CONFLICT WITH OTHER JURISDICTIONS

No additional conflicts with other jurisdictions have been identified.

KANGAROO No. 6703

(6,651 Acres)

DESCRIPTION

STATUS OF ROADLESS AREAS

The Kangaroo Roadless Area was inventoried for study as a potential Wilderness during the RARE II process. It is comprised of three large parcels on the Siskiyou, Klamath and Rogue National Forests. Before the California and Oregon Wilderness Acts of 1984, it extended into both Oregon and California and totaled 100,453 acres. The Siskiyou parcel, which is the only one considered here, contained 14,192 acres of which all but 110 acres were allocated to non-Wilderness use by the RARE II decision of January 1979. Since then, it has been further reduced to 10,832 acres as a result of timber sales and nonconforming features existing prior to RARE II. The final unroaded acreage figure of 6,651 acres was established with the designation of 3,414 acres as the Red Buttes Wilderness via the Oregon Wilderness Act of 1984 The entire area is National Forest System land

A coordinated planning effort between the Klamath, Rogue River, and Siskiyou National Forests began in 1975 to study unroaded lands within the Kangaroo Roadless Area (locally known as Red Buttes) This effort, known as the North Siskiyou Planning Unit, was established as part of a 1976 legal agreement with an appellant group. The North Siskiyou Planning Unit DEIS (1979) was prepared for the area. A Final Environmental Impact Statement for the planning unit was not completed as it was superseded by the RARE II Roadless Area Review and Evaluation (FEIS, 1979). Unit planning was discontinued by direction of the National Forest Management Act of 1976 (NFMA).

Contiguous inventoried roadless area on the Rogue River National Forest adjoins the Siskiyou portion to the east. This large area (over 14,000 acres) of the Kangaroo lies in the headwaters of the Applegate River. The common border of the unroaded area extends from Grayback Mountain to the Red Buttes Wilderness. Management options for this area has been coordinated between the two Forests for several years. Project planning and special uses have coordinated at the District levels. For further information about the eastern part, please refer to the Rogue River National Forest Draft Forest Plan and, in particular, Appendix C of that document (DEIS, 1987).

All projects within or adjacent to the Siskiyou National Forest portion of the Kangaroo area are governed by the Illinois Valley Multiple Use Plan and Chetco-Grayback Land Management Plan (FEIS, 1979). These projects and land uses have been analyzed under National Environmental Policy Act (NEPA) requirements/ process.

CHANGES BETWEEN DRAFT AND FINAL

During the period between 1984 and 1988, a timber sale in the southwest portion of the area (Deadhorse and Tannen Creeks) reduced the available unroaded acreage by approximately 800 acres (Refer to Figure C-1n). The remainder of the area is as previously described.

LOCATION AND ACCESS

The Siskiyou National Forest portion of the Kangaroo Area is located in Josephine County, Oregon, and includes the headwaters of the Grayback and Sucker Creek drainages, both of which are major tributaries to the upper Illinois River system. It is located approximately 17 air miles east of Cave Junction, Oregon

Access to the unroaded portions is provided through extensive road systems on the Siskiyou, Rogue River, and Klamath National Forests. These multi-purpose routes serve recreation, timber haul, and administrative traffic in and adjacent to the area.

PHYSIOGRAPHIC AND BIOLOGIC FEATURES

The area is part of the Siskiyou Mountain portion of the Klamath Mountain Geologic Province This geologic province is a steep, highly dissected mountainous area extending from Northern California across southwestern Oregon Elevations vary from about 4,000 feet to 7,055 feet at Grayback Mountain Most of the area is covered with dense forest, however the upper elevations offer considerable variety in patches of true fir forest, brush fields, large rock outcroppings, and open grassy meadows

Soils are generally very shallow and mixed with rock outcrop at the higher elevations and along ridgelines. Productivity is limited due to very sandy soil textures and shallow, rocky soils which have restricted ability to store water and nutrients. Cold soil temperatures also limit the effective growing season for plants. At lower elevations in glacial troughs where deeper soils are present and soil temperatures are warmer, soil productivity is greatly increased Wet, poorly drained soils scattered throughout the area are generally occupied by grasses, sedges or alders. Some signs of previous instability are present in the form of debris avalanche tracks within steep perennial streamcourses.

Average annual precipitation varies from 60 to 70 inches with the bulk of the precipitation occurring as snow in the elevations above 5,000 feet. In excess of 75 percent of the annual precipitation occurs during the months of November through March. Summer temperatures often exceed 80 and 90 degrees Fahrenheit

The area provides diverse habitat for a variety of wildlife species including blacktail deer, black bear, and various old growth dependent species While no known threatened or endangered species inhabit the area, several sensitive or unusual wildlife species are present or likely to be present. A sensitive species, the northern spotted owl, occupies old-growth habitat at elevations below 5,000 feet (approximately) The Siskiyou Salamander, another sensitive species, undoubtedly occurs in rock rubble habitat within the area.

A large variety of sensitive and uncommon plants is present in the crest zone of the area, especially in the Grayback Mountain and Bigelow Lakes areas Some of these plants occur at the northerly and westerly limits of their known range. Bigelow Lakes and Grayback Mountain, both noteworthy botanical areas, are being considered and evaluated in various alternatives of the FEIS. The Red Buttes Wilderness and the proposed Craggy Peak RNA also contain significant botanical resources (See Appendix F of the FEIS for a description of each proposed RNA and Botanical areas; plants are listed for each individual area).

RESOURCE USES

Limited minerals development and exploration occur in the upper reaches of the Sucker Creek drainage. Much of the area is included in the Illinois Valley Multiple Use Plan and receives a moderate amount of livestock grazing.

Recreational use is largely in the form of dispersed non-motorized and motorized use It occurs chiefly in the form of hunting, hiking, and trailriding on horseback and motorcycles The existing trail system is extensive and provides access to most of the unroaded lands The Boundary Trail has been designated as a National Recreation Trail and receives a moderate amount of use Current use estimates place Recreation Visitor Days (RVD's) in the range of 1,200 RVD's per year.

APPEARANCE, SURROUNDINGS, AND ATTRACTIONS

The appearance of the Kangaroo Area is characterized by moderately rugged, high elevation peaks with meadows, rock outcroppings and brush patches along the ridgetops and a heavy coniferous canopy down the slopes. Conditions surrounding the area vary greatly as the roadless area is a narrow stringer of land whose boundaries have been formed by man's activities along its eastern and western flanks A mosaic of patch cuts of various vegetative stages and ages exists adjacent to the boundary. The southern boundary joins with the Red Buttes Wilderness The mid-western edge abuts a corner of the 480-acre Oregon Caves National Monument.

The area contains Bigelow Lakes and a variety of smaller streams that eventually reach the Illinois River None of the streams within the roadless area support a fishery resource Blacktail deer and bear are the notable wildlife most common to the area.

CAPABILITY

MANAGEABILITY

The Kangaroo area is well defined and compact. Man's off-site activity affects the ability to manage the area in a natural state. The closeness of these roads and units precludes the opportunity for a primitive recreation experience

NATURAL INTEGRITY AND APPEARANCE

Human influences within the unroaded area are limited to old campsites and livestock grazing The impacts of grazing occur yearly as the higher elevations meadows are used as summer range for a Rogue River National Forest allotment One practicable way of lessening these impacts would be to eliminate the allotment

OPPORTUNITIES FOR SOLITUDE AND PRIMITIVE EXPERIENCE

The Siskiyou National Forest portion of the Kangaroo area is a narrow stringer of land bounded on the west by roads and harvest units Opportunities for solitude, thereby, are intruded upon by the sights and sounds of man's activities outside the area To the east of the ridgeline, the Rogue River National Forest portion of the unroaded area extends downslope and out higher ridges. Similar to the Siskiyou portion, roads and harvest units provide the demarcation of the roadless boundary at lower elevations.

The area does not contain many features that are considered challenging to the recreationalist seeking a primitive experience. There are few areas within the unroaded area where they can remain for long periods of time without being reminded of human activity.

SPECIAL FEATURES

Primary features include Mt. Elijah, and Swan, Craggy, Lake, and Grayback Mountains, plus a variety of lesser peaks, ridges, meadows and headwater basins, Bigelow Lakes, and the Oregon Caves National Monument (adjacent to the area). The high ridgetops provide a scenic character somewhat unusual to the Siskiyou. This ridgeline is traversed by the Boundary National Recreation Trail, and through various trails on the Rogue River and Klamath National Forests, provides a tie to the Pacific Crest Trail Sensitive plant communities dot the area, providing the casual visitor or botanists a unique opportunity of viewing unusual or uncommon species.

AVAILABILITY

RESOURCE POTENTIAL

Recreation Settings

The present use occurs primarily in the form of hiking, trail riding on horseback and motorcycle, and hunting. Potential for recreation is increased under development, however, capacity is not likely to be exceeded. The area is quite conducive to through travel or day hikes, providing a higher elevation and scenic experience during various times of the year

Wildlife

Game and non-game wildlife populations will remain constant unless management practices are introduced. Development would promote expansion of deer populations. Old-growth dependent species would decrease in number. They would not be eliminated, however, because considerable habitat variety would remain along streams and unsuitable areas.

Sensitive Plants

A large variety of sensitive and uncommon plants is present in the crest zone of the area, offering the visitor a different experience Sensitive species will be protected in accordance with Standards and Guidelines. The following composite list for the entire roadless area is not complete, as plant inventories have been conducted in only part of the area:

Sensitive Plants	Uncommon Plants
Cupressus bakeri	*Allium siskiyouense*
Erigeron cascadensis	*Aster brickelliodes*
Erigeron cervinus	*Calypso bulbosa*

Water

There are no man-made impoundments or diversions either existing or proposed Increased water yields can and would result from increased timber harvest activity. The greatest demand for the water resource

has been directed toward the maintenance and improvement of downstream water temperatures in the hot summer period, along with providing undiminished flows for irrigation and domestic uses Management of this resource contributes directly to downstream fishery resources

Livestock

Grazing of livestock is an important historical use of the area The potential for increased use is not likely to occur without other resource degradation.

Cultural Resources

The area is known to contain historic and prehistoric sites, specifically aboriginal camps and historic cabins and mining evidence. Trail systems in the southern portion of the area have historic origin. Overall, the area has low archaeological potential.

Energy and Minerals

Activity in the form of exploration and development is low to nonexistent Although mineral occurrence is likely, commercial quantities and development are remote.

Timber

The unroaded area contains 3,702 acres of land tentatively suitable for timber production Standing volume of timber is estimated at 79 MMBF Site productivity is moderate The area is generally stable and can be roaded and harvested without significant adverse consequences by harvest methods common on the Forest.

MANAGEMENT CONSIDERATIONS

Fire occurrence, rated low to moderate, is of principal concern. Most fire occurrences are lightning caused Natural fuels are generally light to moderate with occasional heavy concentrations The greatest fire threat occurs from dispersed recreation use deep within the unroaded area. While risk is low due to use patterns, ignition during critical weather patterns could have dire impacts.

The potential for insect and disease outbreaks within the coniferous forest exists. However, actual occurrences have been minor and localized. Mistletoe is the most prevalent disease.

NEED

OTHER AREAS AND PUBLIC USE

The Kangaroo area abuts the Red Buttes Wilderness and lies in close proximity to many other unroaded areas on the Siskiyou, Rogue River, Klamath and Six Rivers National Forest.

Local users from the Cave Junction, Grants Pass, and Medford areas are more likely to utilize the Kangaroo area than recreationalists from major population centers, such as Portland or San Francisco. People from out of the local area are more likely to seek areas that are both closer and offer more in terms of a recreational experience However, users of the National Monument also hike the local trails. Heaviest use at present comes from the local counties.

ECOSYSTEM REPRESENTATION

The major ecotypes are well represented in other undeveloped Wilderness areas. The rather extensive occurrence of botanical features are evaluated for inclusion in special Management Areas in the FEIS and Appendix F of the FEIS.

PUBLIC INVOLVEMENT

Both the public and Forest managers have had considerable interest and concern for the existing and future management of the Kangaroo area. Public involvement can be traced back to development of the Craggy Mountain Scenic Area Plan of the mid-1960's to establishment of the North Siskiyou Planning Unit and finalization of the RARE II process Since then, extensive public involvement has been sought for site specific projects within the unroaded area. The Oregon Wilderness Act of 1984 provided more opportunity for input, the result was creation of the Red Buttes Wilderness which included much of the southern portion of the Kangaroo Roadless Area. In the current Forest Planning process, the unroaded area question remains a major issue.

The analysis herein is a compilation of input received from public meetings and workshops RARE II input was evenly divided between Wilderness and non-Wilderness interests. Over 7,600 responses were received In the North Siskiyou Planning Unit DEIS (not released), involvement was well represented by all factions.

The State Department of Fish and Wildlife recommended that any development activity be approached with great caution and that emphasis be placed on protection of water quality. The Department of Forestry did not place special emphasis on this area as critical to the State or area timber supply, instead indicate that the unit had attributes that could fill Wilderness system gaps.

The Southern Oregon Resources Alliance organization took the position that values of the area were best managed through a multiple use framework. Some of the smaller sites were suggested for set aside as special interest areas. The local Sierra Club chapter, heavily involved in the disposition of this area over many years, had been a prime mover for seeking Wilderness status for the area With much of the roadless area being incorporated into the Red Buttes Wilderness in 1984 legislation, interest in requesting further Wilderness status for the remaining inventoried portion has waned However, members and other local people are still quite interested in resolution of the Kangaroo Roadless Area through the Forest Planning process.

To date, and primarily as a result of early interest in the area's quality and attributes, it has been left in an unroaded status Public preference has leaned to multiple use, but with a bent toward protection of the more outstanding features and upper elevations. Comments received on the Forest Plan DEIS in 1987 and 1988 also have not added any new insight or concerns as to management of this unroaded area. Discussions now seem more oriented to where to draw the boundary and exactly what recreation management scheme should exist within the area.

ENVIRONMENTAL CONSEQUENCES

The significant effects of each alternative are presented in Chapter IV of the FEIS. Additional site specific effects, mitigations, and potential conflicts are presented here. The Standards and Guidelines for each alternative were considered when evaluating the effects of implementation.

SIGNIFICANT EFFECTS

Cultural Resources

Alternatives NC, A, B, C, D, K, and S call for varying degrees of development which require intensive cultural resource inventory along any proposed road prior to approval. In this way, sites that exist in the project area can be evaluated and valuable sites protected by avoidance or conserved through data recovery. Alternatives E, M, and G call for an unroaded regime which would minimize the need for cultural resource inventory.

Energy and Minerals

The following table is a tabular summary of the estimated potential and accessibility limitations for Kangaroo. The acreages shown are subject to change due to the current withdrawal review by the Bureau of Land Management (BLM), and differences found for site specific needs included in any subsequent withdrawal applications to BLM

Access Restrictions	Mineral Potential (Acres)			
	High	Moderate	Low	Total
Withdrawn	-	-	100	100
High	-	-	-	-
Moderate	-	-	-	-
Low	500	-	6,000	6,500
Total	500	-	6,100	6,600

Improvements

Roads The 3,702 acres of tentatively suitable land could generate about 17 miles of new road for timber harvest. Roads for other purposes would be minor. The Tannen Lake Road, Sucker Creek Road, and Bigelow Lakes Road access the area. All other new construction would be local roads. Some mileage would remain open to passenger car use, depending on the alternative, and other roads would be open to only high clearance vehicles or closed between projects. The following table shows road mileage in the area by alternative:

Alternative	Total Miles	Miles Open to Passenger Car	Miles Open to High Clearance	Miles Closed
NC and A	12	3	4	5
B	17	4	6	7
C	17	3	7	7
D	17	5	5	7
E,G,&M	0	0	0	0
K	11	3	1	7
S	13	3	2	8

Alternatives E, G, and M would have minimal effect on this area due to no roads being built. Alternatives NC, A, B, C, D, K, and S would be roaded to varying degrees. Specific areas would not be roaded; these exceptions are the Botanical area and the much larger Craggy Mountain Supplemental Resource area in Alternatives NC, A, K, and the Backcountry Recreation area in Alternative S.

Since the area is in the headwaters of several streams, none of the proposed routes would cross streams inhabited by fish. Full bench ground would be crossed by roads with excess excavated material hauled

to stable disposal sites Much of the roading would be visible from the Boundary Trail and noise from project activities would be heard by hikers

Trails. None of the alternatives would cause construction or reconstruction of trails within this area, the existing trails are also retained in all alternatives.

Developed Recreation Sites. One new recreation site (at Bigelow Lakes) is identified for construction under Alternatives G and M; the other Alternatives provide for no additional sites.

Wilderness Potential

The roadless area and the Red Buttes Wilderness are similar in character and offer similar recreation opportunities. However, the roadless area is more influenced by management activities on adjacent lands. The area has been inventoried according to ROS criteria and is capable of providing a Roaded Natural recreation experience on approximately 3,500 acres and approximately 3,100 acres of Semi-primitive Motorized recreation opportunities. The carrying capacity for the area is estimated at approximately 8,800 RVD's This figure is high since Roaded Natural coefficients were developed based on the assumption of the presence of roads Current use is low (approximately 1,200 RVD's) and is expected to remain low over the planning period.

Maintaining the current status of the roadless area would, in effect, expand the carrying capacity for the Red Buttes Wilderness; however, the recreation experience would be influenced by adjacent motorized activities so that the quality of the experience is suspect The area could be managed in a roadless condition under Semi-primitive objectives and provide some recreation opportunities while helping to insure the quality of the experience in the designated Wilderness.

All alternatives except E and G assign the area to multiple resource management objectives Under these, approximately 40 percent of the area would be entered for developed and the Roaded Natural recreation setting currently available would shift to a modified setting as a result Alternatives NC, A, K, and S would assign approximately half the area to Supplemental Resource or Backcountry Recreation resulting in maintenance of roadless conditions for a good portion of the upper subalpine setting Retaining the area's Wilderness potential is not provided in Alternatives B, C, and D.

How much of the inventoried roadless area remains unroaded by alternative can be evaluated by either assessing a combination of Management Areas 1-9 (which retain essentially undeveloped conditions), or by viewing the spatial arrangement of blocks of undeveloped area at the end of a given period of time. Management Areas may or may not be contiguous, so the integrity of the roadless area as a whole may be compromised by management around them The following table provides a spatial estimate of acres remaining unroaded at the end of specific decades, these figures differ from the Management Area 1-9 acres in that the minimum criteria is based on the area either (1) bordering designated Wilderness, or (2) being 5,000 acres or greater.

Alternative	Acres Remaining End of Decade 1/		
	1	2	5
A, A-Dep, and NC	3,600	3,600	3,600
B, C, D, and D1	0	0	0
E and M	6,600	6,600	6,600
G	6,600	6,600	6,600
K	4,000	4,000	4,000
S	3,500	3,500	3,500

1/ Minimum criteria is 5,000 unroaded contiguous acres or adjacent to designated Wilderness

Wild and Scenic Rivers

The allocation of the area to roaded or unroaded management objectives will have no effect on the management of the Illinois Wild and Scenic River downstream

Soil, Water, and Fish

No impacts to soil, water, and fisheries are associated Alternatives E, G, and M as no soil disturbing activities occur. All other alternatives allocate all or part of the area to Management Areas which permit development The environmental effects of timber harvest and roading are discussed in the Chapter IV of the FEIS.

The risk of degrading the soil and water resource increases with more timber harvest and road building. Soil disturbing activities included in Alternatives B, C, and D could have a potentially minor to moderate adverse effect on these resources. Soil hazards of mass failure due to road construction and regeneration harvest are not great. However, disturbed soil areas are often slow to revegetate at these higher elevations and soils are sensitive to adverse impacts due to activities associated with site preparation. In Alternatives NC, A, K, and S, approximately half the area remains undeveloped, thereby reducing the potential impacts on fragile soils in the area. Alternative NC would have a slightly greater effect in that more acres are available for development.

Fire

The effects of the alternatives from a fire standpoint are the increase or decrease in fire hazard and risk that will be created. Risk is defined as the probability that an ignition will occur. Hazard is a description of the fuels complex in terms of kind, volume, arrangement, condition and location of the fuels.

The Kangaroo area is predominantly mature and old-growth Douglas-fir and true fir. Fuel loadings in these stands are moderate to high. On some south slopes, dense brushfields exist. Fuels are continuous over most of the area, with breaks found at the higher elevations. In an undeveloped scenario, fuel accumulations would increase and fuel continuity would remain the same or increase. These conditions lend themselves to large, high intensity fires. Added to this is the increased response time for initial attack forces due to poor access. The result is larger fires, higher suppression costs and increased resource losses. In a developed scenario, the hazard increases during timber harvest. As fuels are treated, fire hazard is reduced Over time, continuity of the fuels are broken up, creating a mosaic of fuels and vegetative development. This mosaic, combined with improved access for initial attack forces, reduces the potential for large, high intensity fires, resulting in smaller fires, lower suppression costs and less resource loss.

In Alternatives E, G, and M, all of the area would remain undeveloped, with fuels remaining continuous over the entire area. Alternatives NC, A, K, and S develop approximately 33 to 46 percent of the area. The remaining undeveloped area would be broken into five separate blocks. Alternatives B, C, and D would develop 65 percent of the area. The remaining undeveloped area would be in eight separate blocks. In all alternatives, some of the high priority natural fuels accumulations will be treated

In undeveloped areas, the risk of ignition is low due to the low levels of human use. As development occurs, risk of human-caused fires increase with the increased level of dispersed recreational and other public uses. In Alternatives E, G, and M, the risk from human-caused ignition would be limited primarily to the periphery of the area due to limited access. In Alternatives A, K, and S, industrial operations would result in increased risk over 33 to 46 percent of the area; risk from public use would be increased along the 12-14 miles of road. Alternative NC would increase risk over 46 percent of the area In Alternatives B, C, and D, operations would result in increased risk over 65 percent of the area, with increased risk from public use along 17 miles of road

Vegetation

Effects on vegetation relative to diversity and age class distribution do not significantly differ from the effects on the Forest as a whole (See Chapter IV, FEIS).

Sensitive Plants

The proposed Bigelow Lakes and Grayback Botanical areas are within the Kangaroo area. Both contain an interesting assemblage of sensitive and uncommon plants; plant resources at Bigelow are outstanding. For more detail on the attributes of the individual areas, including individual plant lists, see Appendix F. All alternatives, except NC, A and A-Departure, include at least one of the sensitive plant areas as a Botanical area (see following table).

A large group of sensitive and rare plants are present. Slightly over half of the roadless area is tentatively suitable for timber production; most of sensitive and uncommon plant resources are confined to the areas not suitable for timber management. Cattle grazing is permitted in part of the unroaded area; there is a potential for conflict between protection of plant resources and grazing, but there is no variation by alternative. Sensitive plants will be protected through application of appropriate Standards and Guidelines

Botanical Areas, by Alternative *1/* (Tentatively suitable for timber production)

Area Name	Tentatively Suitable (Acres)	Priority Ranking	Alternative (Acres) NC/A	B/C/D	E/G/M	K	S
SENSITIVE PLANT AREAS							
Bigelow Lakes	136	2	--	--	411	411	411
Bigelow Lakes Addition	160	4	--	--	560	--	--
Grayback Mountain	0	6	--	166	166	--	197
EXISTING BOTANICAL AREAS							
Craggy Peak	0	4	--	101	101	101	101

1/ Total acres for Option 4 are shown. Only a portion of Option 4 is actually within the Shasta Costa Roadless Area

The proposed Craggy Peak RNA is mostly within the inventoried Kangaroo Roadless Area. Two plant communities and 101 acres are on the Siskiyou National Forest are complemented by four more cells and approximately 1,100 acres are on the Rogue River National Forest. The portion of the RNA on the Siskiyou is recommended in all alternatives except NC and A.

Air Quality

The principle agent impacting air quality in the forest environment and surrounding areas is smoke from wildfire and prescribed burning. Only the impacts of prescribed burning are considered. The effect of smoke is a temporary reduction in visibility in an area. Total suspended particulates (TSP) is used as the measurement of local and regional haze Alternatives E, G, and M would contribute no TSP. All other alternatives would produce 14-23 tons of TSP per year.

The probability of a smoke intrusion from burning in the roadless area impacting Cave Junction or Medford, a designated area for air quality, is very low based on past performance. The probability of impacting the

Oregon Caves National Monument is low. The probability of impacting the Red Buttes Wilderness, adjacent to the roadless area, is low to moderate.

Wildlife

Unless specifically mentioned below, effects of the alternatives on wildlife indicator species and wildlife habitat in this roadless area are the same as for the Forest as a whole.

Bald Eagle/Osprey. The roadless area does not contain suitable habitat for bald eagle or osprey.

Spotted Owl/Pileated Woodpecker/Pine Marten Under Alternatives B, C, D, and D1, habitat for mature/old-growth indicator species would be considerably reduced over time. Mature/old-growth habitat would remain at present levels under Alternatives E, G, and M. Moderate impacts on old-growth habitat occur in Alternatives NC, A, K, and S.

Except for Alternative NC, a mixture of habitat enclaves to meet Management Requirements (MR's) for mature/old-growth habitat are located within the roadless area: parts of two spotted owl areas, part of one pileated woodpecker area, and three pine marten areas. At present, the fringes of this roadless area support part of the habitat needs for four to six spotted owl pairs (probably no spotted owl pair can meet all its habitat needs entirely within the roadless area). Mature/old-growth habitat would ultimately be reduced to MR levels in Alternatives B, C, D, and D1. Alternatives NC, A, K, and S would experience a moderate reduction in habitat capability over time, with NC changing the most. There would be no change from present conditions under Alternatives E, G, and M.

Woodpeckers. Snag habitat would remain at or near 100 percent habitat capability for woodpeckers under Alternatives E, G, and M.

Black-tailed Deer/Roosevelt Elk. Elk are not present in the roadless area. Big game management opportunities would increase somewhat in all alternatives, except E, G, and M, due to timber harvest activity on suitable lands. Opportunities for habitat improvement projects for game animals would also be greater in these alternatives.

Wildlife Habitats. The Kangaroo contains approximately 500 acres of meadow habitat (including buffers) in nine separate areas. Much of this meadow habitat is subalpine in character. Meadow habitat is allocated in all alternatives, although meadow buffers are not protected in Alternatives NC, A and A-Departure. The area also contains over 1,000 acres of rock bluffs and cliff sites Rock bluffs/cliffs are allocated for wildlife use in Alternatives E through M, but would probably remain unaffected in Alternatives NC, A through D1. A 25 acre band-tailed pigeon concentration area is present; it is maintained in all alternatives.

Wildlife Recreation Use. Estimated Wildlife/Fish User Days (WFUD's) currently attributed to the Kangaroo area are average or above average. Even though the Kangaroo is unroaded, access from surrounding roads is good and a variety of trails traverse the area. The unique habitats present draw people to the area, non-consumptive use probably is greater than consumptive (hunting). Alternatives B, C, and D, which assign a significant portion of the area to development, may actually produce fewer WFUD's in the future than at present.

Visual Resource

The current visual resource inventory indicates that the area is located in a position visible to recreational and other users. The area is distinctly different in landscape character from the rest of the Forest, and offers some of finest scenery found on the Forest. The area inventory is listed below
9999999

VQO	Acres
Retention	550
Partial Retention	3,400
Modification 1/	2,700

1/ Modification/Maximum Modification VQO

Based on public comment, viewer sensitivity or concern for the visual quality of the area is high. However, recreation use in the area is relatively low. Retention and Partial Retention objectives were assigned in response to the high quality of scenic values, and because of the designation of the Boundary Trail as a National Recreation Trail.

Alternatives NC, A, B, C, D, K, and S would assign the area to management under varying schemes of visual objectives Alternatives B, C, and D would assign the area to management under the Modification visual objective. Under these objectives, a modified environment would occur over time in which management activities would be readily apparent.

Alternatives NC and A emphasize management for inventoried visual objectives; also, 3,000 acres would be assigned to the Supplemental Resource Management Area which has no programmed harvest, and, in effect, upgrades visual objectives to Preservation. The rest of the roadless area would be managed for inventoried visual objectives, resulting in a slightly altered appearance within the first two decades.

Alternatives K and S would assign the area to management under the Modification visual objective. However, activities would not be apparent in over 3,000 acres assigned to Supplemental Resource and Botanical Management Areas. The natural appearance would be modified so that some areas would appear as altered.

Alternatives E, M, and G assign the area to roadless management, resulting in the upgrading of the area to the Preservation visual objective. The natural appearance of the area would remain essentially unchanged over the planning period.

Recreation Settings

While the area is located adjacent to a designated Wilderness, is surrounded on three sides by lands that have been modified by past management activities and, thereby, is very susceptible to the influence of motorized activities. All alternatives, except E, G, and M, would allow for some degree of development and the Roaded Natural recreation setting currently available would shift to a modified Forest setting Motorized opportunities would be enhanced as the area is roaded.

Alternative A would retain the essentially undeveloped character on 3,600 acres due to assignments to Supplemental Resource and Designated Wildlife Habitat areas. Alternative NC provides for 3,000 acres of Supplemental Resource area. Alternatives B, C, and D retain undeveloped character on 1,700 acres due to assignments to Research Natural, Botanical, and Special Wildlife Site areas. Alternatives K, and S would retain undeveloped character on over 3,400 due to the above allocations. Alternatives E, M, and G would

be managed to provide Semi-primitive recreation opportunities, maintaining the Wilderness potential over the planning period.

Economic and Social

There are 3,702 acres of land identified as tentatively suitable for the production of timber in this unroaded area. The general effects on annual allowable sale quantity (ASQ) and long-term sustained yield (LTSY) of allocating these acres to uses that would include timber production are the same as those described in Chapter IV of the FEIS.

The estimated potential ASQ from the inventoried 6,651 acres of the Kangaroo Roadless Area is 0.20 MMCF. The estimated LTSY would be 0.37 MMCF. Following are the estimates of the contribution to timber production (in MMCF) from this area under each alternative:

Alternative	ASQ	LTSY
NC	11	20
A, A-Dep, and S	.09	17
B	18	34
C and D	.15	28
E, G, and M	00	00
K	.08	15

For projecting effects, the alternatives are grouped: (1) Alternatives E, G, and M leave the area in an unroaded status; (2) Alternatives NC, A, K, and S which leave approximately half the area as unroaded, and (3) Alternatives B, C, and D which develop much of the area for timber production.

	Alternatives		
Effects (Changes Compared to Alternative A)	E, G and M (Unroaded)	NC, A, K, and S	B, C, and D (Roaded
Direct Effects			
Timber and Road Expenditures	Reduced	No Change	Increased
Indirect Effects			
Jobs	-8	0	+5
Annual Income (MM $)	-0 19	0	+0 13
Annual Payments to Counties (MM $)	-0.05	0	+0 03
Cumulative Effects			
Social Attitudes of Local Communities			
Timber Related	-	0	+
Primitive Recreation	+	0	-
Fisheries	0	0	-
Wildlife Related			
Hunting	-	0	-
Old-Growth	+	0	-
Mining	-	0	0

The major direct economic effect is government expenditure for the timber and associated road construction program. Alternatives B, C, and D have increases in the amount of timber and road expenditures over

the current direction as provided in Alternative A. Other alternatives have insignificant changes in budget expenditures

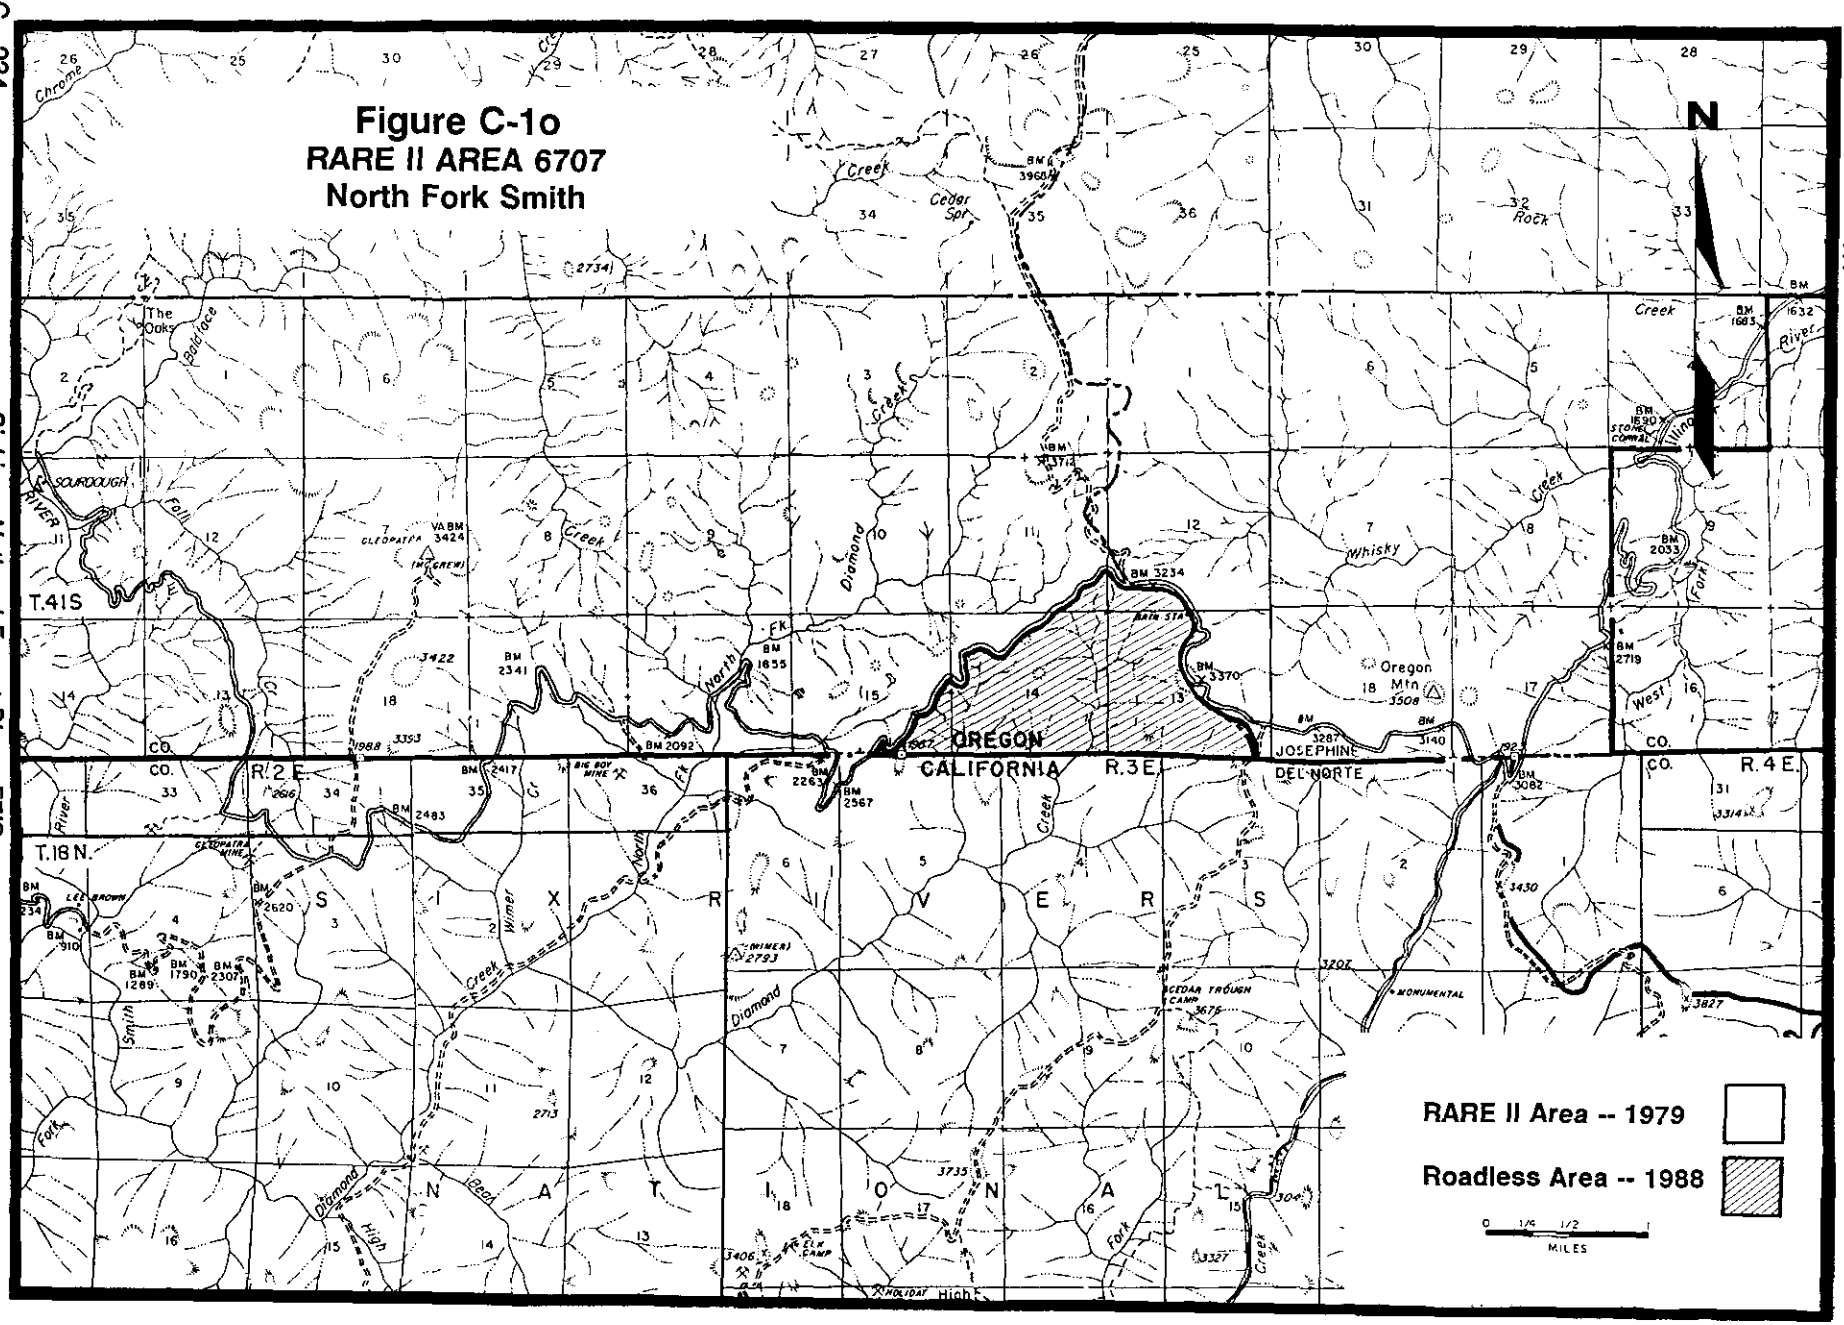
Indirect effects are associated with jobs, income, and payments to counties Assuming no substitution of reduced timber harvest within the area of influence, Alternatives B, C, and D have a moderate increase while the other alternatives have no significant changes.

The cumulative social effects of attitudes of people can be summarized by examining the different interests of the adjacent communities. Previous documentation is found in Chapters 3 and 4 of the FEIS The positive sign indicates a feeling by special interest groups that the Forest is responsive while a negative indicates a social feeling of the Forest not being responsive to particular interests as listed. For example, in Alternative C, primitive recreationalists are predicted to feel negative about forest management while timber interests are predicted to feel the forest is serving their interests Such gains and losses may create additional conflict.

MITIGATION MEASURES

No additional mitigation measures have been identified.

POTENTIAL CONFLICT WITH OTHER JURISDICTIONS



No additional conflicts have been identified.

Figure C-1o
RARE II AREA 6707
North Fork Smith

NORTH FORK SMITH No. 6707

(952 Acres)

DESCRIPTION

STATUS OF ROADLESS AREA

The North Fork Smith Roadless Area was inventoried for study as a potential Wilderness during the RARE II process The National Forest parcel of 952 acres (in Oregon) is contiguous the 39,544 acre portion on the Six Rivers National (California). The RARE II decision of January, 1979, allocated the inventoried area of 39,950 acres to "further planning". The Six Rivers National Forest in California has the responsibility for evaluating the roadless area in it's entirety. **Only the Siskiyou parcel is considered here.** Boundaries of the area have not changed; the entire parcel is National Forest System land

The Chetco-Greyback Land Management Plan (FEIS, 1979) carried the RARE II allocation of further planning Pending consideration of all potential uses, including Wilderness, development activities that may reduce Wilderness potential were prohibited. The North Fork Smith Roadless Area was released from further planning status by the California Wilderness Act of 1984. Due to the small acreage involved, the effects of current status are negligible.

CHANGES BETWEEN DRAFT AND FINAL

During the period between 1984 and 1988, no activity has occurred that would impact the unroaded character of the area. The remainder of the area is as previously described (Refer to Figure C-1p). The unroaded area on the Six Rivers National Forest that is adjacent to the area is presently being considered for multiple use values.

LOCATION AND ACCESS

The North Fork Smith area is located in the headwaters of Diamond Creek, tributary to the North Fork Smith River. The state line divides the roadless area between the Siskiyou portion (952 acres) in Curry County, Oregon, and the remainder of the area immediately south in Del Norte County, California. Distance from the coast is 18 miles as the crow flys. Access is via the old Wimer Road which rims the north boundary The Wimer Road was used in much earlier periods to join the coastal community of Smith River, California, with the interior Illinois Valley at O'Brien.

PHYSIOGRAPHIC AND BIOLOGIC

Location of this area is within the coast range (Klamath Geologic Province). Terrain is mountainous with moderately slopes and dissected by small drainages. Elevation varies between 2,500 and 3,394 feet Vegetation is dense brushfields with scattered small knobcone pine. Half the area supports scattered old-growth trees; groups of conifers occur on the more favorable soils and aspects. The latter portion of the total roadless area is underlain by metagabbro parent materials; much of the balance of the roadless area in California is serpentine-peridotite.

Soils are derived from intrusive igneous parent material and are more productive than the barren, infertile materials which surround the area. Deep soils occur along the saddle area, soils becoming shallower and rockier downslope towards Diamond Creek No significant mass movement activity is present

Climate is heavily influenced by the Pacific Ocean and marine air. Summer temperatures may exceed 90 degrees Fahrenheit, but monthly mean temperatures are mild. Annual precipitation, mostly in the form of rain, averages 115 inches; dry season rainfall (May through September) averages 12 inches.

A variety of wildlife species utilize the area, although populations are not large. The roadless area is too high in the watershed to support anadromous or resident fish. No known threatened or endangered species of animals or plants inhabit the area. Several sensitive plants are present: *Antennaria suffrutescens*, *Castilleja elata*, *Lathyrus delnorticus*. Three unique plants are present: *Aster brickellioides*, *Darlingtonia californica*, *Lilium bolanderi*. Intensive plant inventories would probably turn up other sensitive and unique plants. Other than the stream zones, no wetland ecosystems are present.

RESOURCE USES

Minerals exploration is likely to have occurred, but little evidence exists of site disturbance The only activity common to the area is big game hunting along the upper fringes bordered by the road Recreation is of a "cross country" type Recreation user days is negligible (estimated at 10 RVD's). The recreation opportunity spectrum (ROS) is Roaded Natural.

APPEARANCE, SURROUNDINGS, AND ATTRACTIONS

This southerly-oriented watershed is moderately steep with, well-clothed slopes of brush and scattered trees. Other than it's unblemished nature, few distinguishing features exist. Physical details vary little from the surrounding terrain. Man's activities are not apparent except for the road bordering the north boundary and mining, limited timber harvest, and associated roads nearby. Fire may have played a major role in vegetative conditions existing today; incendiary fires during earlier periods were possibly the result of improving ease of access and exploration for minerals.

The contiguous unroaded area to the south and downstream offers the North Fork Smith River with it's more spectacular inner gorge scenery and recreational opportunities. This upper portion offers similar terrain that are somewhat homogeneous in landscape variety. Several historic mine sites and abandoned roads occur in the lower California portion of the roadless area, but are not seen or easily accessed from the headwaters.

CAPABILITY

MANAGEABILITY

Except for the State line across the southern edge (well monumented survey markers), the North Fork Smith portion on the Siskiyou is highly defined by the Wimer Road However, the roadless boundary of the whole area is relatively well defined by ridges and other features such as roads.

NATURAL INTEGRITY AND APPEARANCE

Human influences have had little impact on the natural appearance or long-term ecological processes This upper portion is free of disturbance. Fire, as part of the natural system, has been important in successional development of the vegetative mosaic.

OPPORTUNITY FOR SOLITUDE AND PRIMITIVE EXPERIENCE

Moderate topographic relief and light vegetative density limit natural screening so that the opportunity for localized solitude and a primitive experience is reduced. The lower position of the area relative to the road is advantageous, but the short distances to the road fail to mitigate the effects of both sight and sound of adjacent timber harvest units and traffic.

The area's primitive setting is limited. With no trails, access is by foot through brush and steep terrain There are no unique, interesting, or challenging features. The very light recreation use is confined to hunting, hiking, camping, and possibly nature study. Most use occurs alongside the road.

SPECIAL FEATURES

The area does not contain notable special features. The mining sites and North Fork Smith River canyon contribute, but are not easily accessed from this portion. The Wimer Road and Bain Station, an old stage road and stop, are the most unique features within the immediate environs. The Smith River and it's primary tributaries in California, including Diamond Creek, are designated Wild and Scenic Rivers; the presence of this classification has little bearing on the special nature of the area or it's use

AVAILABILITY

RESOURCE POTENTIALS

Recreation Settings

The opportunity for measurable change in type or extent of use is limited. Under either dispersed or developed forms of recreation, the potential for increase use is negligible More recreation visitor use would be added under a roaded environment due primarily to hunter traffic in the fall period. Capacity will not be exceeded.

Wildlife

Unroaded, wildlife habitat would remain essentially unchanged. Use is low. Development would increase forage resources for deer. Populations of old-growth dependent wildlife would decrease in number. They would not be eliminated, however, because considerable area would remain in an undisturbed condition

Water

Quality is of greater importance to downstream anadromous fisheries of the Smith River system and it's Wild and Scenic River status than for development purposes Little or no diversion and use of water in this upper reach is foreseen.

Timber

The area contains approximately 399 acres of land tentatively suitable for timber production. Standing volume is estimated at 4 MMBF. Timber harvest can be done with methods in common use elsewhere on the Forest.

Minerals

Activity is low to nonexistent; potential for minerals in nickel laterite soils is moderate in the serpentinite and peridotite material. The metagabbro geology of the upper reaches of Diamond Creek that include most of the Siskiyou portion, though, may not contain significant mineral content. The total roadless area and adjacent lands do contain significant locatable deposits. Entry and development extends back to the 1850's

Cultural Resources

Historic sites mentioned exist on the fringe. No evidence has been found of prehistoric use, but historic usage associated with mining may be present. Activity will be evaluated and provided for under the applicable laws and regulations.

Land Use Authorization

None exist, none are expected except for potential minerals development and accessing.

MANAGEMENT CONSIDERATIONS

Only mineral entry and associated roads would be considered for management evaluation other than normal forest activity. Disease is not a serious problem. Fire history indicates a continued protection need for this area.

NEED

OTHER AREAS AND PUBLIC USE

Several hundred thousand acres of like terrain exist in the immediate vicinity. Because of the inherent low productivity serpentine-peridotite soils and associated economics, has not and likely will not be extensive Considerable area been placed into designated Wilderness and wild and scenic river status nearby (Smith River headwaters), while much of the remainder is inventoried as unsuitable for timber production The principal activities that have and could affect any specific site throughout this area is timber harvest and minerals exploration and development. The probability of roading, timber harvest, and mining is highly dependent on site capability and economics. The degree of roading throughout this area of both the Siskiyou and Six River National Forests generally detract from primitive experience levels.

ECOSYSTEM REPRESENTATION

The major ecotype of this roadless area is well represented in other undeveloped and Congressionally designated areas for air quality nearby.

PUBLIC INVOLVEMENT

For the North Fork Smith River Roadless Area, recent involvement by various public individuals and groups has been quite limited. Reasons for maintaining the area in unroaded status have centered on keeping all roadless all roadless areas intact and unchanged for their inherent values, and the possible occurrence of threatened, endangered, and/or sensitive plants

Both in RARE II and the unit planning completed in the late 1970's, far greater public involvement and subsequent input suggested either the area be allocated to non-Wilderness or placed into a further planning status (preference being a two to one ratio). Few suggested that the area be allocated to Wilderness Most input centered on the moderate mineral potential as well as some timber values and recreational potentials. Public responses were well mixed between individuals, interest groups, local and state governments.

After the Wilderness Acts of 1984 and the release-sufficiency language contained therein, the potential for Wilderness moved to a new theatre. Beginning in 1986, there was a movement to tie the Wild Rogue Wilderness and all contiguous unroaded areas to the the Kalmiopsis Wilderness and areas to the south (including large parts of the Smith River drainage). On the Siskiyou, this large block of land was promoted by several individuals and organizations as a potential National Park. Likewise, the Six Rivers National Forest has been party to a "Park" campaign from California-based interests. As discussed in Chapter II of the FEIS, the proposal was not entertained as an alternative evaluated in detail

Following release of the Forest Plan DEIS in 1987, input relative to the Siskiyou portion of the area has been quite limited. The only concerns expressed related to the addition of this and contiguous areas to create a large block of unroaded area from the Smith River to the Rogue. There were the suggestions for National

Park considerations as alternative management strategies for the National Forests; others suggested multiple use, including developing the area for timber where suitable.

ENVIRONMENTAL CONSEQUENCES

The significant effects of each alternative are presented Chapter IV of the FEIS. Additional site specific effects, mitigations, and potential conflicts are presented here. The Standards and Guidelines for each alternative were considered when evaluating the effects of implementation.

SIGNIFICANT EFFECTS

Cultural Resources

The North Fork Smith area has known historic values At the present time, no archaeological sites are recorded, but this paucity of information is due to a lack of cultural resource survey in the area

All alternatives, except E, M, and G, call for development which, in turn, requires intensive cultural resource inventory along any proposed road prior to approval. Sites that may exist in the project area can be evaluated. Valuable sites can be protected by avoidance or conserved through data recovery Alternatives E, M, and G call for an unroaded regime which would minimize the need for cultural resource inventory

Energy and Minerals

The following table summarizes the estimated mineral potential access limitations for the Siskiyou portion of the North Fork Smith Roadless Area.

	Mineral Potential (Acres)			
Access Restrictions	High	Moderate	Low	Total
Withdrawn	-	-	-	-
High	-	-	-	-
Moderate	-	-	-	-
Low	200	700	-	900
Total	200	700	-	900

Improvements

Roads. The 399 acres of tentatively suitable land could generate about two miles of new road for timber harvest. All would be dead-end local roads built when needed to access timber. Roads for mining exploration and development could equal or exceed this amount All roads would be open to only high clearance vehicles or closed between projects. All alternatives, except E, M, and G, would road this area.

The Wimer Road on the northern boundary is a Forest collector road. The road is maintained for passenger cars only for one-half mile beyond Bain Station, at the very north point of the area. The road system would follow ridges off the Wimer Road or change to midslope roads as the ridges steepen. The midslope roads would cross only small creeks and draws.

Trails No trail construction programmed.

Developed Recreation Sites. No construction is programmed.

Wilderness Potential

The roadless area has a landscape character that is similar to character of the southern end of the Kalmiopsis Wilderness. The area has been inventoried according to ROS criteria and is capable of providing a Roaded Natural recreation experience on approximately 1,000 acres The carrying capacity for the area is estimated at approximately 1,500 RVD's, but this figure is high since Roaded Natural coefficients were developed based on the assumption of the presence of roads Current use is very low (10 RVD's annually) and is expected to remain low over the planning period Recreation demand projections indicate that levels of use will remain well within the carrying capacity over the planning horizon.

All alternatives, except E, G, and M, would assign the area to multiple resource management objectives; Roaded Natural recreation opportunities would remain available in a modified Forest environment. The change in the character of the landscape would result in the loss of Wilderness potential Motorized recreation opportunities would be enhanced as a result of road construction. Alternatives E, G, and M would provide additional capacity for Roaded Natural recreation opportunities. The Wilderness potential of the area would be maintained.

How much of the inventoried roadless area remains unroaded by alternative can be evaluated by either assessing a combination of Management Areas 1-9 (which retain essentially undeveloped conditions), or by viewing the spatial arrangement of blocks of undeveloped area at the end of a given period of time. Management Areas may or may not be contiguous, so the integrity of the roadless area as a whole may be compromised by management around them The following table provides a spatial estimate of acres remaining unroaded at the end of specific decades; these figures differ from the Management Area 1-9 acres in that the minimum criteria is based on the area either (1) bordering designated Wilderness, or (2) being 5,000 acres or greater:

Alternative	Acres Remaining End of Decade 1/		
	1	2	5
A, A-Dep, and NC	0	0	0
B, C, D, and D1	0	0	0
E and M	900	900	900
G	900	900	900
K	0	0	0
S	0	0	0

1/ Minimum criteria is 5,000 unroaded contiguous acres or adjacent to designated Wilderness

Wild and Scenic Rivers

The area is located above and tributary to the designated Wild and Scenic River within California. Assignment of the area to roaded or unroaded management objectives will have no effect on the management of the designated river.

Soil, Water, and Fish

No consequences to soil, water, and fish are associated Alternatives E, G, and M because no soil disturbing activities will occur. All other alternatives assign most of the area to Management Areas which permit development. The effects of timber harvest and road building are discussed in the Chapter IV of the FEIS. The risk of degrading the soil, water, and fish resources in all roaded alternatives are negligible

due to the minimal activity planned for the area and the lack of sensitivity of the soils to impacts related to those activities.

Fire

The area is predominantly brush and knobcone pine Fuel loadings are light and fairly continuous. In an undeveloped scenario, fuel accumulations would increase and fuel continuity would remain the same or increase. These conditions lend themselves to moderate intensity fires, resulting in larger fires, higher suppression costs and increased resource losses.

In a developed scenario, the hazard increases during timber harvest. As fuels are treated, the fire hazard is reduced. Over time, continuity of fuels are broken up, creating a mosaic of fuels and vegetative development. This mosaic, combined with improved access for initial attack forces, reduces the potential for large, high intensity fires. The result is smaller fires, lower suppression costs and less resource loss due to fire.

In Alternatives E, G, and M, the area would remain undeveloped, with fuels remaining continuous over the entire area. All other alternatives would develop 80 to 91 percent of the area.

In undeveloped areas, risk of ignition is low due to the low levels of human use. As development occurs, risk increases with road construction, timber harvest, and treatment of activity slash. As access improves, dispersed recreational and other public uses increases, increasing the risk of human-caused fires.

In Alternatives E, G, and M, risk from human-caused ignition would be limited to the periphery of the area due to limited access. In Alternatives A, B, C, D, K, and S, industrial operations would result in increased risk over 80 to 91 percent of the area; risk from public use would be increased along two miles of road. Risk would be spread over the total area in Alternative NC.

Vegetation

Effects on vegetation relative to diversity and age class distribution do not significantly differ from the effects on the Forest as a whole (See Chapter IV, FEIS).

Sensitive Plants

No Botanical Areas or RNA's are proposed A significant number sensitive and unique plants are present; others may be discovered. Under all alternatives sensitive plants will be protected through application of appropriate standards and guidelines.

Air Quality

The principle agent impacting air quality in the forest environment and surrounding areas is smoke from wildfire and prescribed burning. Only impacts of prescribed burning are considered. The effect of smoke is a temporary reduction in visibility in an area Total suspended particulates (TSP) is used as the measurement of local and regional haze. Alternatives E, G, and M would contribute no TSP. All other alternatives would produce three tons of TSP per year. Based on past performance, the probability of a smoke intrusion from burning in this area impacting a designated area for air quality or the Kalmiopsis Wilderness, a Class 1 area, is very low.

Wildlife

Unless specifically mentioned below, effects of the alternatives on wildlife indicator species and wildlife habitat in this roadless area are the same as for the Forest as a whole.

Bald Eagle/Osprey. The area does not contain suitable habitat.

Spotted Owl/Pileated Woodpecker/Pine Marten. Less than half of the area is suitable for timber production Except for Alternative NC, a pine marten habitat enclave has been installed in the roadless area to help meet Forest-wide Management Requirements (MR's) for mature/old-growth habitat. There is not enough suitable habitat in the roadless area to support a pair of spotted owls. Under all alternatives except E, G, and M, land tentatively suitable for timber production would be developed.

Woodpeckers. Snag habitat would remain at or near 100 per percent habitat capability for woodpeckers under Alternatives E, G, and M.

Black-tailed Deer/Roosevelt Elk Elk do not occur in the roadless area and the deer population is small Management opportunities for deer would increase somewhat in alternatives which open up areas for timber management.

Wildlife Habitats. No special wildlife sites inventoried.

Wildlife Recreation Use. Total estimated Wildlife/Fish User Days (WFUD's) currently attributed to the area are lower than average. Although access to the area is good, game populations are low and the area is not a primary destination point for people interested in non-consumptive uses of wildlife.

Visual Resources

The current visual resource inventory includes 650 acres as Partial Retention and 300 acres in Modification. Viewer sensitivity or concern for the visual quality of the area is low, based on low levels of recreation use Partial Retention objectives were assigned to the area in response to the quality of scenic values in the area, and the presence of a Wilderness access route nearby. However, reappraisal of the 1979 inventory based on the extremely limited use of this route may result in a downward classification.

Alternatives, with the exception of E, G, and M, provide for an unroaded management scheme resulting in the area's upgrading to the Preservation visual objective. The natural appearance of the area would remain essentially unchanged

Alternative NC and A manage for inventoried visual objectives. However, under these two alternatives, the existing natural appearance would shift to an slightly altered appearance within the first two decades Alternatives B, C, D, K and S assign the area to management under the Modification visual objective. Under these objectives, recreation users would be in a modified Forest environment where management activities would readily apparent. The existing natural appearance would appear slightly altered-altered since only 400 acres is considered available for timber harvest

Recreation Settings

The area is influenced by the sight and sound of motorized users. Recreation use in the area is light. All alternatives except E, G, and M would cause the Roaded Natural recreation setting currently available to shift to a modified Forest setting. Access to the area and motorized opportunities would be enhanced as the area roaded. Alternatives E, M, and G would maintain current status. The natural appearance of the area and the Wilderness potential of the area would be maintained.

Economic and Social

There are 399 acres of land identified as tentatively suitable for the production of timber in this unroaded area. The general effects on annual allowable sale quantity (ASQ) and long-term sustained yield (LTSY) of allocating these acres to uses that would include timber production are the same as those described in Chapter IV of the FEIS.

The estimated potential ASQ from the inventoried 952 acres of the North Fork Smith Roadless Area is 0.02 MMCF. The estimated LTSY would be 0.04 MMCF. Following are the estimates of the contribution to timber production (in MMCF) from this area under each alternative:

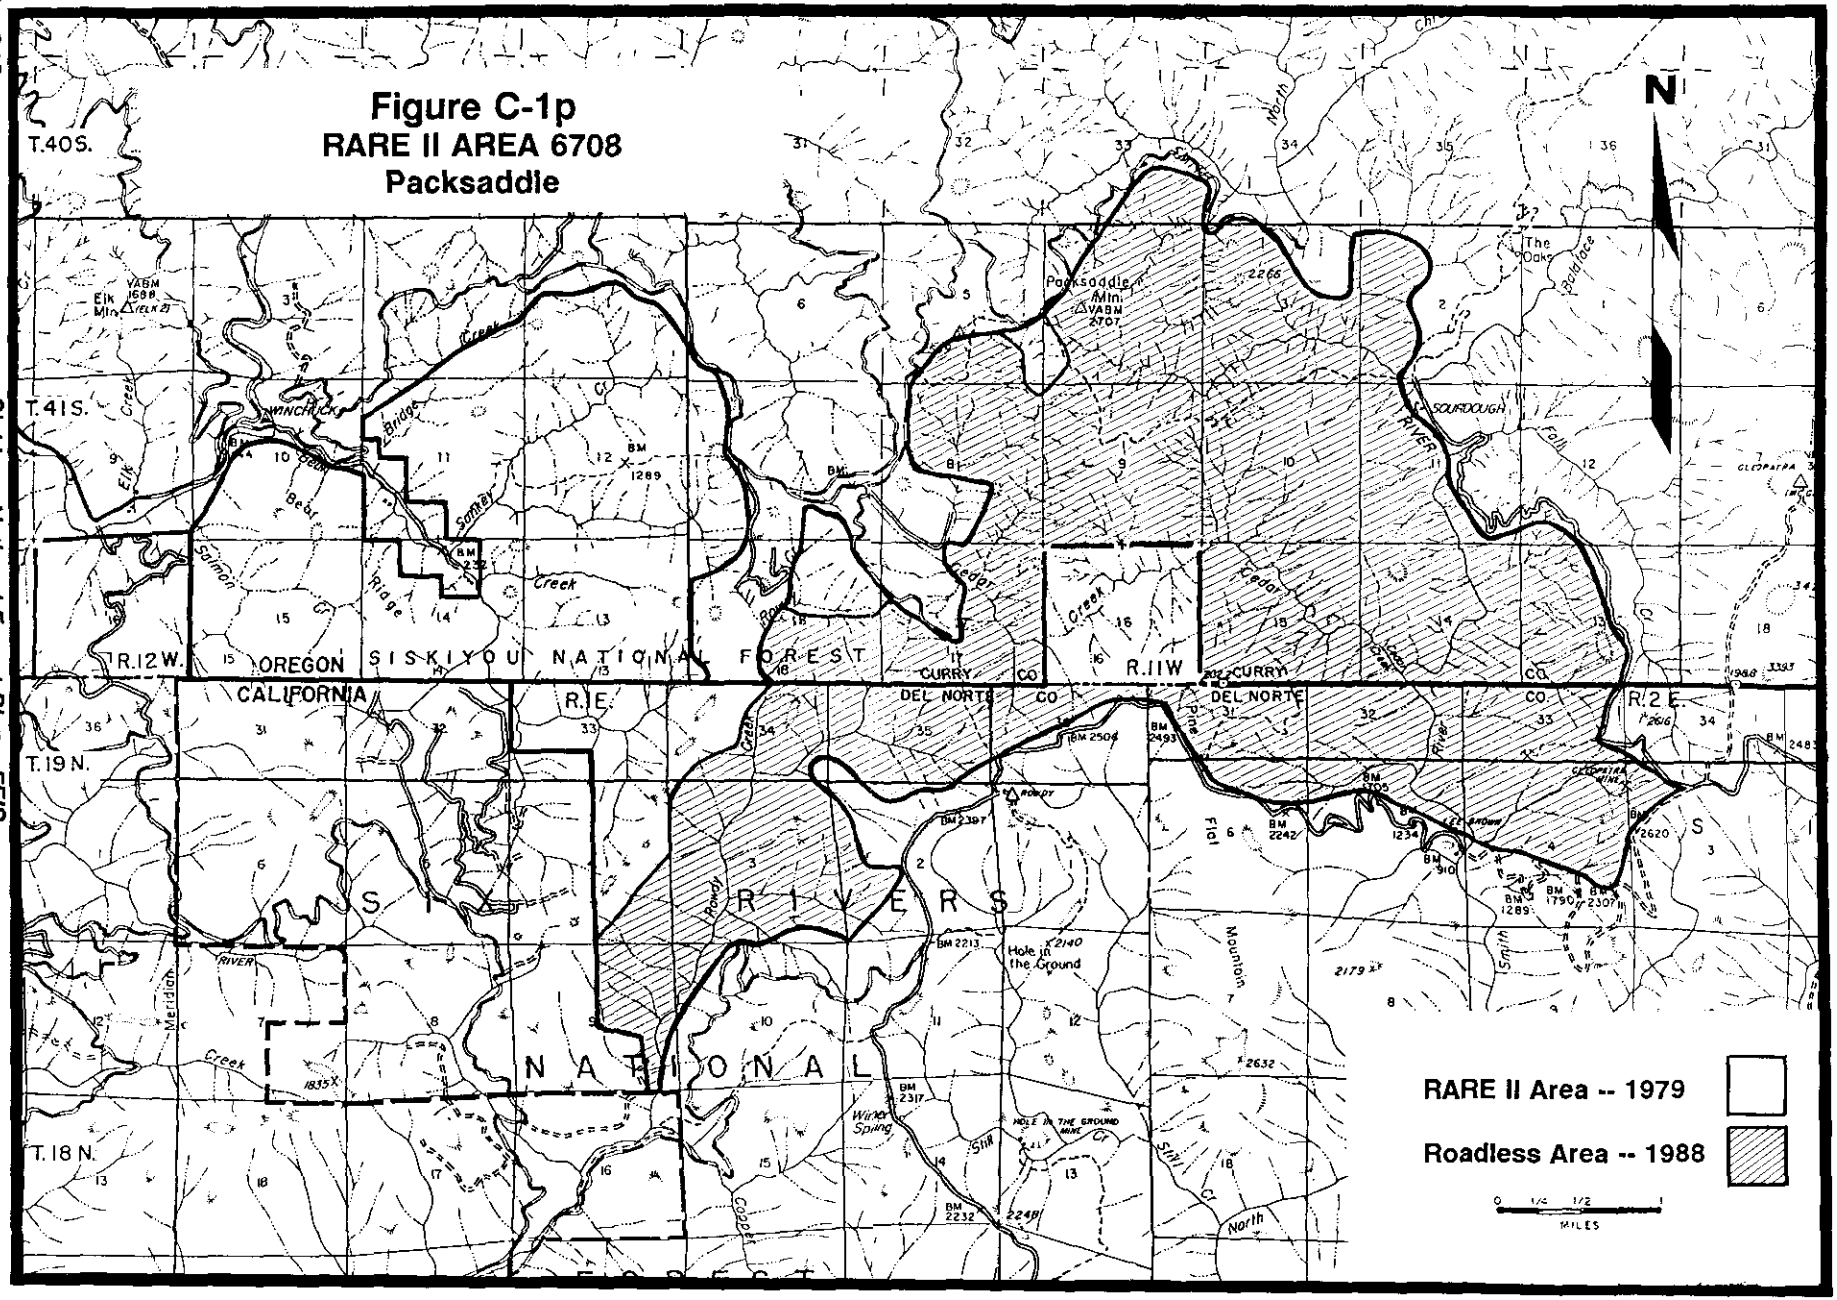
Alternative	ASQ	LTSY
NC, A, A-Dep, C, D, D1, K, and S	.02	.04
B	.02	05
E, G, and M	00	.00

For projecting effects, the alternatives are grouped: (1) Alternatives E, G, and M which leave the area in an unroaded status; and (2) all other alternatives would allow much of the area to be developed.

No significant social or economic effects are projected due to existing limited public use and low total potential for resource outputs. The indirect effects of Alternatives E, G, and M result in a slight reduction in jobs (2), and reduced annual income (0.04 MM $) and payments to the counties (0.01 MM $)

MITIGATION MEASURES

No additional mitigation measures have been identified.



POTENTIAL CONFLICTS WITH OTHER JURISDICTIONS

No additional potential conflicts have been identified.

PACKSADDLE No. 6708 and 5708

(5,289 Acres - Siskiyou National Forest)
(3,600 Acres - Six Rivers National Forest)

(Total - 8,889 Acres)

DESCRIPTION

STATUS OF ROADLESS AREA

The Packsaddle Roadless Area was inventoried for study as a potential Wilderness during the RARE II process. The roadless area straddles the Oregon-California State line which is also the common boundary between the Siskiyou and Six Rivers National Forests. The Packsaddle Area contained a total of 12,915 acres at the time of the RARE II study and was allocated to nonwilderness use by the RARE II decision in January 1979. Road construction and timber harvesting has reduced the area to its present 8,889 acres. The roadless area surrounds a section of State of Oregon land (approximately 640 acres). The roadless area is entirely National Forest System land.

The Chetco-Grayback Land Management Plan (FEIS, 1979) includes analysis of this unroaded area. Management direction assigns most of the area to Coordinated Resource Management to obtain full timber yield consistent with land capabilities, while giving full considerations to other resource values. The area within one-eighth mile horizontal distance from the North Fork Smith River was assigned to Fisheries/ Watershed. As a result of the Oregon Omnibus Wild and Scenic River Act of 1988, this corridor is now mostly within the Congressionally classified Wild River segment.

Readers are directed to the Land Management Plan for a description of the affected environment, evaluation of resources, management alternatives, and other requirements and constraints Since completion of the Land Management Plan, all project activities have been analyzed under it's direction and NEPA requirements/process.

CHANGES BETWEEN DRAFT AND FINAL

In the period between 1984 and 1988, timber sale activity on the west edge of the Siskiyou portion reduced the unroaded area by 350 acres (Refer to Figure C-1p). The remainder of the area is as previously described. The Six Rivers National Forest is currently in the process of determining land allocations and management direction for their portion of lands within and adjacent to the inventoried Packsaddle Roadless Area (Forest Plan DEIS, 1986).

As a result of the Omnibus Oregon Wild and Scenic Rivers Act of 1988, the North North Fork Smith River was added to the National Wild and Scenic Rivers System. This piece of the North Fork Smith River has been Congressionally classified as Wild. Prior to October 1988, the North Fork Smith River was carried as an inventoried Wild and Scenic River. The following alternative discussions, except for Alternative S, offer different river management options and have not been updated to reflect the new legislation. Any alternative selected in the Record of Decision and carried in the accompanying Siskiyou National Forest Land and Resource Management Plan will treat the eastern edge of this inventoried roadless area as part of the Wild and Scenic River System. For additional information of the description and resources in the river corridor, refer to Appendix E of the DEIS.

LOCATION AND ACCESS

The Packsaddle Roadless Area is located in Curry County, Oregon, and Del Norte County, California The area is approximately 11 air miles southeast of Brookings, Oregon, and eight air miles northeast of Smith River, California. Primary road access in Oregon is by the Winchuck-Chetco Road, and in California over the Wimer Road by way of Rowdy Creek.

PHYSIOGRAPHIC AND BIOLOGIC FEATURES

This area is mountainous with elevations ranging from 500 feet to 2,707 feet at Packsaddle Mountain. The eastern portion of the area is drained by the North Fork Smith River, while the western portion is drained by Rowdy Creek. The area is typified by rolling topography with convex sideslopes and deep canyons.

Precipitation averages approximately 120 inches per year. The climate is heavily influenced by marine air. Summer temperatures may exceed 90 degrees Fahrenheit, but month mean temperatures are mild.

Two basic soil types comprise the area. The most common soil is derived from serpentine and peridotite. These soils are shallow, rocky, infertile, and often have only scattered vegetative cover. They are generally stable with the exception of areas within the North Fork Smith Canyon where extremely steep slopes and channel cutting has produced very large natural failures into the streams. Due to a chemical imbalance, these serpentine soils provide a unique substrate which supports a proliferation of rare flowering plants in a climate that could produce lush forest. Serpentine bogs are present. Rare plants are especially abundant in Lemmingsworth Gulch, a proposed Research Natural Area (See Appendix F for additional site information).

Moderately productive soils derived from sandstone of the Dothan Formation occur in the western portion of the area. These soils are generally shallow with abundant rock fragments in the lower horizons. Slopes are moderately stable.

Various wildlife species use the area, but no known populations of threatened or endangered animals exist within the roadless area.

RESOURCE USES

Much of the area is highly mineralized and several old mines are located within the roadless area boundary. Potential locatable minerals include gold, copper, nickel, chromite, and cobalt. Claims covering ferro-nickle laterite deposits in the roadless area are held by CAL-ORE Mining Corporation and others. Plans to initiate mining operations on Gasquet and Pine Mountains, just outside the roadless area boundary, have remained indefinite for several years.

Recreation use of the area is low and generally limited to fishing. The proximity of roads and outside activities keeps the opportunity for wilderness recreation at a Semi-primitive level.

Much of the area has been designated as unsuitable for timber production. However, an area of approximately 3,000 acres in the total roadless area is capable of producing timber.

APPEARANCE, SURROUNDINGS, AND ATTRACTIONS

The distinguishing features of the Packsaddle area are the steep and incised draws and sparse vegetation which exists on the serpentine soils There are pockets and larger areas of typical coniferous forest, but the overall landscape projects an image of a hostile environment.

CAPABILITY

MANAGEABILITY

The Packsaddle area can be accessed by forest roads on all sides. Much of the area located in California has been modified by years of prospecting and mining activities. It is not uncommon for visitors to observe the effects of past mining activity. An exception is the northernmost drainage of the roadless area known as Lemmingsworth Gulch, an area under consideration for recommendation as a Research Natural Area (RNA). The majority of the area has been classified as non-forest, but approximately 3,000 acres are considered suitable for timber production.

The known deposits of critical and noncritical mineral deposits exist throughout the area. Surveys show them to be of commercial size and value. There is considerable interest in mining these deposits in the foreseeable future. Mining companies are planning to begin major operations adjacent to the area within the present decade. Once begun, these operations will last many years and likely spread to the deposits under claim within the roadless area boundaries.

Present recreation use is largely along the North Fork Smith River in the form of fishing. Few people hike the trail from Packsaddle Mountain to the Sourdough campsite on the bank of the North Fork

NATURAL INTEGRITY AND APPEARANCE

Humans have had some impact on the Packsaddle area, the most notably activity being mining. The dramatic variety in vegetative cover is due more to soil type changes than any other factor, natural or human. Fire has not had much impact on the majority of the area.

OPPORTUNITIES FOR SOLITUDE AND PRIMITIVE EXPERIENCE

The Packsaddle area does provide some opportunity for solitude and primitive experiences, but dense brush, steep slopes and lack of hiking trails limit these to localized, short-term events. Opportunities for solitude are reduced by the area's small size, adjacent activities, and steep topography.

SPECIAL FEATURES

Unique features in the Packsaddle area include the Nationally designated Wild and Scenic North Fork Smith River. The river canyon is rugged, very scenic, and provides some wilderness amenities Old mining areas provide some points of historical interest. The North Fork Smith River and Cedar Creek are good salmon and steelhead fisheries. And, the various patches of unique and sensitive plants offer the visitor or botanists a different opportunity.

AVAILABILITY

RESOURCE POTENTIAL

Recreation Settings

Except for fishing, there appears to be little demand for recreation use in the area. Present use is about 200 RVD's per year.

Timber

The unroaded area contains approximately 3,000 acres of land tentatively suitable for timber production. Site productivity is low and moderate. On the Siskiyou portion, 1,891 acres are classed as tentatively suitable. The estimated standing volume on the Siskiyou National Forest portion is 25 MMBF.

Minerals

Demand for the known deposits is high. While development has been rather limited within the unroaded area, plans for similar deposits to the south has somewhat active.

Cultural Resources

The old mining sites are the primary cultural sites. The area could have had some prehistoric use, but nothing to substantiate this has been found.

Wildlife

There are no known threatened or endangered species living in this area. Black-tailed deer is the principal game animal. Habitat exists for Peregrine falcon but they are not known to inhabit the roadless area.

Sensitive Plants

The serpentine soils of the area support many rare plants. The experience afforded to the casual visitor or botanist would be unique. McDonald's rockcress, *Arabis macdonaldiana*, is found in the Packsaddle area. This Siskiyou population was thought to be identical to the *A macdonaldiana* growing on Red Mountain in Mendocino County, California, which is classified as endangered. The USDI Fish and Wildlife Service has since determined that the Siskiyou's version of the plant is an as-yet-undescribed member of the purple *Arabis* complex. The Siskiyou plants (*Arabis* sp. nov./in ed. ["macdonaldiana"]) are now classified sensitive by the Forest Service (Region 6). Plant inventories have been conducted in only part of the area; the following list is not complete:

Sensitive Plants	Uncommon Plants
Arabis "macdonaldiana"	*Angelica siskiyouense*
Castilleja elata	*Antenaria suffrutescens*
Cypripedium californicum	*Arabis aculeolata*
Epilobium rigidum	*Arnica cernua*
Eriogonum pendulum	*Arnica spathulata ssp. spathulata*
Eriogonum ternatum	*Castilleja brevilobata*
Gentiana bisetaea	*Darlingtonia californica*
Hieracium bolanderi	*Dicentra formosa ssp organai*
Monardella purpurea	*Erythromium revolutuma*
Streptanthus howellii	*Hieracium parryihi*
Thlaspi montanum var siskiyouense	*Horkelia sericataar. siskiyouense*
Viola occidentalis	*Iris bracteata*
	Lilium bolanderi
	Lilium vollmeri

Fisheries

The North Fork Smith River and Cedar Creek are important streams for anadromous populations of steelhead, sea run cutthroat trout and Chinook salmon. The streams also support local rainbow

Wild and Scenic Rivers

As noted, the Omnibus Oregon Wild and Scenic Rivers Act of 1988 added this the North Fork Smith River to the National System. This ties both the California and Oregon classified Wild River segments together

MANAGEMENT CONSIDERATIONS

Ownership, including subsurface rights held by others, is not a problem The State of Oregon does own a section surrounded by the Packsaddle area. Fire is not a major threat. Insect or disease infestations are not of significance.

NEED

OTHER AREAS AND PUBLIC USE

Part of the Packsaddle area abuts the Kalmiopsis Wilderness. In addition, the inventoried South Kalmiopsis Roadless Area is in near proximity to the eastern edge of the Packsaddle area

Recreation use of these unroaded areas and Wilderness is extremely light All share many of the same geologic and vegetative features. Most activities are centered along the road system, streams and trails. Local users tend to enter these areas more than recreationists living outside of the coastal communities

ECOSYSTEM REPRESENTATION

Major ecotypes of the Packsaddle area are well represented inside the Kalmiopsis Wilderness and surrounding lands.

PUBLIC INVOLVEMENT

The Packsaddle area has been the subject of public review many times, the last during RARE II planning There has been very limited recent input relative to either this inventoried roadless area or to projects bordering the area. Comments received during the RARE II effort are capsulized in the following State input. The Oregon Department of Fish and Wildlife recommended that a "special management" classification be established to protect the "back country" character, but permit judicious management of wildlife, timber, forage and minerals. The Oregon Department of Forestry listed the value of the Packsaddle area as intermediate in importance, having major impacts within local timbersheds and moderate impacts Statewide. The Department of Economic Development recommended that "there be no further reductions in the State's commercial forest base, especially where such actions would have adverse economic impacts on employment and income..." The Oregon Department of Geology and Mineral Industries noted that the Packsaddle area contains known deposits of strategic metallic mineral commodities.

Public involvement, beginning with early scoping in 1979 and continuing with public meetings, workshops, and other contacts into 1985, has not surfaced any additional concern or movement to seek unroaded allocation of this inventoried roadless area. Comments received on the Forest Plan DEIS in 1987 and 1988 also have not added any new insight or concerns as to the area's management. However, the Citizens Task Force did cite the "high botanic values in lieu of its low timber production" as reason for maintaining the Packsaddle area as roadless. Input by other individuals or groups has been very limited

ENVIRONMENTAL CONSEQUENCES

The significant effects of each alternative are presented in Chapter IV of the FEIS. Additional site specific effects, mitigations, and potential conflicts are presented here The Standards and Guidelines for each alternative were considered when evaluating the effects of implementation.

SIGNIFICANT EFFECTS

Cultural Resources

The Packsaddle area appears to have low to moderate archaeological potentials. Alternatives NC, A, B, C, D, K and S, which allow development, would require intensive cultural resource inventory along any proposed road prior to approval. Sites that may exist in the project area can be evaluated Valuable sites can then be protected by avoidance or conserved through data recovery. Alternatives E, M, and G call for an unroaded regime which would minimize the need for cultural resource inventory.

Energy and Minerals

The following table summarizes the estimated mineral potential access limitations for Packsaddle for the Siskiyou National Forest portion only. The acreages shown are subject to change due to the current withdrawal review by the Bureau of Land Management (BLM), and differences found for site specific needs included in any subsequent withdrawal applications to BLM.

	Mineral Potential (Acres)			
Access Restrictions	High	Moderate	Low	Total
Withdrawn	<100	-	-	<100
High	-	-	-	-
Moderate	700	200	-	900
Low	2,200	400	1,800	4,400
Total	2,900	600	1,800	5,300

Improvements

Roads. The 1,891 acres of tentatively suitable land on the Siskiyou National Forest portion could generate about nine miles of new road for timber harvest All would be dead-end local roads built when needed to access timber harvest units Roads for other purposes would be minor, but some mining roads could be expected. Some mileage would remain open to passenger car use, depending on the alternative, and other roads would be open to only high clearance vehicles or closed between projects. The following table shows road mileage by alternative.

Alternative	Total Miles	Miles Open to Passenger Car	Miles Open to High Clearance	Miles Closed
NC, A, B,and D	8	2	3	3
C	10	2	4	4
E, G, and M	0	0	0	0
K and S	7	2	1	4

Alternatives E, G, and M would have minimal effect on this area due to no roads being built. Alternative C approaches maximum roading. Road 1107 on the western boundary is the main collector in Oregon accessing the area for timber haul. The other collector road on the east boundary (Road 4402) is a low standard road suitable for only high clearance vehicles; this low standard road accesses very little timber. The Rowdy Creek Road (18N20), on the south boundary of the area in California, junctions with Road 4402 at the southeast corner of the unroaded area and serves as the easiest access to the eastern boundary.

The road system would be extensions of existing roads off of Road 1107 or would follow ridges when possible. Some roads would be on the midslopes once ridges became too steep to follow or where shorter reaches for logging were needed. These midslope roads would cross small creeks and draws, but probably above sections inhabited by fish. Roads would be visible to only the few people that travel to the North Fork for fishing and other recreation

Trails. No construction is programmed.

Developed Recreation Sites. No construction is identified.

Wilderness Potential

The roadless area has a landscape character that is similar to the southern end of the Kalmiopsis Wilderness, and to a major portion of the South Kalmiopsis Roadless Area. Current use is low and is expected to remain low over the planning period. Maintenance of the roadless area would expand the carrying capacity for Roaded Natural and Semi-primitive Non-motorized recreation opportunities. Alternatives E, G, M and S would provide additional capacity for Semi-primitive Non-motorized and Roaded Natural recreation opportunities. Wilderness potential would be maintained.

Alternatives other than E, G, M and S would assign the area to multiple resource management objectives; Semi-primitive Non-motorized recreation opportunities currently available would shift to the motorized end of the opportunity spectrum. Roaded Natural opportunities would be available in a modified Forest setting Wilderness potential of the area would be lost. Motorized recreation opportunities would be enhanced.

How much of the inventoried roadless area within the Siskiyou National Forest remains unroaded by alternative can be evaluated by either assessing a combination of Management Areas 1-9 (which retain essentially undeveloped conditions), or by viewing the spatial arrangement of blocks of undeveloped area at the end of a given period of time. Management Areas may or may not be contiguous, so the integrity of the roadless area as a whole may be compromised by management around them. The following table provides a spatial estimate of acres remaining unroaded at the end of specific decades; these figures differ from the Management Area 1-9 acres in that the minimum criteria is based on the area either (1) bordering designated Wilderness, or (2) being 5,000 acres or greater:

Alternative	Acres Remaining End of Decade 1/		
	1	2	5
A, A-Dep, and NC	5,300	0	0
B, C, D, and D1	5,300	0	0
E and M	5,300	5,300	5,300
G	5,300	5,300	5,300
K	5,300	0	0
S	5,300	3,100	3,100

1/ Minimum criteria is 5,000 unroaded contiguous acres or adjacent to designated Wilderness

Wild and Scenic Rivers

A portion of the North Fork Smith River flows along the eastern edge of the area Recreation use is very low. Some of the roadless area would be visible to river users, however, the allocation to roadless management objectives should have little effect on the North Fork Smith River as to management for its Wild and Scenic River values.

Allocation to roaded uses would have a limited effect on the quality of the recreation setting in the river corridor. The recreation setting is currently maintained through the use of VQO's which were assigned to the area in response to presence of a Wilderness access route and an old campsite.

Soil, Water, and Fish

No consequences to soil, water, and fish are associated with Alternatives E, G, and M because no soil disturbing activities will occur. All other alternatives assign all or part of the area to Management Areas which permit development. The risk of degrading the soil, water, and fish resources increases with more timber harvest and road building. These impacts are about equivalent for alternatives which develop the area. On sensitive soils, a small portion of the roadless area has a high hazard for road-related impacts Alternative K and S also have a decreased potential for impact due to the fewer acres considered for management. In all development alternatives, however, the potential for adverse impact is limited because the majority of high hazard soils are removed the suitable land base. The effects of timber harvest and road building are discussed in the Chapter IV of the FEIS.

Fire

The effects of the alternatives from a fire standpoint are the increase or decrease in fire hazard and risk that will be created The Packsaddle area is primarily brushfields, with pockets of timber with heavy brush understories. Fuels are fairly continuous most of the area, though brush loadings are sparse in many areas. In an undeveloped scenario, fuel accumulations would increase and fuel continuity would remain the same or increase These conditions lend themselves to moderate intensity fires. The result is larger fires, higher suppression costs and increased resource losses. In a developed scenario, the hazard increases during timber harvest. As fuels are treated, the fire hazard is reduced. Over time, continuity of fuels are broken up, creating a mosaic of fuels and vegetative development. This mosaic, combined with improved access for initial attack forces, reduces the potential for large, high intensity fires. The result is smaller fires, lower suppression costs and less resource loss due to fire

In Alternatives E, G, and M, all the area remains undeveloped; fuels remain continuous over the entire area. Alternative S and K would develop 31 and 63 percent of the area, respectively. Alternatives NC, A, B, C, and D would develop 70 to 78 percent.

In undeveloped areas, the risk of ignition is low due to the low levels of human use. As development occurs, risk increases with timber harvest, road construction, and with treatment of activity slash. As access improves, the level of dispersed recreational and other public uses increases, accompanied by an increase in the risk of human-caused fires.

In Alternatives E, G, and M, risk from human-caused ignition would be limited primarily to the periphery of the area due to limited access. In Alternative K and S, industrial operations would result in increased risk over 31 to 63 percent of the area; risk from public use would be increased along the four to seven miles of road. In Alternatives NC, A, B, C, and D, industrial operations would result in increased risk over 70 to 78 percent of the area; risk from public use would be increased along eight to ten miles of road.

Vegetation

Effects on vegetation relative to diversity and age class distribution do not significantly differ from the effects on the Forest as a whole (See Chapter IV, FEIS).

Sensitive Plants

No proposed Botanical Areas are contained within the roadless area. However, the Lemmingsworth Gulch area, a proposed RNA, contains a wealth of rare plants. A large group of sensitive and unique plants are present. Sensitive plants in the roadless area will be protected through application of appropriate Standards and Guidelines. On the Siskiyou portion, 40 percent of the area is tentatively suitable for timber production. Most of the sensitive and uncommon plants are restricted to the serpentine soils. These areas are generally not suitable for timber harvest and, other than mining activities by private individuals, will remain relatively untouched for many years.

The proposed 965-acre Lemmingsworth Gulch RNA is entirely within the Packsaddle Roadless Area This site is recommended for RNA status in Alternatives E through S. The Gulch contains an extensive array of sensitive and uncommon plants. Two large *Darlingtonia* bogs harbor many unusual plants.

Air Quality

The principle agent impacting air quality in the forest environment and surrounding areas is smoke from wildfire and prescribed burning Only impacts of prescribed burning are considered. The effect of smoke is a temporary reduction in visibility in an area. Total suspended particulates (TSP) is used as the measurement of local and regional haze Alternatives E, G, and M would contribute no TSP. All other alternatives would produce 7-11 tons of TSP per year.

The probability of a smoke intrusion from burning in the area impacting the Redwood National Park, a Class 1 area, is very low based on past performance. The probability of impacting the Kalmiopsis Wilderness, a Class 1 area, is low to moderate.

Wildlife

Unless specifically mentioned below, effects of the alternatives on wildlife indicator species and wildlife habitat in this roadless area are the same as for the Forest as a whole

Bald Eagle/Osprey. The area is not suitable habitat for bald eagle. It is marginal for osprey; an occasional individual may use the river as a flight corridor.

Spotted Owl/Pileated Woodpecker/Pine Marten Under all alternatives except E, G, and M, habitat for mature/old-growth indicator species would be considerably reduced over time Mature/old-growth habitat would remain at present levels under Alternatives E, G, and M, which continue the roadless status Except for Alternative NC, part of one habitat enclave for pileated woodpecker is present; it is part of the habitat network established to meet MR's for mature/old-growth wildlife habitat. In Alternative NC, habitat would eventually be reduced below MR levels. The Oregon portion of the area does not contain enough old-growth habitat to support a pair of spotted owls. The California portion of can support one or possibly two pair

Woodpeckers Snag habitat would remain at or near 100 percent habitat capability for woodpeckers under Alternatives E, G, and M which assign the area to continued roadless status. In the large areas not suitable

for timber production, snag levels will remain high. Snag habitat near the North Fork Smith River would remain at or near 100 percent in all alternatives.

Black-tailed Deer/Roosevelt Elk. Big game opportunities would increase somewhat in all alternatives, except E, G, and M, which open up limited areas tentatively suitable for timber production.

Wildlife Habitats. The Packsaddle area contains approximately 25 acres of meadow habitat (including buffers) Meadow habitat is allocated in all alternatives.

Wildlife Recreation Use. Estimated Wildlife/Fish User Days (WFUD's) currently attributed to the area are lower than average. Fewer hunters use unroaded areas; non-hunters generally stay on the trails Alternatives E, G, and M, produce fewer WFUD's.

Visual Resource

The current visual resource inventory indicates that the area is
in a location where it is visible to a Wilderness access route and an old campsite. Recreational use of the area is low, so viewer sensitivity is low. The character of the landscape is somewhat unique. The inventory for the Siskiyou portion includes 3,500 acres as Partial Retention and 1,800 in Modification.

Alternatives E, G, and M would be managed to achieve the Preservation objective. The natural-slightly altered appearance of the area would be maintained over the planning period.

Alternatives NC and A assign the area to management for inventoried visual objectives; character of the area would remain natural appearing for the most part, but some management activities would be apparent so that those area would appear as slightly altered. Alternatives B, C, D, K and S manage for a reduced level of visual objectives. Areas inventoried for Partial Retention would be managed to achieve the Modification objective. The existing natural-slightly altered appearance of the area would shift to a modified or altered appearance within the first decade of the planning period Alternative K and S, however, allocate the Lemmingsworth Gulch RNA, and Alternative S assigns another 1,200 acres to Backcountry Recreation. These allocations would maintain the roadless condition and management under a Preservation visual objective

Recreation Settings

Logging roads are located in the vicinity so that the area is influenced by the sight and sound of motorized users. In addition a portion of the North Fork Smith River runs through the area. Recreation use is very light. The area has been inventoried according to the ROS system and is capable of providing approximately 2,300 acres of Semi-primitive Non-motorized and 3,000 acres of Roaded Natural recreation opportunities The estimated carrying capacity for the area based on these figures is approximately 5,300 RVD's annually, the figure being high since the coefficient is based on roaded use. Projected recreational demand will remain well within the carrying capacity over the planning horizon.

All alternatives, except for E, G, and M, would result in some degree of development and acres capable of Semi-primitive Non-motorized recreation would shift to the Roaded Natural end of the opportunity spectrum. Motorized opportunities would be enhanced the area is roaded over time.

Economic and Social

There are 1,891 acres of land identified as tentatively suitable for the production of timber in the Siskiyou portion of the unroaded area. The general effects on annual allowable sale quantity (ASQ) and long-term sustained yield (LTSY) of allocating these acres to uses that would include timber production are the same as those described in Chapter IV of the FEIS.

The estimated potential ASQ from the inventoried 5,289 acres of the Siskiyou National Forest portion of the Packsaddle Roadless Area is 0.10 MMCF. The estimated LTSY would be 0.19 MMCF. Following are the estimates of the contribution to timber production (in MMCF) from this area under each alternative

Alternative	ASQ	LTSY
NC, A, A-Dep, C, D, and K	08	.16
B and D1	.11	21
E, G, and M	.00	00
S	04	08

For projecting effects, the alternatives are grouped: (1) Alternatives NC, A, B, C, D, and K develop most of the area; (2) Alternative S develops about half of the area; and (3) Alternatives E, G, and M leave the area in an unroaded condition.

	Alternatives		
Effects (Changes Compared to Alternative A)	E, G, and M *(Unroaded)*	S	NC, A, B, C, D and K *(Roaded)*
Direct Effects			
Timber and Road Expenditures	None	Moderate Reduction	No Change
Indirect Effects			
Jobs	-7	-4	0
Annual Income (MM $)	-0.17	-0 08	0
Annual Payments to Counties (MM $)	-0 04	-0.02	0
Cumulative Effects			
Eastside Rural Communities			
Timber Related	-	-	0
Primitive Recreation	+	+	0
Fisheries	+	+	0
Wildlife Related			
Hunting	-	0	0
Old Growth	+	+	0
Mining	-	0	0

All economic and social effects for all alternatives are insignificant because of the small amount of resources involved. The amount of these resources indicate substitution of other resources could occur fairly easily resulting in little, if any, impact on the social and economic environment.

The direct economic effect is government expenditure for the timber and associated road construction program. Alternatives E, G, and M have reduce timber and road expenditures; Alternative S has a moderate decrease.

The indirect effects are associated with jobs, income, and payments to counties. Assuming no substitution of reduced timber harvest within the area of influence, Alternatives E, G, and M have the biggest reduction while Alternative S has a moderate reduction.

The cumulative social effects of attitudes of people can be summarized by examining the different interests of the adjacent communities. Additional discussion is found in Chapters III and IV of the FEIS The positive sign indicates a feeling by special interest groups of the Forest being responsive while a negative indicates a social feeling of the Forest not being responsive to particular interests as listed. For example, in Alternative E, fishing interests are predicted to feel positive about Forest management while timber interests as predicted to feel the Forest is ignoring their interests. An "0" indicates no change from current situation Such gains and losses may create additional conflict.

MITIGATION MEASURES

No additional mitigation measures have been identified.

POTENTIAL CONFLICTS WITH OTHER JURISDICTIONS

No additional conflicts have been identified.

SOUTH KALMIOPSIS No. 6709

(104,620 acres - Siskiyou National Forest)
(280 acres - Six Rivers National Forest)

(Total - 104,900 Acres)

DESCRIPTION

STATUS OF ROADLESS AREA

The South Kalmiopsis Roadless Area was inventoried for study as a potential Wilderness during the RARE II process. The roadless area surrounds the southern half of the Kalmiopsis Wilderness. It is in four segments, the largest of which crosses the Oregon-California State line and includes a small area (280 acres) on the Six Rivers National Forest in California.

The South Kalmiopsis Roadless Area contained 111,515 acres and was allocated to non-Wilderness use by the RARE II decision in January 1979. Since that time, road construction and timber harvesting has occurred in several of the segments, particularly the western ones. The area has subsequently been reduced to 104,900 acres. Except for a small area in Mikes Gulch, all is National Forest System land

The Chetco-Grayback Land Management Plan (FEIS, 1979) allocates most of the area to Coordinated Resource Management (*Management Area 1*) to obtain full timber yield consistent with land capabilities and appropriate constraints, along with providing a high level of quality big game habitat and protecting small areas containing exceptional features Three other Management Areas (4, 6, and 9) contain direction for more specialized land assignments.

Management Area 4. Managed as a scenic river. In 1984 it was Congressionally designated as the Illinois Wild and Scenic River.

Management Area 6. River corridors averaging 1/8 mile horizontal distance from each bank are designed to protect or enhance fishery habitat, water quality, and old-growth forest characteristics for dependent wildlife species. These supplemental fisheries/watershed areas have been provided to reaches of the Winchuck and South Fork Chetco Rivers.

Management Area 9. This includes the proposed Hoover Gulch RNA. Primary emphasis has been given to the preservation of natural features for educational and scientific purposes.

Complete descriptions of these management areas can be found in the 1979 Land Management Plan Readers are directed to this document for a broad overview of the affected environment, evaluation of resources and management alternatives, and other requirements and constraints. Since implementation of the Land Management Plan, all project activities have been analyzed under the Plan's direction and NEPA requirements/process.

CHANGES BETWEEN DRAFT AND FINAL

During the period from 1984 to 1988, timber sale activity has occurred in the previously dissected, southwest corner of the unroaded area. This has reduced the area by 800 acres (Refer to Figure C-1q). Very little other activity has taken place, therefore, the area remains as previously described. The Six Rivers

National Forest is currently in the process of determining land allocations and management prescriptions for their 280 acres (refer to the Six Rivers Forest Plan DEIS, 1986).

As a result of the Omnibus Oregon Wild and Scenic Rivers Act of 1988, the North Fork Smith River was added to the National Wild and Scenic Rivers System. The new designation affects the discussion herein to a very limited degree as the inventoried South Kalmiopsis Roadless Area only contacts the classified Scenic River segment in the Sourdough area. Due to the very recent passage of the Act, the Management Area acreages (Table C-5a) and analysis have not been updated to reflect this change. Only Alternative S carries the adjustments. Any alternative selected in the Record of Decision will treat the Congressionally designated land the same in the Land and Resource Management Plan.

LOCATION AND ACCESS

The South Kalmiopsis Roadless Area is located in Josephine and Curry Counties, Oregon, and Del Norte County, California (the 280 acres portion of the Six Rivers National Forest). The two western segments are approximately 10 to 15 air miles east and northeast of the town of Brookings, Oregon. These very irregular shaped segments extend north-south for 12 miles and average about two to four miles in width. The northern portion borders the Kalmiopsis Wilderness. Both are in Curry County. Access is principally off numerous system roads tributary to the main routes from the Chetco River, Wheeler Creek, and Winchuck River.

The two eastern segments are positioned approximately two miles east of U.S. Highway 199 and border the Kalmiopsis Wilderness on the west. The east-west width varies from six to ten miles; the north-south distance is 21 miles.

The northern segment, all in Josephine County, is bordered on the north by the Illinois Wild and Scenic River. Access to this side is via the Illinois River Road. Timber harvest, mining, and Wilderness access serviced by the Onion Camp Road divides these eastern segments. The southern end of the largest segment is marked by the Wimer Road Approximately one-third of the southern segment is in Curry County, and includes the 280-acres portion of the Six Rivers National Forest is in Del Norte County; the remaining area is in Josephine County.

Numerous trails and low standard mining roads exist within the eastern segments, providing relatively good access into the deep interior. The southeast unit, and largest unit, presently has about 50 miles of low standard roads which were built as exploration roads for mining. Approximately eight miles are closed and the remaining miles are open for high clearance vehicles, with four-wheel drive required for access on most.

PHYSIOGRAPHIC AND BIOLOGIC FEATURES

The roadless area is very mountainous with elevations varying from approximately 500 feet along the rivers on the western side to 4,600 feet near Pearsoll Peak. The area drains into the Smith, Illinois, Chetco, and Winchuck River systems. Physical location is on the western side of the coast range within the Klamath Mountain Physiographic Province of extreme southwestern Oregon.

The northeastern portion of the roadless area consists of two major soil types. One soil is derived from serpentine and peridotite and is largely unproductive due to chemical imbalance. The second soil occurs along the band of metavolcanic rocks of the Rogue and Galice Formation that transects the area. This area is more densely forested than the barren surrounding serpentine area, and has low to moderate productivity. These soils are generally shallow with a high gravel or cobble concentration in the surface layer. Some limited mass soil instability has occurred, primarily along geologic contact areas and on over-steepened toe slope. Development activity is generally low.

The southeastern segment of the roadless area is dominated by serpentine and peridotite soils and rounded ridge tops broken by steep inner gorges. Soil productivity is low. Surface soil runoff is often abundant during intense storm periods, creating high natural peak flows.

The western segments have broken and steep topography with deep canyons. Generally, the area is within the marine sedimentary soils having moderate to high productivity. Vegetation is usually dense with Douglas-fir the dominate conifer species. Tanoak and Pacific madrone hardwoods are also present in this mixed conifer and evergreen ecosystem.

Shallow, rocky soils occur most often in ridgetop areas, with moderately deep soils often occupying the midslope areas. Lower slopes contain considerable stream channel instability, especially along the South Fork Chetco and North Fork Smith tributaries.

Annual precipitation ranges from 60 inches on the lower east side to 150 inches in the western portions. An average 5 to 18 inches occurs during the dry season (May through September) While snow is common to the higher areas, most precipitation occurs in the form of rain due to the proximity to the Pacific Ocean and frequent warm frontal storms during the winter. Temperatures, for the most part, are fairly mild and heavily influenced by marine air. However, summer highs may attain 100 degrees Fahrenheit.

Low to moderate populations of game and nongame wildlife species occupy the unroaded area Different use levels are highly related to the significant difference in the ecosystems. Populations of black-tailed deer and occasional black bear frequent the area. Although a peregrine falcon was sighted near Red Mountain in the autumn of 1968, no known populations of threatened or endangered species of wildlife occur within the unroaded area.

The South Fork Chetco, Winchuck, and North Fork Smith River and their tributaries are important salmon and steelhead streams. Resident trout fisheries exist in many of the other streams. Anadromous fish also utilize a few of the eastside streams, but the primary influence of these tributaries are their cooling effect on the Illinois River.

The serpentine soils of the South Kalmiopsis provide a unique substrate which supports a proliferation of rare flowering plants in a climate that could otherwise produce a lush forest. Serpentine bogs are present in a number of areas. Rare plants are especially abundant in five areas which have been evaluated for designation as Botanical Areas.

RESOURCE USES

Current and historic mining dominates use of the area. Both exploration and development has occurred over much of the area where known ore bodies exist or are likely to occur Nickel laterite deposits are located in the serpentine sites. Numerous pits and tailing piles and several active gold mines occur along Josephine Creek, Canyon Creek, and their tributaries where placer gold deposits are extensive Near the State line, at least two copper mines have produced significant amounts in the past. From this activity, the area is crisscrossed with many exploration roads and dotted with sample sites

Some timber harvest activity has taken place around much of the western segments and has entered several areas of the eastern portions. These actions are strongly related to the more productive sites on the sedimentary and metavolcanic soils, and accessing to the intrusive diorite area near Buckskin Peak Occasional entry has been made on the more heavily timbered pockets in serpentine soils. As noted, most of the recent harvest activity has been excluded from the revised unroaded area acreage.

Moderate big game and very minor upland game hunting takes place Most hunting is limited to fringe areas on the westside due to steep and brushy terrain. Fishing is also minor due to tough access Access

is considerably more open and mining roads and trails provide far better ingress to the interior on the eastside

Recreation use is dispersed and highly associated with the larger rivers and their tributaries, the small lakes, and trails. Most use concentrates along the Illinois River and in the adjacent Babyfoot and Vulcan Lake areas inside the Kalmiopsis Wilderness. Use consists primarily of fishing and hunting already mentioned, backpacking, hiking, floating and swimming in the Illinois River, nature study, recreational mining, and photography. Use figures have not been collected for these more dispersed activities, however estimates place recreation visitor days at about 400 to 500 for the westside segments, and from 4,000 to 5,000 along the eastern portions. Recreation use is quite low relative to the size of area involved

APPEARANCES, SURROUNDINGS, AND ATTRACTIONS

The appearance of the South Kalmiopsis is largely associated with the parent geology The serpentine sites contribute the most diversity to an otherwise heavily forested, steep, and mountainous country The serpentine terrain is atypical due to the more open and rounded terrain, especially considering the geologic and climatic factors heavily influencing landform and vegetative development in the Klamath Geologic Province.

The surroundings provide the greatest attractions. The Scenic section of the Wild and Scenic Illinois River and Kalmiopsis Wilderness are primary attributes on the eastside. Within, the serpentine soils, vegetation, and landforms provide an unusual and very pleasing setting Many locations are of particular botanical interest because of the large number of unique or sensitive plants. Historically, mining (Chinese included) adds more character to the area

The western portions of the South Kalmiopsis contain valued commodity resources. Salmon and steelhead fisheries provide a richness to an otherwise uneventful environment. Good stands of conifer cloth these coastal slopes, providing both the attraction and setting for timber harvest in the surrounding lands.

CAPABILITY

MANAGEABILITY

The ability to manage and protect the natural character of the South Kalmiopsis is highly affected by boundary locations and existing access. The eastern boundary abuts private property which has been developed. Numerous access points are located on private land and would be very difficult to control. Numerous roads within this area are used to access active mining claims These claims would likely remain active and include right of access under any land allocation. Most of the boundary, however, is well defined by ridgelines, the Illinois River, and roads.

The western segments present far greater management difficulties due to both their smaller size and highly irregular shape. Topographic boundaries, too, are ill defined. Ability to screen from sights and sounds of external activity is quite limited.

NATURAL INTEGRITY AND APPEARANCE

The South Kalmiopsis is generally in a near-natural condition. The major existing conflicts are:

At least 9,000 acres has extensive exploration and development for mining in the form of primitive roads, pits, mine shafts, old mining equipment, etc. The most concentrated of these workings are in Josephine Creek, Hanson Gulch, Rough and Ready Creek, Rock Creek, Spokane Creek and Woodcock Mountain. Several old cabins exist as part of the mining operation. The area is so large that overall effects of mining is minor on the naturalness of the area. Unless at a mine site, the area appears natural

A power line right-of-way extends across the area in the vicinity of the West Fork Illinois River and Rock Creek near the town of O'Brien The herbaceous vegetation has been left on the right-of-way corridor which minimizes the impact on the area's naturalness. The effect on the area's appearance is high, however, along the this corridor. This area could be removed from the roadless area by a boundary adjustment without changing the overall roadless area attributes.

Livestock grazing is permitted in the allotment covering the Days Gulch and Josephine Creek area. The effect on natural integrity is low; on natural appearance, negligible.

Improvements occur on private land in Mike's Gulch.

Man's activities from outside the eastside segments have had little impact on the interior portions except for some visual changes. The natural processes are mostly intact. On the west side, the midslope boundary for much of the unroaded area creates unfavorable conditions from activities above. Road construction and timber harvest have influenced the adjacent undisturbed terrestrial and aquatic habitats. The discontinuity of activities, i.e., the drainage basin being divided between pure and altered ecosystems, measurably reduces the potential integrity of natural processes and appearance.

OPPORTUNITIES FOR SOLITUDE AND PRIMITIVE EXPERIENCE

The South Kalmiopsis has very diverse topography and vegetation that varies from open to quite dense. Natural screening, thereby, is highly dependent on local features. The coastal and northeastern segments are far better screened than the southeastern area, but adjacent activities are much more pronounced The widest bodies of unroaded area adjacent to the Kalmiopsis Wilderness provide the highest degree of solitude and primitive experience. The overall opportunity is judged as poor to moderate on fringes not bordered by Wilderness, and high in the interior, particularly in the southeastern segment. Several areas drainages are totally screened from sights and sounds.

Use of much of the western area is limited due to vegetative density and rugged terrain. Moving off the roaded adjacent areas a short distance would provide a primitive experience if sound were not present. As recreation use is heavily concentrated, movement away from these sources would also improve the feeling of remoteness and self-reliance. Much of the South Kalmiopsis can provide for primitive and unconfined types of recreation.

SPECIAL FEATURES

The inventoried South Kalmiopsis Roadless Area has unusual and complex geology which includes a large portion of the Josephine ultramatic sheet. Transition zones are small, often as little as 20 feet. Wet serpentine bogs are also present in several areas. The serpentine soils provide for a unique setting of open and shorter vegetation in a climate that could produce lush conditions These inherent differences contribute to the special nature of the area Coupled with the large serpentine landforms, the designated Kalmiopsis Wilderness and Illinois Wild and Scenic River focus considerable attention on this area

AVAILABILITY

RESOURCE POTENTIALS

Recreation Settings

The opportunity for change in type of recreation under an undeveloped scenario is limited Potential for total use should increase similarly to the Kalmiopsis Wilderness and Illinois River However, use in most of the western portions will likely increase at less than the predicted trend due to it's vegetative, terrain, and adjacent uses. The present use of approximately 5,000 recreation visitor days is mostly in the form

of hikers and off-road vehicles. Much of this activity is related to accessing the Kalmiopsis via trails and low standard roads

The potential for increased recreation use is greatest under a roaded environment where many of the existing uses would occur along with the added motorized forms Much of this use would be sightseeing and hunting accessible by roads. In both the developed and undeveloped forms of recreation, capacity would not be exceeded. The most limiting element is Primitive Recreation Opportunity System (ROS); the Primitive type of recreation opportunity will approach capacity in several decades. It's area extent in the South Kalmiopsis is quite small and strongly associated with the Kalmiopsis Wilderness.

Wildlife

Game abundance is minimal throughout the area and would remain essentially unchanged under current practices. Timber harvest would benefit game animals by creating greater food resources through changes in vegetative stages Populations of old-growth dependent wildlife would decrease. They would not be eliminated, however, because considerable habitat would remain along the river corridors, tributary streams, and in areas unsuitable for timber management purposes. Sensitive species would be protected through applicable standards and guidelines.

Soil, Water, and Fish

There are no impoundments or diversions either existing or proposed within the unroaded segments A demand does exist for augmenting the flow of the Illinois River for fisheries. However, no reservoir sites have been proposed on this side of the valley. Current low flows are associated with geology and lowered water tables of the Illinois Valley from irrigation and domestic users. The greatest need to date has been the maintenance or improvement of summer water temperatures and increased minimum flows to sustain the natural steelhead, salmon, and resident trout populations. However, this roadless area, due to it's inherent characteristics, exerts little influence on enhancement of these resources.

The coastal streams for this unroaded area have high potential; substantial increases can be expected through instream and streamside shade improvements. Resident trout populations are stable and not expected to change under various alternatives. Most of this resident trout use occurs in the upper stream areas of the eastern segments.

Livestock

A small amount of livestock grazing takes place in the area. While this use is limited, it is important to the permittee. Development would allow for improved access and better utilization of transitory range.

Energy and Minerals

The area has large, proven deposits of critical and non-critical minerals. Nationally significant amounts of nickel, chrome, and cobalt, as well as potentially important sources of gold, copper, and iron, lie within the eastern segments of the South Kalmiopsis. These deposits appear to be commercially valuable. Mining companies have been intent on developing similar deposits a few miles to the south in Northern California

Cultural Resources

Archeological potential is low. Historic mining dominates the cultural setting on the eastern side. Some Indian use has occurred in the river bottoms and ridgelines of the western segments.

Sensitive Plants

The serpentine soils of the South Kalmiopsis support a great variety of rare flowering plants The area offers the visitor and botanists a unique experience. Rare plants are especially abundant in five areas which have been evaluated for designation as Botanical Areas (Cleopatra, Days Gulch, Oregon Mountain, Rough and Ready Flat, Vulcan (See Appendix F for a description of each area, including individual plant lists)

McDonald's rockcress, *Arabis macdonaldiana*, is found in the Cleopatra area. This Siskiyou population was thought to be identical to the *A macdonaldiana* growing on Red Mountain in Mendicino County, California, and is classified as endangered. It has since been determined by the USDI Fish and Wildlife Service that the Siskiyou's version of the plant is an as-yet-undescribed member of the purple *Arabis* complex The Siskiyou plants (*Arabis* sp. nov /in ed. ["macdonaldiana"]) are now classified sensitive by the Forest Service (Region 6). Many sensitive and uncommon plants occur within the area Plant inventories have been conducted in only a small part of the area; the following list is not complete:

Sensitive Plants	Uncommon Plants
Arabis koehleri var stipitata	*Antenaria suffrutescens*
Balsamorhiza sericea	*Arabis aculeolata*
Calochortus howellii	*Arabis oregana*
Cupressus bakeri	*Arenaria howellii*
Cypripedium californicum	*Arnica cernua*
Dentaria gemmata	*Aster brickelliodies*
Epilobium rigidum	*Castilleja elata*
Erigeron cervinus	*Castilleja brevilobata*
Eriogonum pendulum	*Darlingtonia californica*
Eriogonum ternatum	*Dicentra formosa ssp. organa*
Erythronium howellii	*Erigeron bloomeri var nudatus*
Fritillaria glauca	*Erythromium citrinum*
Gentiana bisetaea	*Gentiana affinis var affinis*
Hieracium bolanderi	*Haplopappus racemosus ssp congestus*
Lewisia oppositifolia	*Horkelia sericata*
Lewisia cotyledon spp purdyi	*Iris bracteata*
Lupinus tracyi	*Kalmiopsis leachiana*
Microseris howellii	*Lewisia cotyledon*
Monardella purpurea	*Lilium bolanderi*
Poa piperi	*Lilium kelloggii*
Sedum laxum spp. heckneri	*Lilium vollmeri*
Senecio hesperius	*Lomatium howellii*
Silene hookeri ssp pulverulenta	*Pinguicula marcroceras*
Streptanthus howellii	*Phacelia corymbosa*
Thlaspi montanum var siskiyouense	*Sanicula peckiana*
Viola occidentalis	*Sarcodes sanguinea*
	Sidalcea malveflora ssp. elegans
	Trifolium howellii
	Trillium rivale
	Vancouveria chrysantha

Land Use Authorization

Few exist or are expected; most will be related to ingress and egress for mining purposes.

Timber

The South Kalmiopsis area contains 28,312 acres of tentatively suitable land for the production of timber Most of the commercial forests are in the western and northeastern segments. Standing volume is estimated at 500 MMBF. Sites that would be considered for harvest vary from stable to moderately unstable; most can be accessed and harvested using systems presently in use on the Forest today Vegetative competition and steep slopes occur on portions of the area; management for timber production would utilize various methods to reduce brush competition for release of crop trees as site-specific conditions warrant.

MANAGEMENT CONSIDERATIONS

Fire occurrence has been low to moderate Most fires are lightning caused; few are man caused Natural fuels are rated light to moderate with scattered heavy concentrations. Most of the variance is due to inherent soil properties. Risk of wildfire also varies greatly; generally it is quite low on the serpentine areas and higher in the western segments and the northeastern area bordering the Illinois River The higher risks/hazards are are a combination of fuel characteristics, likely forest management activities, and greater recreational usage (particularly in the Illinois River corridor). Improved access in these areas would increase risks due to greater numbers and types of users, but would also break fuel continuity and provide for quicker and more efficient forms of suppression response. The western areas, while generally higher hazard, have reduced severity of weather for much of the year due to the maritime influence

Mining exploration and development, and associated access will continue to require close administration to avoid conflicts with other resources. If unroaded, the sensitivity relative to appropriate control of operations will be even greater.

The potential for insects and disease outbreaks within the coniferous forest exists However, actual occurrences have been minor and localized (mistletoe infection in pine species). Management actions can reduce this threat.

NEED

OTHER AREAS AND PUBLIC USE

The South Kalmiopsis surrounds the southern half of the Kalmiopsis Wilderness (179,560 acres). Segments of the area are also adjacent to another five inventoried roadless areas (North Kalmiopsis, Squaw Mountain, Packsaddle, North Fork Smith, and Mt. Emily) The total area of the five unroaded/undeveloped areas exceeds 108,000 acres. A section of the both the Illinois and North Fork Smith Wild and Scenic Rivers also contribute to area in Congressionally designated status.

Recreation use of the Wilderness and unroaded areas is light, most being concentrated along the Illinois River, adjacent roads, Wilderness access trails, and the small lakes. The east side of the South Kalmiopsis receives most use from the interior valley areas The western segments receive very little use; most that occurs is again local and from the nearby coastal communities As a primary attraction for distant population centers, the Illinois Wild and Scenic River is the drawing feature.

ECOSYSTEM REPRESENTATION

The major ecotypes within the South Kalmiopsis are well represented in the Kalmiopsis Wilderness and the Illinois Wild and Scenic River corridor. Additionally, several Botanical areas are being considered for allocation Within the area, over 70,000 acres is inherently protected from most activity due to the land base being largely unsuitable for the production of timber. The exception to non-entry of this land base is mining; however, even this is generally limited in extent.

PUBLIC INVOLVEMENT

Interest and concern for the existing and future management of this large unroaded area has been appreciably high for both the public and Forest managers. Involvement in evaluation of options for the South Kalmiopsis began in the early 1970's through the RARE study. Conflict posed by divergent views persisted into Congressional conference committees during the debate of the Endangered American Wilderness Act of 1978. After many meetings, compromise was reached on the present boundaries of both the North and South Kalmiopsis areas. The legislative process added 103,000 acres to the then existing 76,000-acre Wilderness.

RARE II neither recommended the South Kalmiopsis for Wilderness nor further study; it was allocated to "non-Wilderness" status Public preference for allocation was mostly unanimous for this designation. The involvement and input by individuals, interest groups, local and state governments was major.

Within the same period, the Chetco-Grayback Land Management Plan was underway (FEIS, 1979) Again public input and responses were received. The issue of maintaining the existing wilderness character of the area existed and was covered in the Draft EIS, but direction was received which left decisions for recommending roadless areas for Wilderness to RARE II. Considering both characteristics and values, allocations were made through the Land Management Plan to place most of the area in Coordinated Resource Management (i.e., open to development activities). This consideration and the prior attempts to establish Wilderness over much of the South Kalmiopsis area was strongly influenced by the high potential for strategic minerals.

Since 1979, only limited entry has been made to harvest timber. Some mining activity and associated roading has occurred. Public input into several proposed projects in the unroaded portions of the South Kalmiopsis have been mostly absent. However, limitation of activity is more related to the inherent conditions of the serpentine-peridotite sites and marginal economics than to expressed public objection.

The files provide substantial documentation of issues, concerns, and recommendations relative to the South Kalmiopsis. The form of public input has been through letters, public meetings, project planning and implementation, newspapers, the RARE II process, a Land Management Plan FEIS, and current Forest Planning efforts Primary views to date are:

- The mineral potential is very high; restriction on exploration and development is likely if allocated to an unroaded status.
- Timber harvest and associated roading costs are economically submarginal on much of the serpentine-peridotite areas
- Recreational use of the area is very limited; likewise, not much use occurs in the adjacent designated Wilderness of similar landtype, therefore no need for more when capacity hasn't been approached
- Huge tracts of Wilderness and Wild and Scenic River areas offer equal or better experiences.
- Timber resources are important to the dependent communities for economic stability and local government revenue.

- Old-growth habitat for dependent species is becoming threatened
- The ecosystem is well represented in the adjacent designated Wilderness.
- Protection should be afforded the unusual, sensitive, threatened and endangered plants that inhabit the area.
- The area should be managed on a multiple-use basis supporting recreation, timber harvest, minerals, wildlife, and fisheries.
- The Kalmiopsis Wilderness boundaries were defined through Congressional compromise; it was the intent of Congress to allow development in this area
- Development adjacent to the Wilderness or within the Chetco River watershed may adversely impact their values.
- The pristine viewshed of the unique Wild and Scenic Illinois River may be impacted by sights of management activities.

In the current Forest Planning process, the unroaded area question has remained a major issue Public involvement, beginning with early public scoping in 1979 and continuing with public meetings, workshops, and other contacts into 1985, has not surfaced any new insight or concerns as to management of this unroaded area other than a "Park" campaign.

Immediately before and after release of the Forest Plan DEIS, the roadless area question and potential for Wilderness moved to a new theatre. The option to push for additional Wilderness was essentially closed with the release/sufficiency language contained in the Oregon Wilderness Act of 1984 Beginning in 1986, there was a movement to tie the Wild Rogue Wilderness and all contiguous unroaded areas to the south (including the South Kalmiopsis) with the large Kalmiopsis Wilderness. This large block of land was promoted by several individuals and organizations as a potential National Park. As discussed in Chapter II of the FEIS, the proposal was not entertained as an alternative evaluated in detail.

The importance of the South Kalmiopsis to various interest is high. Mining, timber, and environmental groups desire specific portions of the area be left for purposes essential to their views or needs. Resolution may be possible; a mix of uses accompanied by appropriate management areas and prescriptions could bring about a mosaic of "best" options for all.

ENVIRONMENTAL CONSEQUENCES

The significant effects of each alternative are presented in Chapter IV of the FEIS. Additional site specific effects, mitigations, and potential conflicts are presented here. The Standards and Guidelines for each alternative were considered when evaluating the effects of implementation.

SIGNIFICANT EFFECTS

Cultural Resources

The South Kalmiopsis has abundant historic mining resources, however, archaeological potential of the area is rated as low. Additional inventory is necessary to substantiate this. Some aboriginal use is recorded for the Winchuck portion.

Alternatives A, B, C, and D allow development which, in turn, requires intensive cultural resource inventory along any proposed alignment prior to approval. Alternative NC calls for the greatest amount of development, exceeding all others in the amount of cultural inventory and evaluation needed. Sites that may exist in the project area can be evaluated. Valuable sites can then be protected by avoidance or conserved through data recovery. Alternatives E and M call for an unroaded regime which would minimize the need for cultural resource inventory.

Energy and Minerals

The following table summarizes the estimated mineral potential and access limitations for the Siskiyou National Forest portion of the South Kalmiopsis. The acreages shown are subject to change due to the current withdrawal review by the Bureau of Land Management (BLM), and differences found for site specific needs included in any subsequent withdrawal applications to BLM.

	Mineral Potential (Acres)			
Access Restrictions	High	Moderate	Low	Total
Withdrawn	500	1,500	-	2,000
High	-	-	<100	<100
Moderate	500	400	-	900
Low	33,700	52,100	15,800	101,600
Total	34,700	54,000	<15,900	104,600

Improvements

Roads. The 28,312 acres of tentatively suitable land could generate about 124 miles of new road for timber harvest These would be local roads built to access timber harvest units. Additional roads for mining activities could be expected, especially in the two eastern units where mineralization is present and there is active gold mining.

Only a few of the new timber sale roads which could provide access to the Kalmiopsis Wilderness would be considered for passenger car use. All other roads would be open to only high clearance vehicles or closed between projects. The following table shows road mileage in the area by alternative. Note: Figures shown do not include existing mileages.

Alternative	Total Miles	Miles Open to Passenger Car	Miles Open to High Clearance	Miles Closed
NC, A and B	123	6	68	49
C	127	4	72	51
D	123	7	67	49
E and M	0	0	0	0
G	74	0	30	44
K	115	3	43	69
S	98	3	36	59

Alternatives E and M would have minimal effect on this area due to no roads being built Alternatives B, C, and D would be mostly roaded except for two Botanical areas and Hoover Gulch RNA; the two Botanical areas would not be roaded in Alternative NC and A. Alternatives G, K, and S would close 60 percent of the roads

The new construction would be extensions of new or existing roads from the Winchuck-Chetco Road or Pollywog Butte Road on the two west portions, and from the Onion Camp Road or Wimer Road for the two east portions. Timber stands in the large southeast section are scattered requiring additional roading through unsuitable lands to reach timber. Although no major streams would be crossed, some crossings would be near streams inhabited by fish. Roads would not be visible from any Forest arterial system and probably not from any highway (some possibility of new roads being seen from part of State Highway 46 or U.S. Highway 199), but could be visible from the Kalmiopsis Wilderness rim and the Wild and Scenic Illinois River in the northeast portion of the area.

Trails. Alternatives G and M would provide for the construction of 15 miles of trail; Alternatives K and S for 13 miles; and Alternatives NC, A and E for eight miles. Alternatives B, C, and D would only construct 0 5 miles of trail. Alternatives K and S propose the reconstruction of six miles of trails

Developed Recreation Sites. No construction is proposed.

Wildlife and Fish Habitat Structural Improvements. The South Fork of Chetco and Winchuck Rivers and many of the larger creek systems, like Josephine, Canyon, Rough and Ready, Baldface, and Fourth of July Creeks are candidates for improvements. All alternatives except E, G, and M would facilitate construction of any fish structures by providing better access. Alternative G, however, would provide additional access over the above group. Alternatives E and M retain the existing access limitations

Wilderness Potential

There are 232,495 acres within five designated Wildernesses on the Siskiyou National Forest. Recreation demand projections indicate that the Forest has the capacity to sustain projected levels of use in these areas until approximately the fifth decade of the planning period.

Alternative NC assigns the area to multi-resource management objectives, exposing Wilderness users to the influence of road construction, harvest units, and motorized recreation users. The quality of a primitive recreation experience in the peripheral areas of the Forest would be degraded as a result. Basically the same effects are attributed to Alternatives A, B, C, and D. However, an aggressive trail construction program would be implemented in the Kalmiopsis Wilderness under Alternatives B, C, and D, adding approximately 70 miles to the existing trail system, to partially mitigate the impacts.

Alternatives G, K and S would assign varying amounts of the South Kalmiopsis to Backcountry Recreation management. The Backcountry Recreation assignment in Alternative S would provide for motorized uses designed primarily for ORV's in portions of the area (approximately 54,213 acres) allocated.

Alternatives E and M would allocate all of the South Kalmiopsis to unroaded objectives. The quality of the recreation experience inside the Kalmiopsis Wilderness would be maintained due to the presence of areas maintained in a roadless condition. The Kalmiopsis Wilderness would be maintained in its current condition since the Forest would have the capacity to sustain demand for Non-motorized recreation activities.

How much of the inventoried roadless area remains unroaded by alternative can be evaluated by either assessing a combination of Management Areas 1-9 (which retain essentially undeveloped conditions), or by viewing the spatial arrangement of blocks of undeveloped area at the end of a given period of time. Management Areas may or may not be contiguous, so the integrity of the roadless area as a whole may be compromised by management around them. The following table provides a spatial estimate of acres remaining unroaded at the end of specific decades; these figures differ from the Management Area 1-9 acres in that the minimum criteria is based on the area either (1) bordering designated Wilderness, or (2) being 5,000 acres or greater:

Alternative	Acres Remaining End of Decade 1/		
	1	2	5
A, A-Dep, and NC	75,000	70,000	65,000
B, C, D, and D1	75,000	70,000	65,000
E and M	104,600	104,600	104,600
G	91,000	80,000	80,000
K	75,000	70,000	65,000
S	80,000	76,000	76,000

1/ Minimum criteria is 5,000 unroaded contiguous acres or adjacent to designated Wilderness

Wild and Scenic Rivers

The North Fork Smith was added to the National Wild and Scenic River System through the Omnibus Oregon Wild and Scenic Rivers Act of 1988 (See **CHANGES BETWEEN DRAFT AND FINAL**). The new Congressional designation will have little effect on the South Kalmiopsis. The various management alternative evaluated herein also could have only a minor impact, at most, on the Scenic River segment in the Sourdough area of the Wild and Scenic River corridor.

Much of the northern end of the area adjacent to the Wild and Scenic Illinois River is visible to river users. The allocation of the area to roadless management objectives will not effect the management of the Illinois Wild and Scenic River. However, the allocation could effect the quality of the recreation setting near the river The recreation setting is currently maintained through the use of Visual Quality Objectives (VQO's) which were assigned in response to both the designation of the river as Wild and Scenic and to the high levels of recreation use that occur on the river. Area within the designated Wild and Scenic River corridor is currently managed to achieve a Retention objective, the minimum objective applied to the designated Wild and Scenic River.

Alternative NC and A would manage the area to achieve inventoried visual objectives and result in some modifications in the area as they are entered for timber harvest. The quality of the recreation experience of the river users would be maintained. Alternatives B, C, and D assign the area outside of the designated Wild and Scenic River corridor to a reduced scheme of visual objectives. Areas outside the 1/4 mile corridor currently inventoried for Retention would be managed for Partial Retention resulting in visible harvest activities in proximity to river users. The quality of the recreation experience of the river users would be minimally effected because so little of the area is inventoried for Retention.

Alternatives E and M would manage the area for the Preservation objective, thereby maintaining the natural appearance and the Wilderness potential of the area over the planning period. Alternatives G and S would maintain 65,000 and 61,000 acres, respectively, in a roadless condition Assignment of Backcountry Recreation to the area generally located between the Scenic segment of the Illinois River and the Kalmiopsis Wilderness would be more oriented toward protecting the quality of the wilderness experience rather than the river experience, as the Upper-Illinois viewshed is already assigned to the inventoried VQO's under these alternatives. Alternative K, on the other hand, assigns most of the 13,000 acres of selected Management Areas to provide some degree of buffering to the upper Illinois River corridor.

Soil, Water, and Fish

No consequences to soil, water, and fisheries are associated with Alternatives E and M because no soil disturbing activities will occur. All other alternatives assign all or part of the area to Management Areas which permit development. The effects of timber harvest and road building are discussed in Chapter IV of the FEIS.

The risk for soil, water, and fisheries degradation is negligible to slight for all roading alternatives for areas on the northeast and southeast side of the roadless area. Slight to moderate risk of degradation occurs for Alternatives NC, A, B, C, and D for areas on the westside of the roadless area. These soils have greater inherent sensitivity to road-related activities. Hazards of regeneration occur primarily on the lower slopes. Highest hazards soils have been eliminated from the suitable land base, lessening potential risk of degradation for these alternatives.

Alternative K increases the amount of unroaded acres, some of which have potential risks for adverse effect. With reduced acres subject to disturbance would be a decreased potential for adverse soil and water impacts Further reductions in a large number of developed acres in Alternative G and S result in negligible risks to the soil, water, and fisheries resources.

Fire

The effects of the alternatives from a fire standpoint are the increase or decrease in fire hazard and risk that will be created. The South Kalmiopsis contains extremely variable fuel types. The parts east of the Kalmiopsis Wilderness are primarily sparse brush with a very scattered timber overstory. Throughout the area are scattered pockets of denser timber, particularly in the northern portion. Fuel loadings are light and the continuity broken by rock outcroppings. These conditions tend to produce low to moderate intensity fires, except under extreme conditions. The area west of the Kalmiopsis Wilderness is a mixture of timbered stands with a heavy brush understory, and extensive brushfield and hardwood stands Dead fuel loadings are generally light and continuous, though the heavy brush loadings create a high hazard.

In an undeveloped scenario, fuel accumulations would increase and fuel continuity would remain the same or increase. These conditions lend themselves to large, high intensity fires. Adding to this is the increased response time for initial attack forces due to poor access. The result is larger fires, higher suppression costs and increased resource losses. In a developed scenario, the hazard increases during timber harvest. As fuels are treated, the hazard is reduced. Over time, continuity of fuels are broken up, creating a mosaic of fuels and vegetative development. This mosaic, combined with improved access for initial attack forces, reduces the potential for large, high intensity fires. The result is smaller fires, lower suppression costs and less resource loss due to fire.

In Alternative E, all the area would remains undeveloped, with fuels remaining continuous over the entire area. Less than one percent of the area developed in Alternative M. In Alternatives G and S, 31 to 36 percent of the area would be developed, creating a mosaic of fuels over time while the rest of the area would remain undeveloped. Alternatives NC, A, B, C, D, and K would develop 75 to 81 percent of the area. The remaining undeveloped areas would be in 18-44 separate blocks. In large portions of the area, development will be minimal due to a large amount of land in the unsuitable category.

In undeveloped areas, the risk of ignition is low due to the low levels of human use. As development occurs, risk increases with road construction, timber harvest, and with treatment of activity slash. As access improves, the level of dispersed recreational and other public uses increases, with an increase in the risk of human-caused fires.

In Alternatives E and M, the risk from human-caused ignition would be limited primarily to the periphery of the area due to limited access. In Alternatives G and S, industrial operations would result in increased risk over 31 to 36 percent of the area; risk from public use would be increased along the 124 to 148 miles of road. In Alternatives NC, A, B, C, D, and K, industrial operations result in increased risk over 75 to 81 percent of the area; risk from public use is increased along 165 to 177 miles of road. Another source of ignition in these areas could be the planned use of naturally occurring fire in the Kalmiopsis Wilderness adjacent to the area. If fires are allowed to burn, there is a chance of fire escaping from the Wilderness boundaries.

Vegetation

Effects on vegetation relative to diversity and age class distribution do not significantly differ from the effects on the Forest as a whole (See Chapter IV, FEIS).

Sensitive Plants

Half of the existing Babyfoot Lake Botanical Area is partially within the roadless area (the other half is part of the Kalmiopsis Wilderness). Portions of five of the Forest's 19 candidate Botanical areas for sensitive plants are also within the area (following Table). Alternatives B, C, D, E, M and S include sensitive plant areas as Botanical areas (See Appendix F for more detail on individual sites). The proposed Hoover Gulch RNA is within the South Kalmiopsis Roadless Area; it is recommended in all alternatives.

A large group of sensitive and unique plants are present under all alternatives; sensitive plants will be protected through application of appropriate standards and guidelines. Approximately 28 percent of the roadless area is tentatively suitable for production of timber. Most of the sensitive and uncommon plants are restricted to serpentine or peridotite soils. These areas are generally not suitable for timber harvest, and other than mining activities by private individuals, will remain relatively untouched for the near future.

Botanical Areas, by Alternative *1/* (Tentatively suitable for timber production)

Air Quality

The principle agent impacting air quality in the forest environment and surrounding areas is smoke from wildfire and prescribed burning Only impacts of prescribed burning are considered. The effect of smoke is a temporary reduction in visibility in an area. Total suspended particulates, or TSP, is used as an indicator of potential impacts. The potential for regional haze is a function of TSP production over the surrounding areas. Alternatives E and M would contribute little or no TSP. Alternative G and S would produce 62-68 tons of TSP per year, while Alternatives NC, A, B, C, D, and K produce 131-149 tons.

The probability of a smoke intrusion from burning in the roadless area impacting Grants Pass, a designated area for air quality, or Redwood National Park, a Class 1 area, is very low based on past performance. The probability of impacting the Kalmiopsis Wilderness, a Class 1 area, or Cave Junction, is low

Wildlife

Unless specifically mentioned below, effects of the alternatives on wildlife indicator species and wildlife habitat in this roadless area are the same as for the Forest as a whole.

Bald Eagle/Osprey. No bald eagle or osprey are known to inhabit the South Kalmiopsis, except for the Illinois River corridor, there is little available habitat for these two species Under any alternative, management of eagle habitat would be governed by the Pacific Bald Eagle Recovery Plan (USDI-Fish and Wildlife Service 1986). All alternatives offer adequate protection to the Illinois River corridor

Spotted Owl/Pileated Woodpecker/Pine Marten. All alternatives, except E, G, M and S, would reduce habitat for mature/old-growth indicator species would be over time. Mature/old growth-habitat would remain at present levels under Alternatives E and M; Alternative G, which leaves half of the area unroaded, preserves most of this habitat type Alternative S preserves over half the area.

Except for Alternative NC, a mixture of habitat enclaves to meet Management Requirements (MR's) for mature/old-growth habitat are located within the roadless area: three for spotted owls, four for pileated woodpeckers, and ten for pine marten (one of the pileated and four of the marten areas are only partially within the roadless area). At present this unroaded area supports approximately eight pairs of spotted owls, mostly on the northwest and western portions of the area There would be no change from present conditions under Alternatives E and M. Alternative G and S could probably support four owl pairs indefinitely. Mature/old-growth habitat would ultimately be reduced to MR levels in all alternatives except E, G, and M. In Alternative NC, habitat would eventually be reduced below MR levels.

Woodpeckers. Snag habitat would remain at or near 100 percent habitat capability for woodpeckers under Alternatives E and M which allocate the area to continued roadless status. In areas not tentatively suitable for the production of timber, snag levels will remain high. Snag habitat along the Illinois River would remain at or near 100 percent all alternatives.

Black-tailed Deer/Roosevelt Elk. Big game opportunities would increase somewhat in Alternatives NC, A, A-Departure, B, C, D, D1, and K, which open up areas suitable for the production of timber. Opportunities for habitat improvement projects for game animals would also be greater in these alternatives.

Wildlife. The South Kalmiopsis contains approximately 80 acres of meadow habitat (including buffers) at four separate sites Meadow habitat is allocated in all alternatives, although meadow buffers are not protected in Alternative NC or A. Two pond areas/wet sites are assigned in all alternatives except NC and A. The area contains over 1,000 acres of rock bluffs and cliff sites. Rock bluffs/cliffs are allocated for wildlife use in Alternatives E through S, but would probably remain unaffected in Alternatives NC through D1.

Wildlife Recreation Use. Estimated Wildlife/Fish User Days (WFUD's) currently attributed to the South Kalmiopsis are lower than average on the eastern portion of the area (higher than average near roads and the Illinois River). User-days on the western portion of the area are assumed to be equal to or slightly less than the General Forest. Fewer hunters use unroaded areas and non-hunters generally stay on the trail system. Alternatives E, G, and M produce fewer WFUDs; other alternatives generate more.

Visual Resource

The South Kalmiopsis Roadless Area has been inventoried for its Visual Quality Objectives (VQO's); the estimated acreages for each is provided below:

VQO	Acres
Retention	5,800
Partial Retention	39,100
Modification 1/	59,600

1/ Modification/Maximum Modification VQO

Areas inventoried as Retention and Partial Retention respond to recreation use and attendant viewer sensitivity from the Wilderness access route to Babyfoot Lake, the Illinois Wild and Scenic River, and to some of the trails in the Kalmiopsis Wilderness and roadless area. Recreation use is occurring primarily on the Illinois River, with trail use being low to moderate. Areas identified for visual objectives are primarily foreground and middle ground distance zones located adjacent to the above locations.

Alternative NC and A would manage the area for the current inventory and provide that management activities subordinate to the character of the landscape (Partial Retention) be visible in the viewsheds adjacent to Wilderness access routes and trail systems and the Illinois River, resulting in a slightly altered-natural appearing landscapes. Areas inventoried for Modification would result in an altered appearing landscape except in those areas not suitable for timber harvest. Alternatives B, C, and D assign VQO's only to the roadless areas within the Upper-Illinois viewshed in response to recreation use on the Illinois River Areas adjacent to Wilderness routes and trail systems would be allocated to Modification objectives.

Alternatives E, G, and M maintain the current visual inventory or upgrade the inventory to management under the Preservation objective in areas allocated to roadless management. Alternative E and M upgrade the inventory of the entire roadless area to Preservation. Alternative G, with allocations of approximately 56,000 acres to Backcountry Recreation and other special Management Areas, would subsequently upgrade the inventory to management under the Preservation objective

Alternative K and S assigns part of the South Kalmiopsis to Backcountry Recreation Management The area is comprised of the lands generally located between the Scenic section of the Illinois River and the Kalmiopsis Wilderness Visual objectives are allocated to areas within the Upper Illinois viewshed. All other areas would be managed under the Modification objective However, the Backcountry Recreation allocation in Alternative S would maintain upgrade the visual objectives for major portions of the unroaded area to Preservation

Land allocations to roadless management discussed for the alternatives above are located on the east side of the Kalmiopsis Wilderness. Unless the entire South Kalmiopsis is assigned to roadless objectives, the area on the west side of the Wilderness has been assigned to roaded objectives.

Recreation Settings

The roadless area has been inventoried according to the Recreation Opportunity Spectrum (ROS). The inventory shows that the area has the ability to provide a full spectrum of recreation opportunities The inventoried acreage and the estimated carrying capacity for each ROS class is shown in the table below.

ROS Class	Acres	Capacity (M RVD)
Roaded Natural 1/	31,200	50 5
Semi-primitive Motorized 1/	31,000	41 0
Semi-primitive Non-motorized	41,200	8 7
Primitive	1,100	0 1

1/ Carrying capacity shown is based on a roaded recreation use coefficient and is misleading since the Roaded Natural and Semi-primitive Motorized classifications are based on the presence of motorcycles on trail systems accessing the area.

The area is capable of offering Semi-primitive Non-motorized recreation opportunities on approximately 42,000 acres located on both the east and west sides of the Kalmiopsis Wilderness. The area on the east side consists primarily of lands not suitable for the production of timber. For the most part the landscape is rocky with scattered stands of timber and brushfields. It is estimated that approximately 70,000 acres of this area will remain in a roadless condition regardless of the management alternative selected since no management activities would be programmed. The area could still be roaded under several alternatives if large scale mineral development were to occur.

The 31,000 acre area identified as Semi-primitive Motorized falls in this category because of current management which provides for the use of trail bikes and motorcycles on trail systems within the area, and due to the presence of mining roads (some of which are used on a regular basis). If motorized use is

restricted, these areas would shift to the non-motorized end of the opportunity spectrum. The majority of these areas are located on the east side of the Kalmiopsis Wilderness.

Recreation use is light in all four parts that comprise the South Kalmiopsis and is estimated at approximately 5,000 RVD's in the entire area. The majority of recreation use in the roadless area occurs within the Illinois River corridor at the northern end of the roadless area on the east side.

Alternatives A, B, C, and D, inventoried as Semi-primitive Non-motorized recreation opportunities except the 70,000 acres spoken to above, would be lost by the second decade of the planning period. The area would lose its pristine character and present a roaded modified Forest setting to the recreation user Roadless character and Wilderness potential would be lost as a result. Portions of existing trail systems would not be replaced as a result of road construction. These four alternatives retain the essentially undeveloped character on 8,000 to 9,000 acres due to allocations to Wild River, Research Natural, Botanical, Supplemental Resource, and Designated Wildlife Habitat Management Areas.

Under Alternatives E and M, all of the inventoried Semi-primitive Non-motorized area would be maintained. An expanded capacity for Semi-primitive Non-motorized opportunities would result as motorized use on trail systems would be restricted in favor of non-motorized recreation opportunities.

Alternatives G, K and S assign varying portions of the South Kalmiopsis to roadless management objectives. Under the Alternative K, 1,500 acres of the South Kalmiopsis would be assigned to Backcountry Recreation. The assignment would include the lands within the viewshed adjacent to the Scenic section of Illinois River. The essentially undeveloped character of the area would be retained on an additional 11,500 acres due to allocations to RNA, Botanical, Supplemental Resource, and Designated Wildlife Habitat Management Areas.

The proximity of harvest activities and related road construction to recreationists in much of the rest of the area would result in the reduction of Semi-primitive opportunities that would be the same as those identified for the A, B, C, and D alternatives, and more so with Alternative NC. The shift in the opportunity spectrum would occur within the first two decades of the planning period.

Under Alternative G, 61,000 acres would be allocated to roadless management. Under this alternative, Semi-primitive Non-motorized opportunities would be maintained at inventoried levels. The allocation would include the viewshed adjacent to the Scenic section of the Illinois River. Additional acres would retain the essentially undeveloped character due to allocations similar to those cited for Alternative K.

Under Alternative S, approximately 54,200 acres would be allocated to Backcountry Recreation Management. Under this alternative semi-primitive Non-motorized opportunities would be maintained at inventoried levels. The allocation would include the viewshed adjacent to the Scenic section of the Illinois River. Additional acres would retain the essentially undeveloped character due to allocations similar to those cited in Alternative G above.

Economic and Social

There are 28,312 acres of land identified as tentatively suitable for the production of timber in this unroaded area. The general effects on annual allowable sale quantity (ASQ) and long-term sustained yield (LTSY) of allocating these acres to uses that would include timber production are the same as those described in Chapter IV of the FEIS.

The estimated potential ASQ from the inventoried 104,620 acres of the South Kalmiopsis Roadless Area is 1.56 MMCF. The estimated LTSY would be 2.83 MMCF. Following are the estimates of the contribution to timber production (in MMCF) from this area under each alternative.

Alternative	ASQ	LTSY
NC and A-Dep	1 53	2 75
A, C, and D	1 43	2 60
B	1.73	3 13
D1	1 56	2 82
E and M	00	00
G	.65	1 18
K	1 37	2 48
S	59	1 07

For projecting effects, the alternatives are grouped: (1) Alternatives E and M leave the area in an unroaded status; (2) Alternatives G and S leaves over half the area undeveloped, (3) Alternative K develops much of the area; and (4) Alternatives NC, A, B, C, and D develop most of the area.

	Alternatives			
Effects (Changes Compared to Alternative A)	E and M (Unroaded)	G and S	K	NC, A, B, C, and D (Roaded)
Direct Effects				
Timber and Road Expenditures	None	Largely Reduced	Minor Change	No Change
Indirect Effects				
Jobs	-130	-76	-6	0
Annual Income (MM $)	-3 00	-1 76	-0 15	0
Annual Payments to Counties (MM $)	-0 65	-0 42	-0 03	0
Cumulative Effects				
Attitudes of Communities in the Local Area				
Timber Related	-	-	0	0
Primitive Recreation	+	+	0	0
Fisheries	+	+	+	0
Wildlife Related				
Hunting	-	0	0	0
Old-Growth	+	+	0	0
Mining	-	-	0	0

The major direct economic effect is government expenditure for the timber and associated road construction program. Alternatives E, G, M and S have large reductions in the timber and road expenditures Alternatives NC, B, and D1 have an increase in expenditures, while Alternative K has a slight

decrease Alternative A provides the reference from which to gage other alternatives; Alternatives C and D are essentially the same.

The indirect effects are associated with jobs, income, and payments to counties Assuming no substitution of reduced timber harvest within the area of influence, Alternatives E and M have the largest reduction while Alternatives G and S have mid-level reductions. Alternatives NC, B, and D have the higher levels of employment, income, and payments to counties than Alternative A, Alternative B being particularly greater during this planning period.

The cumulative social effects of attitudes of people can be summarized by examining the different interests of the adjacent communities. Previous documentation is found in Chapters III and IV of the FEIS The positive sign indicates a feeling by special interest groups of the Forest being responsive while a negative indicates a social feeling of the Forest not being responsive to particular interests as listed For example, in Alternative E people interested in old growth habitat are predicted to feel positive about forest management while timber interests are predicted to feel the forest is not responsive to their interests. Such gains and losses may create additional conflict.

MITIGATION

No additional mitigation measures have been identified beyond those already listed for each alternative in the DEIS.

POTENTIAL CONFLICTS WITH OTHER JURISDICTIONS

No conflicts are anticipated.

INTRODUCTION

Standards and Guidelines state the bounds or constraints within which all practices will be carried out in achieving the resource objectives of the alternatives. The management of the Forest is subject to all applicable laws and regulations. Standards and Guidelines are intended to help the manager achieve the goals and objectives, while staying within constraints prescribed by law. Some of the management activities on the Forest could have adverse effects on the environment; the Standards and Guidelines provide mitigating measures for these activities.

Two categories of Standards and Guidelines are applied to management of the Forest: (1) Forest-wide Standards and Guidelines applying to all Management Areas and (2) Standards and Guidelines specific to individual Management Areas The allocations to the Management Areas vary widely and do not follow those shown in the Forest Plan for other than the Preferred Alternative; however, the direction for the Management Areas differs little between alternatives. The Standards and Guidelines for the Preferred Alternative are found in Chapter IV of the Forest Plan. Most of the Standards and Guidelines in the Forest Plan are common to all alternatives and are not repeated here; the reader is referred to the Forest Plan document. The purpose of this Appendix (D) is to list those Standards and Guidelines for alternatives which are different from those found in the Forest Plan.

STANDARDS AND GUIDELINES THAT DIFFER FROM THOSE IN THE FOREST PLAN

The Forest-wide Standards and Guidelines and the Management-Area-specific Standards and Guidelines in Chapter IV of the Forest Plan are applicable to all alternatives with the exceptions noted below.

ALTERNATIVE NC (NO CHANGE)

The No Change Alternative would not adopt the Standards and Guidelines of the Forest Plan. The Standards and Guidelines for this alternative were established in the existing documents listed below. This direction has not been revised to comply with the National Forest Management Act (NFMA):

Powers Ranger District Multiple Use Plan, Siskiyou National Forest, April 1968

Illinois Valley Ranger District Multiple Use Plan, Siskiyou National Forest, April 1968

Land Use Plan for Rogue Planning Unit, Final Environmental Statement, Siskiyou National Forest, February 1975

Land Use Plan for the Mt. Butler-Dry Creek Planning Unit, Final Environmental Statement, Siskiyou National Forest, May 1976

Chetco-Grayback Land Management Plan, Final Environmental Statement, Siskiyou National Forest, December 1979

Rogue-Illinois Land Management Plan, Final Environmental Statement, Siskiyou National Forest, December 1979

Illinois Wild and Scenic River Management Plan, Siskiyou National Forest, October 1985

Rogue River Plan, Siskiyou National Forest, September 1969

ALTERNATIVE A (NO ACTION)

This alternative is based on the same direction and documents as the No Change Alternative except it also meets the direction of NFMA; specifically it incorporates standards to meet the Management Requirements and incorporates direction from the Regional Guide for the Pacific Northwest Region (1984) as amended by the Final Supplement to the EIS for Spotted Owl Guidelines (1988), as does the Forest Plan.

All riparian areas allocated to Management Area 11 would be managed under Riparian Prescription B.

ALTERNATIVE A-DEPARTURE

Same as Alternative A except that the nondeclining flow direction would not apply.

ALTERNATIVE B (RPA)

Snag levels would maintain 20 percent of woodpecker habitat capability.

The nondeclining flow direction would not apply.

Both Riparian Prescription B and C would be used for riparian areas allocated to Management Area 11, but the Planning Basins where they would be applied are different than the Forest Plan

ALTERNATIVE C

Snag levels would maintain 20 percent of woodpecker habitat capability.

All riparian areas allocated to Management Area 11 would be managed under Riparian Prescription B

ALTERNATIVE D

Snag levels would maintain 20 percent of woodpecker habitat capability.

Both Riparian Prescription B and C would be used for riparian areas allocated to Management Area 11, but the Planning Basins where they would be applied are different than the Forest Plan.

ALTERNATIVE D1

Snag levels would maintain 20 percent of woodpecker habitat capability.

Both Riparian Prescription B and C would be used for riparian areas allocated to Management Area 11, but the Planning Basins where they would be applied are different than the Forest Plan.

Minimum rotation age for General Forest areas managed for timber production would be two decades shorter than 95 percent of Culmination of Mean Annual Increment (CMAI).

ALTERNATIVE E

No timber harvest would be programmed from riparian areas.

ALTERNATIVE G

Riparian Prescription C would be used for all riparian areas allocated to Mangagement Area 11.

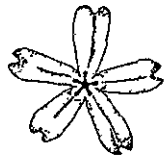
ALTERNATIVE K

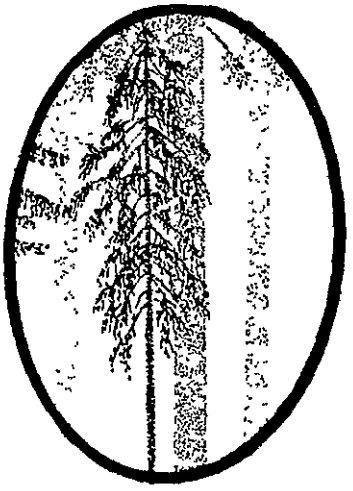
Both Riparian Prescription B and C would be used for riparian areas allocated to Management Area 11, but the Planning Basins where they would be applied are different than the Forest Plan.

ALTERNATIVE M

Minimum rotation age for all areas managed for timber production would be 250 years.

No timber harvest would be programmed from riparian areas.





ALTERNATIVE S

The Forest Plan is based on Alternative S; all Standards and Guidelines in the Forest Plan apply.

INTRODUCTION

Appendix F provides the description and management options for each existing or potential Botanical area or Research Natural Area (RNA). In this appendix each area is treated separately; in the Final Environmental Impact Statement (FEIS) Botanical areas and RNA's are treated as an aggregate land assignment per alternative. In the body of the FEIS, the issues, analyses, and alternative ways of managing these areas are evaluated as part of a resource management scheme for the Forest as a whole

All proposed areas have sufficient values to warrant their consideration for establishment as RNA's or Botanical areas. However, not all areas have been recommended in the preferred alternative. Although complete inventories are not available for any of the sites, extensive inventory data is available for Bigelow Lakes, Cedar Log Flat, Days Gulch, Eight Dollar Mountain, Green Knob, Hoover Gulch, Iron Mountain, Lemmingsworth Gulch, and Oregon Mountain.

Inventory data are compiled from a variety of sources such as, local botanists (Veva Stansell, H. Robert Mansfield, Mary Paetzel, and others), the Oregon Rare and Endangered Species Task Force, the Oregon Natural Heritage Data Base, herbarium records, and field surveys by the Forest Service and other institutions Forest personnel who provided data were: Tom Atzet and David Wheeler (Forest Service Area Ecologists), Dennis Vroman (Silvicultural Technician), biologists, seasonal botanists, and a number of District employees. Except where otherwise noted in the text, this appendix was prepared by Lee Webb, Forest Wildlife Biologist

Each proposed area was first outlined on a U.S. Geological Survey (USGS) topographic map. Boundary lines were then transferred to the computerized Land Inventory Mapping System (LIMS), which was used to calculate acreage figures. The boundaries of any site proposed for RNA or Botanical area status would need to be accurately located on the ground. Ground truthing may show that actual boundary lines and acreage figures differ slightly from those listed in this report.

SENSITIVE PLANT BOTANICAL AREAS

The unique geologic and climatic history of southwest Oregon and northwest California is responsible for the occurrence of a number of rare plants not found elsewhere. The ranges of some of these plants are almost exclusively within the Forest boundaries. Two categories of rare plants receive special consideration from Siskiyou National Forest land managers:

1. Endangered or Threatened species which are Federally listed or proposed must be protected from adverse impact (presently, none are known on the Forest).

2. Sensitive species are those species identified by a Regional Forester for which viability is a concern, as evidenced by (a) significant current or predicted downward trends in population numbers or density or (b) significant current or predicted downward trends in habitat capability that would reduce a species' existing distribution. As of 1988, the Forest harbored 64 sensitive species, and an additional 30 species may occur here. Ten other species are potential candidates for the Region Six Regional Forester's list of sensitive plants (nine known to occur on the Siskiyou).

In addition to sensitive species, Forest personnel collect data on rare plant species which need to be monitored or inventoried further before their status can be accurately determined This is done as an informal cooperative effort with the Oregon Natural Heritage Data Base, Oregon Native Plant Society, and the California Native Plant Society.

Common and scientific names of all uncommon plants are listed in the current *Status List of Endangered, Threatened, Sensitive, and Rare Plants on the Siskiyou National Forest.* In addition, the Forest maintains a field *Guide to Sensitive Plants of the Siskiyou National Forest* (Webb 1988); Siskiyou employees and

volunteers use the guide as an aid to field identification These documents are available for public review at the Siskiyou National Forest headquarters in Grants Pass, or at the District offices

The Siskiyou has one of the most diverse floras of any National Forest. Concentration areas of sensitive plants occur frequently on the Siskiyou; many are outside existing wilderness and botanical areas Sensitive plants are clustered at a minimum of 22 sites on the Forest: 3 existing and 19 potential Botanical areas (Figure F-1). These concentration sites are individually described in the **Narratives** section of this appendix Concentration sites for sensitive plants encompass 35,596 acres (Table F-1).

The Siskiyou's sensitive plants occupy a variety of habitat types, but many are restricted to serpentine/peridotite soils. These soils are most prevalent in the southeast corner of the Forest, from Eight Dollar Mountain southwest to Oregon and Packsaddle Mountains, and including the southern third of the Kalmiopsis Wilderness. Serpentine/peridotite soils are also present in scattered locations such as Red Flat, Iron Mountain, Chrome Ridge, and Onion Mountain (Figure F-2).

Although the same general soil types occur at various geographic locations, the plant communities supported on individual sites are often quite different from one another because of local variations in topography and climate. Climatic variations are probably responsible for the localized and endemic flora of the Illinois Valley (Selma to Takilma). For instance, annual precipitation varies considerably from place to place on the Forest. The eastern edge of the Kalmiopsis Wilderness receives approximately 140 inches of rain yearly; Eight Dollar Mountain receives approximately 60 inches (Figure F-3).

Stereo aerial photographs (1979; 1:24,000 color) of the serpentine/peridotite areas of the Forest and adjacent lands were examined for the presence of large bogs (2 acres or larger). Bog habitat appears to reach maximum development on Eight Dollar Mountain, in terms of size and concentration. A few bogs smaller than those on Eight Dollar Mountain were located on aerial photographs of Cedar Log Creek, Josephine Creek, Tennessee Mountain, Woodcock Mountain, Oregon Mountain, and Lemmingsworth Gulch. Although many small *Darlingtonia* bogs are scattered throughout the serpentine/peridotite areas of the Forest, no bogs in the Kalmiopsis Wilderness were large enough to be visible on the aerial photographs.

Bog habitat in the Siskiyou Mountains contains a significant share of the area's rare plant species. However, drier habitats (both serpentine/peridotite and non-serpentine/peridotite substrates) also support a variety of rare plants. Specific sites on the Forest have unique values not associated with habitat available in the Kalmiopsis Wilderness For example, the Iron Mountain area contains a large number of plant species on the periphery of their ecological ranges; the Bigelow Lakes area, a non-serpentine site, contains a wide variety of rare plant species not found elsewhere on the Forest.

Rare plants are not unique to sensitive plant concentration sites; they occur in many parts of the Forest An extensive table was developed to display the known locations of the Forest's rare plants (Table F-2).

OLD GROWTH BOTANICAL AREAS

Five unique old growth sites on the Forest were identified as potential Botanical areas by Forest employees and others (Figure F-1). One site contains the northernmost stand of redwood trees. Another encompasses a group of outstanding redwood groves, and a third contains the world's largest Port-Orford-cedar. The other two sites are outstanding examples of old-growth Douglas-fir stands; the uniqueness of these areas lies in their individual large-diameter trees Most of sites have considerable recreation potential as outdoor education sites. The five old-growth sites encompass 1,321 acres (Table F-1). Individual sites are described in the **Narratives** section of this appendix.

RESEARCH NATURAL AREAS

The Siskiyou Mountains represent a complex pattern of vegetation across a base of varied geological types. White fir is the dominant climax species in much of the area. It is associated with Douglas-fir, ponderosa pine, sugar pine, and Shasta red fir, which are commonly seral to white fir but, together, make up the mixed conifer formation. Tanoak is also a major climax dominant, particularly on the coastal Districts. It is associated with redwood, Douglas-fir, madrone and oaks forming the mixed evergreen formation (Franklin and Dyrness 1973).

The Research Natural Area system has been set up to preserve examples of all significant natural ecosystems, such as those just discussed, for comparison with those influenced by man. RNA's are reserved for scientific and educational use. Many plant communities are not yet represented by RNA's The Siskiyou presently has three RNA's; four additional areas on the Siskiyou have been proposed by Forest Service researchers and others for inclusion into the RNA system (Dyrness and others 1975).

The Port Orford Cedar and Coquille River Falls Research Natural Areas, both on the Powers Ranger District, were established in 1937 and 1945 respectively. The Wheeler Creek Research Natural Area on the Chetco Ranger District was established in 1972. The four proposed sites on the Siskiyou are Hoover Gulch, Lemmingsworth Gulch, Cedar Log Flat, and Craggy Peak. The Cedar Log Flat and Lemmingsworth Gulch areas also contain a number of sensitive plant species. Figure F-1 displays the locations of existing and proposed RNA's. The individual sites are described in the **Narratives** section of this appendix.

In May 1981, the Forest Supervisors of the Rogue River, Siskiyou, and Umpqua National Forests requested that Forest Service ecologists make a field search to locate "cells" needed for the Research Natural Area Program in the Pacific Northwest. The four areas listed as proposed RNA's in the Siskiyou Forest Plan were part of the analysis. In addition, the following areas were reviewed in the field, but were not selected.

KINNEY CREEK

The Kinney Creek area on the Rogue River National Forest was considered for its stand of canyon live oak (*Quercus chrysolepis*), indicative of shallow soils and hot sites. The stand was only several acres and without access. A river crossing was necessary to access the stand. Douglas-fir, incense-cedar and sugar pine were all represented and some of the stand was not climax to the oak.

TAYLOR CREEK

Taylor Creek, on the Galice Ranger District, was also considered for filling the canyon live oak cell need, but as with the Kinney Creek Site, both size and access were problems The stand is located just inside the Siskiyou National Forest boundary near the Taylor Creek road. The proposed Hoover Gulch RNA was a better option than either Kinney Creek or Taylor Creek.

ELKHORN PRAIRIE

Elkhorn Prairie is on the border of the Rogue River and Siskiyou National Forests (Applegate and Illinois Valley Ranger Districts). Grayback Mountain is the nearest well known landmark. Cells considered were herblands (grass balds), large, high elevation, cold springs, green fescue meadows and the red fir/white fir interface. It was considered as part of a larger area including cells on the Rogue River National Forest, but was not recommended because of the high degree of disturbance and domestic animal use.

WINDY VALLEY

Windy Valley, located on the northern quarter of the Chetco District, was considered for a representative of a typical marsh and coastal stream with riparian hardwoods The flat valley is somewhat atypical of

coastal streams and the area is too disturbed. Additionally the area does not meet the criteria for a typical coastal marsh

VALUES OF OTHER RESOURCES

TIMBER

Most sensitive plant concentration sites contain commercial timber land Some areas, such as Bear Camp, have high timber values; Eight Dollar Mountain and other areas have low or non-existent timber values. Potential timber volumes for sensitive plant concentration areas were calculated from empirical yield tables developed for the Forest Plan Average timber volumes represent a managed yield, i.e., the volume each acre would produce during a normal (managed) rotation. Potential timber volume (long-term sustained yield (LTSY)) for all proposed Botanical areas is 9.464 million board feet (MMBF) annually during a 100-year rotation; proposed RNA's represent .812 MMBF (Table F-3(a)) Potential timber volume (LTSY) in Alternative S (preferred) for all recommended Botanical areas is 2 526 million board feet (MMBF) annually during a 100-year rotation, recommended RNA's represent 812 MMBF (Table F-3(b)).

MINERALS

Many sensitive plant concentration sites contain locatable mineral deposits; inactive chromium and gold mines are located in or near a few of the areas (Table F-4). Ultramafic rock is common to 14 of the proposed sensitive plant Botanical areas and 2 of the Proposed RNA's (Figure F-2). Serpentine/peridotite soils derived from this rock type are abnormally high in magnesium and iron, and relatively low in silica, alumina, sodium, and calcium. Serpentine/peridotite soils contain nickel in concentrations varying from 0.1 to 2 0 percent. These soils are commonly referred to as nickel laterites (see Table F-4) Chromium, cobalt, and iron are associated with nickel laterites; except for iron, these metals are considered "strategic," especially chromium and cobalt. Len Ramp, former resident Geologist in Grants Pass for the Oregon Department of Geology and Mineral Industries, believes it may someday become economically feasible to mine nickel lateritic soils which contain nickel at concentrations of one-half of one percent or more (00.5+%)

Other than the Nickel Mountain deposit near Riddle, Oregon, Ramp (1978·63) states:

> Two other main areas of future nickel production potential lie in Oregon. One is in the Illinois Valley, in which a centrally located plant could draw from the larger, better grade, and more accessible deposits in the Josephine peridotite sheet; the other is in the Red Flat area southeast of Gold Beach. Several factors will affect this possible expansion of Oregon's nickel industry; future supply of and demand for nickel, chromium, and cobalt; national and local political policy regarding domestic production of these strategic minerals; the ability to develop efficient, inexpensive, and nonpolluting metallurgical processes, and the ability to develop satisfactory and inexpensive reclamation procedures.

MANAGEMENT OF PLANT RESOURCES

Forest managers have been directed by the Endangered Species Act of 1973 and the Regional Forester's Policy on Sensitive Plants (Forest Service Manual 2670), to take all necessary actions to assure that management activities do not jeopardize the continued existence of endangered, threatened, or sensitive species. Additionally, compliance with Public Law 93-452 (Sikes Act) requires the maintenance and enhancement of the habitats of endangered, threatened, and sensitive plant (and animal) species.

Publication of this appendix helps insure greater recognition and better management of the Siskiyou's rare plant resources, regardless of land assignments made in the various Forest Plan alternatives. This appendix serves as a "yellow flag" to our field-going personnel--that botanical values in these areas are especially important and need to be protected.

SENSITIVE SPECIES LISTS

Common and scientific names of all rare plants are listed in the current *Status List of Endangered, Threatened, Sensitive and Rare Plants on the Siskiyou National Forest* The various plant lists are categorized in Table F-5. The Siskiyou cooperates with two private organizations which maintain lists of sensitive and rare plants the Oregon Natural Heritage Data Base (ONHDB 1987) and the California Native Plant Society (Smith and York 1984) A field guide to the Siskiyou's sensitive plants is maintained for use by Forest Service volunteers and employees (Webb 1988).

INDICATOR SPECIES/MONITORING

Four indicator habitats for sensitive plants are designated in the Forest Plan: (a) bog and wet/moist places, serpentine subgroup; (b) bog and wet/moist places, non-serpentine sub-group; (c) rocky places (serpentine/non-serpentine), dry and moist, and, (d) open slopes, fields, meadows, and woods (serpentine/non-serpentine) (see Table F-6 for a complete list of species).

Selected locations will be monitored during the life of the plan to determine population trends of sensitive plant species. Where possible, sites selected for monitoring will be those with the most potential for resource conflicts· (a) timber harvesting; (b) road building, (c) mining; (d) recreation, and, (e) areas where unauthorized digging of sensitive plants may occur Concentration areas of sensitive plants will be sampled, and management activities will be reviewed as a gauge on the effectiveness of Standards and Guidelines If management reviews show that sensitive plants are being detrimentally (significantly) affected by ground-disturbing activities, this will trigger a review of Standards and Guidelines. As part of the Forest Plan, a detailed Monitoring Plan has been developed (Forest Plan, Appendix D).

Species Management Guides are prepared for sensitive species adversely affected by standard management practices. Such guides prescribe management direction, monitoring, and protection for a species based on the species needs over its entire range rather than on a local population or individual site.

FOREST PLANNING PROCEDURES

Treatment of botanical resources in the Forest Planning process is discussed in depth in the FEIS. For more information, see the VEGETATION and SENSITIVE PLANT sections of Chapter II (Alternatives Including the Proposed Action), Chapter III (Affected Environment), and Chapter IV (Environmental Consequences).

A subjective ranking system was used to analyze all potential RNA and Botanical areas (Table F-7). This scheme guided the land assignment decisions displayed in the Siskiyou National Forest FEIS (area allocations are listed by alternative in Table F-8 of this appendix). Important concentration areas of sensitive or rare plants are logical candidates for designation. Certain areas on the Forest, such as Eight Dollar Mountain, are more unique than others. The **Summaries** section of this appendix presents a short synopsis of each proposed area, ranked in order of priority. Rankings are a combination of data presented in Table F-7 and the expertise of the Forest Wildlife Biologist/Botanist. Allocation arrays by alternative for RNA and Botanical areas are discussed in detail in Chapter II of the FEIS (under Sensitive Plants).

STANDARDS AND GUIDELINES

There are two ways of employing standards and guidelines to manage plant resources: (1) Forest-wide; or, (2) by specific Management Area. Chapter IV of the Land and Resource Management Plan (Forest Plan) (not the FEIS) is summarized below. No Forest Plan alternative is expected to adversely affect habitats of sensitive plants. Most species are not found in areas subject to land-disturbing activities; but in any case, available data on sensitive plants locations are reviewed prior to development of planned activities.

Forest-wide. Forest-wide standards and guidelines will govern timber harvesting, road building, mining activities, and livestock grazing in candidate areas not selected in a given alternative This is also true for non-candidate (general forest) areas where sensitive/rare plants are more widely dispersed.

Biological evaluations are prepared for each project authorized, funded, or conducted on National Forest land to determine the possible effects the proposed activity will have on sensitive species (FSM 2672 4, including R-6 Supplement 41). It is often helpful to consult with professional Botanists or local knowledgeable and interested botanical authorities Habitat for sensitive plants is managed to ensure that species do not become threatened or endangered because of management activities

Sensitive plant concentration sites not converted to Botanical areas as part of the Forest Plan Preferred Alternative will be outlined on management overlays of the Total Resource Information (TRI) system and labeled as "Protect Rare Plants." Whenever ground-disturbing activities are planned at these sites, intensive field surveys for sensitive plant species will be done as part of the Environmental Analysis (EA) process.

Management Areas. Direct land assignments are made for plant resources under Management Area 3 (Research Natural Areas) and Management Area 4 (Botanical). Descriptions of these allocation areas (in Chapter IV of the Forest Plan) contain detailed management outlines. Many topics are covered, including recreation, visuals, wildlife, range, timber, water, minerals, lands, facilities, and fire management Natural physical and biological processes will prevail with minimal human intervention.

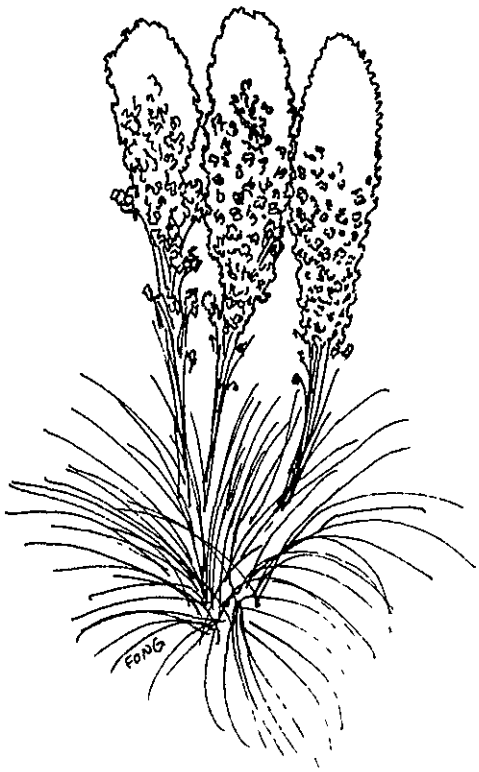
An Establishment Record must be written for each RNA recommended in the preferred alternative of the Forest Plan (procedures described in Forest Service Manual 4063). The Forest will continue to evaluate other areas for RNA status, under the guidance of Area Ecologists and the Interagency RNA Committee. Botanical areas are classified under 36 CFR 294.1 and managed to protect areas of the Forest with important botanical resources (Forest Service Manual 2370 Special Recreation Designations, Areas Designated Administratively). Management plans may be developed for individual Botanical areas; plans may supplement direction provided in the description of the Management Area.

MITIGATION

Standards and Guidelines (described in Chapter IV of the Forest Plan) have been developed to protect, maintain, and enhance sensitive plant habitat Standards and guidelines, along with direct land assignments, act as mitigation measures to insure the perpetuation of sensitive plant resources on the Siskiyou National Forest.

Special precautions are taken in layout of timber sales and location of roads to make sure that the needs of sensitive species are met. Care is taken to avoid spraying when herbicide use is allowed in areas where sensitive species are known to exist. Site plans for private mining operations on Forest Service administered land are analyzed and approved by the Forest Service before ground-disturbing activities can begin; sensitive plant needs are part of the analysis. In some cases, individual management plans will be devised for specific species, such as *Bensoniella oregana*, a plant which could be significantly impacted by timber management activities All of these methods act as mitigation measures to insure that the Siskiyou's diversity of existing plant species is not abridged.

Some of the management activities relating to minerals and mining on the Forest would cause significant environmental damage if done without means of mitigating potential adverse effects. The Forest Service has the opportunity to work with individual miners and companies to design, prescribe, and recommend ways to prevent resource damage. Coordination usually occurs during the development of a plan of operations (required by law) prior to the start of any mining project. If adverse environmental concerns cannot be adequately resolved within the plan of operations, the the Forest Service must, by law (National



Environmental Policy Act of 1969 (NEPA)) be prepared to fully analyze environmental effects and their potential mitigation

Most mining mitigation measures available to the Forest Service relate to, (a) method, type, and scope of a mining operation, (b) location, design, type, and timing of access; and, (c) site specific requirements relating to reclamation, erosion, water and air quality, fish, wildlife, cultural resources, timber, fire, recreation, and human conflicts. Of course, the ultimate mitigation is to withdraw an area from mineral entry Recommendations for withdrawal from mineral entry will be limited to RNA proposals and to Botanical areas where mitigation will not adequately protect surface resource values Mitigation measures will be identified for those Botanical areas not withdrawn.

Given the abundant acreage of public land in southwestern Oregon and northwestern California, viable populations of sensitive plant species will be maintained on the Siskiyou and connecting National Forests/ Bureau of Land Management (BLM) Districts If in the future, new data on plant habitat requirements show a need for increased allocations of certain types of habitat, the Forest will have the ability to make those allocations for at least the next two decades, and possibly longer.

RESEARCH NEEDS

Detailed habitat requirements for many rare or sensitive plant species are unknown This makes it difficult to predict the effects of management activities on habitat The Species Management Guides mentioned above are helping fill in some of our knowledge gaps. Forest Botanists and Biologists also have long range plans to survey all of the Forest's potential sensitive plant habitat (including areas suggested by the public, in their comments on the Draft EIS and Plan). The capital investment tables in Appendix B of the Forest Plan provide information on future plant inventories, habitat improvements, management plans, seed banking, and other planned activities Specific research needs are listed in the beginning of Chapter II of the Forest Plan

1/ Plants found predominately in coastal environments. May not occur on the Siskiyou National Forest.

2/ Region Five. (Forest Service Pacific Sowthwest Region California).

S = SENSITIVE SPECIES. Listed as sensitive in California by Pacific Southwest Region.

1, 2, 3, 4 = see note 4/ CNPS for explanation.

3/ Region Six. (Forest Service Pacific Northwest Region, Oregon).

S = SENSITIVE SPECIES. Those plant and animal species identified by a Regional Forester for which population viability is a concern, as evidenced by: (a) significant current or predicted downward trends in population numbers or density, and (b) significant current or predicted downward trends in habitat capability that would reduce a species' existing distribution.

R = REVIEW LIST. Species still under review in Oregon. Coincides with R list under COLUMN ONHDB (5/)

W = WATCH/MONITOR list (Oregon). Basically coincides with W list under COLUMN ONHDB (5/). A few additional plants have been added to the Sisikiyou list at the discretion of the Forest Wildlife Biologist/Botanist. Species listed as W in this column should be monitored on the Siskiyou.

4/ CNPS. (California Native Plant Society--Inventory of Rare and Endangered Vascular Plants of California--September 1984--Special Publication No. 1, 3rd Edition--2380 Ellsworth, Suite D, Berkeley, California 94704).

1 = List 1: Plants of highest priority (1a: plants presumed extinct in California and 1b: plants rare and endangered in California and elsewhere).

2 = List 2: Plants rare or endangered in California, but more common elsewhere.

3 = List 3: Plants about which we need more information.

4 = List 4: Plants of limited distribution (a watch list).

5/ ONHDB. (Oregon Natural Heritage Data Base--Rare, Theatened and Endangered Plants and Animals of Oregon--March 1985--1234 NW 25th Avenue, Portland, Oregon 97210--$4.00).

R = The Review List contains species for which more information is needed before status can be determined, but which may be threatened or endangered in Oregon or throughout their range.

W = The Watch List species are those which are currently stable, but which may become threatened in Oregon in the forseeable future. These species currently do not need active management attention. However, they may need some type of continued monitoring.

The following represent occurrences in above table:

X = Species occurs within the area.

Number = Number of separate occurrences within the area.

Table F-4. Mineral Values of Proposed Botanical Areas (Sensitive Plant Areas)

Botanical Area	Acres	Nickel Laterites (Main Deposits) Acres	(% of Area)	Nickel Laterites 1/ % of Composition of Nickel	Cobalt	Chrome	Iron	Notes on Mineral Values
Bear Camp	5,927	---No lateritic soils---						None known
Bigelow Lakes	971	---No lateritic soils---						None known
Bolan Lake	451	---No lateritic soils---						Inactive gold mine
Chrome Ridge	1,014	---Unknown---						Some chromite deposits mined
Cleopatra	800	---Nearby---						Mercury prospects
Days Gulch	987	---No lateritic soils---						Active gold mine
Eight Dollar Mountain	2,350	225	(10)	0 53	0 03	0 73	--	Nickel latrites, chromite
Grayback Mountain	166	---No lateritic soils---						None known
Green Knob	153	---No lateritic soils---						Possibly some coal
Iron Mountain	1,866	18	(1)	0 70	--	--	--	Chromite, copper, and coal prospects nearby
Oregon Mountain	4,401	85	(2)	0 50	0 04	1 36	--	Some nickel laterites, some chromite copper prospect
Red Flat	7,172	710	(10)	0 80	0 15	1.14	18 0	Nickel laterites, chromite
Rough and Ready Flat	934	320	(34)	0 45	0 03	1 00	16 0	Extensive thin rocky nickel laterites, gold, and platinum mined from area
Snow Camp	1,475	50	(3)	0 63	0 06	--	--	Some chromite
Sourgame	3,640	---No lateritic soils---						Ultramatic soil present
Squaw Mountain	638	---No lateritic soils---						Ultramafic soils present
Vulcan	133	---Unknown---						Chromite prospect
Waldo Ridge	707	---Unknown---						None known
Windy Collier	147	---Unknown---						Chromite deposits nearby

1/ Values listed are from samples, average percents listed are not values for entire proposed Botanical area Nickel mining may become economically feasible where nickel concentrations are 0 5 percent or greater (Len Ramp, former resident Geologist for Oregon Department of Geology and Mineral Industries, Grants Pass)

Table F-5. Endangered, Threatened, Sensitive, and Rare Plants of the Siskiyou National Forest, Categorized by Status. The Various Lists Encompass 223 Different Plant Species (Overlap Between Lists - Data as of May 19, 1988)

Sidalcea setosa ssp querceta (1) 1/
Vancouveria chrysantha (8)

1/ Plants should be represented by at least two sites (unless only one is known)
2/ A large population of Lilium vollmeri on the Gold Beach Ranger District should be monitored, it is the largest known population of this species (see TRI Sensitive Subsystem for details)

Table F-7. Priority Ranking Methods for Proposed Botanical and Research Natural Areas

I. Ranking criteria for Botanical Areas - Sensitive Plant Areas

A How many different sensitive species are present (as of 1985)?

Score	No. Species
1	17+
2	13-16
3	9-12
4	5-8
5	1-4

B. How botanically unique is this area? How important is this area to professional/amateur botanists?

Score	Value
1	Very Important
2	Quite Important
3	Important
4	Somewhat Important
5	Low Importance

C. Competing resources. Would designation as a Botanical area (no timber harvest plus other restrictions) be positive, negative, or neutral in relation to sensitive plants vs. other resource values, significantly timber. If timber harvesting would enhance plant resources in a specific area, this would actually result in a more negative criteria value (larger number).

Score	Ranking
1	Positive for sensitive plant resources
2	Somewhat positive benefits for sensitive plant resources
3	Neutral - Plant resources vs other resources
4	Somewhat negative for other resources
5	Negative for other resources

Table F-7. Priority Ranking Methods for Proposed Botanical and Research Natural Areas (Continued)

Name of Area	Criteria - Scores A	+	B	+	C	=	Total Score	Priority Ranking

Snow Camp	3	+	2	+	3	=	8	5
Snow Camp Addition	4	+	2	+	3	=	9	5
Sourgame	3	+	3	+	3	=	9	6
Sourgame Addition	4	+	3	+	3	=	10	7
Squaw Mountain	5	+	4	+	3	=	12	9
Vulcan	4	+	3	+	1	=	8	5
Waldo Ridge	3	+	4	+	3	=	10	7
Waldo Ridge Addition	5	+	4	+	4	=	13	10
Windy Collier	5	+	4	+	3	=	12	9

Lowest Total Score indicates Highest Value as a Botanical area.

Highest Total Score indicates Lowest Value as a Botanical area

II. Ranking Criteria for Botanical Areas - Old Growth Sites

The five areas listed have basically similar values. Ranking criteria (recreation value, timber values, etc) were so similar that the five sites had essentially the same total value. All sites are priority ranked as number 1.

Table F-7. Priority Ranking Methods for Proposed Botanical and Research Natural Areas (Continued)

III. Ranking Criteria for Research Natural Areas

A How many cells would be filled (how many plant communities would be represented that are not included in existing RNA's)?

Score	Cells Filled
1	5+
2	4
3	3
4	2
5	1

B. Importance of the area to the Pacific Northwest Research Station

Score	Importance
1	Primary
2	Secondary

C. Does the area contain significant sensitive plant resources?

Score	Significance
3	High
4	Medium
5	Low

	Criteria - Scores							
Name of Area	A	+	B	+	C	=	Total Score	Priority Ranking
Cedar Log Flat	5	+	2	+	3	=	10	3
Craggy Peak	4	+	2	+	4	=	10	4
Hoover Gulch	3	+	1	+	5	=	9	2
Lemmingsworth Gulch	1	+	1	+	3	=	5	1

Most of the proposed Craggy Peak RNA is within the Rogue River National Forest (the Rogue River portion is called Oliver Matthews RNA)

Lowest Total Score indicates Highest Value as a Research Natural Area.

Highest Total Score indicates Lowest Value as a Research Natural Area.

1/ Alternative S includes Hunter Creek Bog
2/ Alternative S includes Game Lake and Sourdough Camp
3/ Seventy-Six percent of the existing acreage for Botanical areas is within the Kalmiopsis Wilderness (3,408 Acres).

SUMMARIES

This section presents a short synopsis of each proposed area, ranked in order of importance. Rankings are based on a combination of the data presented in Table F-7 and the expertise of the Forest Wildlife Biologist/Botanist. Future inventories would likely influence the rankings. The boundaries of some areas were modified in the Preferred Alternative (S); refer to the narratives of individual areas for maps and explanations of changes.

SENSITIVE PLANT BOTANICAL AREAS

All three areas were established by authority of the Chief of the Forest Service and represent permanent land assignments not subject to review in this Forest Plan Most of the Big Craggies, some of Babyfoot, and all of York Creek are within the Kalmiopsis Wilderness (3,408 or 76 percent of the 4,475 total acres is within the Wilderness).

EXISTING

1 *Babyfoot Lake.* The Babyfoot Unusual Interest Area (Botanical) (350 acres) was established in 1966 to protect Brewer spruce and other rare plant species; sensitive plant species are present Parent material is diorite/gabbro; mining potential is low.

2 *Big Craggies* The Big Craggies Botanical Area (3,800 acres) was established in 1964, primarily to protect Brewer spruce and *Kalmiopsis leachiana.*

3 *York Creek.* The York Creek Unusual Interest Area (Botanical) (320 acres) was established in 1966 primarily to protect an extensive patch of *K. leachiana*

PROPOSED PRIORITY CLASS A

These are the most important Botanical Sites on the Siskiyou National Forest.

1. *Eight Dollar Mountain.* Sixteen (16) sensitive species are present, over one-fourth of those known to be on the Siskiyou, this same assemblage is not known to be present elsewhere (as a group). Sensitive species are located on both bog and dry sites at a variety of locations; the largest *Darlingtonia* Bogs on the Forest are within this area Some species are known from Eight Dollar Mountain and only a few other sites; some species reach their greatest development here. This site has been continually botanized since the 1880's and is of much historical interest in regard to early-day botanists. A number of species were first collected in this area. Additional plant inventory of the area is desirable. This is an ideal site for studies of plant distribution and development. extensive elevation range of 1200-4000 feet; full range of aspects; one type of parent material, uniform climate (rainfall). Livestock grazing has occurred in portions of the area and may have a detrimental impact on some sensitive plant species. There are moderate to high conflicts with mineral values; most of Eight Dollar Mountain is covered by mining claims. The most important nickel laterite deposits on the mountain are not on National Forest land. Nickel laterites would only be important if a processing plant was already in operation at a nearby mining site. At the present time, nickel laterite resources at this site alone are probably not sufficient to warrant development. Land on the east side of the mountain under the jurisdiction of the Bureau of Land Management has been designated as an Area of Critical Environmetal Concern (ACEC).

Eight Dollar Mountain - First Priority

Eight Dollar Mountain Addition - Second Priority

2 *Bigelow Lakes.* A large variety of sensitive species are present at this alpine, non-serpentine site. Some plant species are at their most northerly or westerly limits. Substantial plant inventory data is available. This concentration of plants is not known elsewhere on the Siskiyou or adjacent National Forests. Boundaries are easily locatable on-the-ground. This area is within a grazing allotment (Applegate Ranger District). The impact of grazing on botanical values needs to be assessed. There are no mineral conflicts.

Bigelow Lakes - First Priority

Bigelow Lakes Addition - Second priority, but both options together make a more logical unit.

3. *Days Gulch.* This area is part of the Eight Dollar Mountain complex. It is just southwest of Eight Dollar and contains a much visited *Darlingtonia* bog inhabited by a number of sensitive plants. The Days Gulch site is separated from the Eight Dollar site by the Illinois Wild and Scenic River corridor. At least 11 sensitive species are present.

4. *Iron Mountain* Many species at this site are at the periphery of their ranges. A large variety of plant species are present, including a number of sensitive species. Extensive inventory data is available. Boundaries are easily locatable on-the-ground. Timber values are minor; most of the area is low site land and marginal at best. Mineral conflicts are not major; a small portion of the area contains a nickel laterite deposit

Iron Mountain - First Priority

Iron Mountain Addition - Second Priority, but both options together make a very logical unit.

5 *Bear Camp.* A variety of non-serpentine plants are present, including an interesting variety of nonsensitive plants. This is a concentration area for *Bensoniella oregana*, a sensitive species with a severely restricted range. Several other plants found here are not otherwise known from southwest Oregon A large amount of commercial timber land is present. Sensitive species and unique botanical values can be preserved by selecting out specific habitat types, rather than designating the entire area More plant inventory is needed to determine full extent and range of sensitive/rare plant values over the entire area

Option 1 First Priority

Option 2 Second Priority

Option 3 Third Priority (Lower Priority)

Option 4 Fourth Priority (Lower Priority)

PROPOSED PRIORITY CLASS B

These areas are important sensitive plant sites, and the priority is nearly as high as in A.

6 *Snow Camp.* A number of sensitive plants are present on both dry and moist sites. The site has considerable habitat variety. More plant inventories are needed to determine the full extent of rare plant resources. Part of this sensitive plant site contains nickel laterite deposits. An interesting stand of Brewer spruce is present.

Snow Camp - First Priority

Snow Camp Addition - Second Priority, but plant values high here also.

7 *Chrome Ridge.* A number of sensitive plants are present. Parts of the area have been intensively inventoried, but extensive plant surveys are needed to determine total extent of rare plant resources No nickel laterite deposits are known, although some chromite has been mined in the area.

8 *Oregon Mountain.* A large variety of sensitive species (16) are present There is some overlap with sensitive species known from Eight Dollar Mountain The area has been botanized since the 1880's and is of historical interest, in regards to early-day botanists. Additional plant inventory is needed Nickel laterite deposits are present, along with copper and chromium prospects. There is opportunity to locate a joint Botanical area at this site with the Bureau of Land Management.

9. *Rough and Ready Flat.* This is a concentration area for sensitive/rare plants More plant inventory is needed. There is some overlap with botanical values of Oregon Mountain and Eight Dollar Mountain. A state park (Rough and Ready Botanical Wayside) is nearby. Important deposits of nickel lateritic soil are present. There is opportunity to locate a joint Botanical area at this site with the Bureau of Land Management and Oregon State Parks.

10 *Sourgame.* This area is near the Snow Camp site, but has its own unique characteristics. A variety of soil types are present, which provide a number of contact zones harboring a rich mix of plant species. This is a fairly large area, which has been divided into two parts. The Sourgame area needs to be intensively inventoried Game Lake and Sourdough Camp are located within the area; both sites contain very interesting botanical resources

Sourgame - High Priority

Sourgame Addition - Moderate Priority

11 *Vulcan.* A number of sensitive plant species are present. This area is on the edge of the Kalmiopsis Wilderness A chromite prospect is located within the area. There are no known deposits of nickel laterites. The area is almost a de facto Botanical area because of its location. More plant inventory work is necessary

12 *Grayback Mountain.* This area is located on the Forest's highest mountain (7,055 feet). The eastern half of the mountain is located on the Rogue River National Forest. Soils are derived from gabbro and quartz diorite There are no timber values The area is very interesting botanically, an intensive plant inventory of the area is needed. The Bigelow Lakes site is a few miles to the south.

13. *Bolan Lake.* This is an interesting site for *Lewisia* species and *Pedicularis howellii*, but other botanical values are not well-known. The Bolan area contains a significant population of *P. howellii*, a plant with a very limited range. The Klamath and Siskiyou are working on a joint management plan for the species. More plant inventories are needed Other than construction of recreation facilities or roads, no man-made habitat change is likely. Gold has been mined within the area, but no other mineral values are known.

14 *Red Flat.* A number of sensitive plants are present, primarily serpentine endemics. The area needs extensive plant inventories. There are fairly high timber values, and the boundary probably needs refinement. Major conflicts are possible in the western portion of the area where important nickel laterite deposits are located. The eastern edge of the drainage basin for Hunter Creek Bog (BLM) is located in the Red Flat area.

Red Flat - No clear distinction between Red Flat and Red Flat Addition. This portion of the area is on Chetco Ranger District.

Red Flat Addition - This portion of the area is on Gold Beach Ranger District

15. *Waldo Ridge.* A number of sensitive plant species are present. The nearby town of Waldo was a major collecting location for early-day botanists Fairly high timber values are present in the part of the area described as the Addition; the area needs extensive plant surveys and the boundary of the addition may need to be refined There are no known mineral deposits. There is opportunity to locate a joint Botanical area at this site with the Bureau of Land Management.

Waldo Ridge - High Priority

Waldo Ridge Addition - Low Priority

PROPOSED PRIORITY CLASS C

Areas with lower priority.

16 *Cleopatra.* This area contains the only known site in Oregon for a undescribed *Arabis* formerly thought to be *Arabis macdonaldiana.* A population of *A. macdonaldiana* located on Red Mountain in Mendocino County, California is listed as endangered by the Federal Government (USDI Fish and Wildlife Service). The Siskiyou population of *Arabis* nov./in ed. ("macdonaldiana") is considered sensitive. Intensive plant survey work is needed to establish a range for our "*macdonaldiana*" and to ascertain the extent of other rare plant values. Boundaries will need to be better defined. There are no known deposits of nickel laterites; mercury prospects are present.

17. *Green Knob.* Plant species of this area have been extensively inventoried; some sensitive species are present. The area is also a cultural site. This site is presently designated as Protect Rare Plants and Protect Cultural Sites in the TRI system. This is probably adequate for protection of the site's rare plant values.

18. *Windy Collier.* This site contains a very interesting assemblage of intermixed bog and dry sites in serpentine habitat. Extensive plant inventory is needed. Chromite prospects have occurred, but no other mineral values are known.

19 *Squaw Mountain.* This area in the vicinity of Serpentine Lookout on the Galice and Illinois Valley Ranger Districts has not been intensively surveyed. A few sensitive plants are known; undoubtedly others will be added to the list. The area contains both metavolcanic and ultramafic rock types

OLD-GROWTH BOTANICAL AREAS

These five areas are deemed relatively equal in value and are not ranked by priority.

PROPOSED

1. *Big Tree.* This old-growth site contains the world's largest Port-Orford-cedar. The area is located along the South Fork of the Coquille River, south of Elk Creek. A trail winds through the grove and a nearby picnic area Recreation and educational potential is good. This area was listed as a Supplemental Resource area in the DEIS.

2 *Lobster Grove.* This is an old growth grove, mostly large Douglas-fir, near the mouth of Lobster Creek. The site is close to the Rogue River; access could be easily provided to the public Visitor use of nearby areas is very high. This site has high potential for recreation and environmental education. The site has some visual restrictions. An 89 acre site to the south was added to the area between the draft and final plans, in response to public comment; this area contains a recreation trail which winds through a grove of very large Douglas-fir, tanoak, and other species.

3. *Page Mountain Grove.* This is an old growth grove of large Douglas-fir and Port-Orford-cedar in the southeastern portion of the Illinois Valley Ranger District. The grove is along the Happy Camp Road near the divide between the Siskiyou and Klamath National Forests. The area is quite accessible to the public and has high potential for recreation and environmental education use. Part of the site (not the Addition) is within a 300 acre MMR site for pileated woodpeckers, (Management Area 8, Designated Wildlife Habitat, see the Forest Plan).

4 *Redwood Groves.* This proposed Botanical area was created between the draft and final plans, in response to public comments. The area contains a number of separate stands, which represent some of the best remaining old-growth redwood forest on the Siskiyou (and in Oregon). Several stands are near the existing Wheeler Creek RNA.

5. *Snaketooth Redwood* This 21 acre site is the northern-most coastal redwood grove. Half of the original 40 acre site was harvested in the early 1960's. It is located on the Chetco Ranger District, in the Little Redwood Creek drainage.

RESEARCH NATURAL AREAS

EXISTING

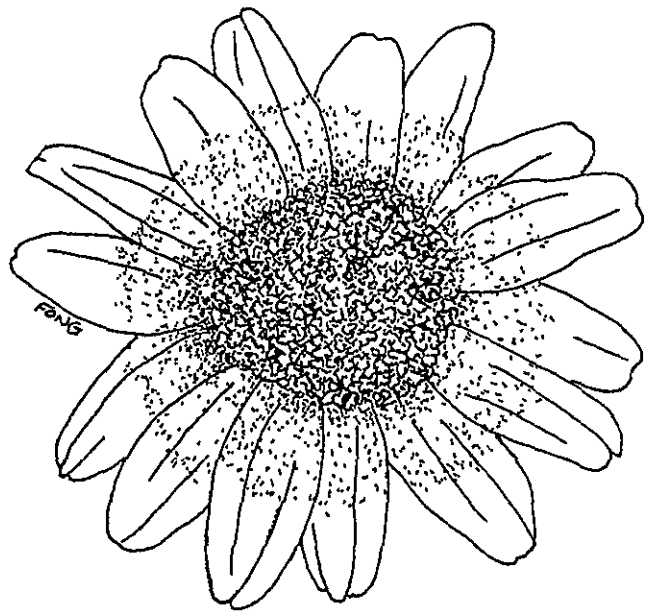
1. *Coquille River Falls.* The Coquille River Falls RNA contains two plant communities (cells) not represented in other RNA's: (a) mixed forest of Douglas-fir, tanoak, and Port-Orford-cedar; and (b) red alder/swordfern

2. *Port Orford Cedar.* The Port Orford Cedar RNA contains six plant communities (cells) not represented in other RNA's: (a) mixed stand of grand fir, bigleaf maple, and western hemlock, with understory dominated by swordfern; (b) open vegetational mosaic on serpentine ridge with stunted Douglas-fir, canyon live oak, and coffeeberry; (c) swale dominated by red alder and slough sedge (*Carex obnuta*); (d) swale dominated by Oregon ash and slough sedge (*Carex obnuta*); (e) mixed-forest stand located on serpentine and dominated by Douglas-fir, with minor amounts of Port-Orford-cedar and Pacific madrone in the overstory, and tanoak and beargrass in the understory; and (f) mixed upland forest dominated by Douglas-fir, Port-Orford-cedar, and western hemlock, with understory of tanoak and swordfern.

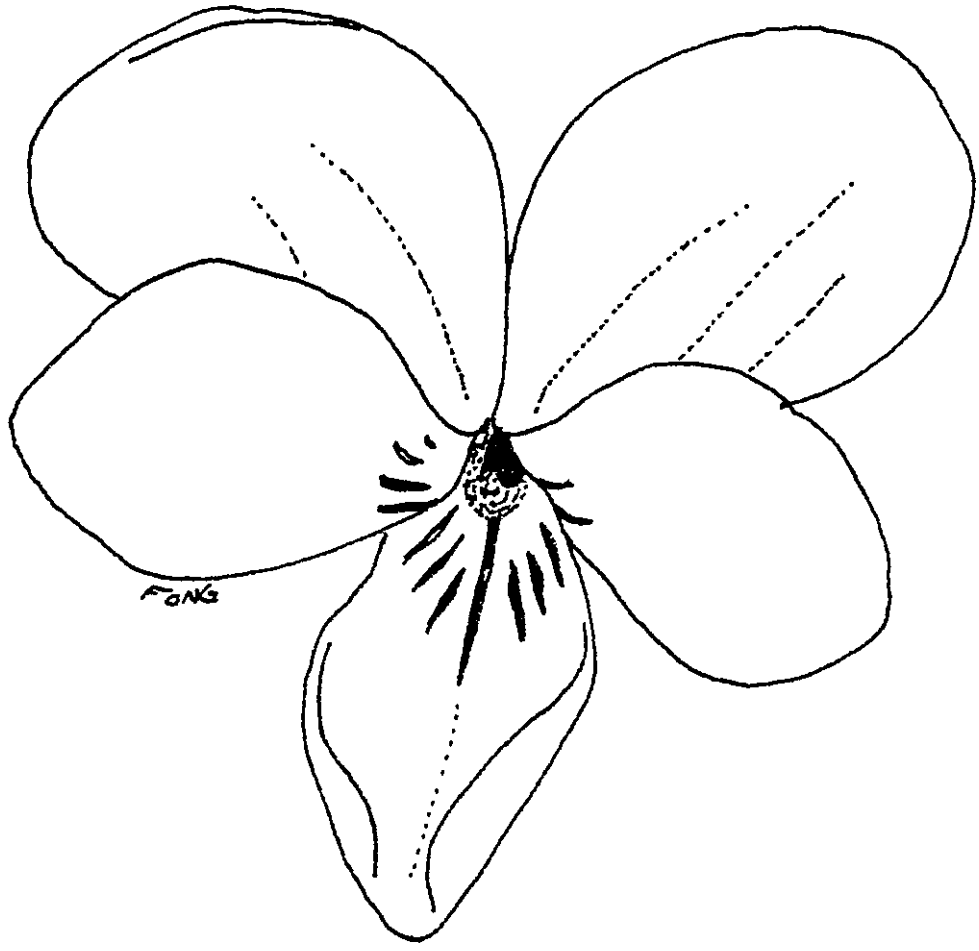
3 *Wheeler Creek.* The Wheeler Creek Research Natural Area was established to preserve (a) a redwood stand near the northern limit of its range. Two additional cells in this RNA are: (b) forested riparian zone with a major hardwood component of bigleaf and vine maple, and abundant herbaceous cover; and (c) mesic forest with understory of tanoak, Evergreen huckleberry, and Pacific rhododendron.

PROPOSED

Forest ecologists have identified four sites on the Forest suitable for establishment of new RNA's They are listed by priority order.



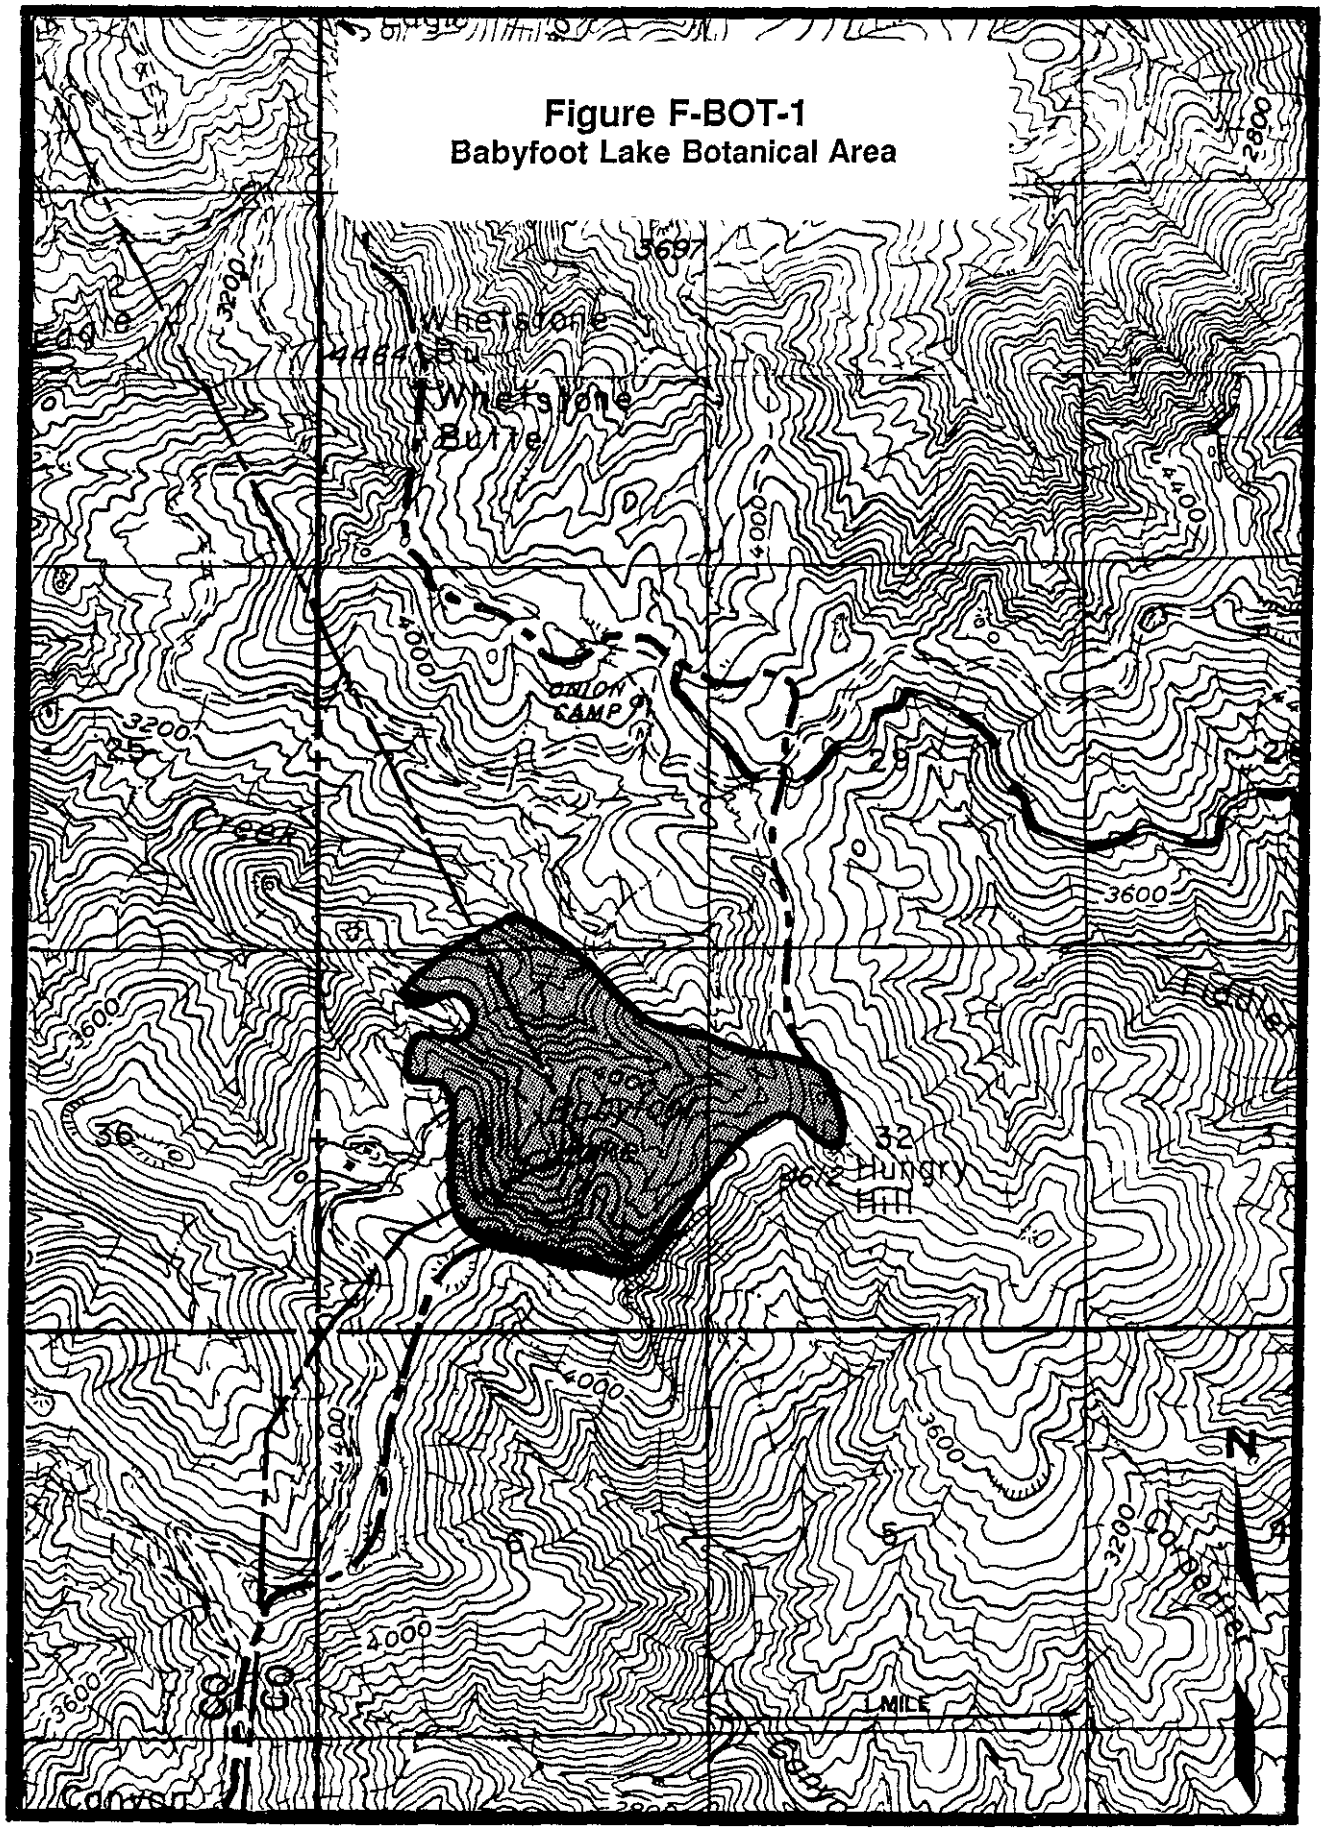
1 *Lemmingsworth Gulch.* Lemmingsworth Gulch (Chetco Ranger District) contains eight cells: (a) mixed-evergreen forest (Douglas-fir and evergreen hardwoods--minor component), (b) tanoak/madrone forest, (c) knobcone pine, (d) Jeffrey pine/grass on serpentine at high elevation, (e) serpentine vegetation matrix and normal soil island with good representation of contacts, (f) stream drainage in serpentine at mid- to high-elevation, and (g) mountain bog in serpentine area with *Darlingtonia* This site also contains a variety of sensitive and rare plant species



2. *Hoover Gulch.* Hoover Gulch (Illinois Valley Ranger District) contains three plant communities (cells) not represented in other existing or proposed Research Natural Areas. (a) canyon live oak, (b) mixed evergreen forest (Douglas-fir and evergreen hardwoods), and (c) a major drainage in mixed-evergreen forest These plant communities are common in southwest Oregon and northwest California, but suitable

locations for RNA's are not. The lower portion of the area is within the Wild and Scenic Illinois River corridor This site is also part of a spotted owl habitat area (SOHA) (see Management Area 8, Forest Plan). There are no existing mining claims in the area.

3. *Cedar Log Flat.* Cedar Log Flat (Galice Ranger District) contains an important plant community not represented in other existing or proposed Research Natural Areas: Jeffrey pine-grass at low elevation This is an uncommon plant community. There are no other sites available to represent this plant community in the RNA system. This site has not been grazed. In 1984 Dennis Vroman (Galice Ranger District) discovered six sensitive plant species at the site, most of which are otherwise confined to the Illinois Valley area.



4. *Craggy Peak.* The Craggy Peak site (Illinois Valley Ranger District) contains six cells: (a) vernal pond at mid- to high-elevation, (b) cold springs, (c) Shasta red fir - white fir forest, (d) Brewer spruce showing maximum development, (e) Baker cypress in the eastern Siskiyou Mountains, and (f) mountain herblands at high elevation. The largest portion of the proposed Craggy Peak RNA is located on the Rogue River National Forest (the portion on the Rogue River is called Oliver Matthews RNA). Cells b and f are on the Siskiyou portion of area; the cold springs cell is especially important.

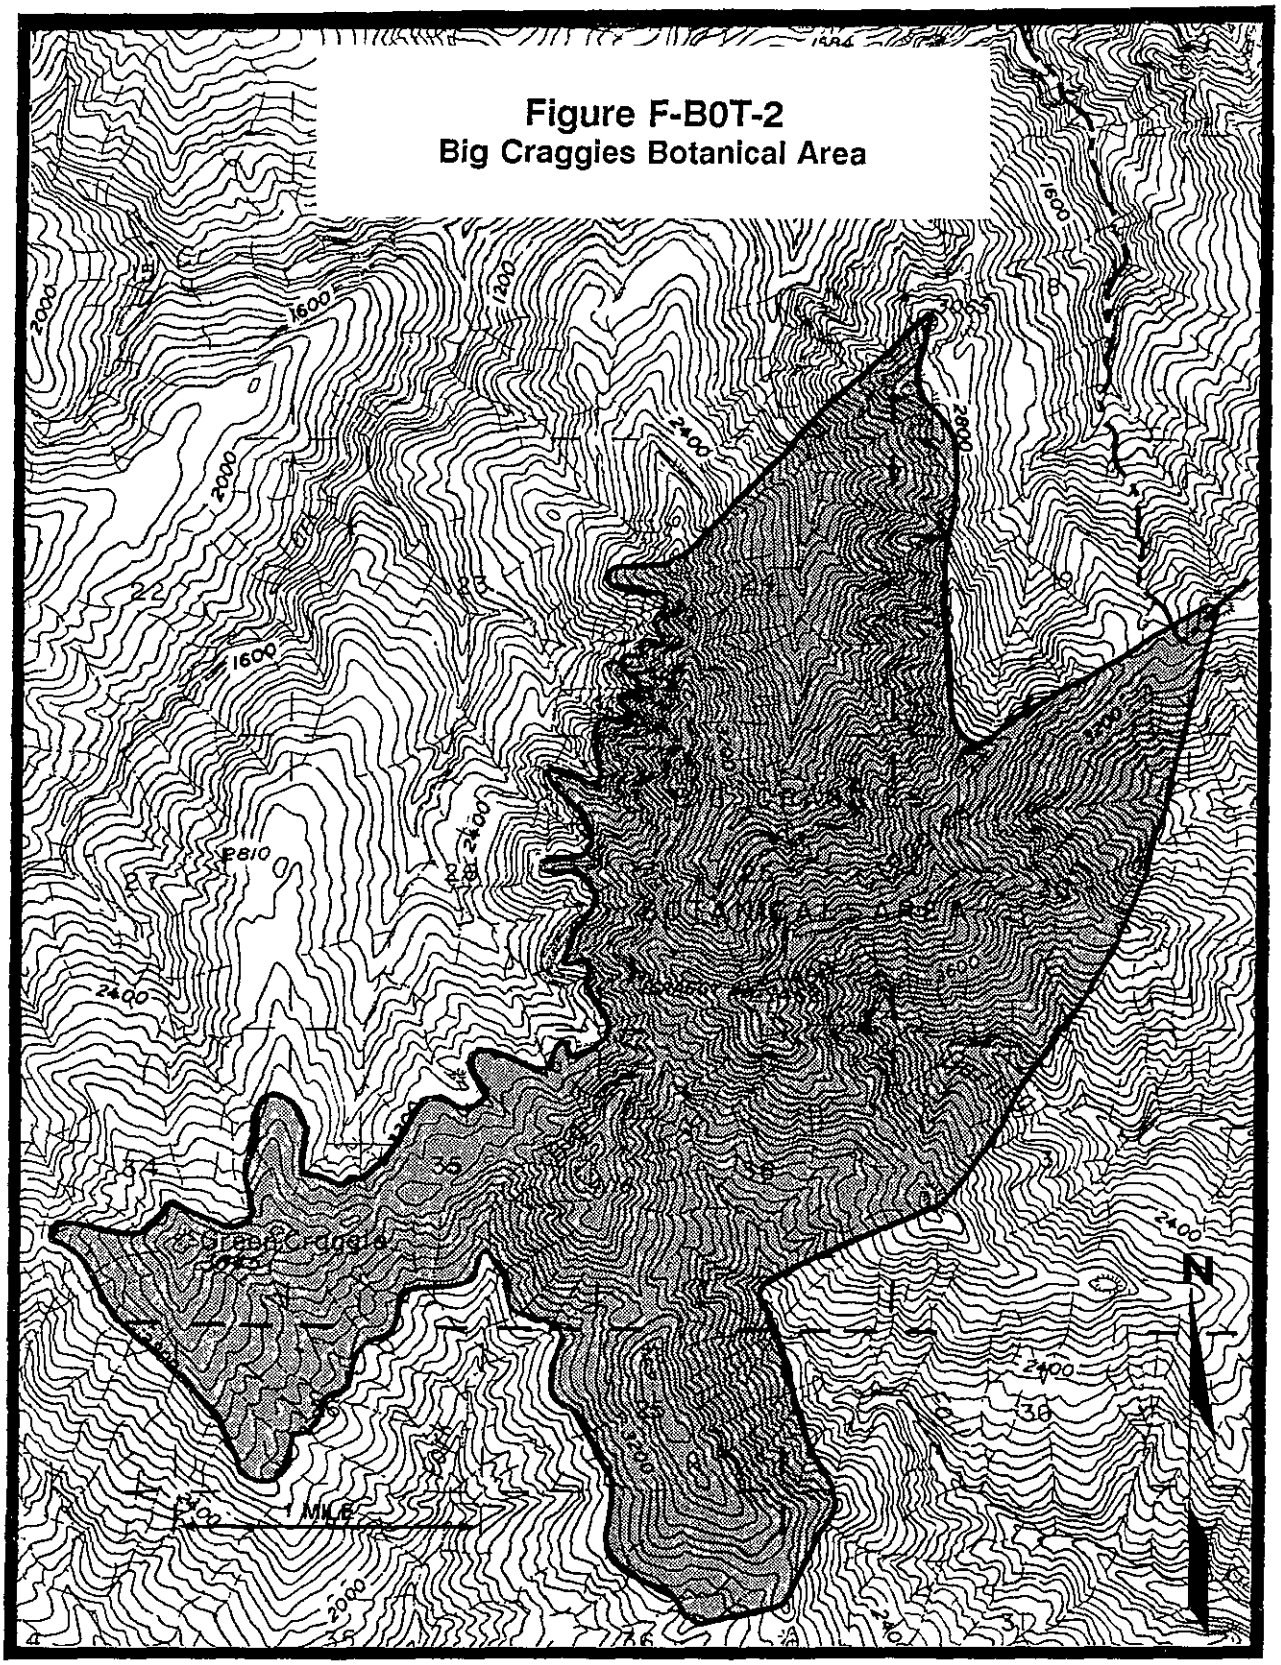
SENSITIVE PLANT BOTANICAL AREAS - EXISTING

BABYFOOT LAKE - F-BOT-1

The Babyfoot Unusual Interest Area (Botanical) (352 total acres, of which 144 are in the Kalmiopsis Wilderness) was established in 1963 to protect Brewer spruce and other rare plant species (Figure F-BOT-1) Sensitive plant species are listed in Table F-BOT-1. An application for mineral withdrawal has been submitted to the Bureau of Land Management (BLM) (for lands outside the wilderness). The area was established by authority of the Chief of the Forest Service and represents a permanent land allocation not subject to review in this Forest Plan.

The following information is excerpted from the Establishment Report for Babyfoot Lake Botanical area (on file at the Supervisor's Office):

Topographic features quite effectively isolate this area. Babyfoot Lake lies in a spectacular glacial cirque at the head of Babyfoot Creek, a tributary of the Chetco River. Slopes throughout the area are precipitous except for the floor of the cirque surrounding the lake. The rock structure is very complex, mostly of a metavolcanic type formed by metamorphosis of tuffs and lava flows.



Diorite, greenstone, and layered tuffs predominate. Some serpentine is present. The vegetative cover is typical of the semi-alpine portions of the Siskiyou mountains except that the area being established contains the largest stand of Brewer spruce known on the Siskiyou Forest. On the cirque floor near the lake the Brewer spruce specimens are large, tall, and well formed. From the vicinity of the lake they grade down to alpine forms near the ridgetop. The spruce grows in association with Douglas-fir, Shasta red fir, sugar pine, Port-Orford-cedar, and incense-cedar.

Shrub species include Sadler oak, squaw-carpet, creeping juniper, prostrate ceanothus, and tanoak.

Table F-BOT-1. Unusual Plants in the Babyfoot Lake Botanical Area.

Scientific Name	Common Name
Sensitive Species	
Calochortus howellii	Howell's mariposa Lily
Fritillaria glauca	Siskiyou fritillaria
Lewisia cotyledon ssp. *purdyi*	Purdy's lewisia
Lewisia oppositifolia	opposite-leaved lewisia
Lupinus tracyi	Tracy's desert parsley
Watch/Review Species	
Erigeron cervinus 1/	deer erigeron
Sedum laxum ssp. *heckneri* 1/	lax stonecrop

BIG CRAGGIES - F-BOT-2

The Big Craggies Botanical Area (3,803 total acres, of which 2,944 are in the Kalmiopsis Wilderness) was established in 1964 primarily to protect Brewer spruce and *Kalmiopsis leachiana* (Figure F-BOT-2). Sensitive plant species are present (Table F-BOT-2). An application for mineral withdrawal has been submitted to the Bureau of Land Management (for lands outside the wilderness). The area was established by authority of the Chief of the Forest Service and represents a permanent land allocation not subject to review in this Forest Plan.

The following information is excerpted from the Establishment Report for the Big Craggies Botanical Area (on file at the Supervisor's Office):

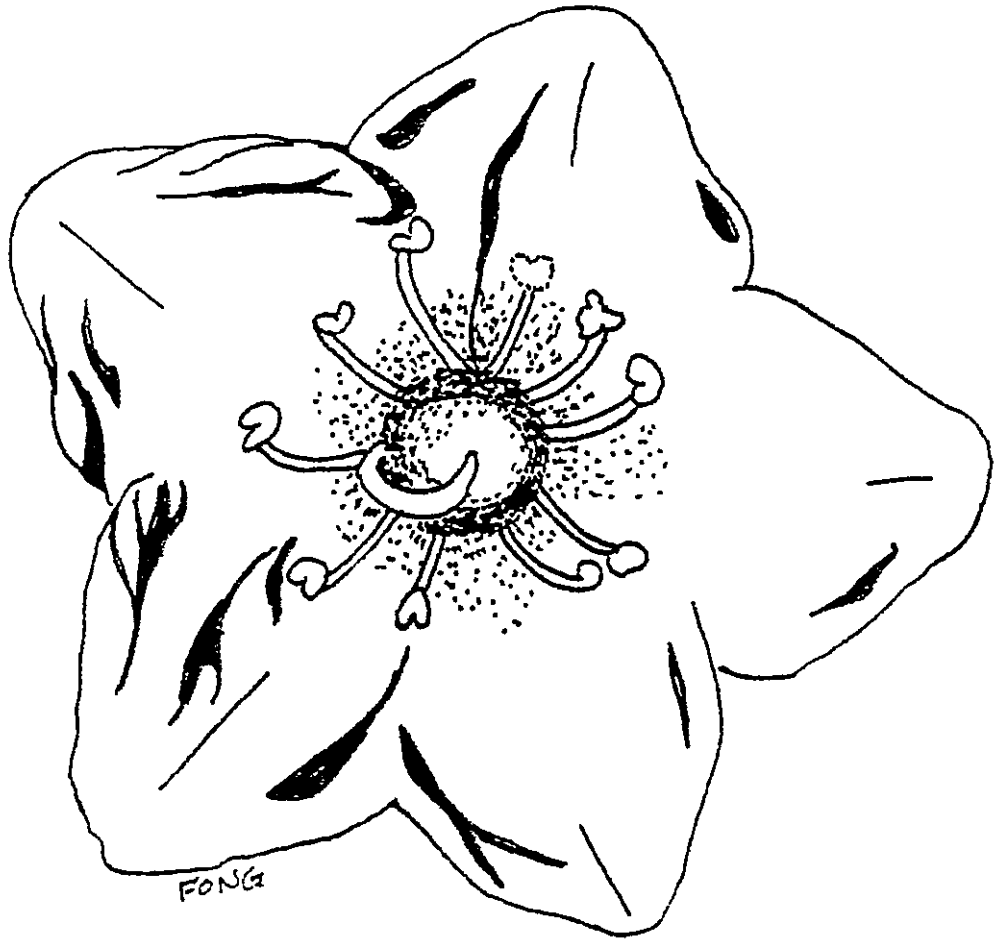
Big Craggies Mountain includes perhaps the roughest terrain on the Siskiyou National Forest. The highest elevation on the mountain is 4,621 feet. Slopes on the south side of the mountain are extremely steep. Slopes on the north side are precipitous and composed mostly of series of cliffs with slides and talus intervening. The primary formation is peridotite (a basic magma rock) with areas modified or metamorphosed to serpentine. Very little soil has accumulated on the mountain.

Ground cover on the ridge tops and south slopes is composed mostly of shrubby species.

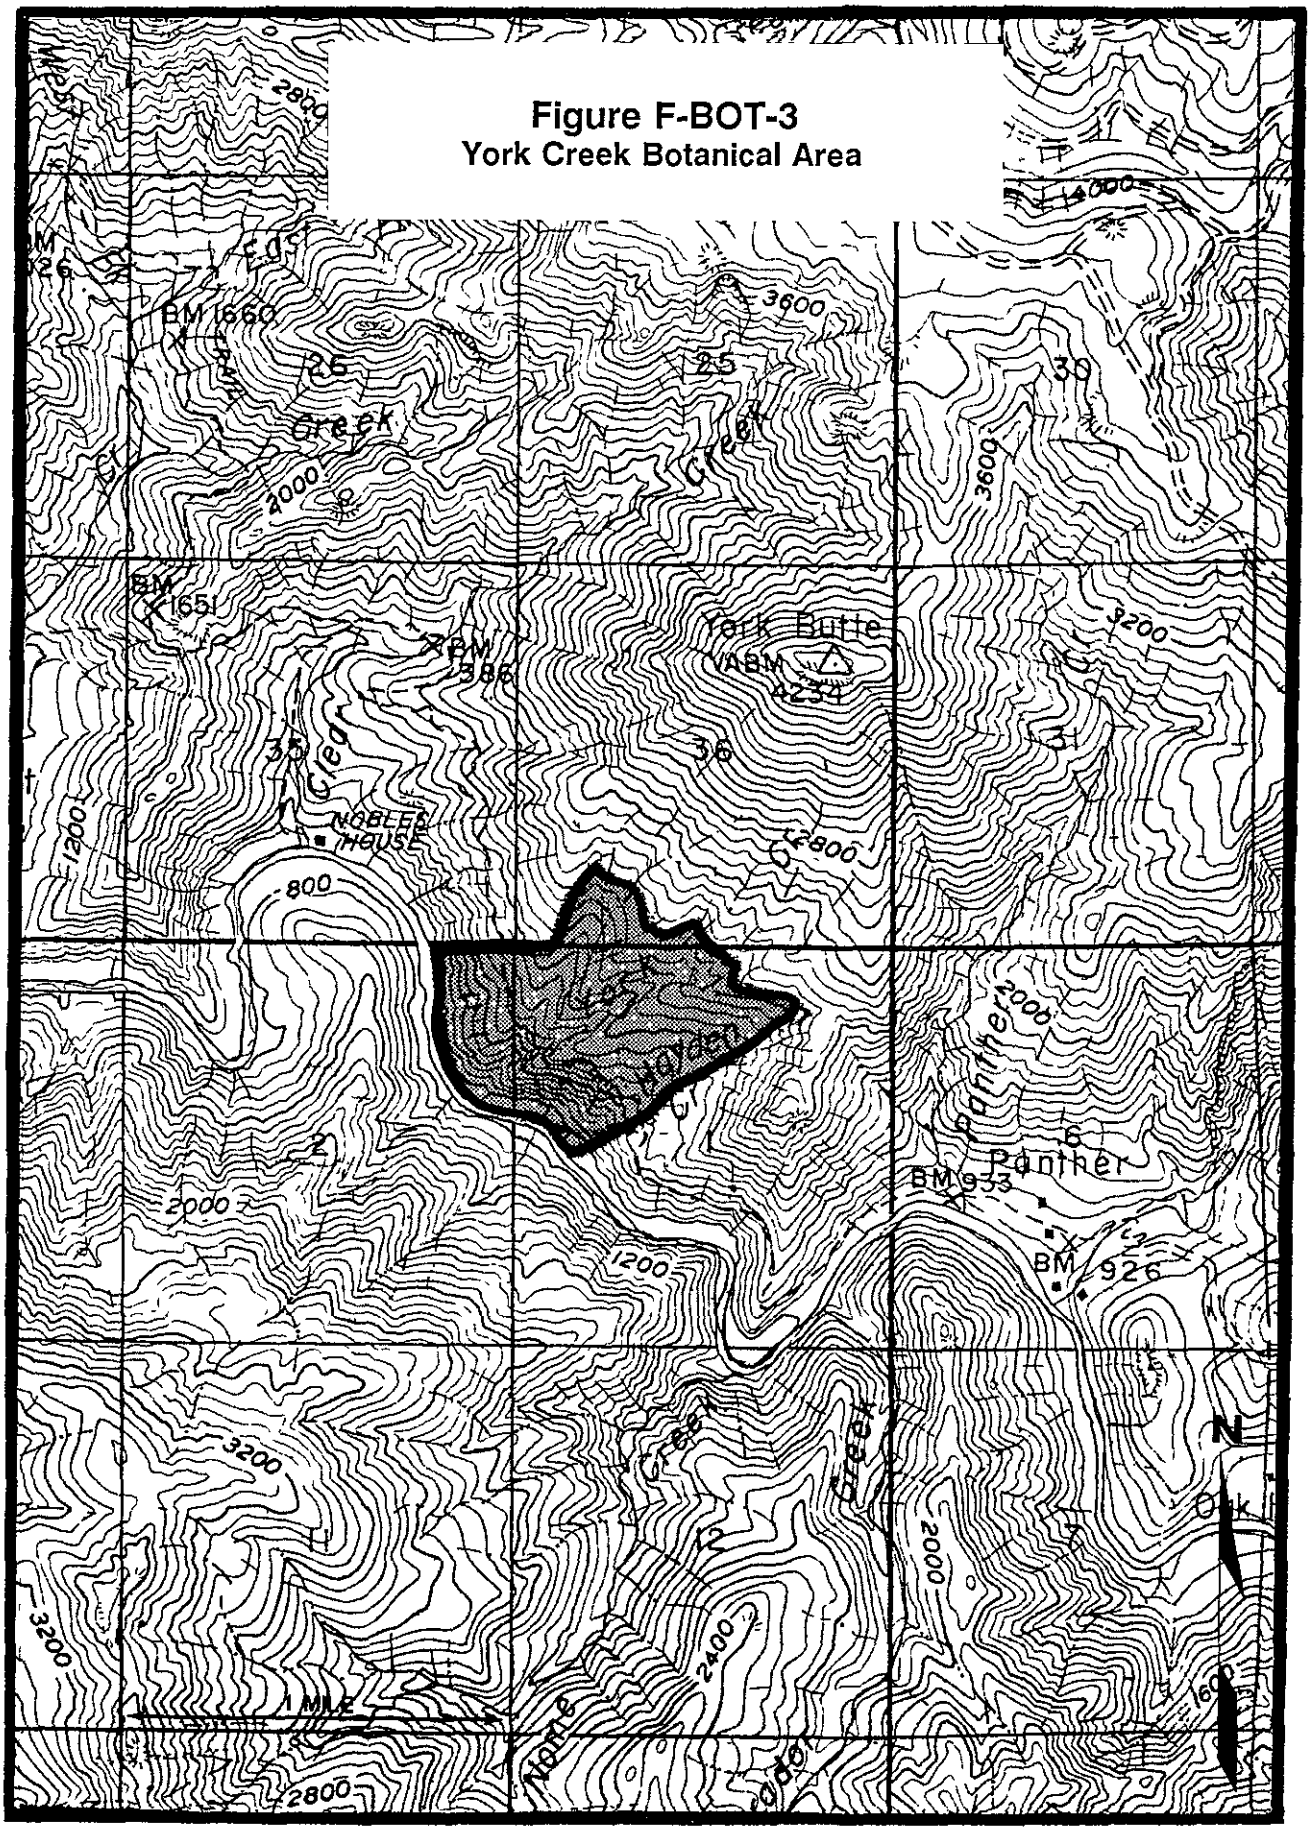
There is little or no ground cover on the north slopes above the bottom of the cliff and slide area. Some pockets of old-growth Douglas-fir are found below the cliffs and slides. Brewer spruce was found growing abundantly in the heads of the glacial basins to the very summit. Some western white pine and an occasional western yew were also growing near the summit.

The entire Big Craggies Botanical Area is extremely interesting botanically. The following list is from the Establishment Report.

Scientific Name	Common Name
Tree species found in the area include:	
Picea breweriana	Brewer or weeping spruce
Pinus monticola	western white pine
Pinus jeffreyi	Jeffrey pine
Taxus brevifolia	western yew
Pseudotsuga menziesii (stunted growth forms)	Douglas-fir
Pinus attenuata	knobcone pine



Species list (Cont'd)



Scientific Name	Common Name
Shrub species include:	
Rhododendron californicum	rhododendron
Rhododendron occidentale	western azalea
Quercus sadleriana	Sadler oak
Quercus vaccinifolia	huckleberry oak
Garrya fremontii	silktassel bush
Kalmiopsis leachiana	kalmiopsis
Quercus chrysolepis	canyon live oak
Manzanita spp.	
Juniperus sibirica	creeping juniper
Ceanothus prostratus	prostrate ceanothus
Holidiscus spp.	oceanspray
Vaccinium ovatum	evergreen huckleberry
Ceanothus velutinus	varnish-leaf ceanothus
Herbaceous species of special interest include:	
Penstemon rupicola	rock penstemon
Lewisia cotyledon	imperial lewisia
Arnica spp.	
Senecio spp.	
Iris spp.	
Xerophyllum tenax	beargrass
Lotus spp.	

Table F-BOT-2. Unusual Plants in the Big Craggies Botanical Area.

Scientific Name	Common Name
Sensitive Species	
Carex scabriuscula	cascade sedge
Fritillaria glauca	Siskiyou fritillaria
Watch/Review Species	
Arctostaphylos hispidula 1/	Howell's manzanita
Kalmiopsis leachiana	kalmiopsis

1/ Potential candidate for Regional Forester's sensitive list.

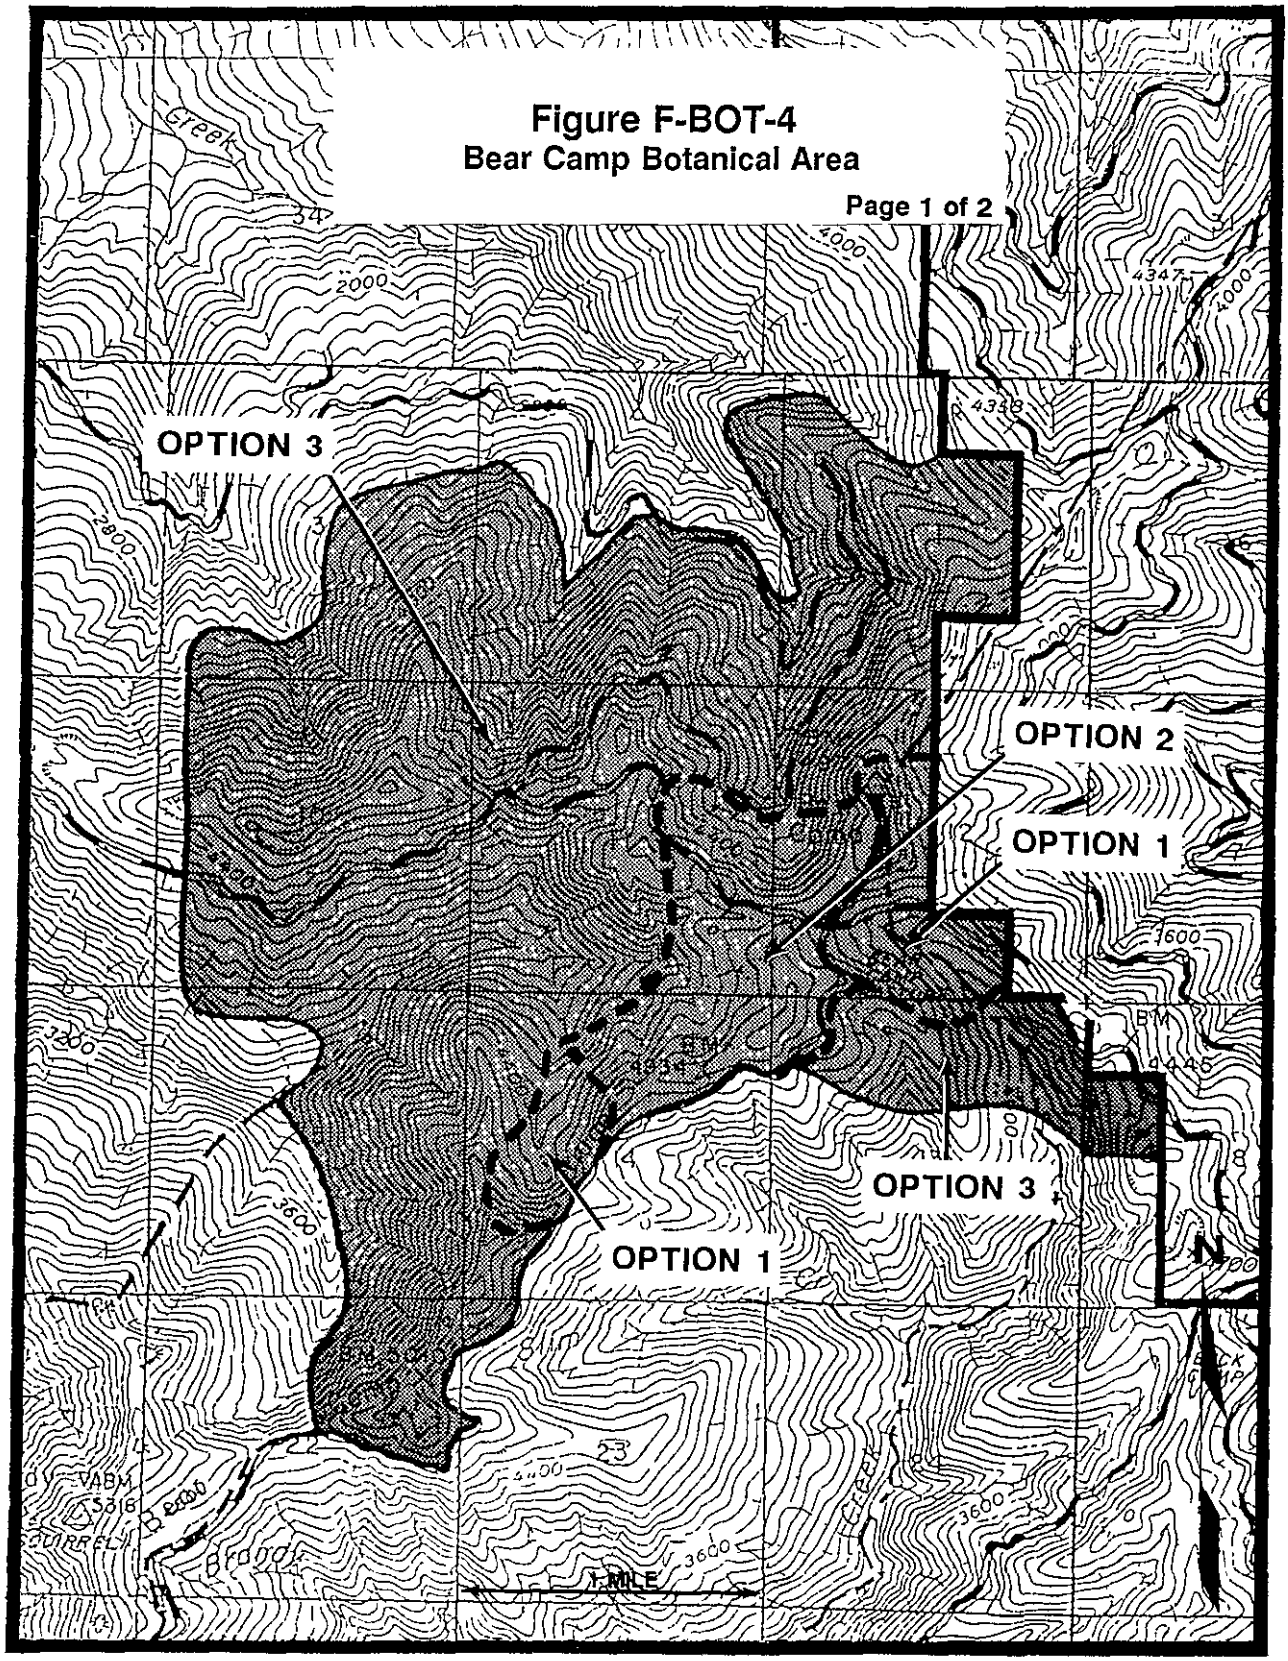
YORK CREEK - F-BOT-3

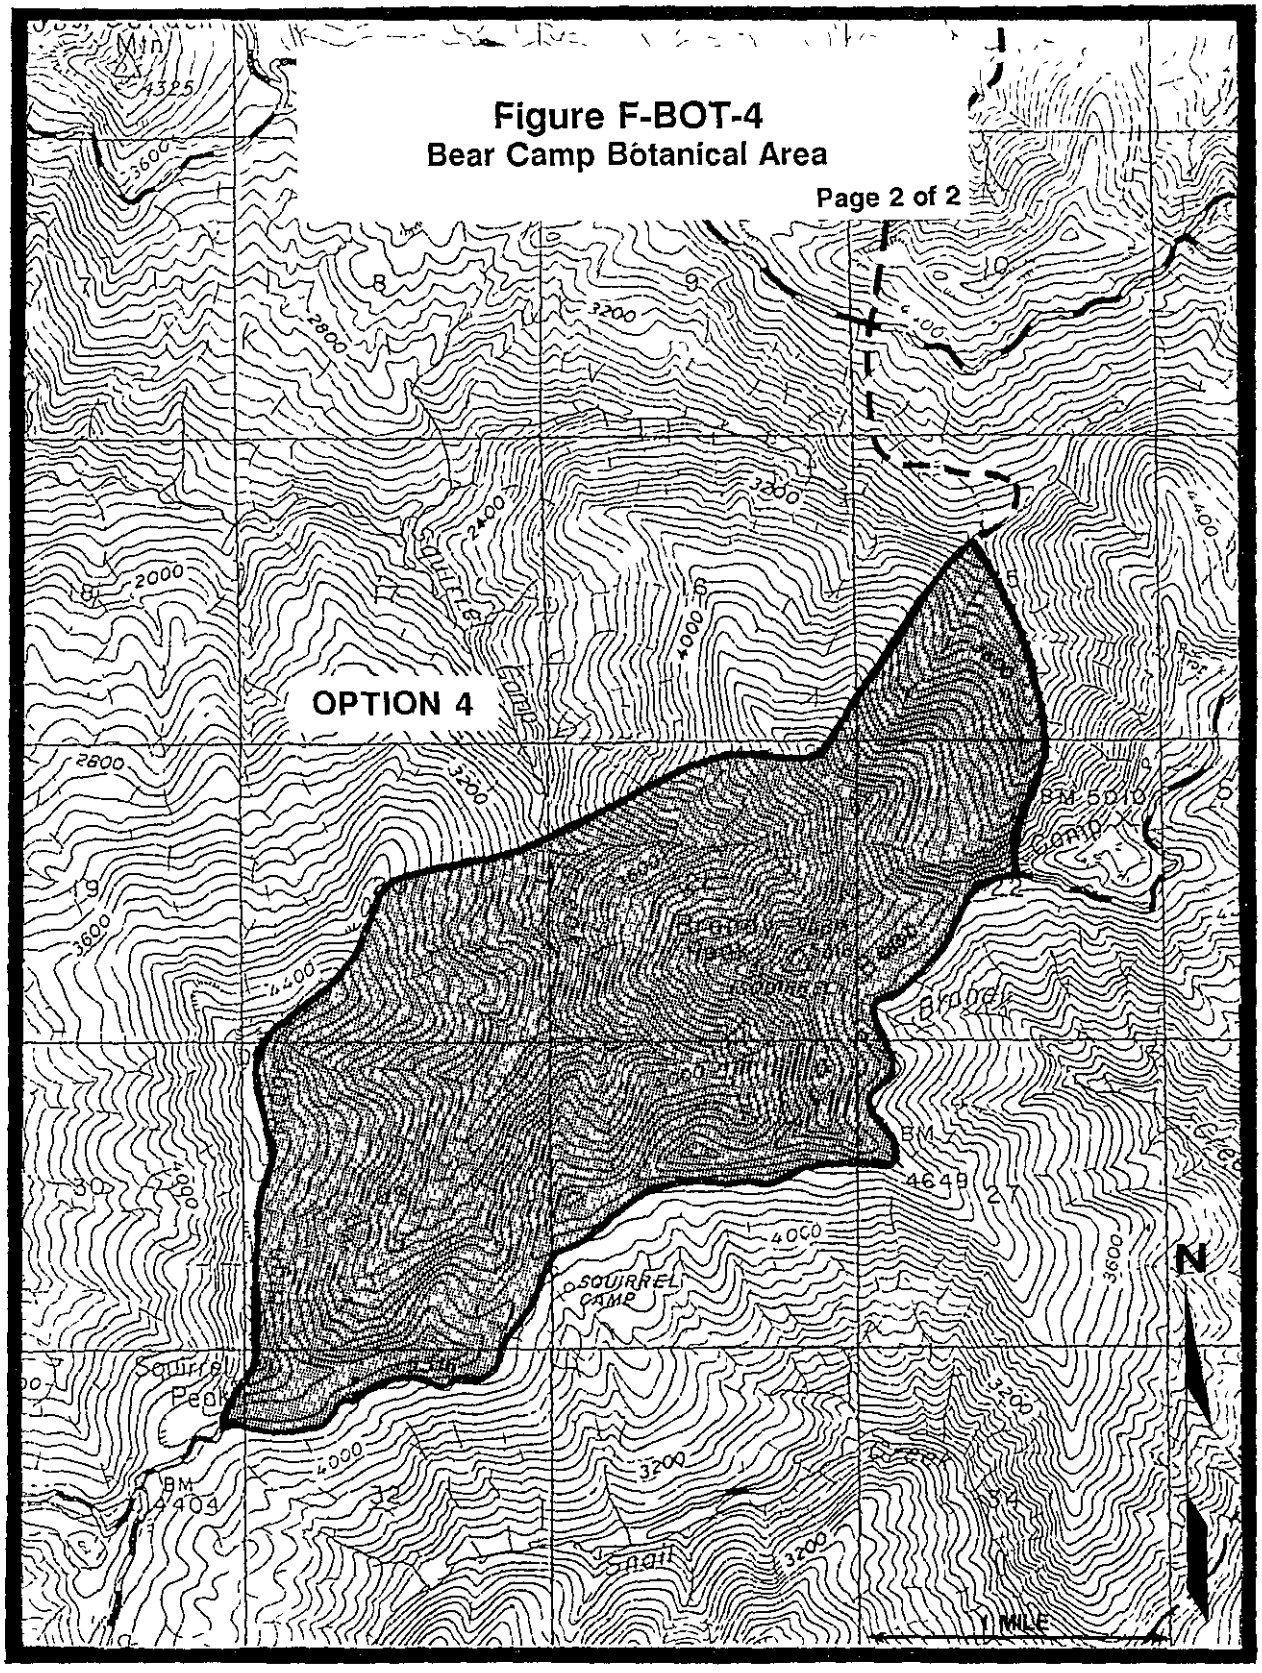
The York Creek Botanical Area (320 acres, all in the Kalmiopsis Wilderness) was established in 1963 primarily to protect an extensive patch of *Kalmiopsis leachiana* (Figure F-BOT-3) Sensitive plant species are present (Table F-BOT-3). Because the area is within a wilderness, mineral entry is not permitted. The area was established by authority of the Chief of the Forest Service and represents a permanent land allocation not subject to review in this Forest Plan.

The following information is excerpted from the Establishment Report for York Creek Botanical Area (on file at the Supervisor's Office):

This small patch of *Kalmiopsis* is the most accessible patch of the shrub to be found on the Siskiyou Forest It is located astride the Illinois River Trail. The actual area covered by the plant is approximately .18 acres on a very dry northwest slope above the East Fork of York Creek.



The basic rock formation in this area is peridotite. Large masses of this peridotite have been altered to serpentine throughout the York Creek-York Butte locality The site actually occupied by the plant is in broken but unaltered peridotite.



Shrub growth associated with the *Kalmiopsis* in this location includes tanoak (*Lithocarpus densiflorus*), canyon live oak (*Quercus chrysolepis*), and evergreen huckleberry (*Vaccinium ovatum*). There is a sparse overstory of rather stunted Douglas-fir and Jeffrey pine. Some sugar pine occurs in the vicinity.

Table F-BOT-3. Unusual Plants in the York Creek Botanical Area.

Scientific Name	Common Name
Sensitive Species	
Monardella purpurea	Siskiyou monardella
Sophora leachiana ?	western sophora

SENSITIVE PLANT BOTANICAL AREAS - PROPOSED

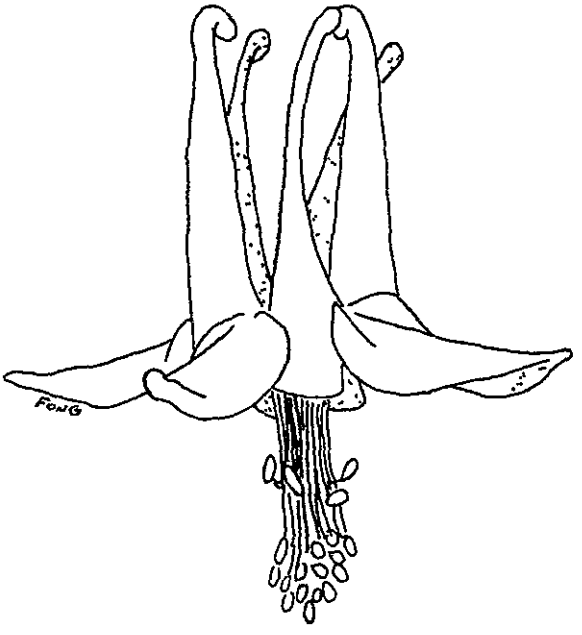
BEAR CAMP - F-BOT-4

The proposed Bear Camp Botanical Area is located on the Galice Ranger District at T 34S , R 10W (approximately 5,927 acres) Elevation range is from approximately 3,500 to 5,000 feet, slopes vary from gentle to steep (Figure F-BOT-4, 2 parts).

The proposed area is mainly a true fir and Doulgas-fir mix with scattered areas of rimrock and other open places, including meadows such as Bear Camp Pasture (T.34S , R.10W., Section 12 SW 1/4) and Elk Wallow (Section 14 NW 1/4). Soils are derived from the Dothan formation and are non-mineral in character (Ramp and Peterson 1979) Many timbered acres contain openings with scattered conifers and moist soils; this is typical habitat for *Bensoniella oregana*, a small, inconspicuous member of the Saxifrage family. *Bensoniella*, a sensitive species, is found only in a few locations, basically above 3,500 feet elevation in the Bear Camp area and west to the Fishhook Peak area, and in the Fairview Meadow area (the type locality). *Bensoniella* populations seem to be associated with cloud/fog banks that blanket the mountain tops at certain times of year (Joan Seevers, Botanist, Bureau of Land Management - personal communication). A few small sites are also known in the vicinity of Snow Camp Peak near Arcata, California. Most of the *Bensoniella* plants in existence occur on the Siskiyou National Forest

Local botanists describe the Bear Camp flora as interesting, diverse, and locally unique (Table F-BOT-4). For example, the Bear Camp area contains a variety of *Ribes* spp. (*bracteosum*, *binominatum*, *cruentum*, *lacustre*, *sanguineum*) and at least 5 species of *Penstemon* (*anguineus*, *cardwellii*, *deustus*, *parvulus*, *rupicola*) in close proximity to one another. The Bear Camp area also contains a few plant species uncommon or otherwise absent in southwest Oregon. Plants in this category are *Stenanthium occidentale*, *Frasera umpquaensis*, *Chamaecyparis nootkatensis* (Alaska yellow-cedar), *Isopyrum hallii*, and *Saxifragia caespitosa*

In a letter to the Forest Service on 14 September 1984, local botanist Veva Stansell described the Bear Camp area.



> These ridges and their flanks are locations for an assortment of plant species that includes plants of the Siskiyous, the Coast Range, and the Cascades. For instance, the range of *Isopyrum hallii* (found at Elk Wallow) is supposed to be from Marion County and the Columbia Gorge northward. *Penstemon deustus*, *Frasera umpquaensis* and *Saxifraga caespitosa* are from the Cascades. Five or six species of *Penstemon*, five of *Ribes*, and four species of *Sedum* are found along these ridges. These are unusual concentrations.

About 4,675 acres in this proposed Botanical area are tentatively available and suitable for timber production; this land is capable of producing about 2,525 thousand board feet (MBF) of harvestable timber on a long-term sustained yield (LTSY) basis (see Table F-3). The Bear Camp area has been divided into four options (Table F-7). This provides flexibility to land managers who must make decisions on land allocations. For further information on the options see Table F-3, Figures F-1 and F-BOT-4 (2 parts).

Options 1 and 2 have been recommended in the Preferred Alternative (S). These options contain the most important botanical elements. The land in Options 3 and 4 will be managed for a variety of resources, including timber production, with populations of sensitive species individually protected.

Table F-BOT-4. Unusual Plants in the Proposed Bear Camp Botanical Area.

Scientific Name	Common Name
Sensitive Species	
Bensoniella oregana	Oregon bensonia
Frasera umpquaensis	Umpqua frasera
Fritillaria glauca	Siskiyou fritillaria
Watch/Review Species	
Lilium vollmeri	Vollmer's lily

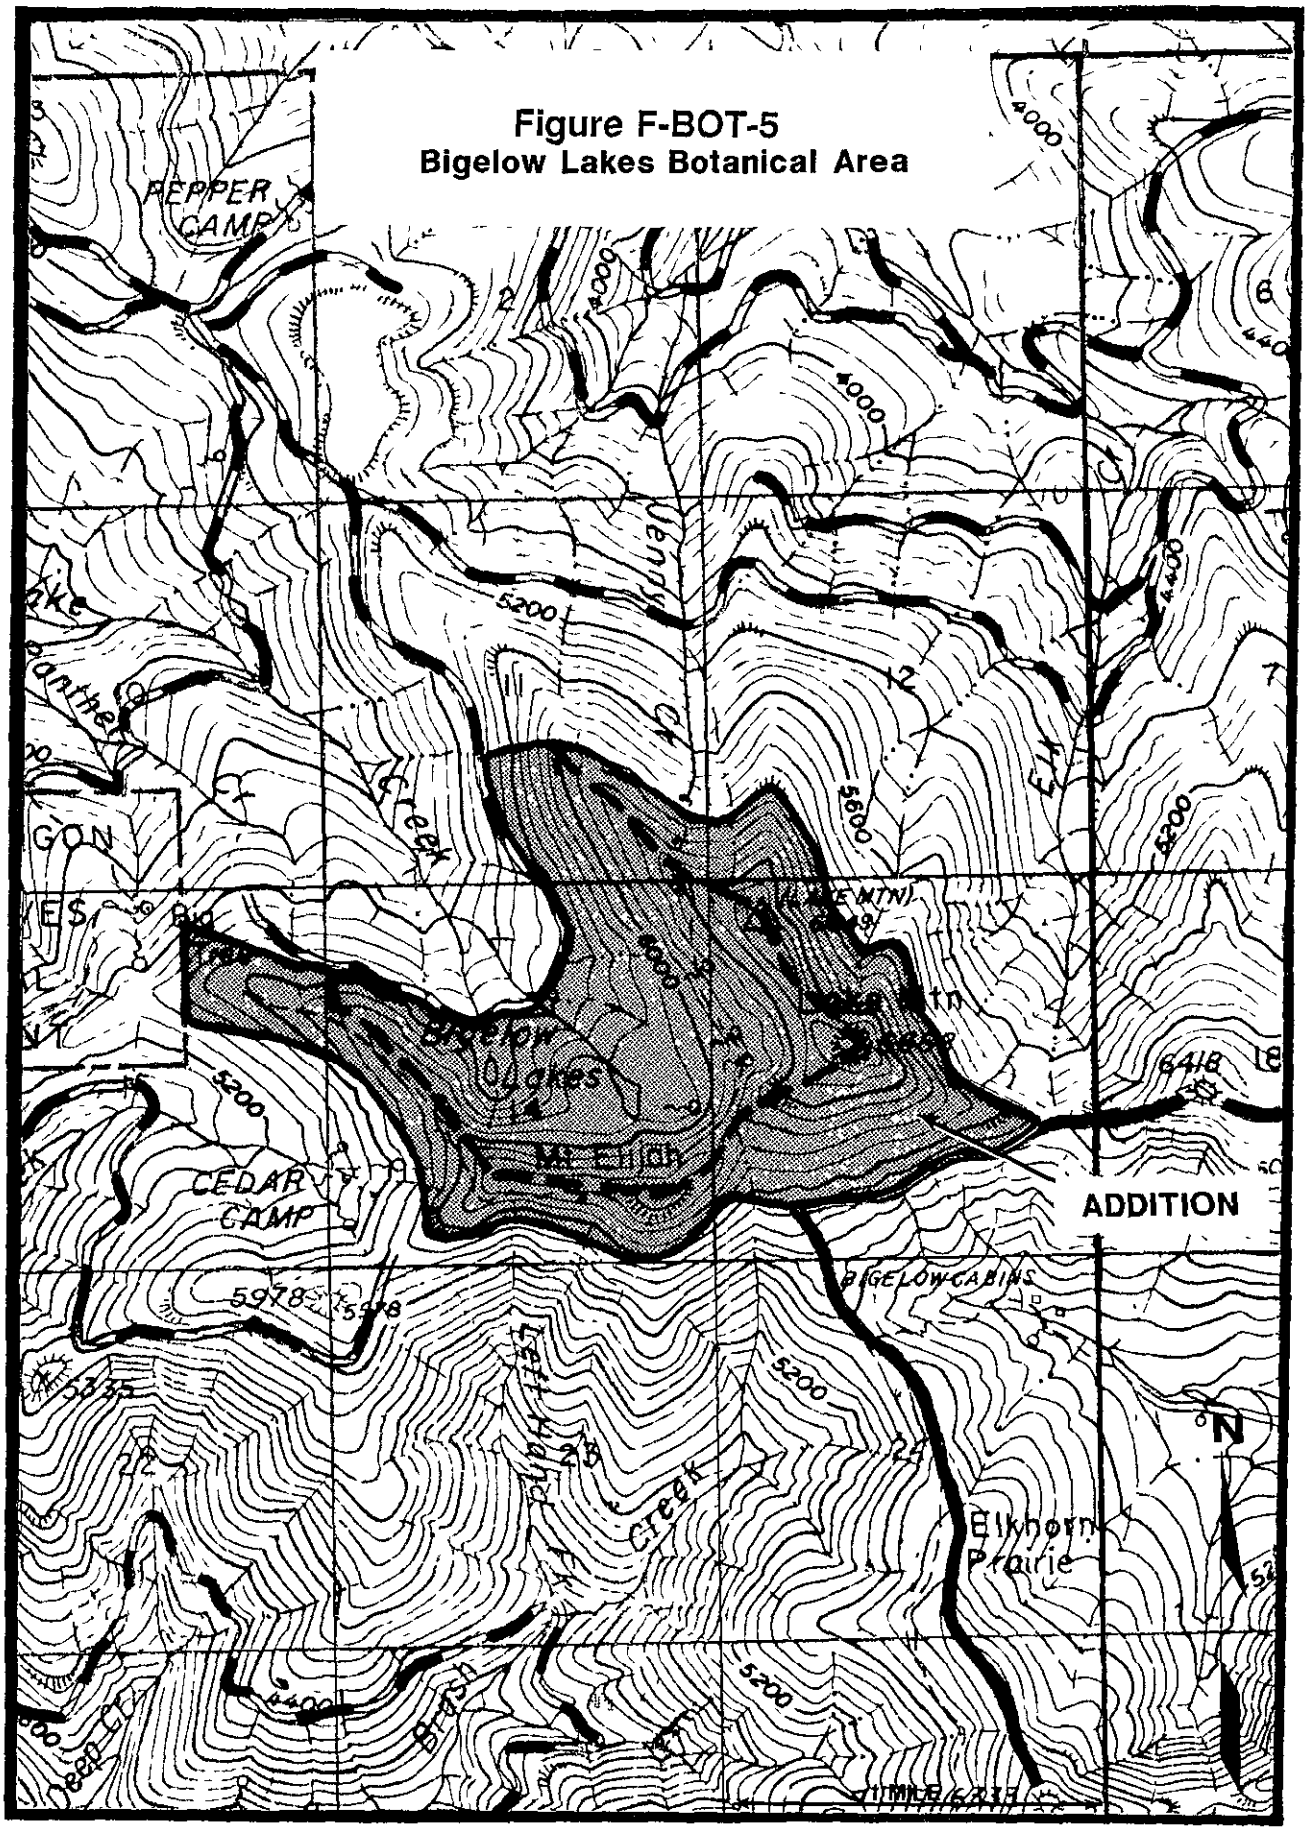


Figure F-BOT-5
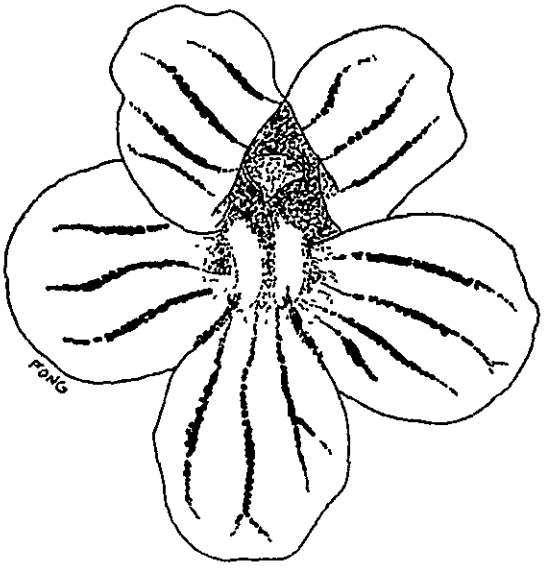
Bigelow Lakes Botanical Area

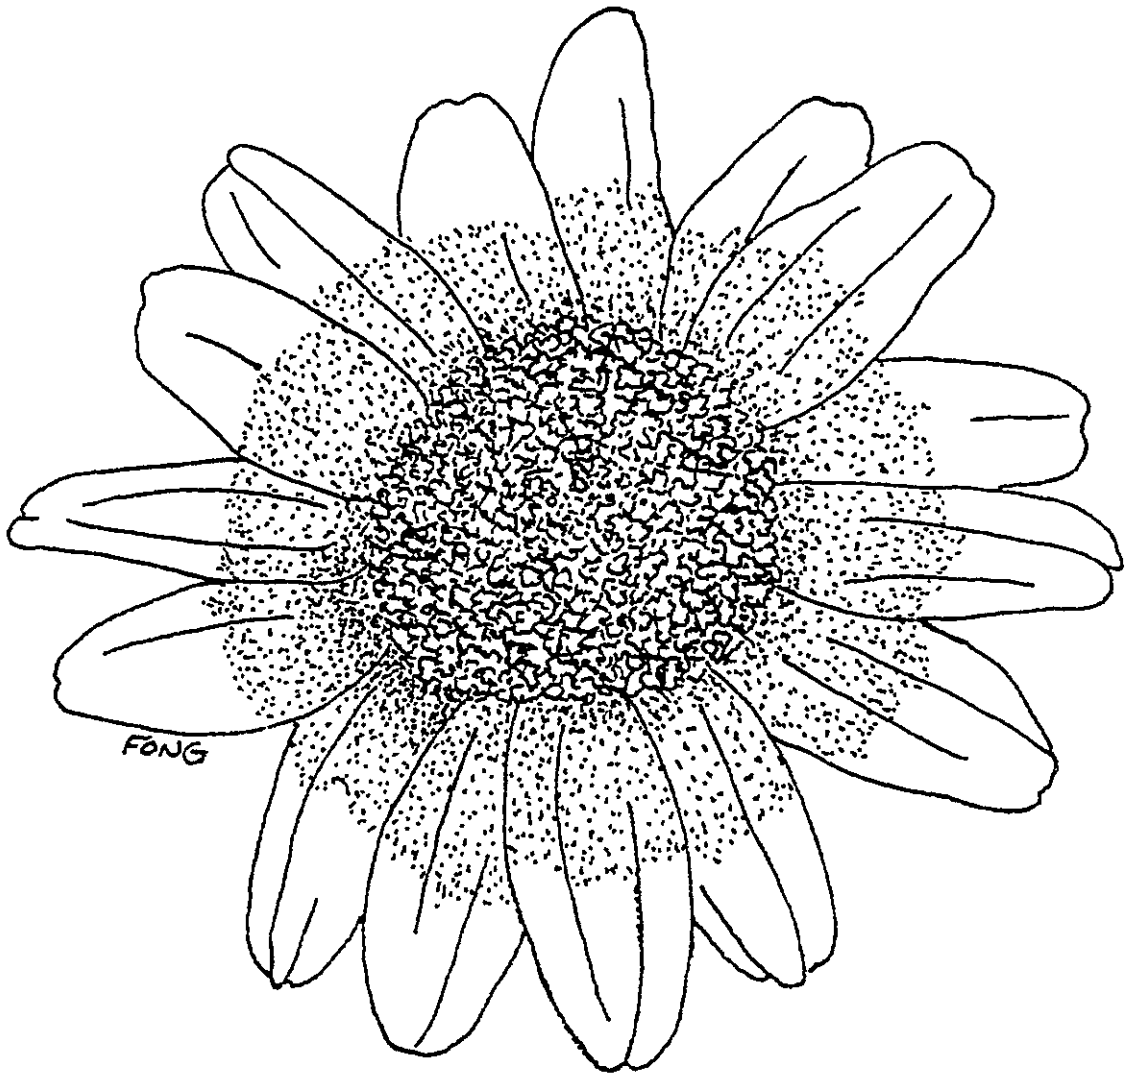
BIGELOW LAKES - F-BOT-5

The proposed Bigelow Lakes Botanical Area is located in a glacial cirque on the Illinois Valley Ranger District, approximately one mile east of Oregon Caves National Monument (T.40S., R.6W., Sections 13, 14) The boundary follows topographic and legal lines (Figure F-BOT-5). The proposed area is approximately 971 acres Elevation range is approximately 5,200 to 6,668 feet Soils are derived from diorites, gabbros, and scattered inclusions of other rock types; no mineral deposits are known (Ramp and Peterson 1979). Mt. Elijah and Lake Mountain are both on the boundary of the proposed area

Local and nonlocal botanists alike extol the unique and diverse plant resources of the Bigelow Lakes vicinity Habitats are so varied and interspersed that a large variety of plant species with different habitat requirements are found growing in close proximity to one another. Habitats vary from dry meadow, wet meadow, moist shrub, dry shrub, and forested areas to rocky areas and cliffs. Local botanist Mary Paetzel cataloged over 100 species of plants in the vicinity of the larger lake. In 1986 Veva Stansell, a botanist from Pistol River, reported large numbers of *Erigonum declinum* in the upper lake area. Genera such as *Penstemon*, *Haplopapus*, and *Epilobium* are well represented; a large variety of trees and shrubs are also present, including a number of manzanita species, mountain and western hemlock, true fir species, incense-cedar, rocky mountain maple, willow species, Sitka alder, and the only known quaking aspen stand (shrub form) on the Forest. The area is one of the few glaciated places in the Siskiyou mountains where cirque lakes are still present. The shallower of the two lakes sometimes dries up during the summer, which makes it botanically interesting.



A number of unusual plants are residents of the proposed area (Table F-BOT-5) The concentration and variety of unusual plants is greater here than in any other non-serpentine area on the Forest. Some of the plants, such as *Lilium wigginsii* and *Gentiana setigera* (*pleurisetosa* [sp nova]), are at the northern limit of their range. Other species, such as mountain hemlock and quaking aspen, are at the western edge of their range.



About 296 acres in this proposed Botanical area are tentatively available and suitable for timber production; this land is capable of annually producing about 159 thousand board feet (MBF) of harvestable timber on a long-term sustained yield (LTSY) basis (Table F-3). The Bigelow Lakes site has been divided into two sections; this provides flexibility to land managers who must make decisions on land allocations. The main area contains the lakes and their drainage basin. The addition contains surrounding land outside of the primary drainage basin. The main area is recommended in the Preferred Alternative (S); the addition is not. For further information on these options see Figures F-1 and F-BOT-5.

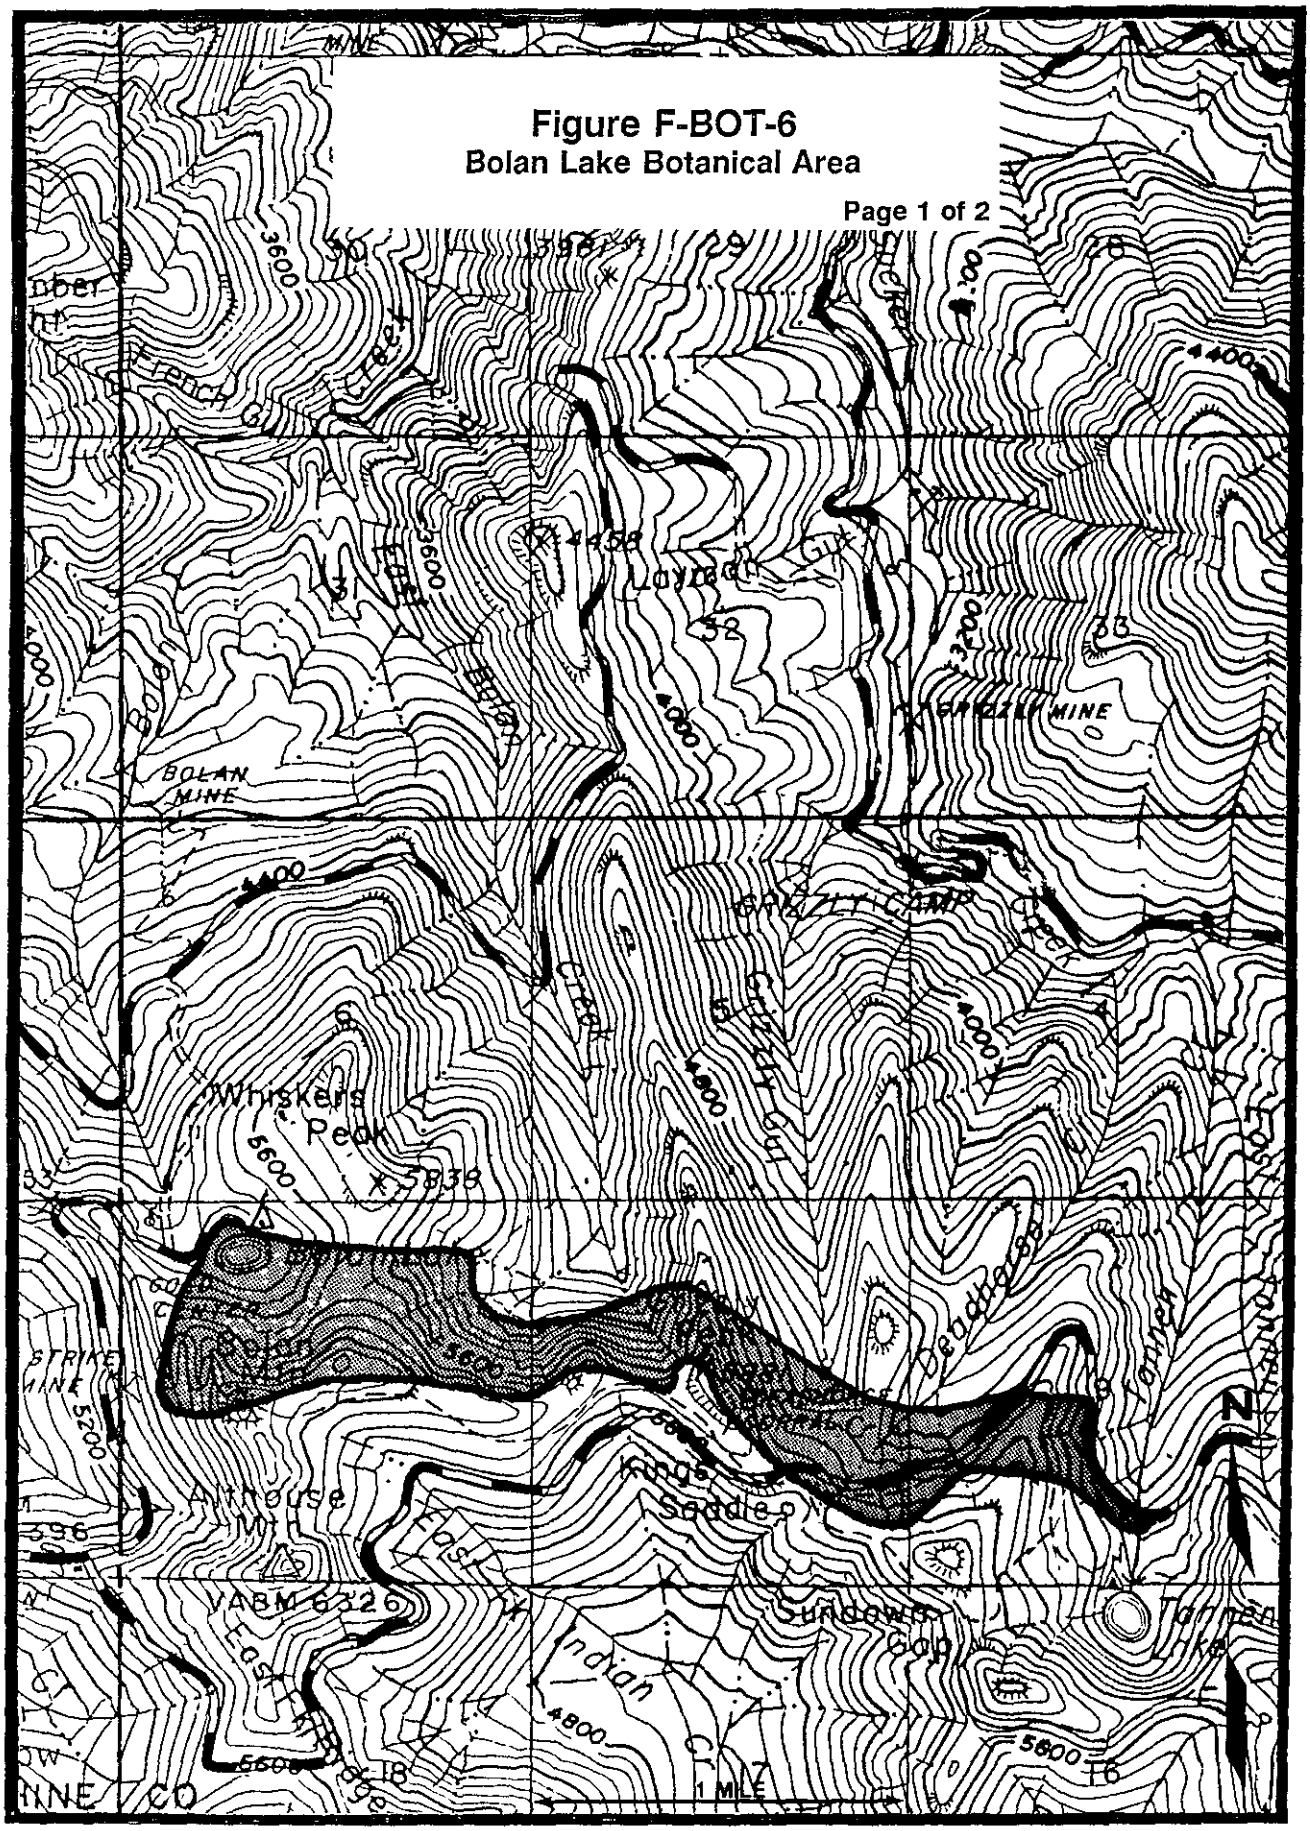


Table F-BOT-5. Unusual Plants in the Proposed Bigelow Lakes Botanical Area

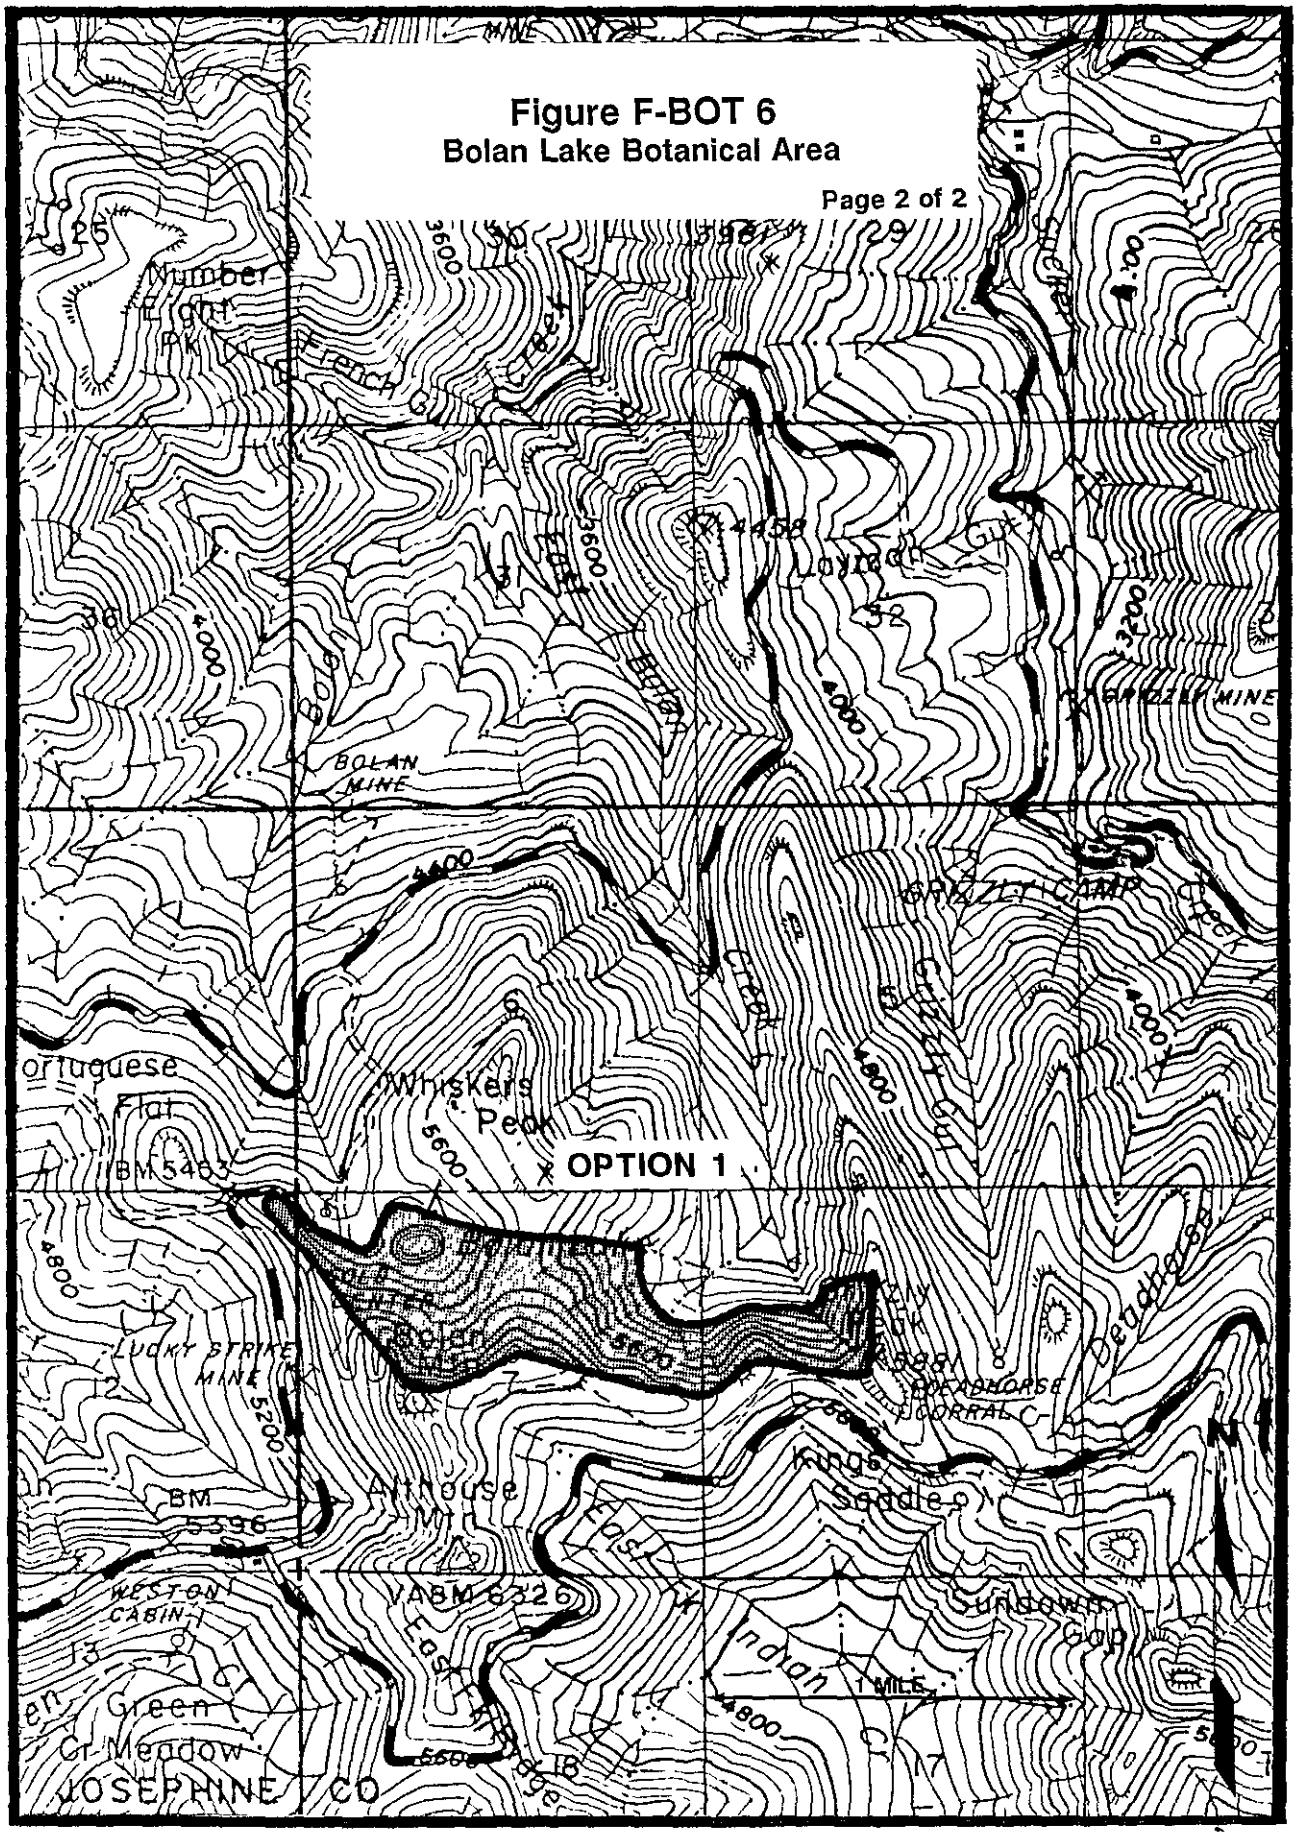

Scientific Name	Common Name
Sensitive Species	
Eriogonum declinum	buckwheat-knotweed
Erythronium howellii	Howell's fawn lily

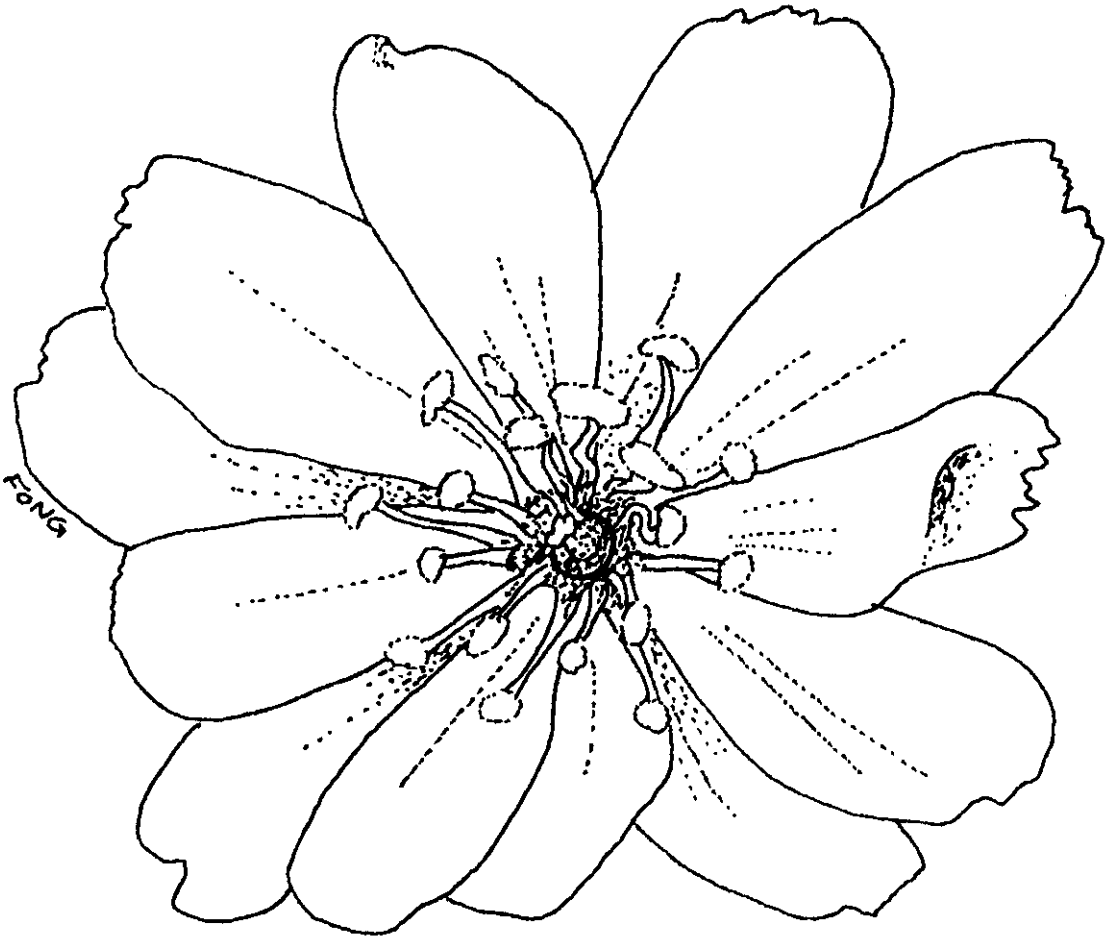
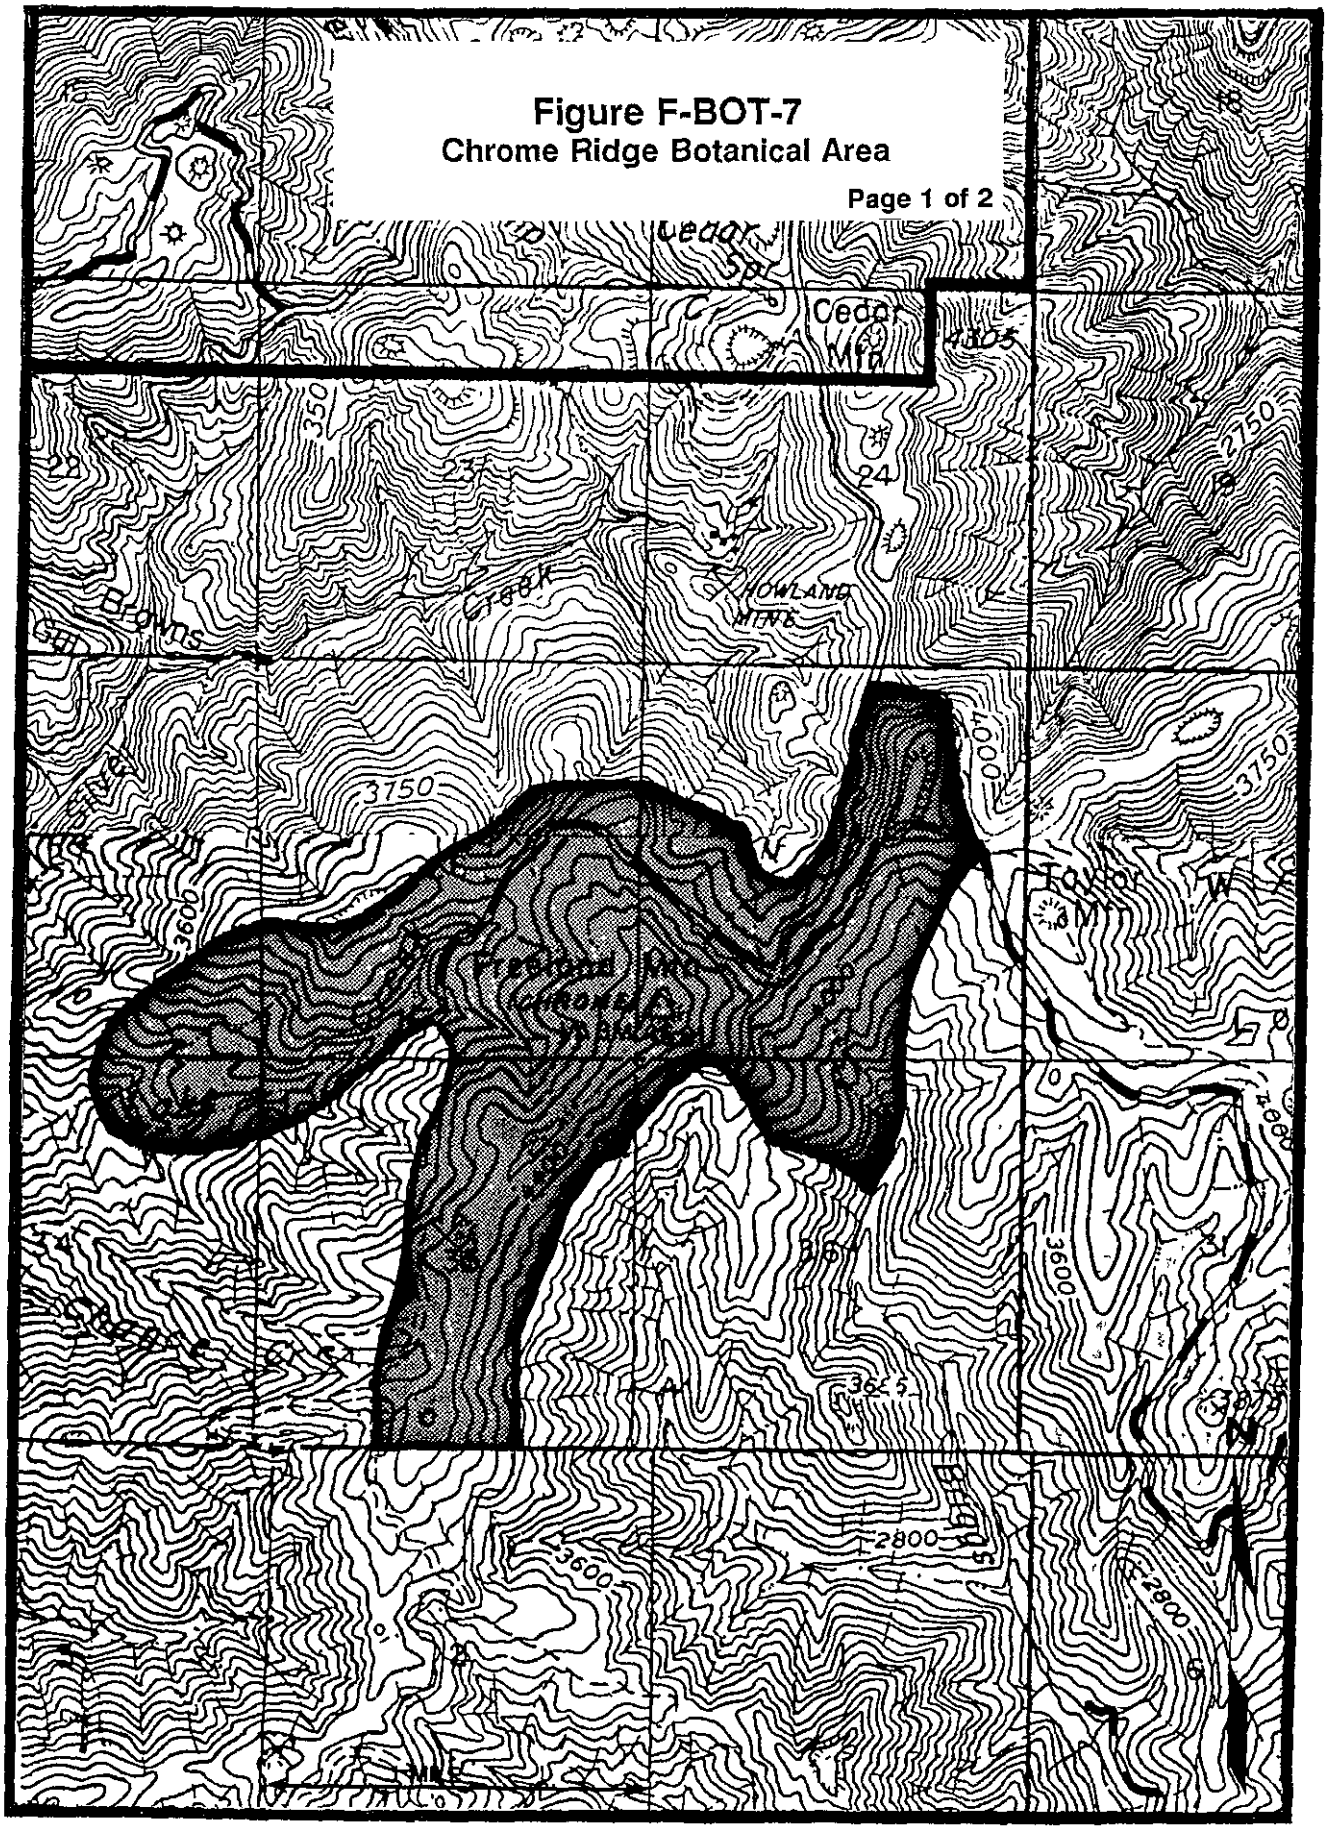
BOLAN LAKE - F-BOT-6

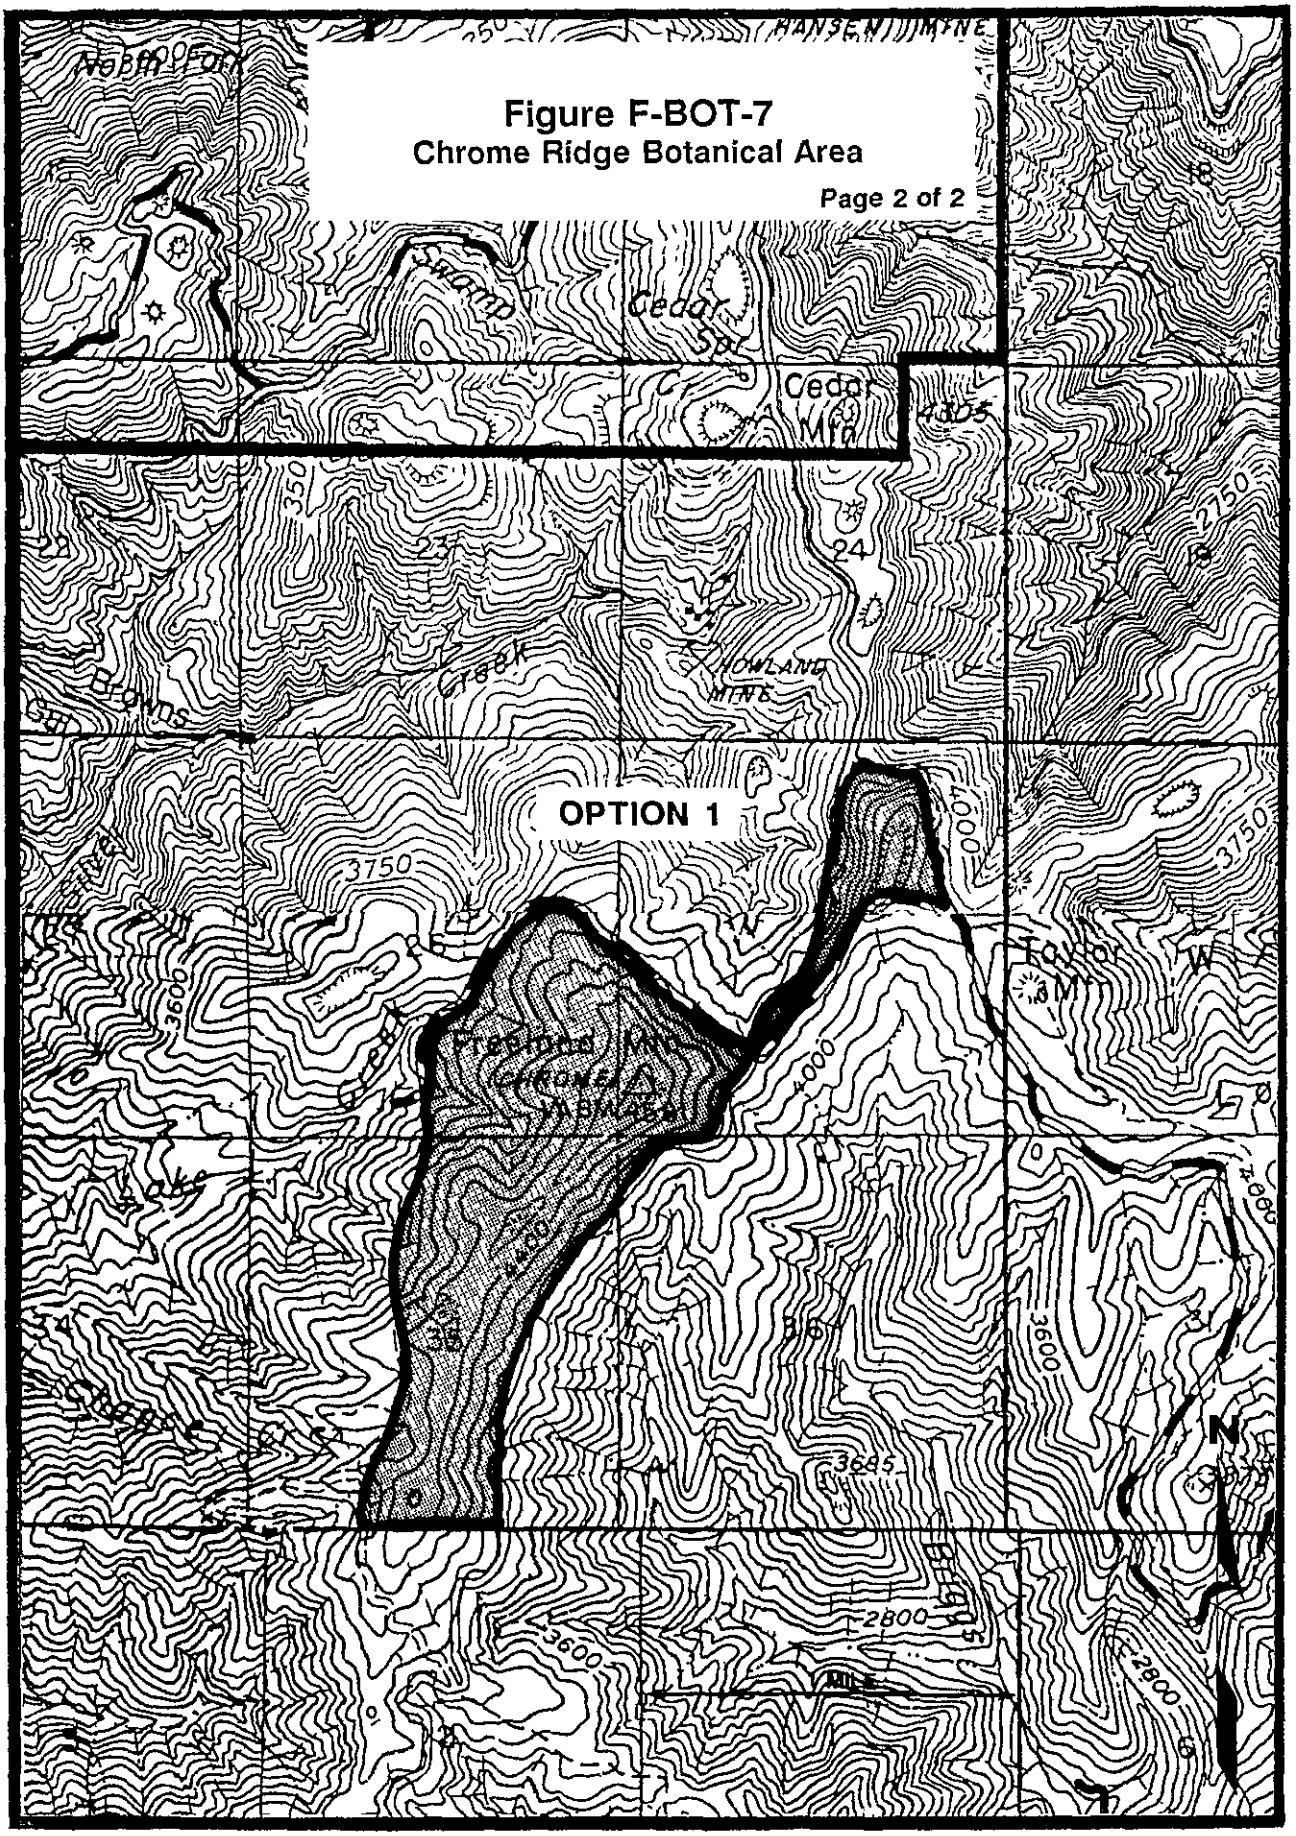
The proposed Bolan Lake Botanical Area is located in the corner of Illinois Valley Ranger District, near the California Border (T.41S., R 6W, Sections 7-9) (Figure F-BOT-6). The proposed area contains approximately 451 acres and is centered on the relatively steep north and west-facing slopes above Bolan Lake and extends east to the Tannen Lakes area. Elevation ranges from 5,000 feet in Grizzly Gulch to 6,269 feet at Bolan Peak Metavolcanic rocks underlay the area At least one abandoned gold mine is located within the area, and recoverable quantities of gold may still be present in the area and nearby vicinity (Ramp and Peterson 1979)



Although intensive general plant inventories of the proposed Bolan Lake Botanical Area are lacking, cliff areas on the north slope are known to contain two species of *Lewisia* (*cotyledon* and *leana*) (Table F-BOT-6). *Lilium wigginsii*, a yellow "tiger lily," occurs in the proposed area near the shore of Bolan Lake In the summer of 1983, Dave Maercklein of the Klamath National Forest conducted an extensive search of the Bolan/Tannen Lakes area for *Pedicularis howellii* (a sensitive species); he found thousands of individual plants in and around the proposed Botanical area (report on file at the Supervisor's office) The Klamath and Siskiyou National Forests are developing a management plan for this species.



About 124 acres in this proposed Botanical area are tentatively available and suitable for timber production, capable of producing about 67 thousand board feet (MBF) of harvestable timber annually on a long-term sustained yield (LTSY) basis (see Table F-3)



In the Preferred Alternative (S) slightly more than half of the area proposed in the DEIS is recommended, plus a small additional piece west of Bolan Lake (Figure F-BOT-6, Page 2 of 2). The boundary adjustments better reflect the distribution of important botanical resources, primarily *Pedicularis howellii*. This species is endemic to the Siskiyou Mountains in a narrow range along the Oregon and California border Some populations are in areas where timber harvesting and road building may take place. An important component of the pending management plan for *Pedicularis howellii* will be the protection of some major Oregon populations including those in the vicinity of Bolan Lake.

Table F-BOT-6. Unusual Plants in the Proposed Bolan Lake Botanical Area.

Scientific Name	Common Name
Sensitive Species	
Lewisia leana	Lee's lewisia
Pedicularis howellii	Howell's lousewort

CHROME RIDGE - F-BOT-7

The proposed Chrome Ridge Botanical Area is located on a ridgetop in the Galice Ranger District (T.35S., R 9W , Sections 25, 26, 35) (Figure F-BOT-7). The proposed area contains some 1,014 acres, 60 percent of which is serpentine habitat Brushfields comprise another 20 percent. Elevation range is about 4,000 to 4,580 feet. Freeland Mountain is in the center of the area Much of the area is open serpentine with scattered shrubs and Jeffrey pine, although some forested areas are also included.

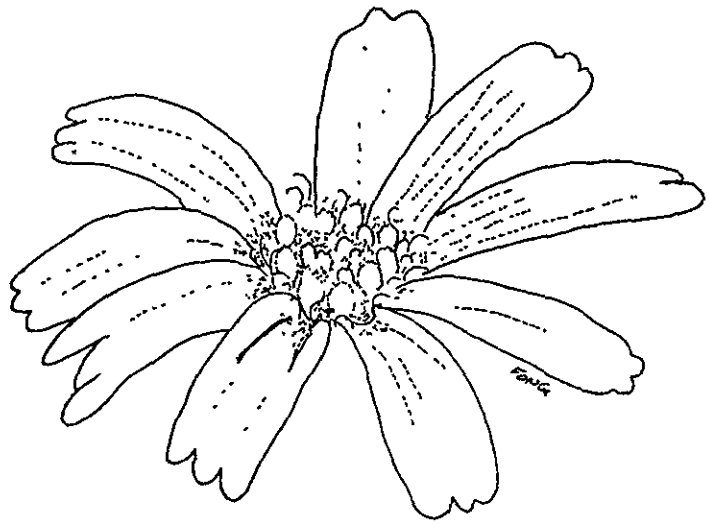
Forest Service personnel for years have been aware of the high botanical values of the Chrome Ridge Area and several times have informally proposed the site as a Botanical area Although the proposed Chrome Ridge Botanical Area has not been thoroughly inventoried, a variety of rare plants have been found there by local botanists (Table F-BOT-7) The only patch of *Kalmiopsis leachiana* presently accessible by road is located in the northwest corner of the proposed area A local botanist, Mary Paetzel, has located several sites that contain relatively large numbers of *Lilium bolanderi*. Mary has conducted numerous plant surveys of the area and catalogued well over a 100 plant species (reports are on file at the Supervisor's Office). After a trip to the area in July 1981, she had this to say about the headwaters of Lake Creek

> In the upper levels, at this time of year, the water runs a few hundred feet then goes underground, suddenly reappearing farther down. Through the middle part, where the tree and brush cover is most dense, the water runs continuously, forming pools and small waterfalls where the maidenhair ferns grow among rocks wet with spray. Islands of *Darlingtonia* are dotted all along the streamside, even on the drier upper reaches. They become thicker and taller deeper into the canyon. Snow-plant and Bolander's lily are seen occasionally on the dry banks above the stream, and young Brewer spruce are scattered all along the middle and lower levels.

She also noted the presence of California lady's slipper and other interesting plants, and further wrote·

> Here is an unique, untouched little piece of wilderness with a most interesting ecosystem. Rugged, to the point of being almost impassable on foot, yet a very fragile, finely balanced community of associated plants, trees and water.

Most of the soils in the proposed area are derived from ultramafic rock. No deposits of nickel-bearing laterites have been mapped within the area, but some chromite deposits have been mined and may be of commercial interest in the future (Ramp and others 1977).



About 430 acres in this proposed Botanical area are tentatively available and suitable for timber production; this land is capable of producing about 232 thousand board feet (MBF) of harvestable timber annually on a long-term sustained yield (LTSY) basis (see Table F-3).

In the Preferred Alternative (S) a portion of the area is recommended; this area contains the best rare plant resources (Figure F-BOT-7, Page 2 of 2).

Table F-BOT-7. Unusual Plants in the Proposed Chrome Ridge Botanical Area.

Scientific Name	Common Name
Sensitive Species	
Fritillaria glauca	Siskiyou fritillaria
Watch/Review Species	
Arabis aculeolata	Waldo rock cress
Darlingtonia californica	California pitcher plant
Kalmiopsis leachiana	kalmiopsis
Lilium vollmeri	Vollmer's lily
Sedum laxum ssp *heckneri* 1/	lax stonecrop

1/ Potential candidate for Regional Forester's sensitive list.

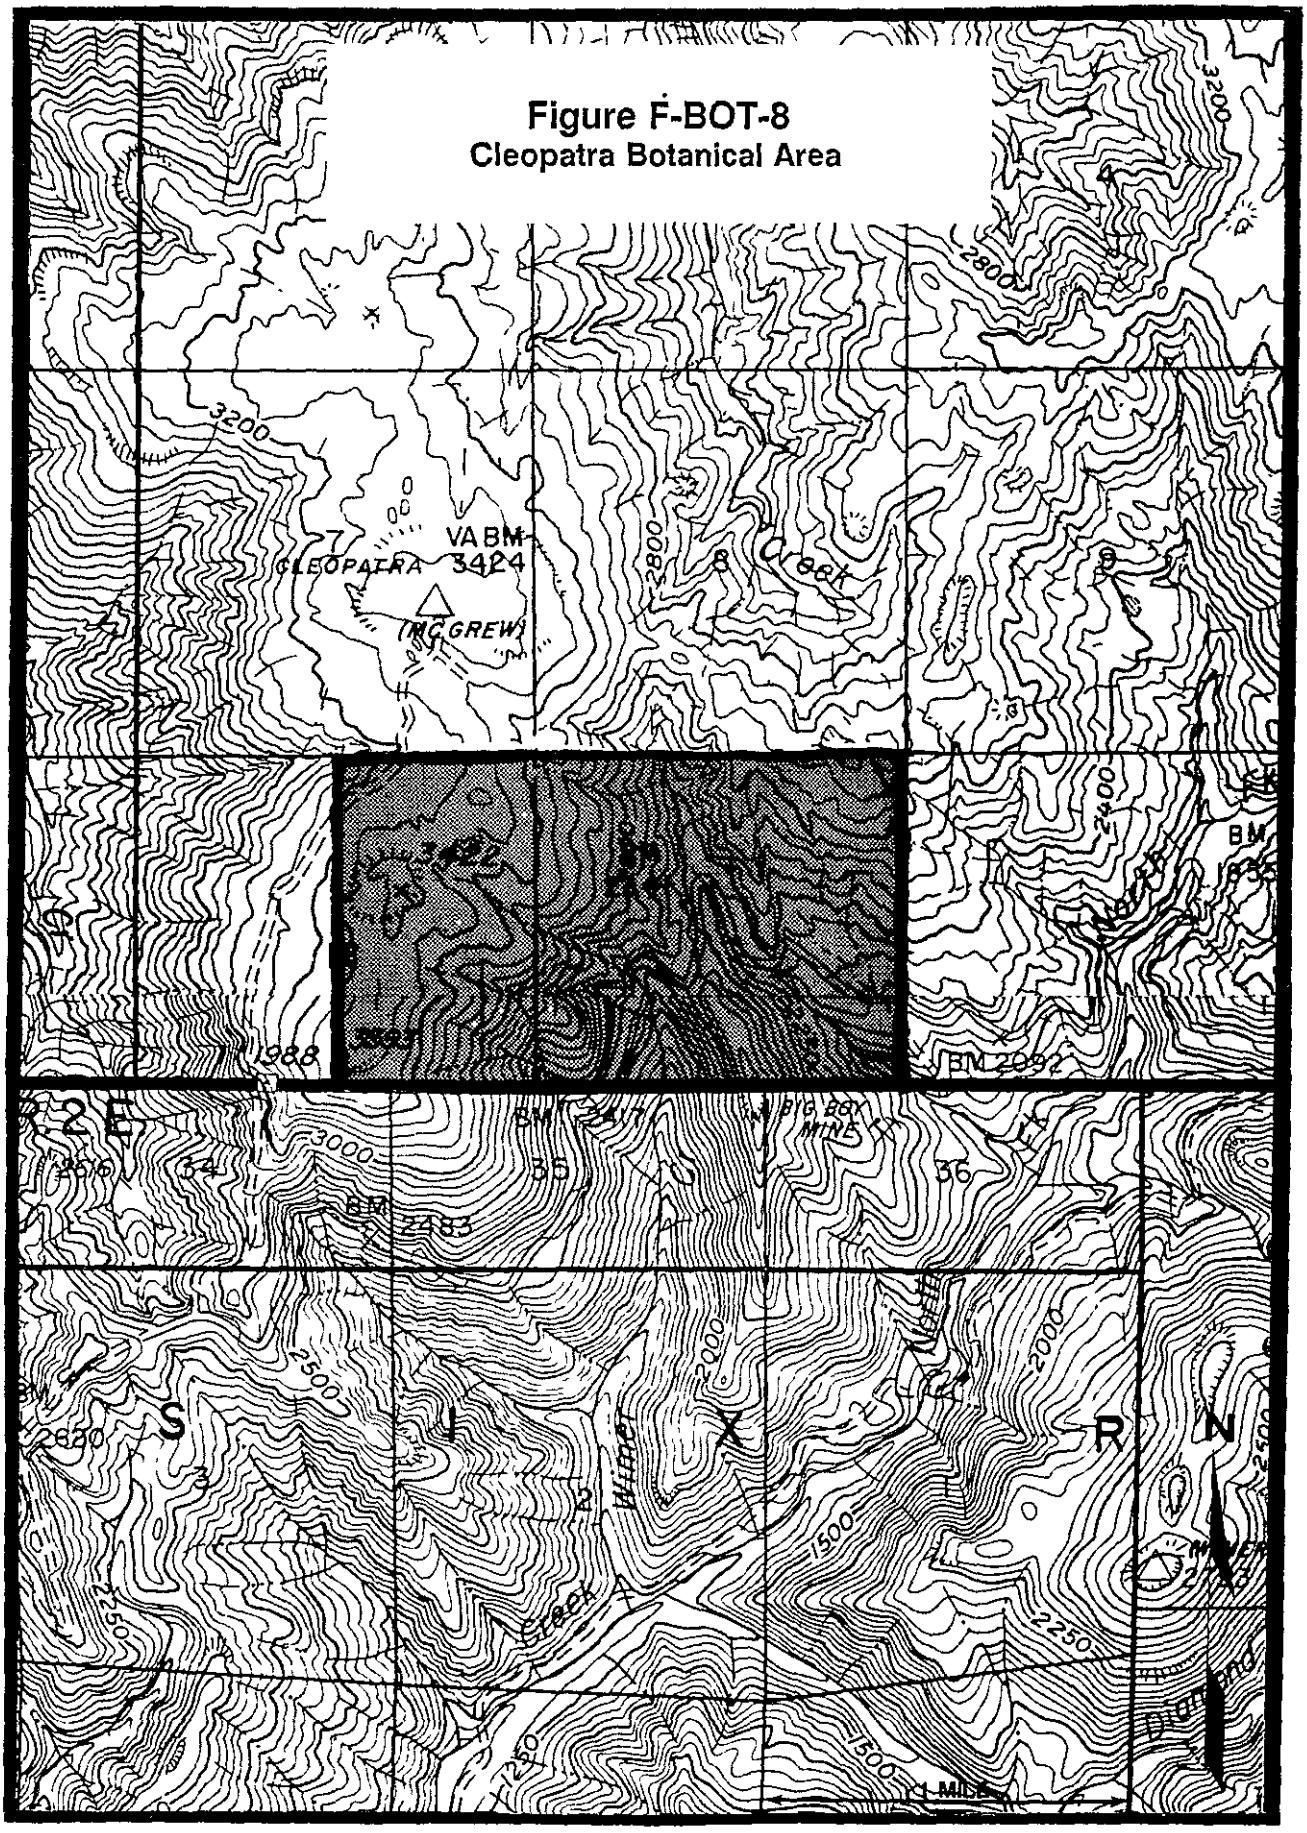


Figure F-BOT-8
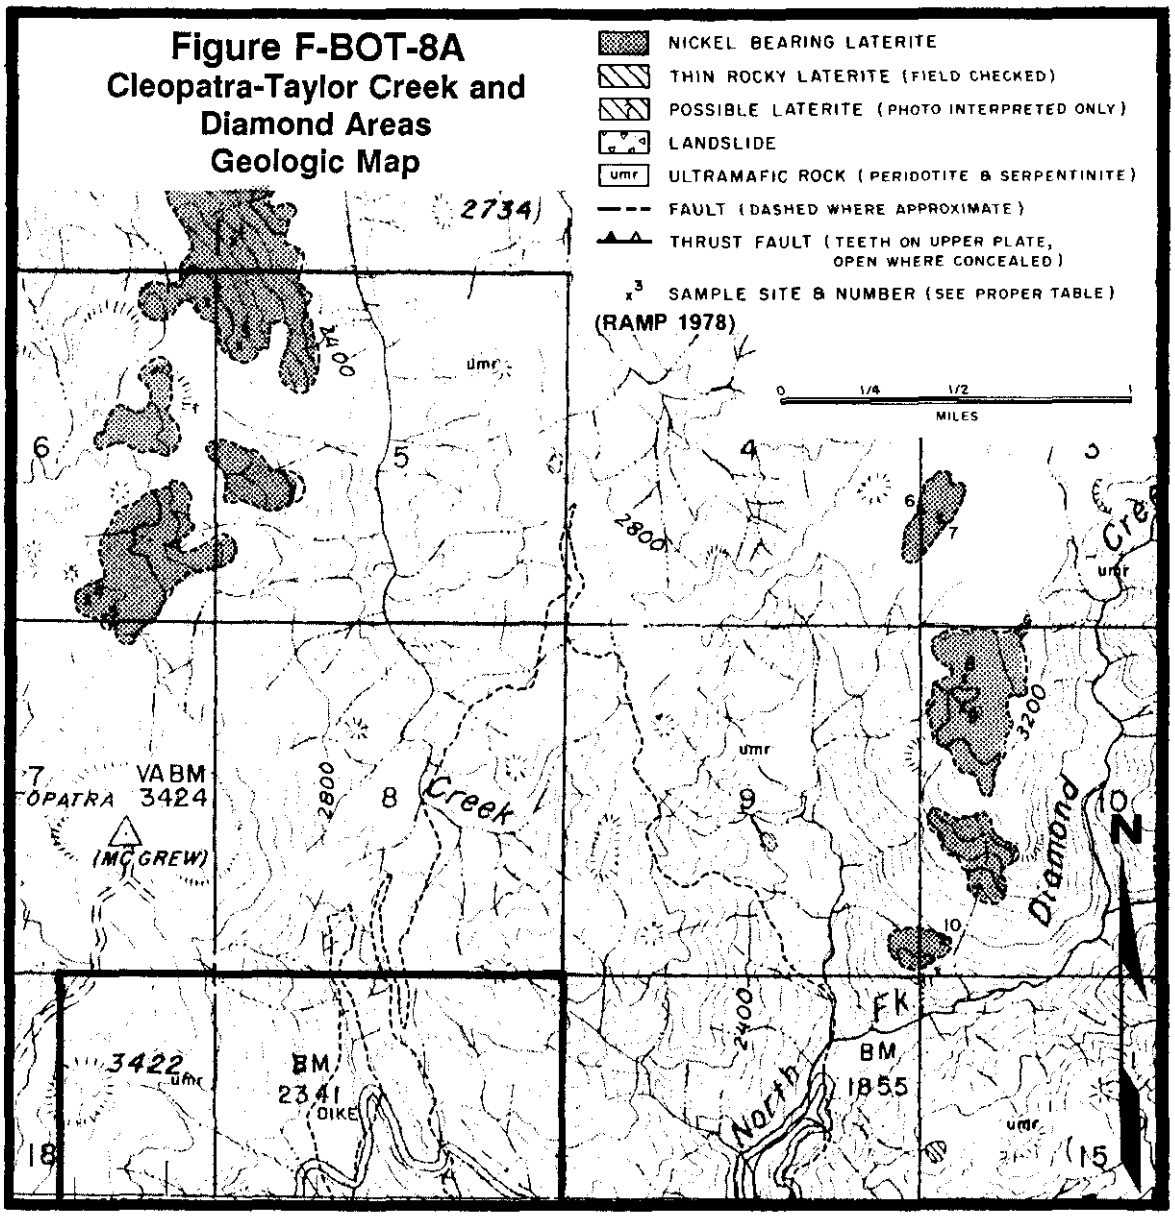
Cleopatra Botanical Area

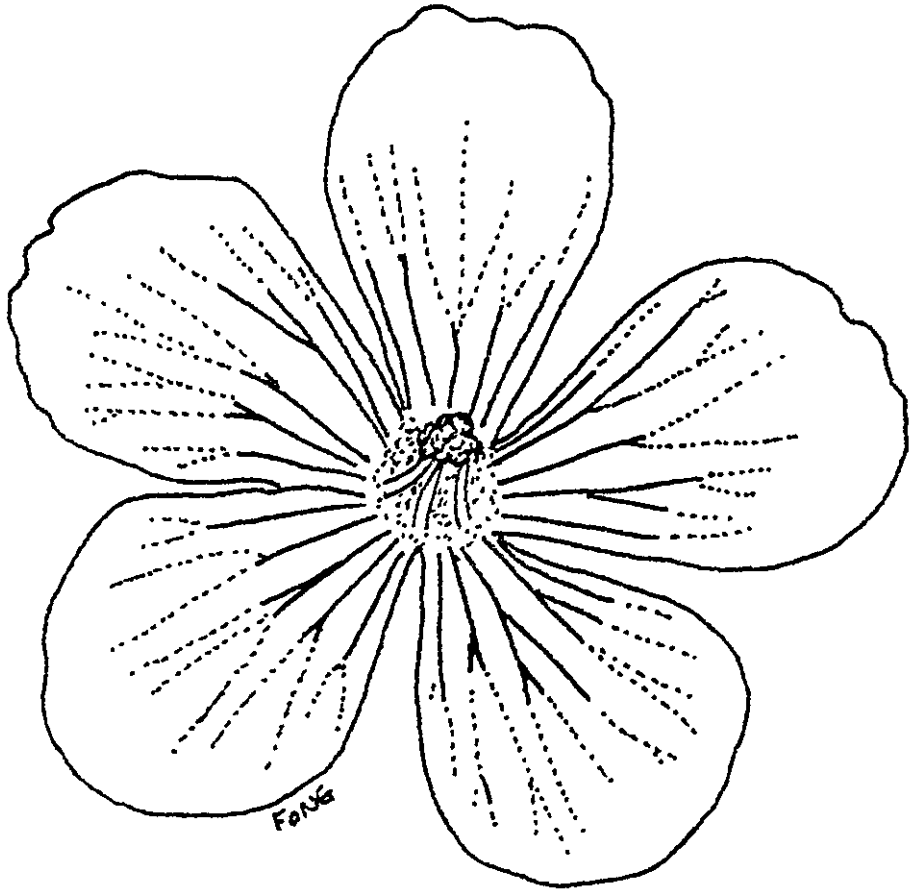
CLEOPATRA - F-BOT-8

The proposed Cleopatra Botanical Area is located in the southwest corner of the Illinois Valley Ranger District, just southeast of Cleopatra Mountain and adjacent to the California border (T.41S., R 10 W., Sections 17 and 18) (Figure F-BOT-8). The proposed area contains 800 acres; 97 percent is serpentine habitat Elevation range is approximately 2,000 to 3,422 feet.

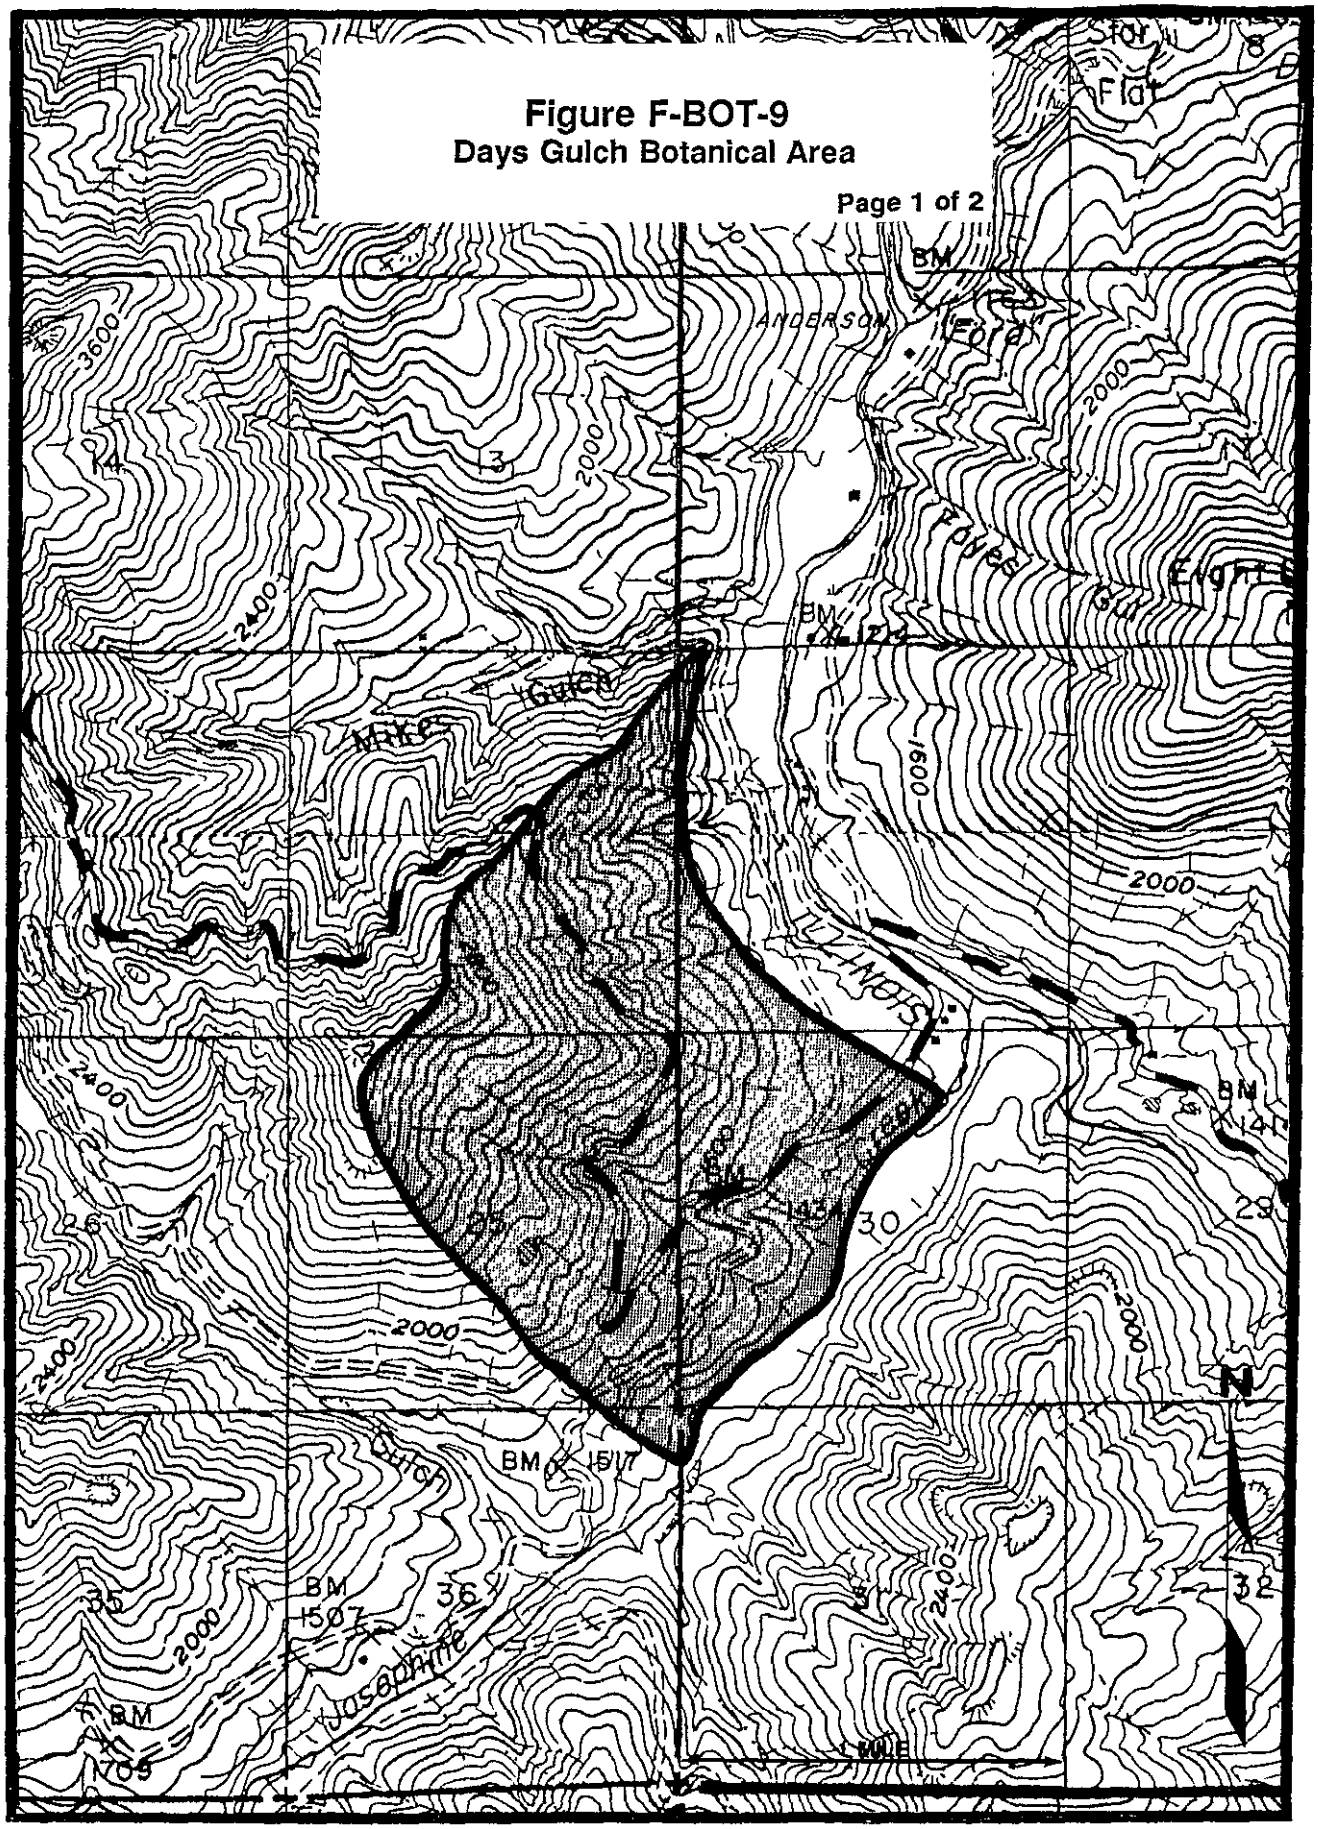
The Cleopatra area is the only known occurrence site in Oregon for McDonald's Rock Cress (*Arabis "macdonaldiana"*), except for a small population in the Packsaddle Mountain area a few miles west. Most of *Arabis "macdonaldiana's"* range is within California, in Del Norte County near the Oregon border, and on a small site in Mendocino County. Less than 100 plants are known to occur at two locations in the proposed Cleopatra Botanical Area (Figure F-BOT-8).



The Siskiyou population of *Arabis "macdonaldiana"* was at one time classified as endangered, because it was thought to be identical to a species of rock cress growing on Red Mountain, Mendocino County, California It has since been determined by the Fish and Wildlife Service (USDI), that the Siskiyou's version of the plant is an as-yet undescribed member of the purple *Arabis* complex. The NW California/SW Oregon populations of *Arabis* sp. nov./in ed (*"macdonaldiana"*) are now classified sensitive by the Forest Service (Region 6) A few other unusual plants also occur in the proposed Cleopatra Botanical Area (Table F-BOT-8). Future field surveys will probably turn up additional populations of *Arabis "macdonaldiana"* and other uncommon species. Cleopatra is not recommended in the Preferred Alternative (S)



About 249 acres in this proposed Botanical area are tentatively available and suitable for timber production, this land is capable of producing about 134 thousand board feet (MBF) of harvestable timber annually on a long-term sustained yield (LTSY) basis (see Table F-3).



Most of the soils in the area of this proposal are derived from ultramafic rock. No deposits of nickel-bearing laterites have been mapped within the area, but prospects for mercury are present (Ramp and Peterson 1979) (Figure F-BOT-8A).

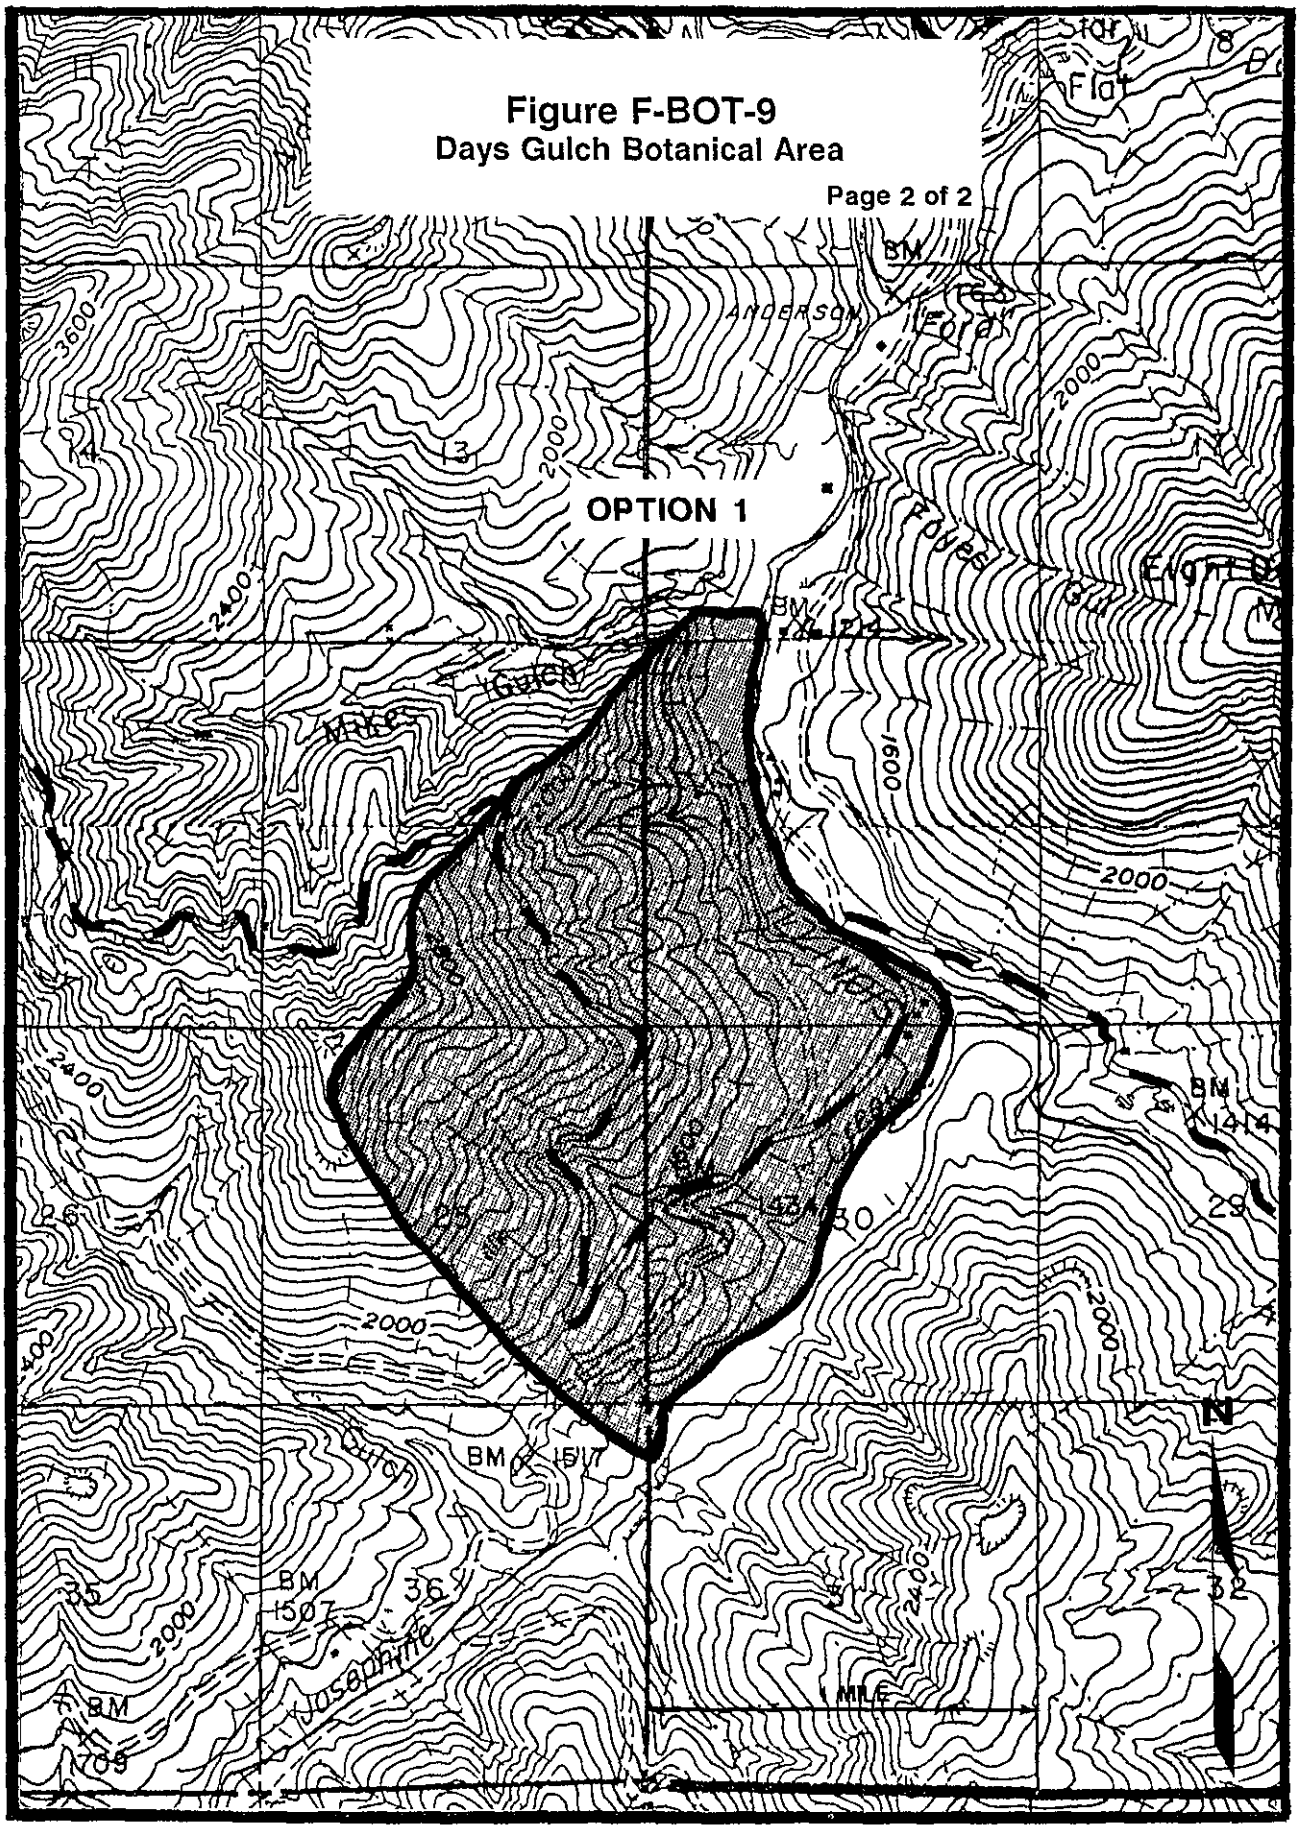


Table F-BOT-8. Unusual Plants in the Proposed Cleopatra Botanical Area.

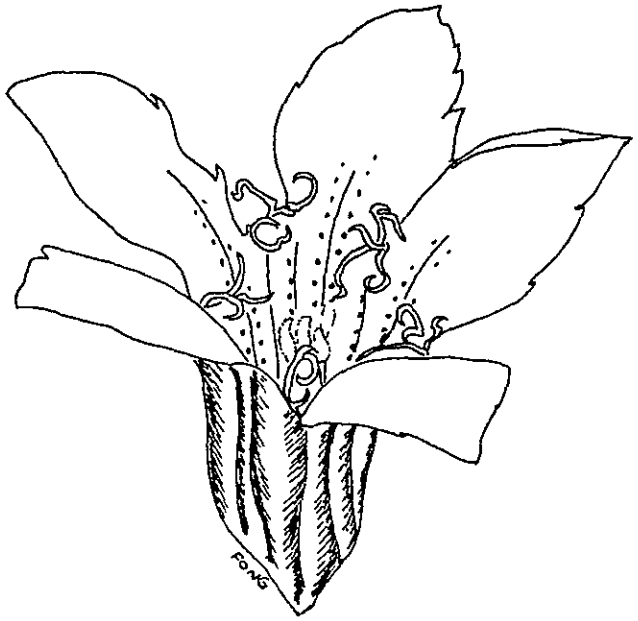
DAYS GULCH - F-BOT-9

The proposed Days Gulch Botanical Area is located two miles southeast of Eight Dollar Mountain, on the Illinois Valley Ranger District (T 38S., R 8W., Secs. 19 and 30, and T.38S., R 9W , Secs. 24 and 25) (Figure F-BOT-9) The proposed area contains some 1,252 acres, all serpentine habitat. Elevation range is approximately 1,500 to 3,200 feet; slopes face east. The proposed Botanical area is bordered by Josephine Creek on the southeast and is bisected by Forest Service road 4201. This general area is well known to botanists and popularly referred to as "Days Gulch", although Days Gulch itself is located just southeast of the proposed Botanical area This proposed site is home to a large number of sensitive and unusual plants (Table F-BOT-9).

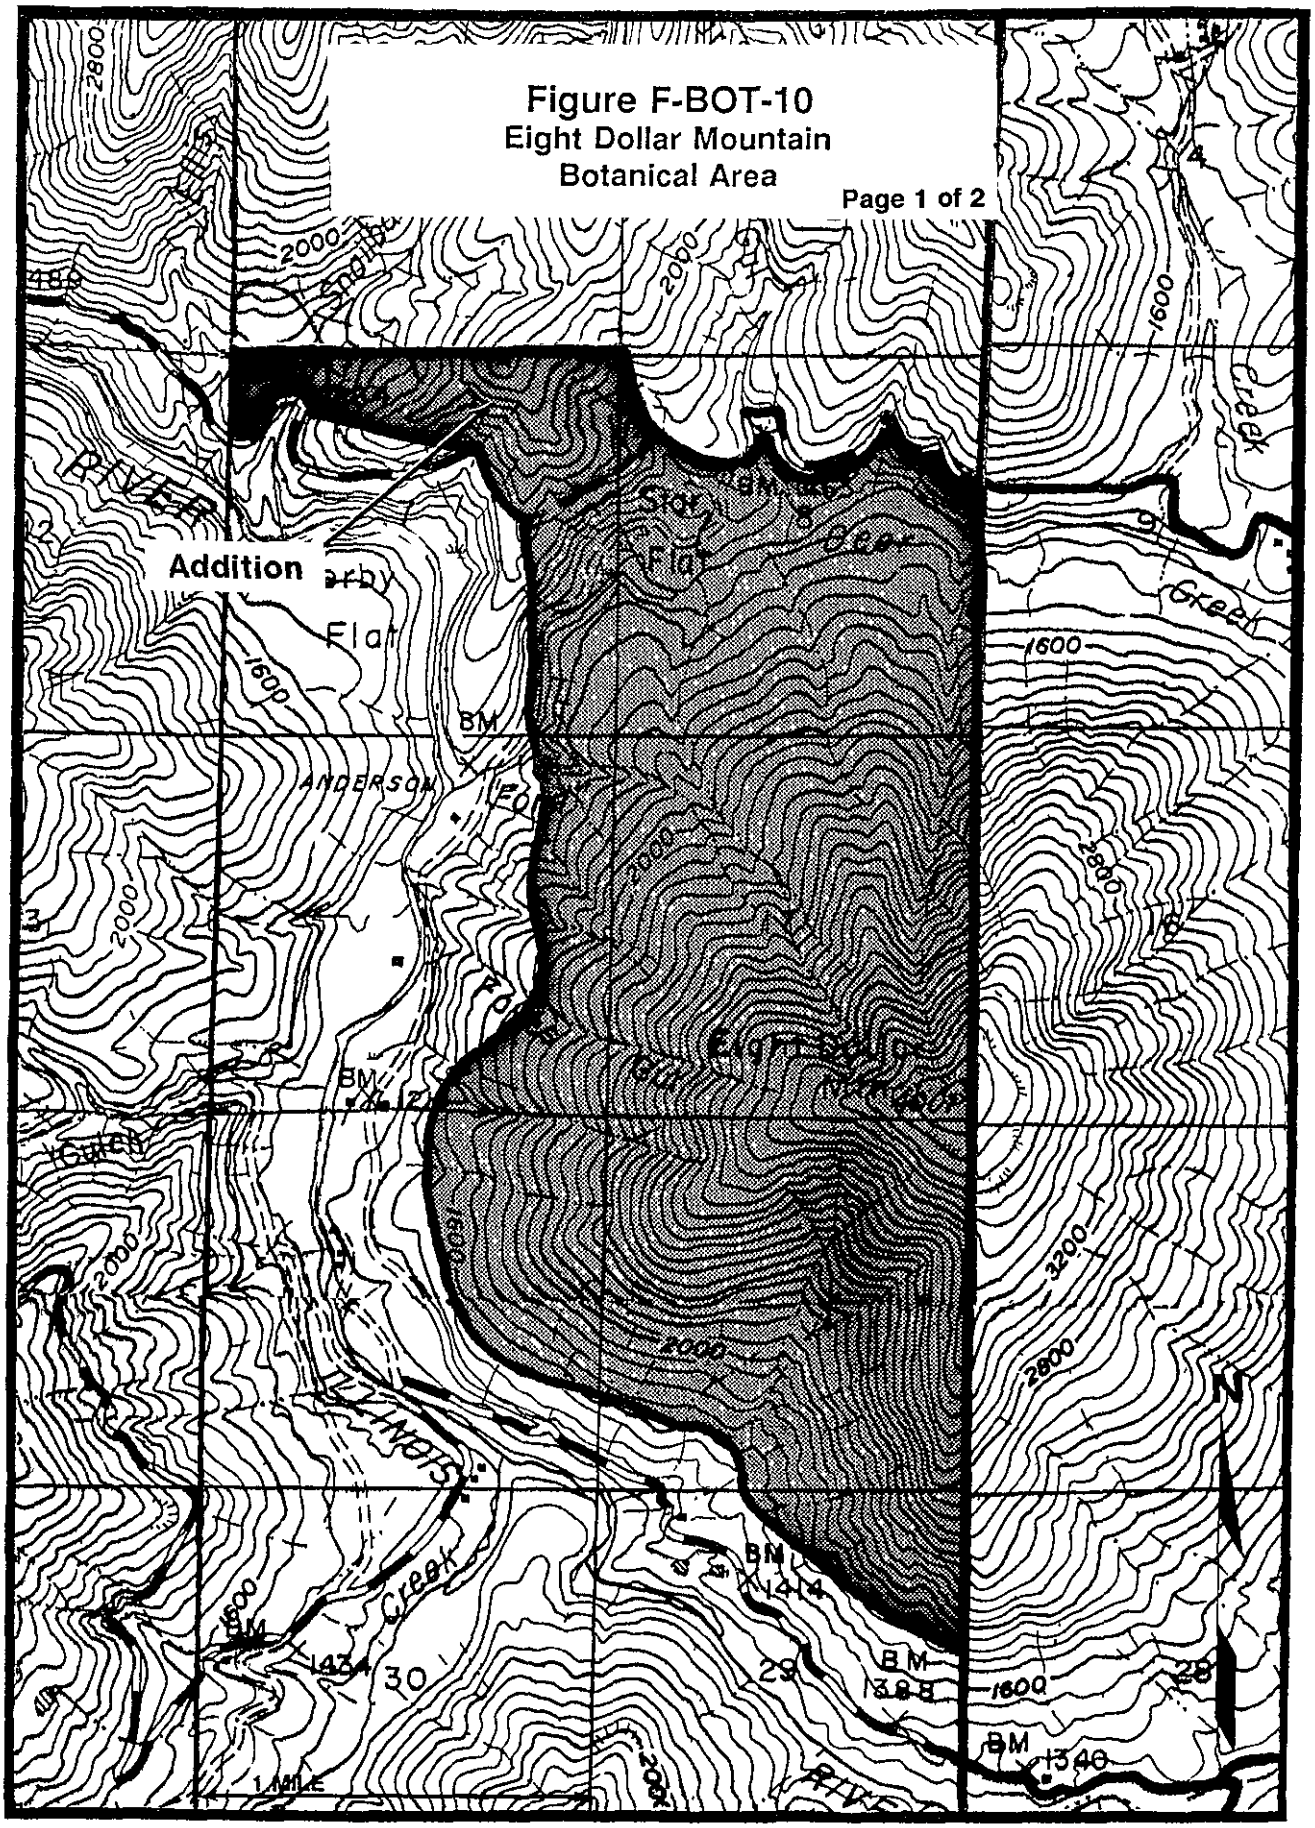
The centerpiece of the Days Gulch area is a large *Darlingtonia* bog in the southeastern corner of section 25, near the switchback on road 4201; the site is a frequent destination for people who want to view the botanical wonders of the Eight Dollar Mountain area. This delicate bog harbors a number of interesting species; among them are Waldo gentian, California lady's-slipper, California pitcher-plant, western azalea, butterwort, and California coneflower. Surrounding the bog one can find shooting stars, lewisia, Siskiyou butterweed, pennycress and many other species.

Other *Darlingtonia* bogs are present in the area, and a small shallow pond is located near the center of section 25 In 1983 a permanent transect (for plant inventory) was laid out SW to NE from above the pond, down hill to the Illinois River. The pond border harbors an extensive display of shooting stars. Intensive plant inventories have not been conducted in much of the area; future field surveys will undoubtedly turn up fascinating botanical details about this important site.

In the FEIS The Illinois Wild and Scenic River corridor adjacent to the Days Gulch site is included in the proposed area The river corridor is just as interesting botanically, but in the DEIS had not been included in the proposed Days Gulch Botanical Area. Designation of the Illinois River as Wild and Scenic results in protection of plant resources in the corridor. For more information on this botanically unique corner of the Forest, refer to the following narrative about Eight Dollar Mountain.



Only 21 acres of the land in this proposed Botanical area is tentatively available and suitable for timber production; this land is capable of annually producing about 11 thousand board feet (MBF) of harvestable timber on a long-term sustained yield (LTSY) basis (see Table F-3). The soils in the area are derived from ultramafic rock. No deposits of nickel-bearing laterites have been mapped within the area, but an active gold mine is located in the southern tip of the area A small amount of chromite was mined in the northern portion of the area in the 1950's (Ramp and Peterson 1979).



The Days Gulch Botanical area is recommended in the Preferred Alternative (S), and includes the adjacent Scenic River corridor along the east bank of the Illinois River (Figure F-Bot-9, Page 2 of 2).

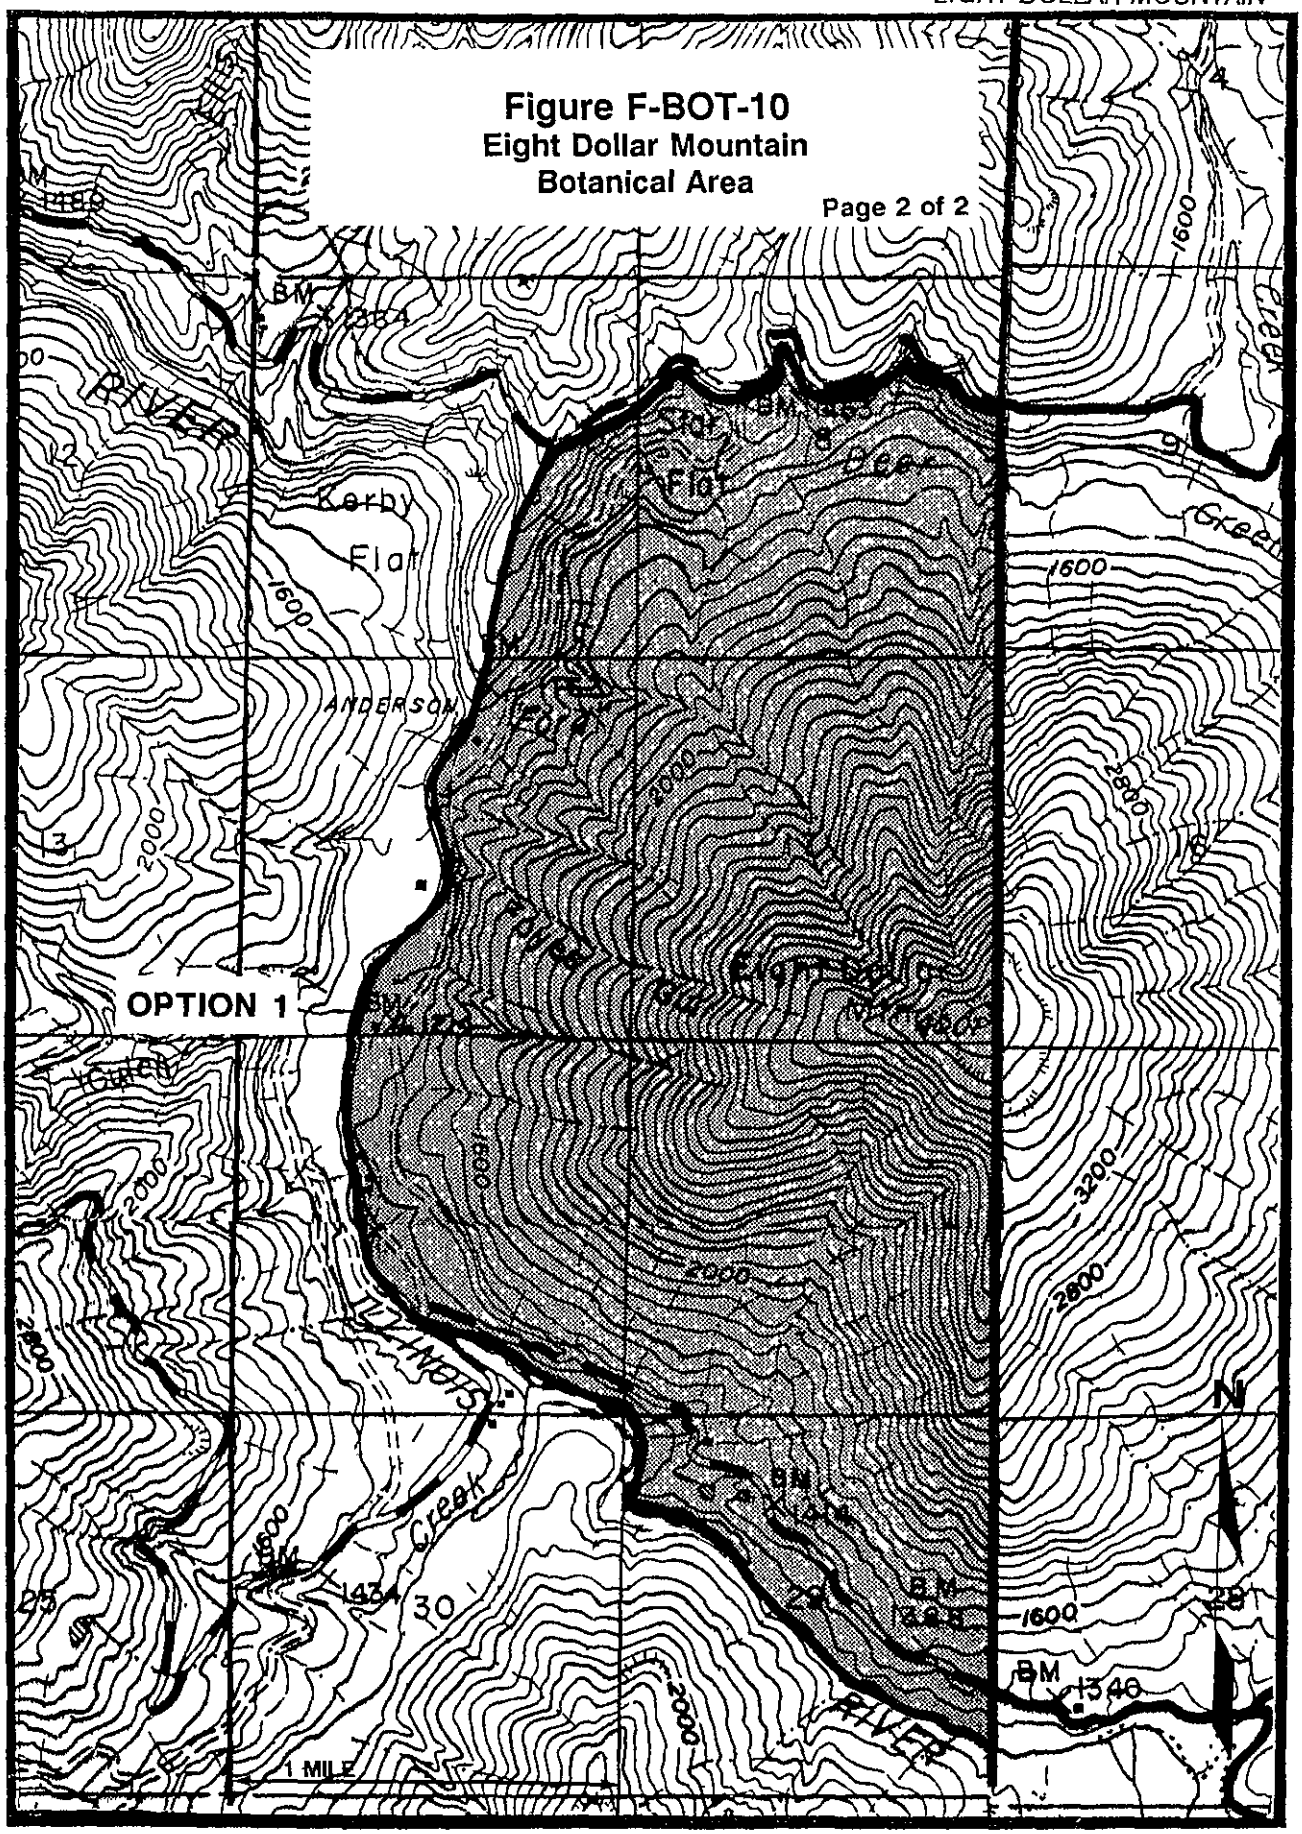


Table F-BOT-9. Unusual Plants in the Proposed Days Gulch Botanical Area.

Scientific Name	Common Name
Sensitive Species	
Allium bolanderi	Bolander's onion
Balsmorhiza sericea	silky balsamroot
Calochortus howellii	Howell's mariposa lily
Epilobium oreganum	Oregon willow-herb
Fritillaria glauca	Siskiyou fritillaria
Gentiana bisetaea	Waldo gentian
Hastingia bracteosa	large-flowered rush lily
Lewisia oppositifolia	opposite-leaved lewisia
Microseris howellii	Howell's microseris
Senecio hesperius	Siskiyou butterweed
Viola lanceolata ssp. *occidentalis*	western violet
Watch/Review Species	
Arabis aculeolata	Waldo rock cress
Castilleja elata	slender paintbrush
Cypripedium californicum 1/	California lady's-slipper
Darlingtonia californica	California pitcher-plant
Dicentra formosa ssp. *oregana*	Oregon bleeding heart
Lilium vollmeri	Vollmer's lily

EIGHT DOLLAR MOUNTAIN - F-BOT-10

The proposed Eight Dollar Mountain Botanical Area is located on the Illinois Valley Ranger District (T.38S , R 8W., Secs. 7, 8, 17, 18, 19, 20, and 29) (Figure F-BOT-10) The proposed area contains some 2,738 acres; almost all is serpentine habitat. Elevation range is approximately 1,200 to 4,000 feet. The proposed Botanical area encompasses the west half of Eight Dollar Mountain, including Star Flat and the mouth of Deer Creek In the FEIS The Illinois Wild and Scenic River corridor adjacent to Eight Dollar Mountain is included in the proposed area. The river corridor is just as interesting botanically, but in the DEIS had not been included in the proposed Days Gulch Botanical Area. Designation of the Illinois River as Wild and Scenic results in protection of plant resources in the corridor. In the Preferred Alternative (S), the entire National Forest portion of Eight Dollar Mountain is recommended, including the adjacent Scenic River corridor; the Addition is not included (see Figure F-Bot-10, Page 2 of 2).

The proposed Eight Dollar Mountain Botanical Area has been divided into two parts (the "Addition" contains land not part of the Mountain); this provides flexibility to land managers who must make decisions on land allocations. For further information on these options see Figures F-1 and F-BOT-10. The "Addition" area is part of the Squaw Mountain Roadless Area (see Appendix C, FEIS). The plant list for the Squaw Mountain Roadless Area primarily represents plants found in the "Addition" area

The entire Eight Dollar Mountain ecosystem encompasses about 4,400 acres of private and public lands in southwest Oregon. Ownership or administration of the lands on the east half consists of private (including The Nature Conservancy), Josephine County, State of Oregon, and the BLM (Bureau of Land Management). Except for a small amount of private land, the west half of the mountain is managed by the Forest Service (this is the proposed Botanical area).

Eight Dollar Mountain is one of the most significant botanical sites in Oregon, representing the major area of species endemism in the state. The mountain provides diversified habitats for eleven candidate species (9 percent of those listed for Oregon) which are under review by the USDI Fish and Wildlife Service for listing as threatened or endangered.

Since the 1880's, botanists from Oregon and many other parts of the world have known Eight Dollar Mountain (and Oregon Mountain) as an important focal point for uncommon plants Many of the serpentine endemics found in southwest Oregon and northwest California are most abundant here. Many large *Darlingtonia* bogs are present on Eight Dollar Mountain; an especially large hillside bog is located in the southwest quadrant of the Mountain (National Forest land). A number of other rare plants are associated with these bogs, such as *Cypripedium californicum*, *Lilium vollmeri*, *Senecio hesperius*, *Viola lanceolata* ssp. *occidentalis*, *Gentiana bisetaea*, and *Hastingsia bracteosa* (the last two are known from Eight Dollar Mountain and only a few other sites). Unusual plants on dry serpentine sites are also well represented, with species such as *Arabis aculeolata*, *Dicentra formosa* ssp. *oregana*, *Microseris howellii*, and a number of others. Sixteen sensitive plant species are known to occur on the National Forest portion of Eight Dollar Mountain; this is 25 percent of the total for the Forest (Table F-BOT-10).

Eight Dollar Mountain is an ideal site for the study of plant distribution and development. Where plants are and how they develop (or change over time) is very much related to elevation and aspect The proposed Eight Dollar Mountain Botanical Area has an extensive elevation range and all aspects are represented. In addition, the soils are derived from one type of parent material and rainfall is uniform in the entire proposed area (approximately 75 inches).

Aerial photographs (1:24,000 color) of the serpentine/peridotite areas of the Forest and adjacent lands were examined for the presence of large bogs (approximately two acres or larger). In terms of size and concentration, bog habitat reaches maximum development on Eight Dollar Mountain. The largest bogs are outside of the Forest boundary, on the east half of the mountain. However, bogs within the proposed area are larger and more numerous than elsewhere within the Forest.

Timber Resources. About 50 acres in this proposed Botanical area are tentatively available and suitable for timber production (all in the Eight Dollar Mountain Addition); this land is capable of annually producing about 27 thousand board feet (MBF) of harvestable timber on a long-term sustained yield (LTSY) basis (see Table F-3).

Mineral Resources. There is moderate to high potential for user conflicts between plant and mineral resources Much of the proposed Eight Dollar Mountain Botanical Area is covered by mining claims.

Soils in the proposed area are derived from ultramafic rock. A number of nickel-bearing laterite deposits have been mapped in the general area; some are within the proposed area (Figure F-BOT-10A, Table F-4) Nickel assay samples from ore deposits within the Eight Dollar Mountain area, range from 0.32 to 1.00 percent. Chromite ore has been mined at several locations within the area.

Len Ramp (1978:28) has mapped mineral deposits in the Eight Dollar Mountain Area. He described the mountain as:

> .. a roughly cone-shaped erosional landform of periodotite (hazburgite) and serpentinite intruded by a few small basic to intermediate dikes, e.g., diabase. The ultramafic rocks have a relatively high-angle, west-dipping fault contact; with steeply dipping slatey siltstone and sandstone of the Galice Formation near the east base of the mountain; and a high-angle, northeast-trending fault contact with Jurassic metavolcanic rocks of the Rogue Formation, a short distance down the Illinois River from the mouth of Deer Creek.
>
> The main ore deposits are on the southeast flank of the mountain in Section 21 and NW1/4 Section 28 [not on National Forest land]. They appear to be remnants of old landslide or slump deposits. A fair abundance of silica boxwork float, at various places on Eight Dollar Mountain, indicates the probability of some garnierite at fairly shallow depths.

In a informal discussion between State Geologist Len Ramp and Forest Wildlife Biologist Lee Webb, Ramp indicated he felt the most important nickel laterite deposits on Eight Dollar Mountain are not on the Siskiyou National Forest Laterite deposits on the proposed Botanical area (National Forest land) would only be commercially important if smelting grade deposits, such as those in the proposed area, were used to amortize investments made in a smelter initially built to utilize ore from higher grade deposits.

A cursory estimate of the nickel resources of the proposed area indicates that potential gross value could be as high as 200 million dollars. This gross value is based on a set of problematical assumptions: (a) five million tons of nickel laterite ore are available within the Botanical area (less than this amount may actually exist), (b) average nickel content of the ore is 0.7 percent; (c) the value of nickel is $3.00 per pound, or $42 00 per ton of ore; (d) the cost of transporting ore to the smelting site is not prohibitive. It is important to realize that nickel laterite deposits in the botanical interest area have **potential** value, rather than **actual**; at present, these deposits could not possibly be mined at a profit.

Impacts of Grazing and Water Withdrawal. Parts of Eight Dollar Mountain have been grazed in the past by cattle Potential impacts of grazing on the mountain's plant resources need to be assessed In a 2 July 1979 letter from Gilbert Muth (Pacific Union College) to Tom Jimerson (Botanist, Six Rivers National Forest), Muth described a site on Eight Dollar Mountain that was visited in conjunction with a Six Rivers National Forest contract to determine the range of certain sensitive plant species. Muth noted that in May 1979 Clifton and Overton surveyed a seepage where *Hastingsia bracteosum* occurred and "found the population was considerably trampled, grazed, and polluted by cattle." The site described is in the southwest quadrant of the mountain, on National Forest land. In 1978, Bill Copeland, Plant Ecologist for The Nature Conservancy, noted that the south and west portions of National Forest Land on Eight Dollar Mountain were fairly heavily grazed

On the southeast quadrant of the mountain (non-National Forest land), water sources for some of the bogs are being tapped for domestic use. This could affect the viability of plant communities in bogs located down-slope from the withdrawal point. Water withdrawal on the National Forest portion of Eight Dollar Mountain is not believed to be a problem at present.

Land on Eight Dollar Mountain Managed by Other Agencies. Because of important plant resources, The Nature Conservancy and Josephine's Environment Matters (JEM) proposed to the BLM that land on Eight Dollar Mountain under the Bureau's jurisdiction be designated an Area of Critical Environmental Concern (ACEC-Bureau of Land Management Designation). This same area was also evaluated for National Natural Landmark designation by the Heritage Conservation and Recreation Service (Federal).

The Federal Land Policy and Management Act requires the Bureau of Land Management to identify sites which may be candidates for ACEC status. Because of the botanical values present, on 23 October 1986 the Bureau found that Eight Dollar Mountain met the identification criteria for nomination as an ACEC. Bureau administered lands were formally designated as an ACEC on 27 February 1987.

Section 16, on Eight Dollar Mountain, is under the jurisdiction of the Oregon Division of State Lands. On August 10, 1978, the Natural Area Preserves Advisory Committee recommended that the Division of State Lands decline to issue mineral exploration permits for Section 16. The Committee "determined that the unique and important biological values at Eight Dollar Mountain, especially those within Section 16, would be severely jeopardized or destroyed by mineral exploration or by mining activity." The committee based this recommendation on part of the information in a report entitled *Botanical Survey of Eight Dollar Mountain - May 6-9, 1978.* In the report, Bill Copeland, Plant Ecologist for The Nature Conservancy's Oregon Natural Heritage Program, described the plant communities of the mountain. His field activities were concentrated in Section 16, but a few bog communities were surveyed on other parts of the mountain as well. Much of the data in his report has application to plant communities on that portion of the mountain managed by the Forest Service

Eight Dollar Mountain as an RNA. Scientists in the Pacific Northwest are aware that Eight Dollar Mountain contains cells (plant communities) that are not yet included within existing Research Natural Areas. Cell needs are described in the "Yellow Book" (Dyrness and others 1975).

Unfilled cells present on Eight Dollar Mountain are:

from Table 53

15. Jeffrey pine/grass on serpentine at low elevation
16. Jeffrey pine/grass on serpentine at high elevation

from Table 54

14. Mountain bog in serpentine

Lemmingsworth Gulch, a proposed Research Natural Area on the Chetco Ranger District (Figure F-RNA-7), contains cells which partially overlap with those at Eight Dollar Mountain. This includes numbers 14 and 16 above However, Copeland compared the plant communities and species of Eight Dollar Mountain with the proposed Lemmingsworth Gulch Research Natural Area; significant differences were evident. Basically, Eight Dollar Mountain is an inland version of serpentine habitat and receives one-half the rainfall of Lemmingsworth Gulch, which is influenced by a maritime climate that includes frequent summer fogs. Cell 15 would be filled by the proposed Cedar Log Flat RNA (see RNA narrative section).

Research in progress on the plant communities of southwest Oregon may show the need for representation by more plant communities (cells) than are presently shown in Dyrness and others (1975)

Research Natural Area status for Eight Dollar Mountain has not been actively sought in the past because of perceived conflicts with mineral resources There is a possibility that Research Natural Area status might be pursued at a later date

Eight Dollar Mountain Consensus Group. An Eight Dollar Mountain Consensus Group, composed of private citizens, The Nature Conservancy, and public agencies with land management responsibilities on the mountain, was formed in 1984 Potential conflicts between mineral and botanical resources prompted formation of the group. They held a series of meetings between May 1984 and May 1985 to review the resources and resource management issues on Eight Dollar Mountain.

In April 1986, this group published a final report. *Eight Dollar Mountain Coordinated Management Framework*. The participants (Forest Service, Bureau of Land Management, Josephine County, Division of State Lands, The Nature Conservancy, and Eight Dollar Mountain Landowners Association) also have developed a Memorandum of Understanding (MOU) agreement to manage the mountain in compliance with the Framework. The MOU is still (as of **1 November 88**) in the process of being signed by the participants. Copies of the "Framework" report and MOU agreement are on file at the Supervisor's Office

Management guidelines recommended as a part of this process are outlined in an Executive Summary dated May 1985: *Eight Dollar Mountain Recommended Management Guidelines* (on file at the Supervisor's Office). The consensus group considered five alternative approaches for management of the Mountain These approaches have all been considered during the Forest planning process and are represented in our range of alternatives for the Forest Plan.

Coordinated Management Framework. The Coordinated Management Framework provides for a MOU to establish a cooperative relationship between the public agencies, The Nature Conservancy, and Eight Dollar Mountain Landowner Association. There will be a provision in the MOU for a biannual meeting of the involved agencies and publics to review and renew the Plan.

A Coordinated Management Plan will be prepared for Eight Dollar Mountain that integrates the management of all public agencies and The Nature Conservancy, and encourages the participation of private landowners owning property within the boundaries of the management area The Plan will be general in nature, with flexibility that will allow resource use with protection of all the resources (resource use includes botanical, wildlife, timber, mineral, and communication sites, for example). It is expected that each agency and private landowner will provide some type of special designation that recognizes and protects the botanical and other resource values

The Coordinated Management Framework highlights the following subjects: minerals, transportation system, timber management, grazing, communications, scenic, wildlife, fire management, recreation/tourism, community involvement, and establishment of baselines for monitoring. An included action plan features the following items: Coordinated Management Plan, Memorandum of Understanding, research/monitoring, minerals, transportation, timber management, grazing/wildlife/ communications, fire management, community involvement, and land exchange.

Memorandum of Understanding. The intent of the Memorandum is to establish a cooperative management relationship between, Josephine County (County), the State of Oregon (State), the USDI Bureau of Land Management (BLM), the USDA Forest Service (USFS), The Nature Conservancy (TNC), and participating private landowners in the Eight Dollar Mountain Landowners Association for management of lands in the Eight Dollar Mountain Special Management Area

The objective of the Memorandum is to facilitate the preparation and execution of a Coordinated Research and Management Plan for Eight Dollar Mountain that integrates the actions of the public agencies, The Nature Conservancy and other private landowners on the Mountain and encourages public participation. The plan will provide for maintaining the integrity of the plant communities while allowing other resource

activity on the mountain. All resource use would be subject to monitoring and mitigation based on protecting the botanical values of the area

Alternatives developed by the Consensus Group The five alternatives all have a management focus that preserves the botanical integrity of the mountain. Activities described will protect the basic resource values of clean air, quality water, and soils for present and future generations

Alternative 1 National Natural Landmark

Designation. National Natural Landmark (exception private lands).

Management Direction. Basically unchanged to preserve the natural botanical systems and other noncommodity resource values.

Corresponding Alternative(s) in Forest Plan. Although no specific alternative in the Forest Plan recommends Eight Dollar Mountain as a National Natural Landmark, alternatives which allocate the National Forest portion of the land to Botanical area status accomplish essentially the same objectives (B, C, D, D1, E, G, K, M, S)

Alternative 2. Coordinated Management Plan.

Designation. Eight Dollar Mountain Coordinated Management Area. USFS· Special Management Area.

Management Direction. Active management to restore the area, research and monitor to provide future direction. Existing activities are integrated and coordinated.

Corresponding Alternative(s) in Forest Plan. Alternatives which allocate the National Forest portion of the land to Botanical area status meld with this Consensus Group Alternative (B, C, D, D1, E, G, K, M, S)

Alternative 3. Botanical Area.

Designation. Eight Dollar Mountain Botanical Area (each agency uses a Special Use area designation).

Management Direction. Manage the mountain more conscientiously than in the past while allowing existing uses to continue. Maintain the integrity of existing plant communities

Corresponding *Alternative(s) in Forest Plan.* Alternatives which allocate the National Forest portion of the land to Botanical area status meld with this Consensus Group Alternative (B, C, D, D1, E, G, K, M, S).

Alternative 4. Modified Current.

Designation. Eight Dollar Mountain Resource Management Area (each agency uses a Special Area designation).

Management Direction. Limited commercial activity is allowed while preserving and protecting the botanical and other resources.

Corresponding Alternative(s) in Forest Plan Alternatives which allocate the National Forest portion of the land to Botanical area status meld with this Consensus Group Alternative (B,

C, D, D1, E, G, K, M, S). There are no timber values in the National Forest portion of the area; regulated mining activities are allowed under the prescription for Botanical areas (see Chapter IV of the LRMP, Standards and Guidelines.

Alternative 5. Current.

Designation. No formal designations. USFS has special botanical designation (informal designation - Botanical Interest Area).

Management Direction. Commercial and other activities occur based on past patterns.

Corresponding Alternative(s) in Forest Plan. Alternatives which extend the current management regime for the National Forest portion of the mountain are NC, A and A-Departure.

Supporting Document - Ken Chambers. On December 15, 1981, in a letter to the manager of the Medford District Office of the BLM, Kenton Chambers, Herbarium Curator at Oregon State University, described the significance of Eight Dollar Mountain's plant resources. Portions of Chambers' letter have important application to National Forest Land on Eight Dollar Mountain:

> Information and testimony you have already received from botanists will attest to the richness of species in the localized and endemic flora of the Illinois River Valley and its tributaries, centered in the region running approximately from Takilma on the south to Selma on the north A significant number of plant species are known to occur *only* in that region, and being thus highly localized, they qualify as rare plants The extent to which they may also be classified as threatened or endangered depends on the size and stability of their populations, and perceived or potential threats to their habitat These plants' status is well known to, and acknowledged by, the professional plant taxonomists at Oregon's major universities and herbaria. I have personally been active in studying the biological relationships of certain of these species, in connection with a determination of their taxonomic status and classification.
>
> The earliest botanical exploration for plants of the upper Illinois River date from the 1880's, when Thomas Howell in particular was active in bringing this flora to the attention of leading taxonomists such as Asa Gray and Sereno Watson, at Harvard University. These two scientists received numerous collections from Howell which represented newly discovered and undescribed species; in publishing descriptions of these, Gray and Watson often applied the specific epithet "*howellii*" to them, in honor of the discoverer. The exact sites where Howell and others made these new species discoveries are usually known through published accounts, or the sites may be deduced today from information on the travel itineraries of the collectors The original discovery site of each species is called its "type locality " We known for sure that the "type locality" of three rare plants-- *Aster paludicola, Schoenolirion* [*Hastingsia*] *bracteosum,* and *Thlaspi montanum* ssp *siskiyouense*--is Eight Dollar Mountain; and for another species, *Senecio hesperius*, it is a good assumption that the type locality is on or near this mountain Still others of Howell's rare species discoveries were published as being from "Waldo," a defunct mining town south of present-day Cave Junction, and as they are known also from Eight Dollar Mountain (a site known to have been visited by Thomas Howell), this mountain stands as an important locality in the botanical history of the rare flora of the Illinois Valley The importance to science of the "type locality" is that it is the one most authentic place where representatives of the named species can today be seen and studied. Populations of the same species from other sites may vary in one respect or another from the description as originally published by the botanical authority.
>
> The Bureau of Land Management ownership on Eight Dollar Mountain complements and supplements the Forest Service Land on the same mountain, in terms of its representation of the

ecologically to be expected that the different slopes of a symmetrical mountain, for example southwest versus northeast, will differ in vegetation and species composition, and these factors, along with others such as soils and water seepage for marsh development, are quite evident on Eight Dollar Mountain In biological terms, it would not be correct to assume that a botanical preserve on Forest Service Land would obviate the need for similar preservation of flora on Bureau of Land Management land

The Kalmiopsis Wilderness likewise does not represent a botanical substitute for an Area of Critical Environmental Concern on Eight Dollar Mountain Many of the rare and possibly endangered plant species which I made reference to above, do not occur in the Kalmiopsis, as far as is known They would not be expected to occur there, due to the distinct climatic, altitudinal, and vegetational difference existing between the two areas The reverse is also true; many significant rare plants known from the Kalmiopsis Wilderness have not been found on Eight Dollar Mountain The soils, topography, and climate of the mountainous southwestern corner of Oregon (comprising the general Siskiyou Mountains area) are remarkably diverse and change dramatically over short distances, as can be observed in comparing Eight Dollar Mountain with established wilderness to the west and south

Eight Dollar Mountain has many notable qualities as a site for special management aimed at preserving botanical and wildlife values. It has a greater range of elevation, and hence habitat diversity, than most other possible sites for preservation on public lands in the upper Illinois River region.

Table F-BOT-10 Unusual Plants in the Proposed Eight Dollar Mountain Botanical Area.

Scientific Name	Common Name
Sensitive Species	
Allium bolanderi	Bolander's onion
Balsamorhiza sericea	silky balsamroot
Calochortus howellii	Howell's mariposa lily
Epilobium oreganum	Oregon willow-herb
Erythronium howellii	Howell's fawn lily
Fritillaria glauca	Siskiyou fritillaria
Gentiana bisetaea	Waldo gentian
Hastingsia bracteosa	large-flowered rush lily
Lewisia leana	Lee's lewisia
Lewisia oppositifolia	opposite-leaved lewisia
Microseris howellii	Howell's microseris
Ribes marshallii	Applegate's gooseberry
Senecio hesperius	Siskiyou butterweed
Streptanthus howellii	Howell's streptanthus
Thlaspi montanum var *siskiyouense*	wild candytuft
Viola lanceolata ssp. *occidentalis*	western violet
Watch/Review Species	
Arabis aculeolata	Waldo rock cress
Arabis koehleri var. *stipitata* 1/	Koehler's rock cress
Arenaria howellii	Howell's sandwort
Camassia howellii	Howell's camas
Castilleja elata	slender paintbrush
Cypripedium californicum 1/	California lady's slipper
Darlingtonia californica	California pitcher plant
Dicentra formosa ssp. *oregana*	Oregon bleeding heart
Eriogonum pendulum	long-stalked eriogonum
Lathyrus delnorticus	Del Norte pea
Lilium vollmeri	Vollmer's lily
Sidalcea malvaeflora ssp. *elegans*	mallow sidalcea

1/ Potential candidate for Regional Forester's sensitive list.

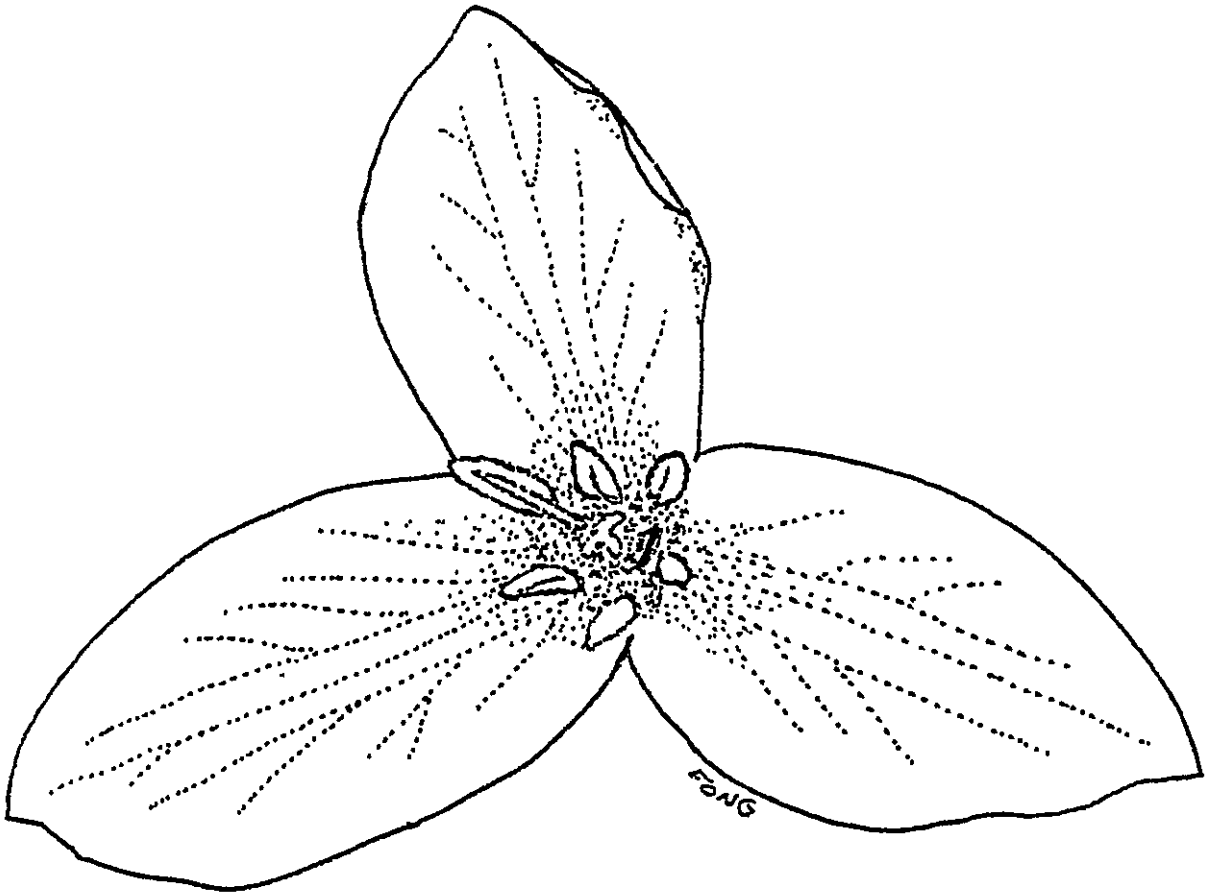
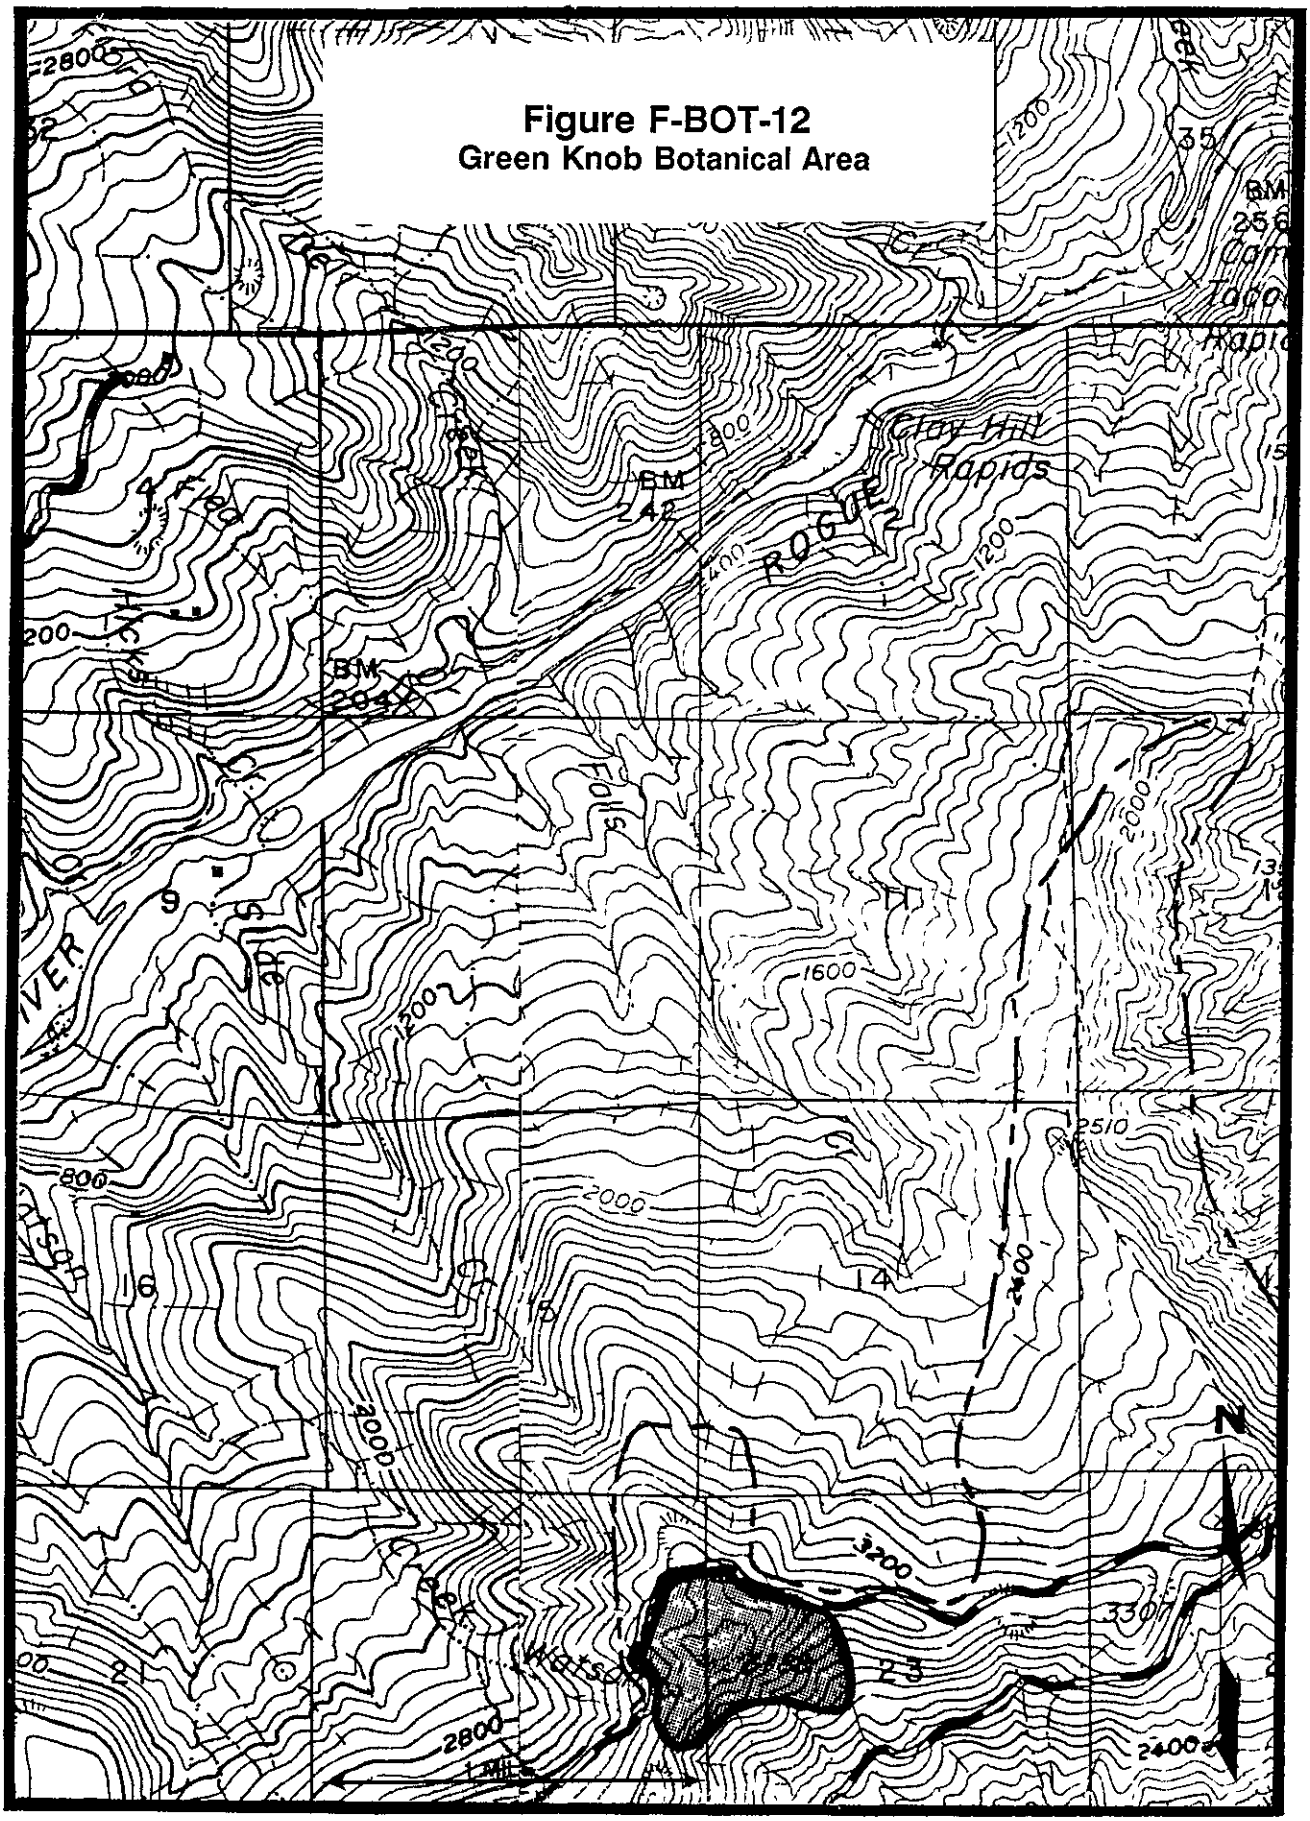
GRAYBACK MOUNTAIN - F-BOT-11

The proposed Grayback Mountain Botanical Area is located about six miles northeast of Oregon Caves in the northeast corner of the Illinois Valley Ranger District, and borders the Rogue River National Forest (T 40S , R 5W , Sections 5 and 8) (Figure F-BOT-11) At 7,055 feet, it is the highest mountain on the Forest (the lowest elevation in the proposed area is about 6,000 feet) The entire area is botanically interesting, however, only the western half of the Mountain is within the Siskiyou National Forest and described here The proposed area contains some 197 acres. Grayback Mountain is within the Kangaroo Roadless area (see Appendix C, Roadless Areas). Planners on the Rogue River National Forest are considering Botanical Area status for the east side of Grayback Mountain The west half of the Mountain is recommended as a Botanical area in the Siskiyou's Preferred Alternative (S), with a boundary reconformed to better match the Botanical area proposed by the Rogue River NF (Figure F-Bot-11, Page 2 of 2).



The Boundary Trail traverses through part of the proposed Botanical area Lower slopes on the Siskiyou portion of Grayback Mountain contain Douglas-fir, white fir, and some Shasta red fir. The upper slopes are generally open, with shrub-fields, talus, and outcrops predominating The Siskiyou side of the mountain site contains a variety of interesting plants, many of them sensitive (Table F-BOT-11). Matthew's cypress, Cascade daisy, Lee's lewisia, Applegate's gooseberry, and Washington lily, are a few of the known species. The Rogue River (National Forest) side of the mountain shows past glaciation and has some plant communities not represented on the Siskiyou side, in particular an extensive hillside bog on compacted glacial till Interesting plants on the Rogue River side include *Gentiana setigera* (*pleurisetosa* sp.nov./in ed.), *Spiranthes porrifolia*, *Lewisia nevadensis*, *Botrychium multifidum*, and the largest population of *Anemone occidentalis* (Pasque flower) in the Siskiyou Mountains. Grayback mountain has not been heavily botanized and the Forest Service species list for the area is sketchy. Future inventories will no doubt turn up interesting additions to the list.



None of the land in this proposed Botanical area is tentatively available and suitable for timber production (see Table F-3). The soils in the area are derived mainly from gabbro, with some quartz diorite There are no known locatable minerals in the proposed Botanical area (Ramp and Peterson 1979)

Table F-BOT-11. Unusual Plants in the Proposed Grayback Mountain Botanical Area

Scientific Name	Common Name
Sensitive Species	
Cupressus bakeri ssp matthewsii	Matthew's cypress
Lewisia leana	Lee's lewisia
Lilium parvum	small tiger lily
Ribes marshallii	Applegate's gooseberry

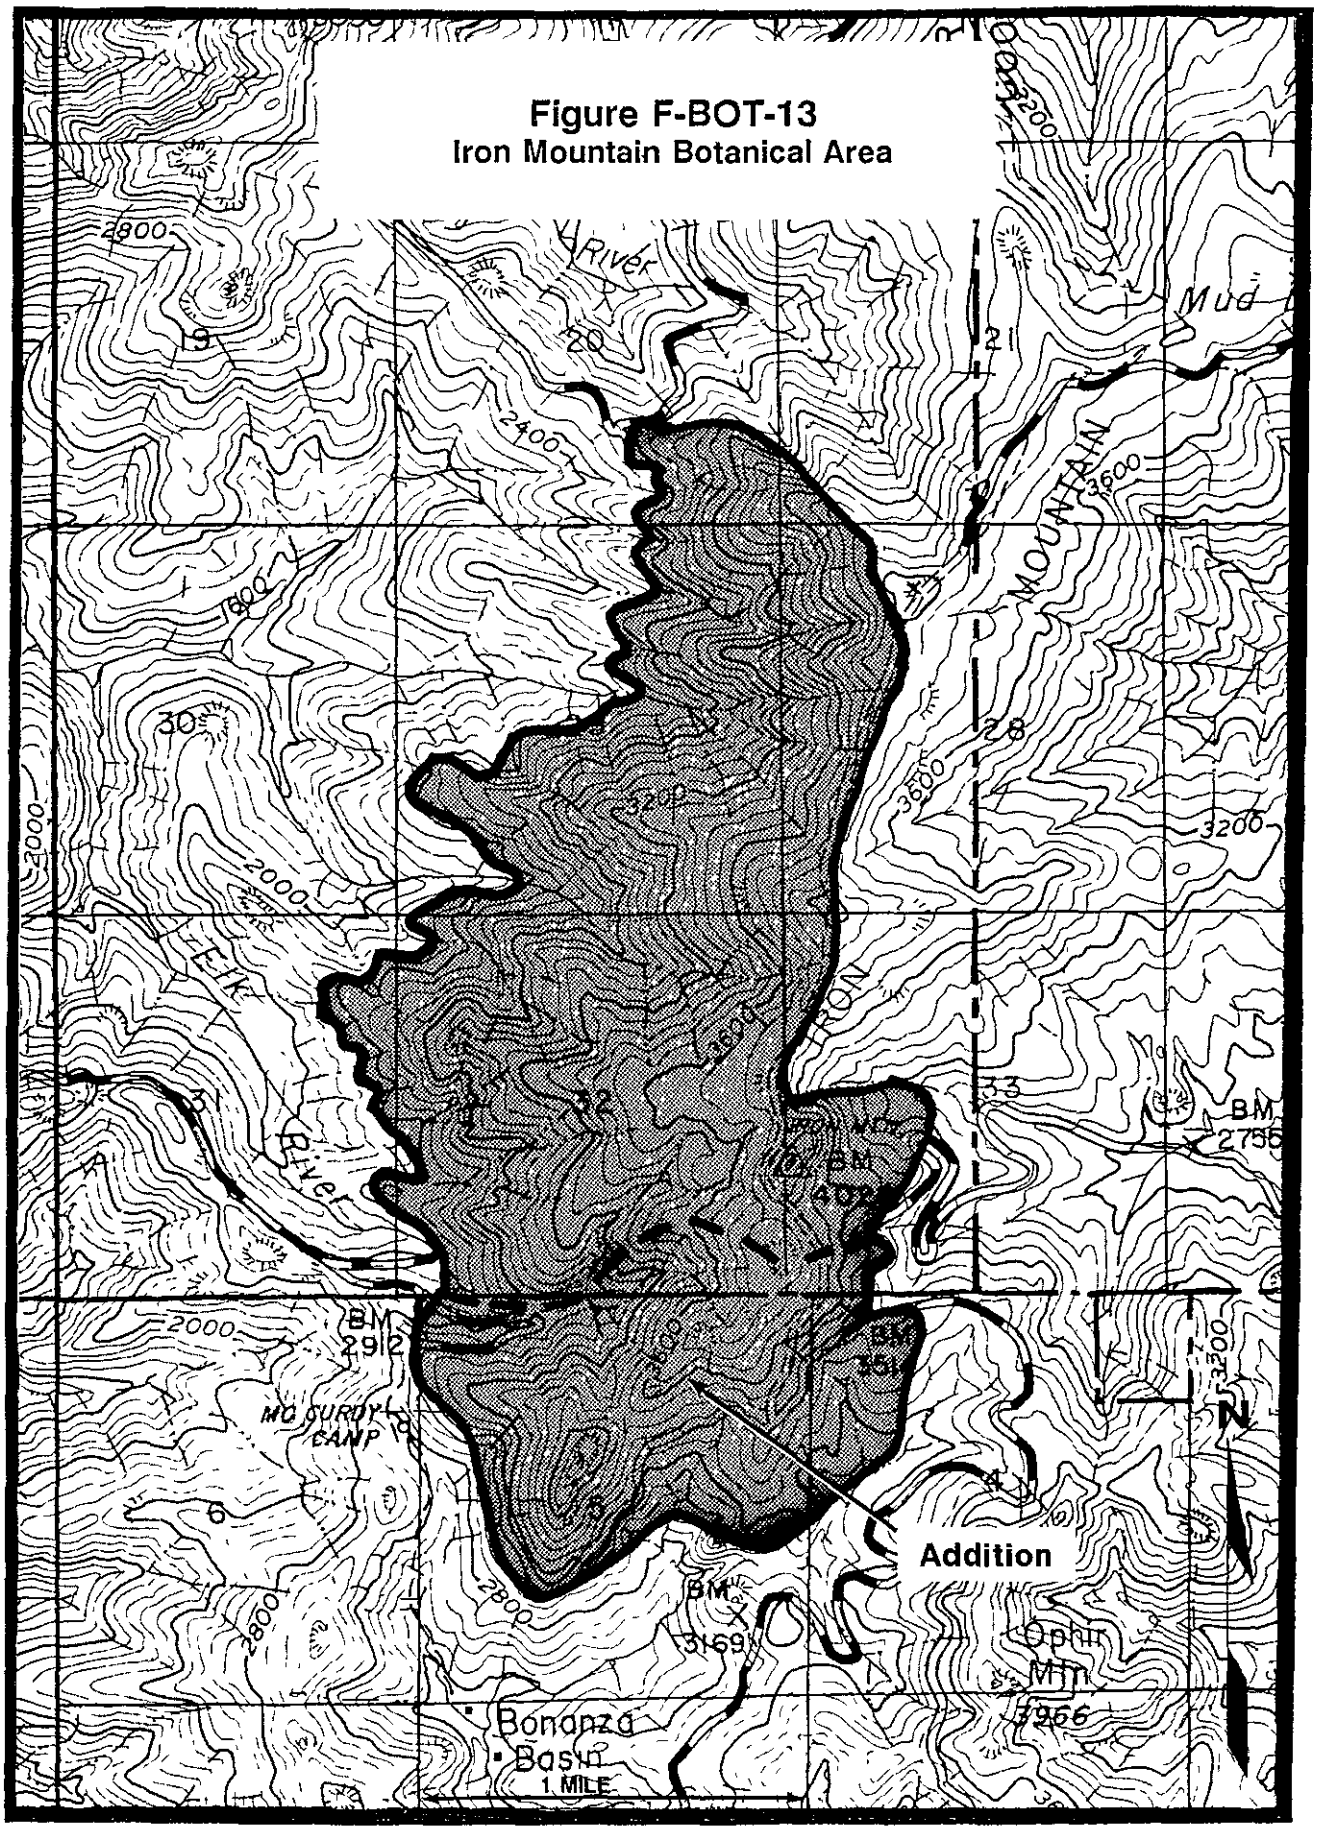
GREEN KNOB - F-BOT-12

The 153 acre proposed Green Knob Botanical Area is located on the Gold Beach Ranger District approximately 1.5 miles northeast of Green Knob at the headwaters of Watson and Slide Creeks (T.34S., R.11W., Sections 22 and 23) (Figure F-BOT-12).

Elevation range is 3,650 to 3,780 feet Soils are derived from sedimentary rock (marine) No mineral resources are known to be present; there is a possibility that coal deposits may be interbedded with the rock layers (Ramp and others 1977). The area is also an archaeological site (Indian ceremonial rocks).

The diverse plant resources of the Green Knob area were extensively inventoried in 1977 and 1978 by Rosamond Hess and Helen Planeto, residents of the Gold Beach area (report on file at the Supervisor's Office). They catalogued 122 plant species from 37 different plant families. One of the plants they found is listed as sensitive by the Forest Service (Table F-BOT-12).



About 132 acres in this proposed Botanical area are tentatively available and suitable for timber production; this land is capable of producing about 71 thousand board feet (MBF) of harvestable timber annually on a long-term sustained yield (LTSY) basis (see Table F-3)

The Green Knob site is presently designated as "Protect Rare Plants and Protect Artifacts or Sites" in the Total Resource Information (TRI) system. This area is not recommended as a Botanical area in the Preferred Alternative (S).

IRON MOUNTAIN - F-BOT-13

The proposed Iron Mountain Botanical Area sits astride the boundary between the Powers and Gold Beach Ranger Districts (T 33S., R 12W., Sections 20, 21, 28, 29, 31, 32, 33 and T 34S., R.12W , Sections 4 and 5) The Iron Mountain site has been divided into two parts (based on District boundaries); this provides flexibility to land managers who must make decisions on land allocations. For further information on this division see Figures F-1 and F-BOT-13.

The proposed Iron Mountain Botanical Area encompasses approximately 1,866 acres About 1,466 acres are considered tentatively available and suitable for timber production and are capable of producing 781 thousand board feet (MBF) per year of harvestable timber on a long-term sustained yield (LTSY) basis (Table F-3).

The area is drained almost entirely on the west side by tributaries of the Elk River, and on the east side by Rock Creek. The topography is broken and rugged, due to much erosion and to the nature of the old and metamorphosed geologic formations Intrusive masses of granitic rocks form much of the Mountain, along with greenstones, marble, serpentine, and peridotite. The headwaters of Iron Mountain Creek (Section 29) contain interesting travertine deposits and formations. Elevation range is 2,400 to 4,050 feet.

Len Ramp (1978:48) has mapped mineral deposits in the Iron Mountain Area, which includes the proposed Botanical area (Figure F-BOT-13A). He described Iron Mountain as:

> ...underlain by a body of partly serpentinized harzburgite a little more than a mile wide and 5 miles long, which trends about N.20oE. These ultramafic rocks appear to have a fault-contact relationship with the surrounding Upper Jurassic Galice Formation, which is composed of dark slaty siltstone, sandstone, and lesser metavolcanic rocks (greenstone).
>
> The high point of Iron Mountain on the line of Sections 32 and 33 is underlain by a small gabbro body which intrudes the ultramafic rocks. A slightly larger quartz diorite body is exposed on the south end of Iron Mountain in Section 5. Other minor dikes of similar composition occur in the area. Small erosional remnants of fossil-bearing Tertiary marine sediments are exposed along the eastern fault zone near the road junction and township line between Sections 4 and 33 A small deposit of coal was once prospected in these Tertiary rocks. Among other prospects in the area are the Miss Dolly Copper Prospect in the NE1/4 Section 5 and the Rock Creek chromite occurrence in SW1/4 of the NE1/4 of Section 33.

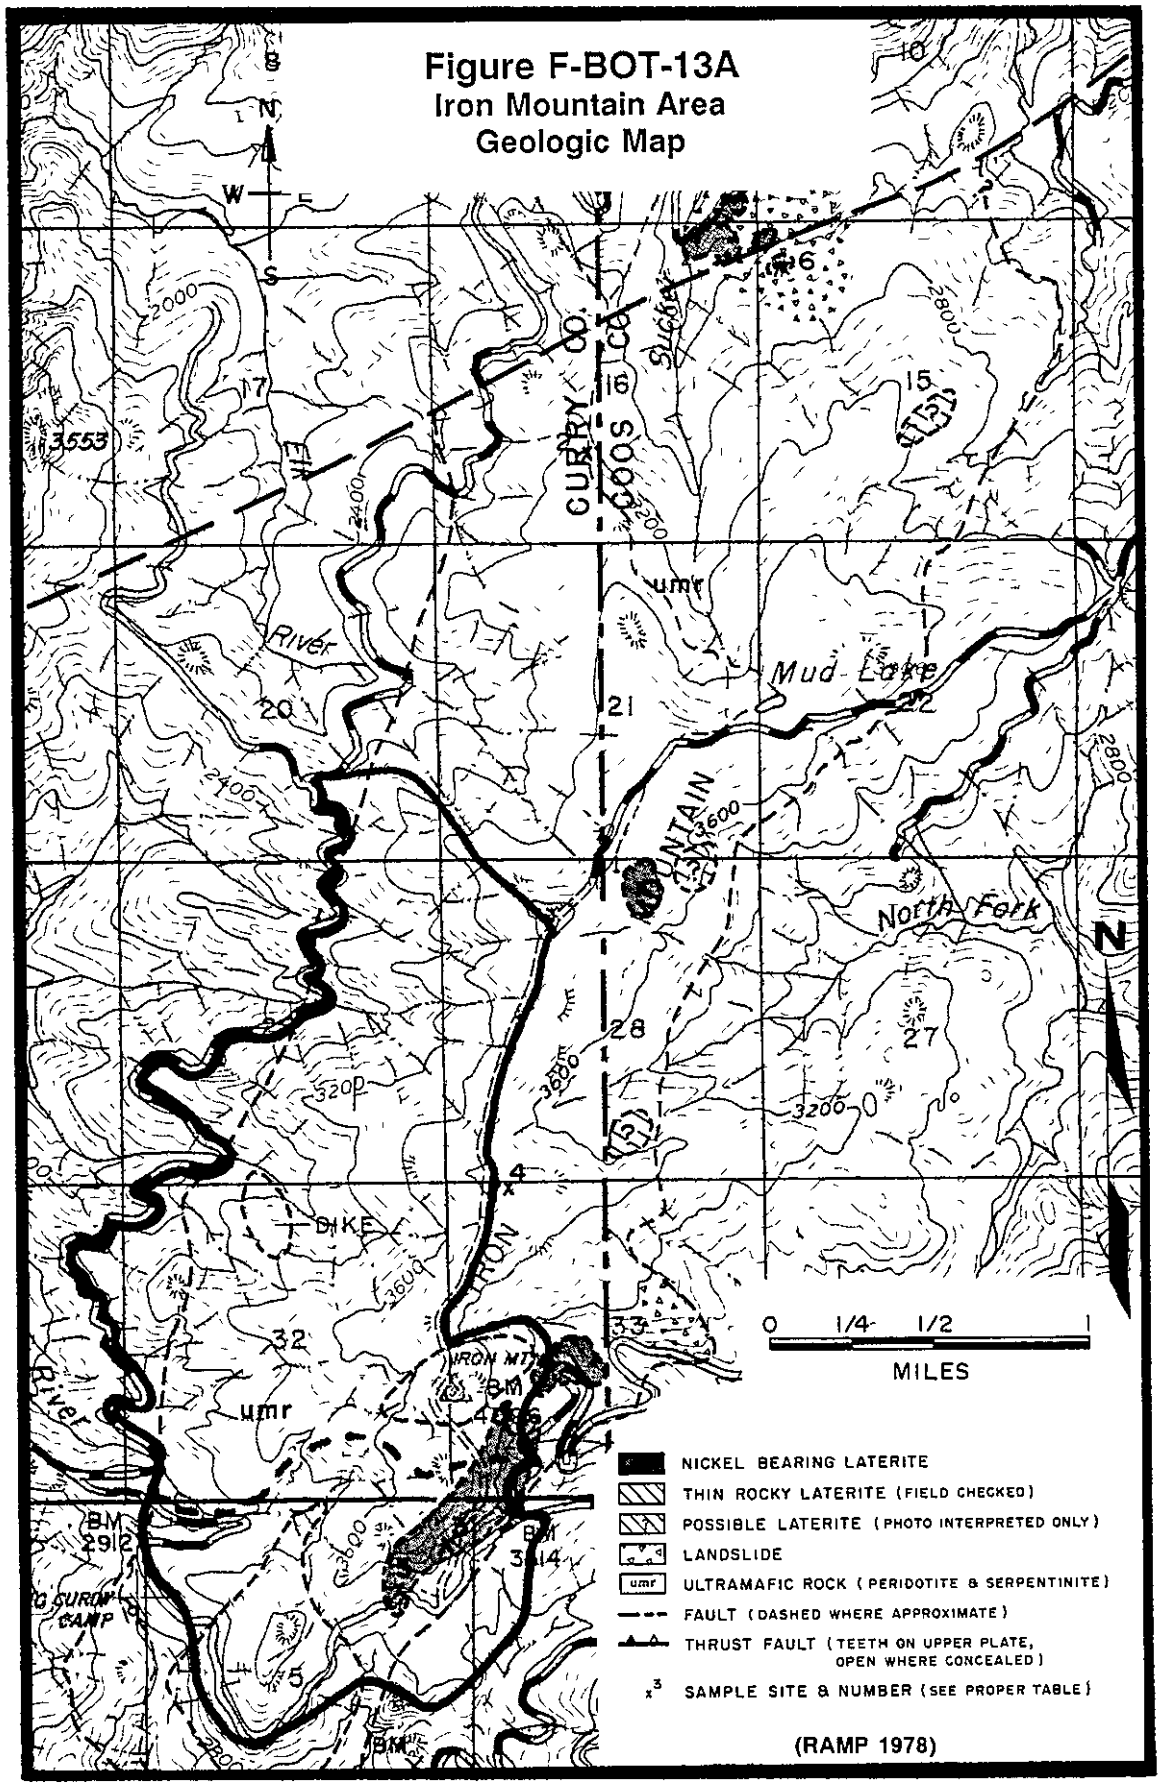
The main deposit of nickel lateritic soil is on the southeast slope of Iron Mountain in Sections 4, 5, and 33 in an area about 800 feet wide and a mile long. The two patches forming this main area cover about 74 acres (12 acres within the Botanical area); the soil is relatively thin and rocky. Percent of nickel is 0.70.

The proposed area contains uncommon plants (Table F-BOT-13). However, the area's most significant botanical values center on the Mountain's unique location; the ranges of many plant species do not extend beyond Iron Mountain.

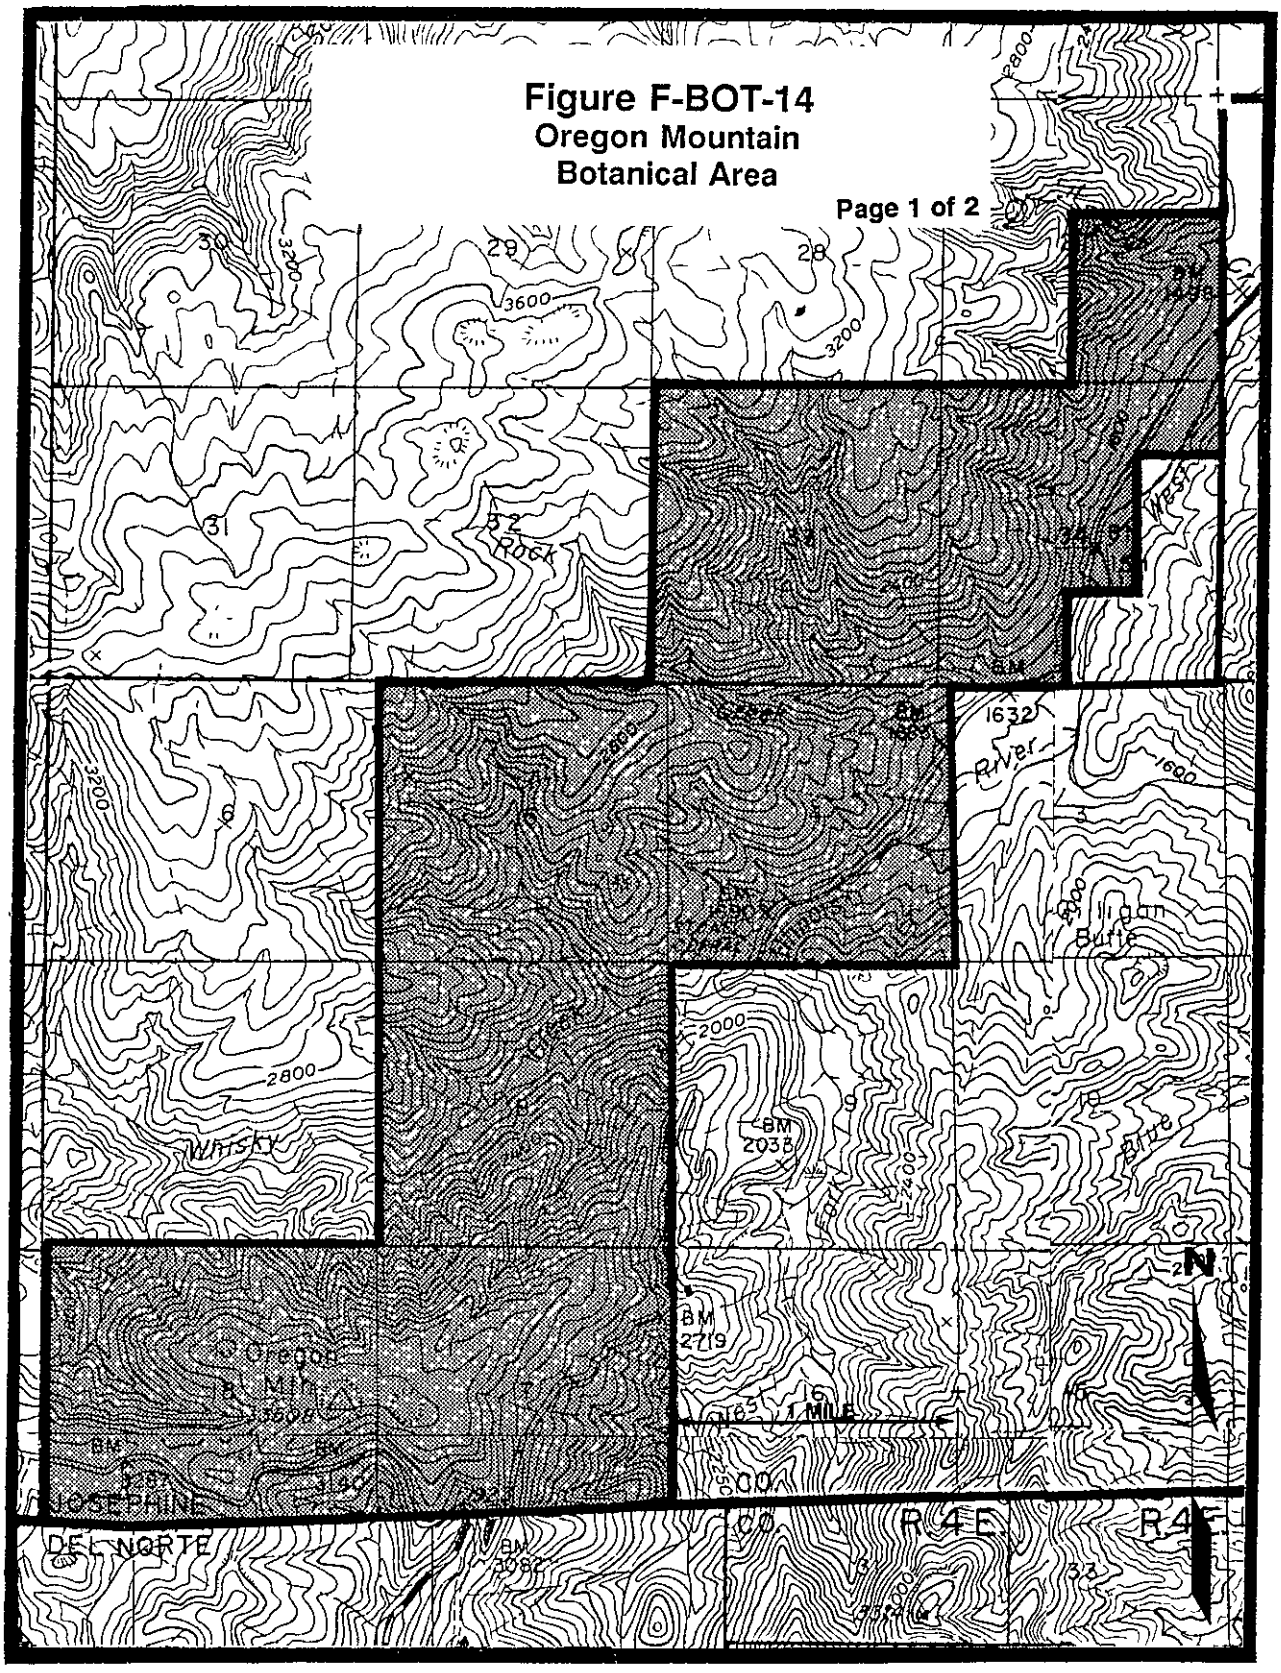
In 1956, W. H. Baker published the results of a comprehensive study of the plants of Iron Mountain (Am. Midland Nat., 56:(1) pp. 1-53). His report shows that at least 300 species of plants are found on Iron Mountain. Approximately 60 species either reach their known northern limits here, (such as Brewer spruce, *Picea breweriana*) or do not extend any great distance beyond the Mountain; approximately nine species reach their southern limits here. These plants comprise about 23 percent of the total flora of Iron Mountain. A total of at least 59 plant families are represented at Iron Mountain (50 percent of the total for the State of Oregon). This represents a very diverse flora, including several unusual species such as *P. breweriana*, *Iris innominata*, *Sedum laxum*, *Arnica cernua*, *Cirsium acanthodontum*, *Phacelia corymbosa*, and many others at the limits of their ranges.

Common tree species in the Botanical area include lodgepole (*Pinus contorta*) and western white pine (*Pinus monticola*), Douglas-fir (*Pseudotsuga menziesii*), Port-Orford-cedar (*Chamaecyparis lawsoniana*), golden chinquapin (*Castanopsis chrysophilla*), huckleberry oak (*Quercus vaccinifolia*), Sadler oak (*Quercus sadleriana*), and Brewer spruce. A large stand of Brewer spruce is located in the SW1/4 of Section 33.

Common shrubs include green (*Arcotostaphylos patula*) and hairy manzanita (*A columbiana*), Pacific rhododendron (*Rhododendron macrophyllum*), western azalea (*R occidentale*), coffeeberry (*Rhamnus californica*), silktassel (*Garrya* sp.), and salal (*Gaultheria shallon*). The California pitcher-plant (*Darlingtonia california*), grows in large numbers on the west side of the mountain in wet serpentine-peridotite areas.



A small communications site in the northeast corner of the Botanical area has been deleted from the proposal, otherwise the entire area is recommended as a Botanical area in the Preferred Alternative.



This Iron Mountain narrative was written by Dave Shea, former Wildlife Biologist on the Powers Ranger District.

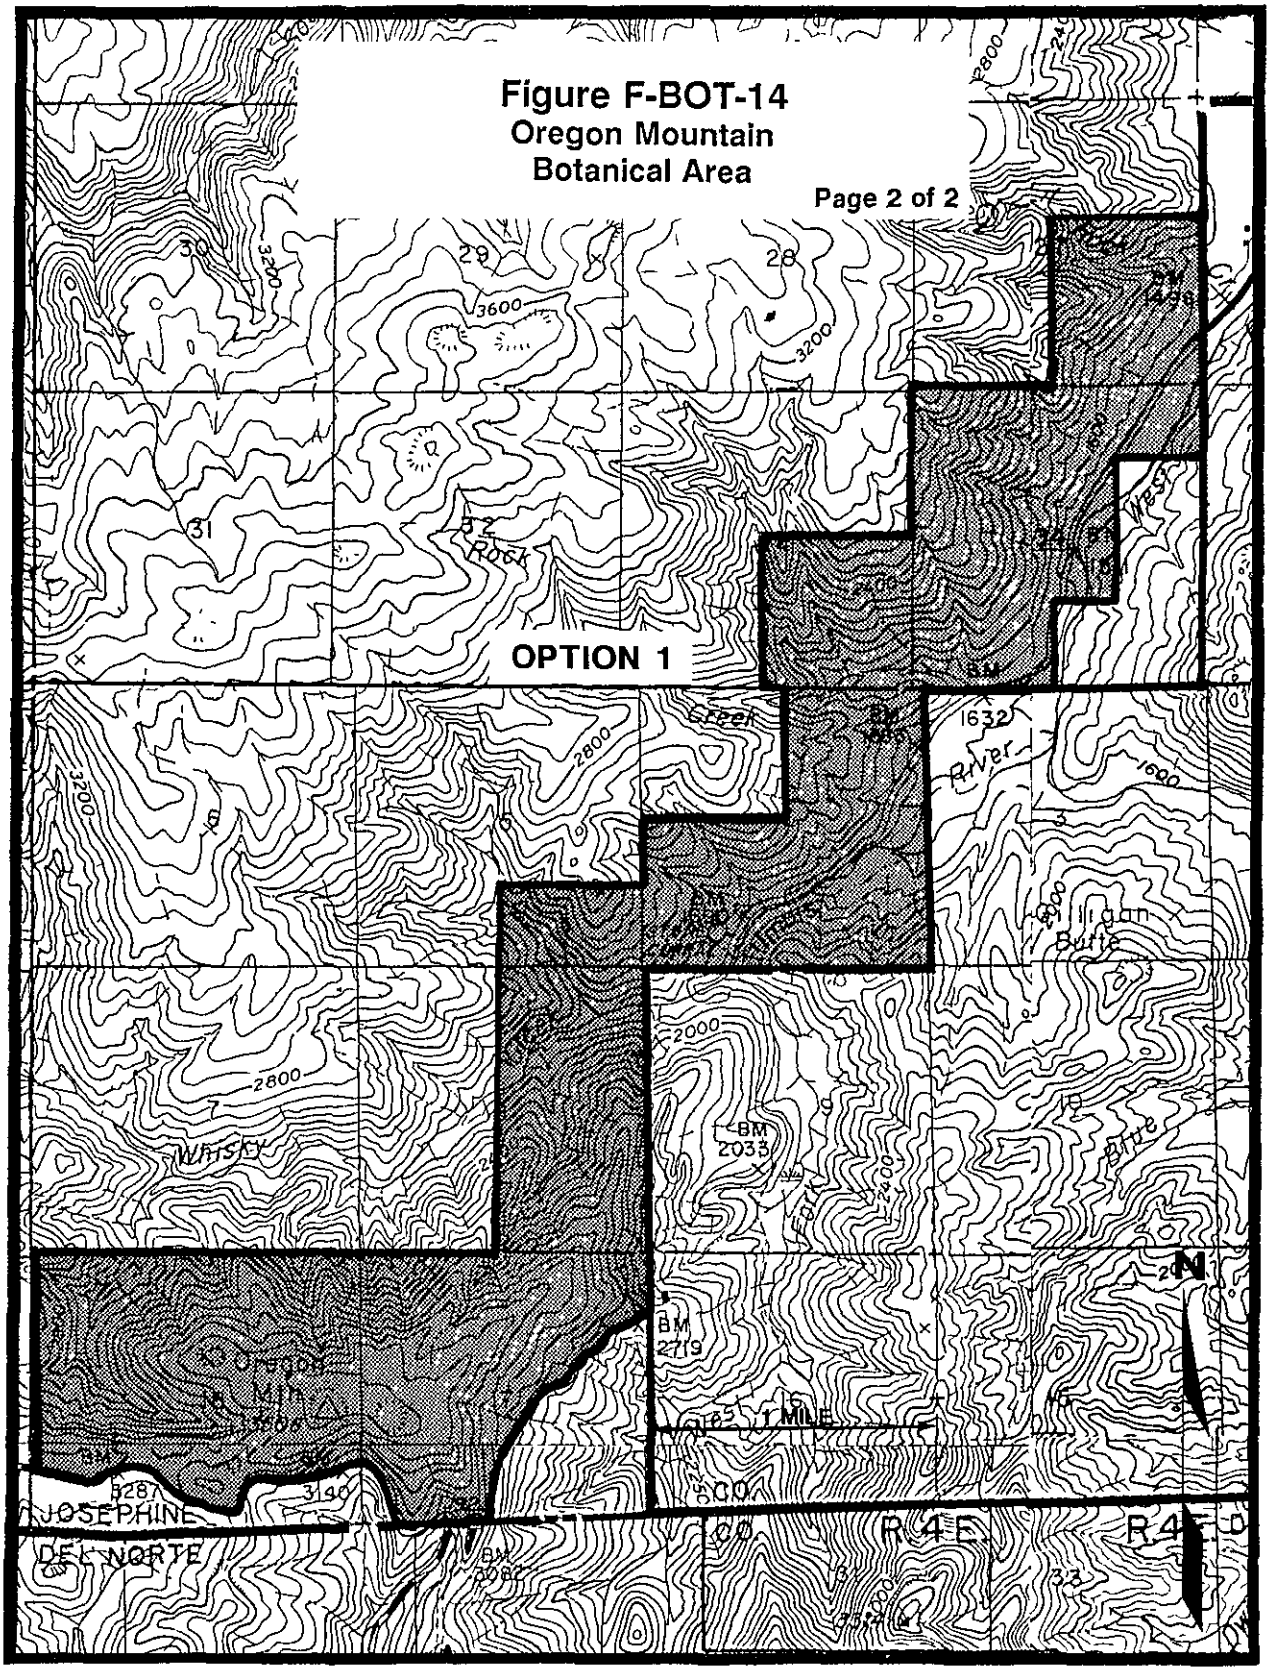


Table F-BOT-13. Unusual Plants in the Proposed Iron Mountain Botanical Area

Scientific Name	Common Name

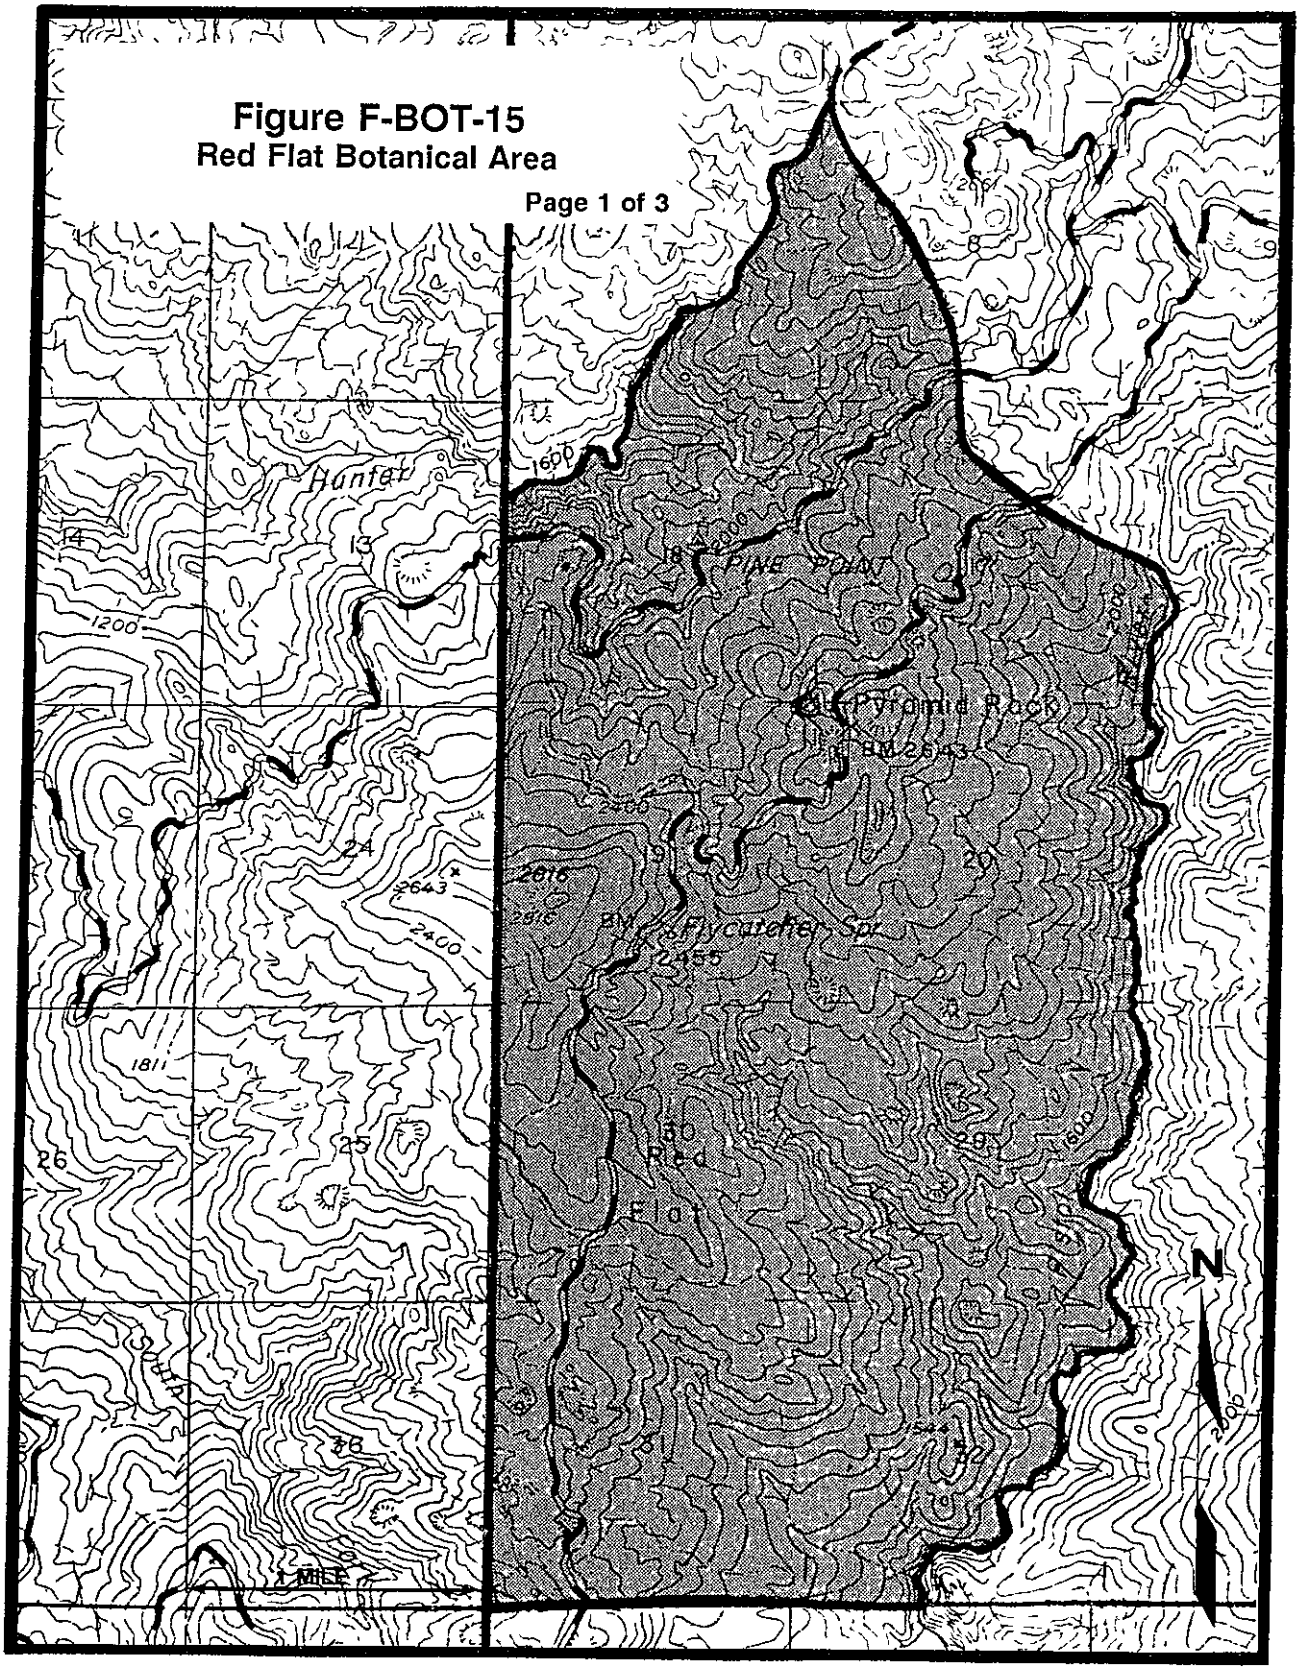
OREGON MOUNTAIN - F-BOT-14

The proposed Oregon Mountain Botanical Area is located on the Illinois Valley Ranger District, a few miles southwest of the town of O'Brien (T.40S., R.9W., parts of Sections 27, 33, 34, and T.41S., R 9W., parts of Sections 4, 5, 8, 17, 18) (Figure F-BOT-14). The Botanical area contains some 4,401 acres, most of which is serpentine habitat. Elevation range is approximately 1,500 to 3,500 feet. Oregon Mountain, the Stone Corral, and parts of Rock and Whiskey Creeks are within the proposed Botanical area. Basically, the proposed area encompasses a band of serpentine land on the west side of the West Fork Illinois River and stretches from just southwest of O'Brien to the California border.

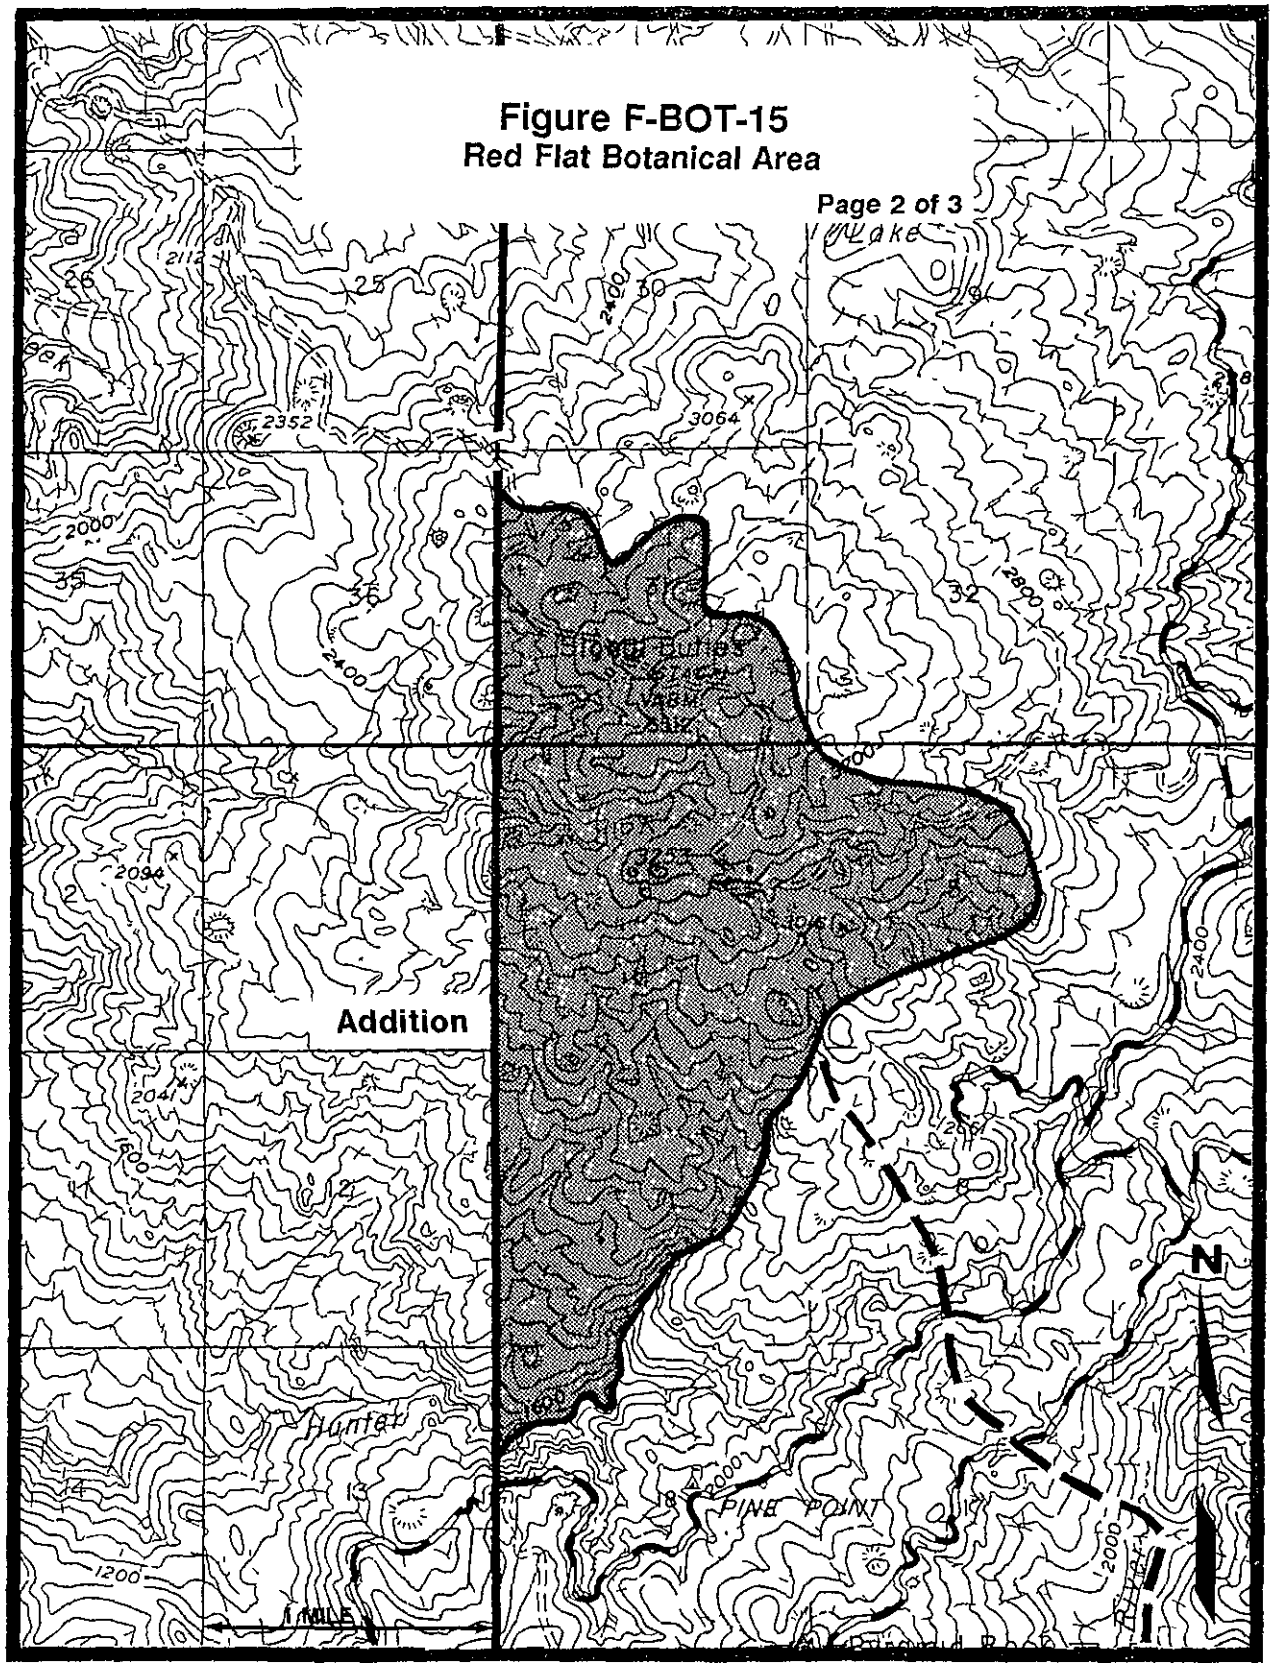
Botanists from Oregon and many other parts of the world know Oregon Mountain (and Eight Dollar Mountain) as important focal points for unusual plants. Many of the serpentine endemics found in southwest Oregon and northwest California are most abundant here Many *Darlingtonia* bogs are present, along with associated species such as *Cypripedium californicum*, *Gentiana bisetaea*, and *Viola lanceolata* ssp. *occidentalis*. Dry serpentine sites support such plants as *Lilium bolanderi*, *Lomatium howellii*, *Streptanthus howellii*, and *Vancouveria planipetala*. Seventeen sensitive plant species are known to occur in the Oregon Mountain area, this is 25 percent of the total for the Siskiyou National Forest (Table F-BOT-14)

The old mining settlement of Waldo, just a few miles east of the proposed Botanical area, was an important center of interest for early botanists; "Waldo" is the type locality for a number of unusual plants endemic to southwest Oregon and northwest California.

About 117 acres in this proposed Botanical area are tentatively available and suitable for timber production; this land is capable of producing about 63 thousand board feet (MBF) of harvestable timber annually on a long-term sustained yield (LTSY) basis (see Table F-3).



Soils in most of the proposed area are derived from ultramafic rock. A deposit of nickel lateritic soils is located in the southeast corner of Section 27; nickel content ranges from 0.36 to 0.65 percent (see Figure F-BOT-16A) The area also contains several chromite deposits, plus a copper prospect on Rock Creek (Ramp and Peterson 1979)



The best concentrations of rare plants occur along the western and southern portions of the proposed Botanical area This 2,623 acre section is recommended as the Oregon Mountain Botanical area in the Preferred Alternative (S) (Figure F-Bot-14, Page 2 of 2). Much of the land adjacent to the recommended area is managed by the Bureau of Land Management; similar botanical values are present, and the Bureau may eventually designate a Botanical area here to complement the Forest Service classification.

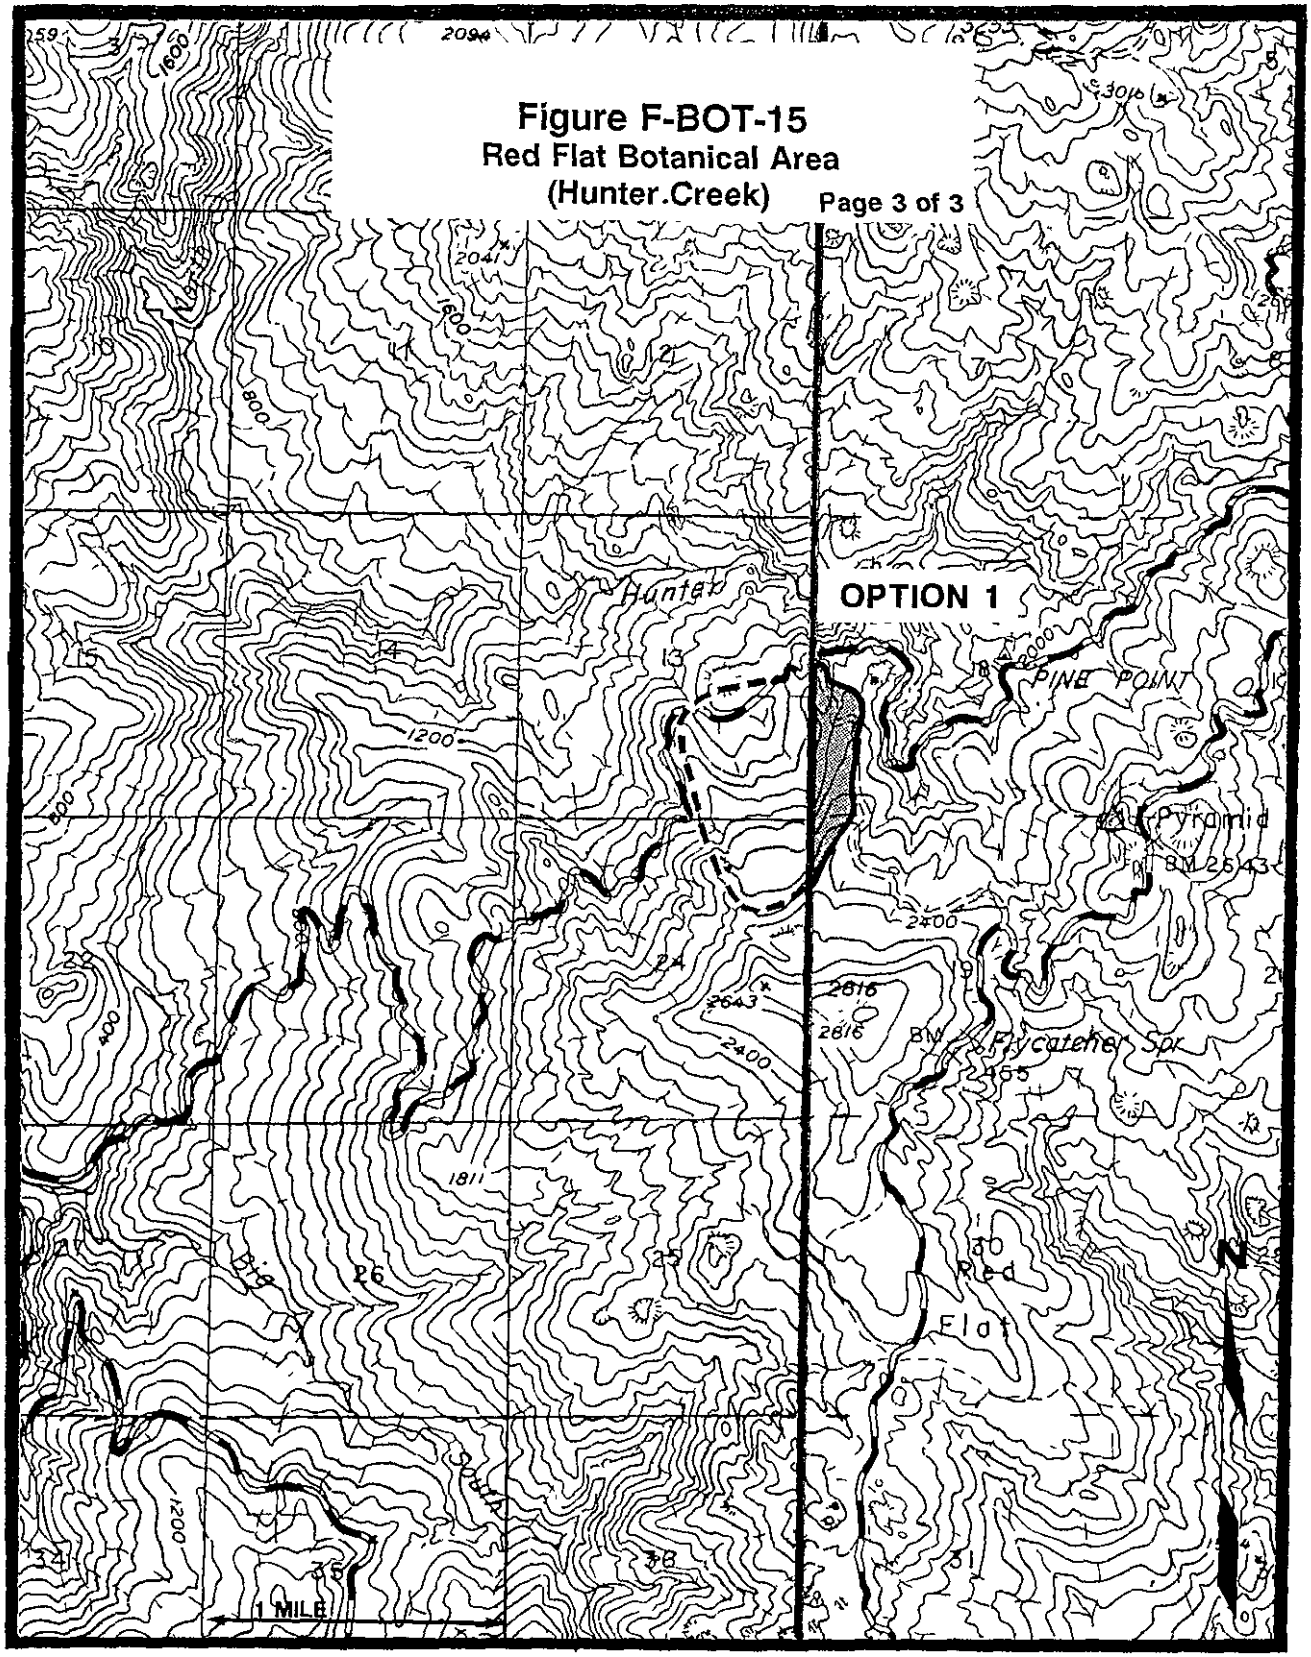


Table F-BOT-14. Unusual Plants in the Proposed Oregon Mountain Botanical Area

Scientific Name	Common Name
Sensitive Species	
Allium bolanderi	Bolander's onion
Balsamorhiza sericea	silky balsamroot
Calochortus howellii	Howell's mariposa lily
Cupressus bakeri ssp. matthewsii	Matthew's cypress
Dentaria gemmata	purple toothwort
Epilobium rigidum	rigid willow-herb
Erythronium howellii	Howell's fawn lily
Gentiana bisetaea	Waldo gentian
Lewisia oppositifolia	opposite-leaved lewisia
Microseris howellii	Howell's scorzonella
Monardella purpurea	Siskiyou monardella
Senecio hesperius	Siskiyou butterweed
Streptanthus howellii	Howell's streptanthus
Thlaspi montanum var. siskiyouense	wild candytuft
Viola lanceolata ssp occidentalis	western violet
Watch/Review Species	
Arabis aculeolata	Waldo rock cress
Arabis koehleri var. *stipitata* 1/	shrubby rock cress
Arenaria howellii	Howell's sandwort
Aster brickellioides	rayless leafy aster
Cypripedium californicum 1/	California lady's slipper
Darlingtonia californica	California pitcher-plant
Dicentra formosa ssp. *oregana*	Oregon bleeding heart
Eriogonum pendulum	long-stalked eriogonum
Fritillaria glauca	Siskiyou fritillaria
Lilium kelloggii	lilac lily
Lilium vollmeri	Vollmer's lily
Sidalcea malvaeflora ssp *elegans*	mallow sidalcea
Vancouveria chrysantha	yellow vancouveria

RED FLAT - F-BOT-15

The 7,172 acre proposed Red Flat Botanical Area straddles the boundary between the Gold Beach and Chetco Ranger Districts. The area is bounded on the east by the North Fork Pistol River, on the south by a township line, on the west by the Forest Proclamation Boundary, and on the north by Signal Buttes (T 37S., R.13W , Sections 5, 6, 7, 8, 17, 18, 19, 20, 29, 30, 31, 32; T.36S., R 13W., Section 31 (Figure F-BOT-15, 2 parts) Elevation range is 1,200 to 2,643 feet Pyramid Rock, Flycatcher Spring, Signal Buttes, Pine Point Campground and part of Hunter Creek are within the proposed area. The Red Flat site has been divided into two sections; this provides flexibility to land managers who must make decisions on land allocations. For further information on these options see Figures F-1 and F-BOT-15 (3 parts).

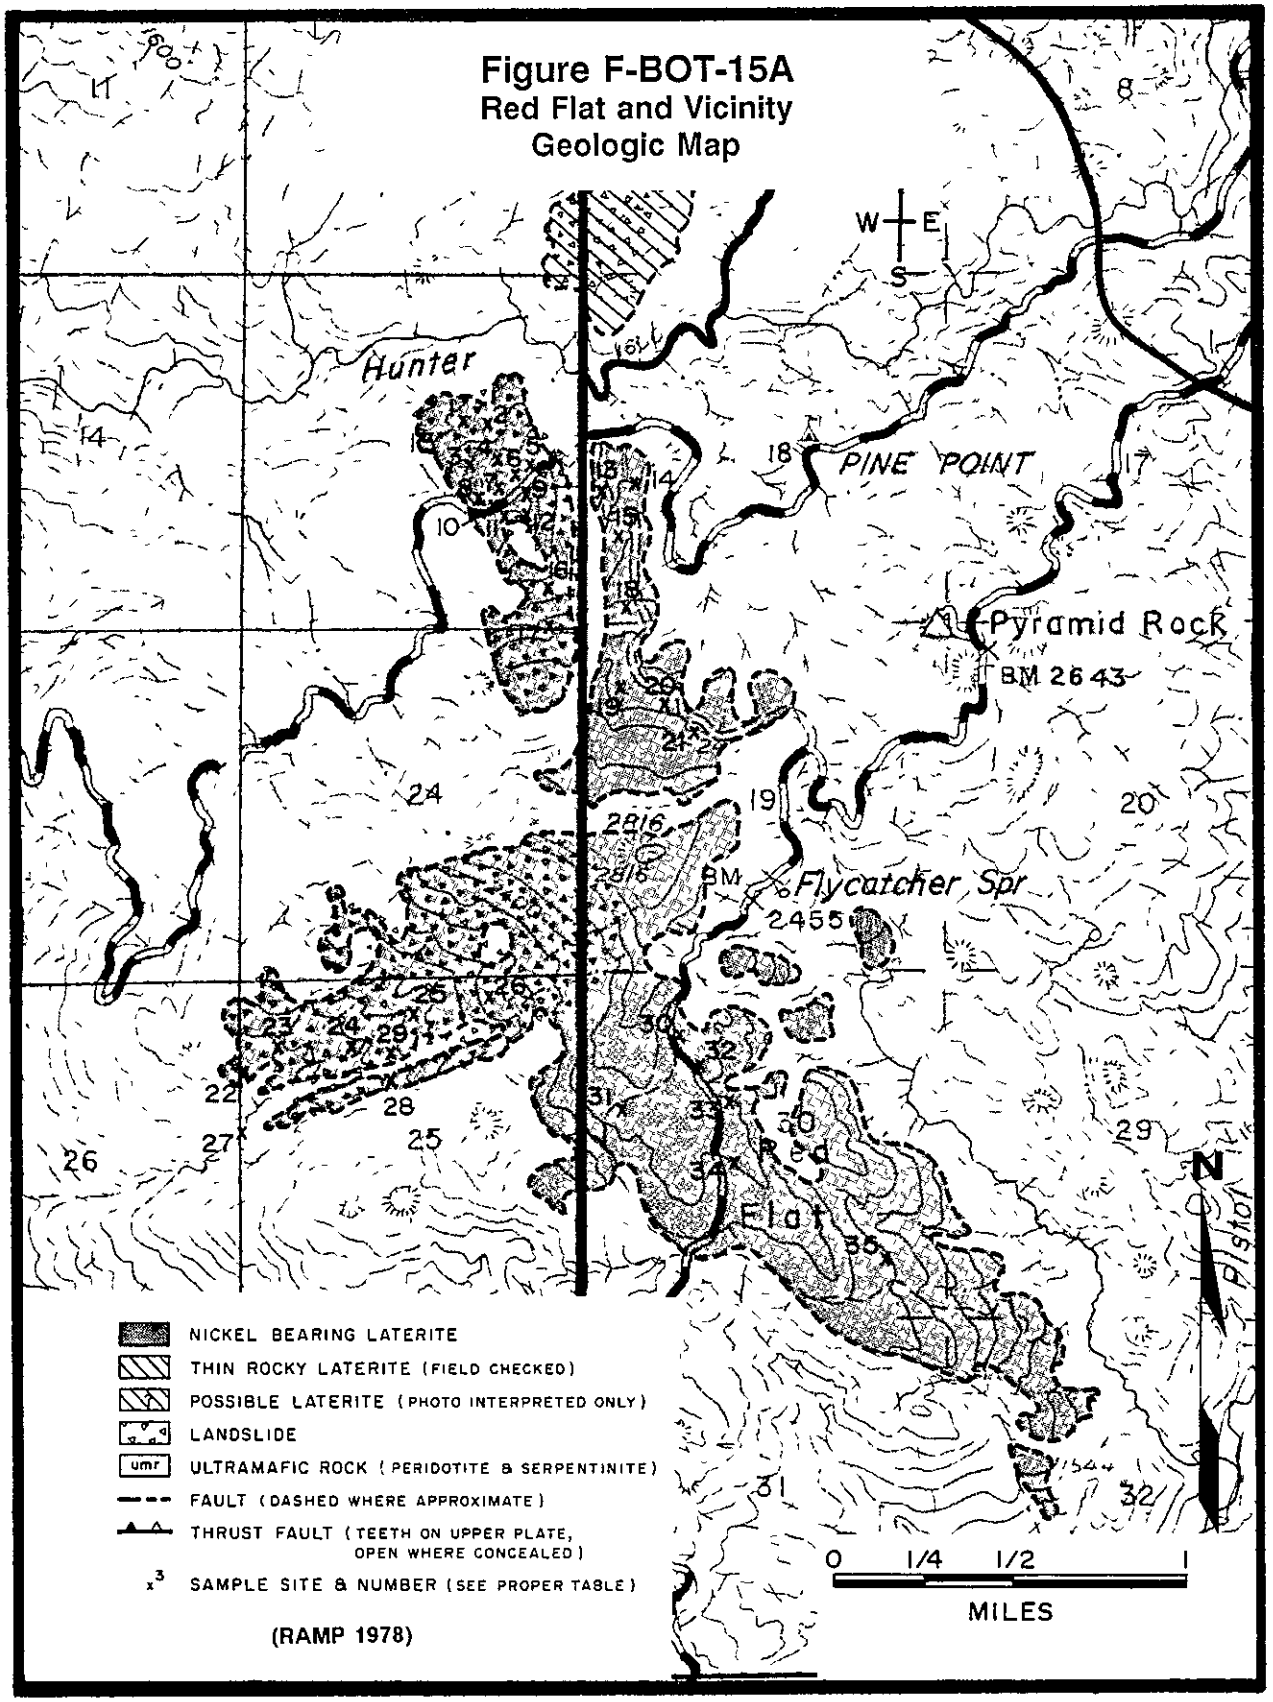
The plant resources of the Red Flat area have not been extensively inventoried One sensitive species, *Microseris howellii*, occurs in the area (Table F-BOT-15). A number of *Darlingtonia* bogs are present, along with such associated species as *Cypripedium californicum* and *Lilium vollmeri*. Hunter Creek Bog lies just to the west of the Forest boundary, along Road 3680 on land administered by the Bureau of Land Management Part of the drainage basin for the bog lies on National Forest land The bog had been proposed as a Research Natural Area as early as 1973 This effort was abandoned in August 1978, after it became apparent that the bog area was blanketed with mining claims. Up to that point, it had been the Forest Service's intention to further protect the bog's drainage basin by a set-aside of land within the National Forest in the W1/2 of the SE1/4 of Section 18 and the W1/2 of the NW1/4 of Section 19, T.37S , R.13W. (on file at the Supervisor's Office under FSM 4060/Proposed Hunter Creek Bog Research Natural Area).

The mineral values of the proposed Red Flat Botanical Area are considerable. Much of the area is under claim. The western section of the area contains extensive areas of nickel lateritic soil. Nickel content of the soil averages 0.8 percent. The soil also contains relatively high concentrations of cobalt, chrome, and iron. The total known area of lateritic soil cover on land administered by the Forest Service is approximately 710 acres. Len Ramp (1978:15) has mapped mineral deposits in the Red Flat Area (F-BOT-15A). He describes this area as·

> ...a relatively thin erosional remnant of an ultramafic thrust sheet together with a thin sheet of Colebrooke Schist overlying the Dothan-Otter Point Formation. Patches of partly serpentinized harzburgite overlie sheared serpentinite, which in turn overlies and is intermixed with thin lenses and sheets of Colebrooke Schist. This assemblage overlies relatively unaltered Dothan-Otter Point marine sediments and minor volcanic rocks. Nickel-bearing lateritic soils and saprolite have developed on the partly serpentinized harzburgite.
>
> The maximum depth of soil and saprolite development with or without nickel-enriched serpentinite is about 50 feet, but the average thickness of the nickel-rich serpentinite deposit is 12.5 feet. A few surface patches of iron-shot accumulation occur on the untransported residual soil on the ridge top in the W1/2 of Section 30. Garnierite occurs in the nickel-enriched serpentinites a few hundred feet north of the spring near the south end of the ridge in SW1/2 of Section 30. The presence of garnierite in the serpentinite probably best explains its anomalous nickel content.

About 4,773 acres in this proposed Botanical area are tentatively available and suitable for timber production; this land is capable of producing about 2,578 thousand board feet (MBF) of harvestable timber annually on a long-term sustained yield (LTSY) basis (see Table F-3).

Most of the proposed Red Flat site is not recommended as a Botanical area in the Preferred Alternative (S). More Botanical inventory is needed to pinpoint any important concentrations of rare species. If future inventories turn up new information about the area, it will be reviewed at the next revision of the Forest Plan. The Bureau of Land Management is presently involved in a land management planning process, Hunter Creek Bog will be considered for Botanical area status Among other proposals, the BLM will consider



designation of the Bog's entire watershed The portion of the Bog's watershed within the boundary of the Siskiyou National Forest has been recommended as a Botanical area by the Forest Service (53 acres; see Figure F-Bot-15, Page 3 of 3)

ROUGH AND READY FLAT - F-BOT-16

Approximately 1,700 acres are considered for recommendation in the proposed Rough and Ready Botanical Area. One proposal covers 934 acres, the other includes 1499 acres (Figure F-BOT-16, 2 parts) This site is located on the Illinois Valley Ranger District, one mile northwest of the town of O'Brien (T 40S., R 9W., Sections 13, 14) (Figure F-BOT-16, 2 parts). The eastern one-third of the proposed Botanical area is relatively flat (approximately 1,550 feet elevation) The western two-thirds is relatively steep; elevation range is 1,600 to near 3,000 feet Rough and Ready Creek bisects the proposed area, and Rough and Ready Creek Forest Wayside State Park is a mile to the east.

The 1,499 acre area is recommended as a Botanical area in the Preferred Alternative (S) (Figure F-Bot-16, Page 2 of 2) This area differs from the 934 acre proposal by containing more steep hillsides, rock outcrops, and creek bottom, some of the flat alluvial ground to the east is not included. These changes increase the breadth of plant communities and habitats within the Botanical area. A three-agency Botanical area could be designated in the area. The Bureau of Land Management could designate land in section 18, which would connect the Forest Service and State Park holdings.

Although the plant resources of the area have not been thoroughly inventoried, ten sensitive species are known to be present Included are two species of rock cress (*Arabis*) and four members of the lily family (*Liliaceae*) (Table F-BOT-16).

The area contains no land tentatively available and suitable for timber production.

Soils in the proposed Rough and Ready Creek Botanical Area are derived from ultramafic rock (Figure F-BOT-16A). Approximately 500 acres of thin rocky laterites (Rough and Ready outwash) have been mapped within the proposed Botanical area. The Oregon Department of Geology and Mineral Industries calculated nickel content of the soil at 0 45 percent. A small area of approximately 20 acres of nickel-bearing laterite is located on Parker Ridge in the NW1/4 of the NE1/4 of Section 14 Oregon Department of Geology and Mineral Industries calculated the nickel content here at 1.0 percent, chrome and cobalt content was 2 0 and 0.1 percent respectively Early-day gold placer miners recovered small amounts of gold and platinum metals along part of the bench gravel area along Rough and Ready Creek (Ramp 1978).

SNOW CAMP - F-BOT-17

The 1,475 acre proposed Snow Camp Botanical Area is located in the northwest corner of the Chetco Ranger District, both Snow Camp Meadow and Snow Camp Mountain are within the area (T 37S , R 12 1/2 W , Sections 13, 24, 25; T.37S., R.12W., Sections 19, 20, 30, 31) (Figure F-BOT-17). Elevation range is approximately 3,350 to 4,223 feet The Snow Camp site was initially divided into two sections, this provided flexibility to land managers who must make decisions on land allocations. A 1,041 composite area is recommended as a Botanical area in the Preferred Alternative (S) (F-Bot-17, Page 2 of 2), most of the core area is included, plus that part of the addition with more important botanical elements (Huntly springs, an area of Brewer spruce, and Meg's meadow, which contains a large population of *Bensoniella oregana*). For further information on the options see Figures F-1 and F-BOT-17 (2 parts)

The flora of the Snow Camp area is quite varied. The area is home to at least six sensitive species (Table F-BOT-17) Wet sites contain such sensitive plants as *Carex scabriuscula* and *Lilium vollmeri*; dry sites are inhabited by plants such as *Lilium bolanderi* and *Streptanthus howellii*. Snow Camp Meadow contains native grasses including species of *Danthonia* and *Deschampsia*.

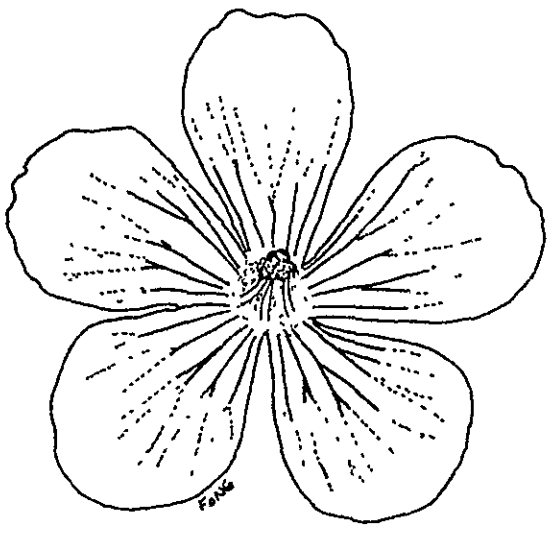
Huntly Springs is located in the Snow Camp Addition (Figure F-BOT-17). This is one of those exciting spots treasured by botanists. The spring area contains *Darlingtonia* and a good representation of bog species such as *Lilium vollmeri* and *Cypripedium californicum*. Nearby dry sites harbor such noteworthy plants as *Picea breweriana*, *Lilium bolanderi* and a good-sized population of *Arabis koehleri* var. *stipitata*.

The Snow Camp area has long held the fascination of serious botanists Veva Stansell, an expert botanist from Pistol River, described the area as follows:

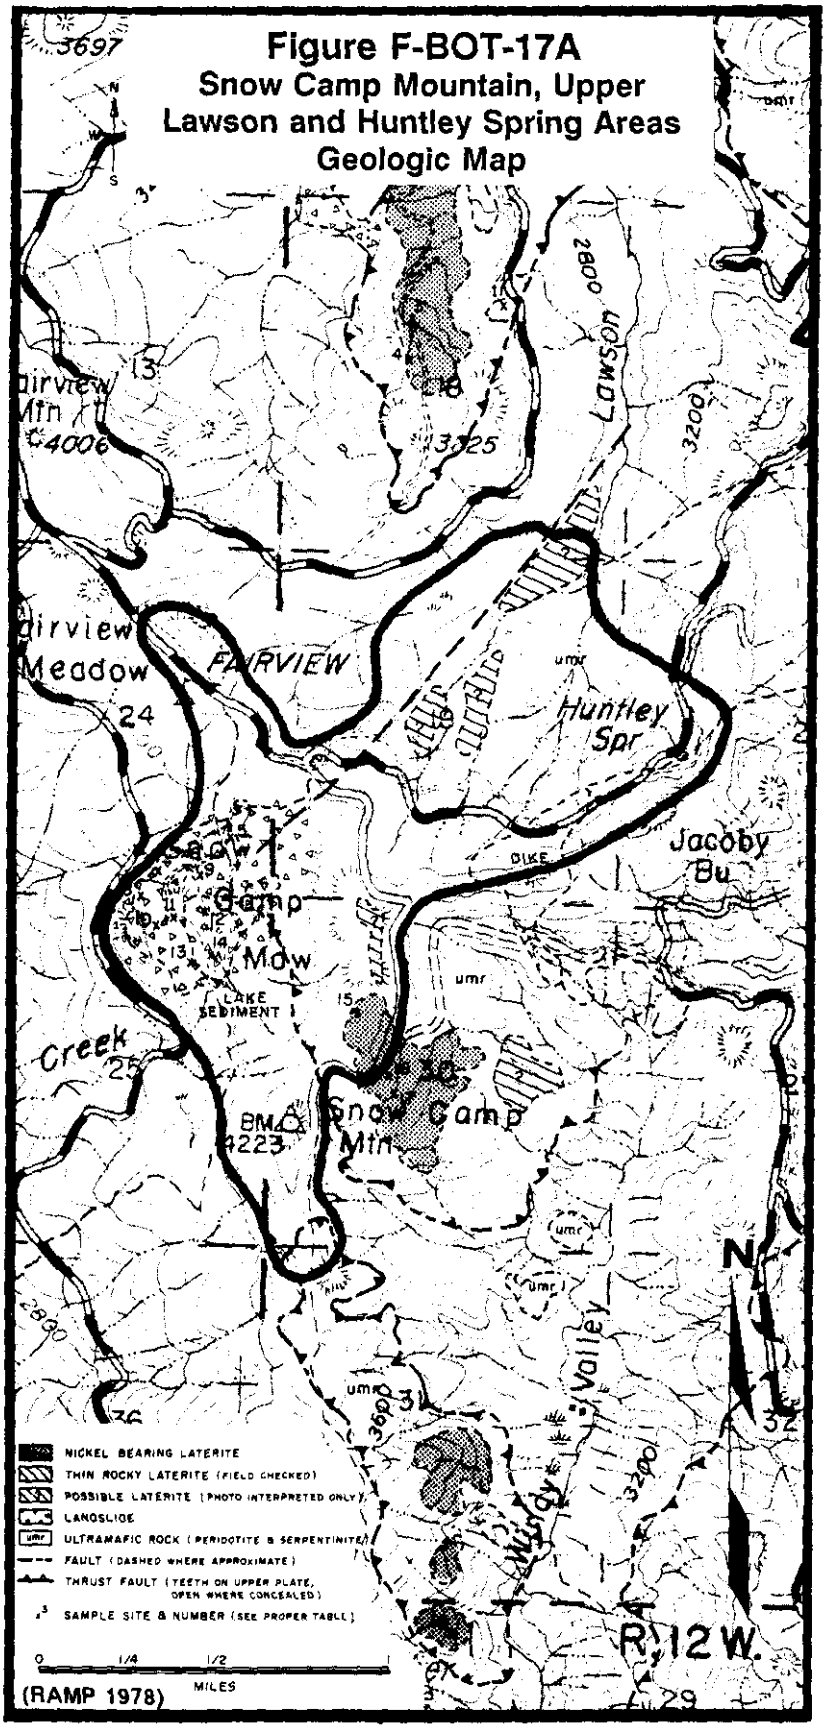
> Snow Camp Botanical Area with its varied geology provides botanists and wildflower enthusiasts with a generous spring display. The meadows along the road near the Lookout Junction harbor an assortment of belly-flowers in addition to the sensitive species *Bensoniella oregona* and *Erythronium revolutum*. There is also botanical history here as this is thought to be the area where *B. oregona* was first collected as a genus new to science. The type locality is given as simply Snow Camp, and this is the logical site, being along the old trail.
>
> Snow Camp meadow supports a good assortment of native grasses. At Huntley Springs metavolcanics and ultramafic rocks meet for more botanical diversity. *Picea breweriana* and *Acer glabrum* are next-door to *Darlingtonia californica*, *Lilium vollmeri* and the Pines. The old-growth Douglas-fir association which includes several non-chlorophyll species near Fairview rounds out an outstanding package of diverse habitats.

About 1,263 acres in this proposed Botanical area are tentatively available and suitable for timber production, this land is capable of producing about 682 thousand board feet (MBF) of harvestable timber annually on a long-term sustained yield (LTSY) basis (see Table F-3)

Two types of surface rock are present in the Snow Camp Botanical area: ultramafic (partly serpentinized harzburgite) and metavolcanic (Colebrooke Schist) In some places the harzburgite appears to be thrust over Colebrooke Schist. Both of these rock types overlay rocks of the Dothan-Otter Point Formation (sedimentary/volcanic). The proposed area contains approximately 50 acres of mapped nickel laterite deposits (Figure F-BOT-17A). Len Ramp (1978.54) describes most of the deposits as shallow and rocky. He further states that



> .the Snow Camp Meadow deposit is a large landslide area that at one time contained a small, 15-acre slide lake in the central part of the meadow This area has a fairly thick deposit of pale, greenish-gray, fine-grained lake sediments exposed in the creek banks near the south end of the meadow The outer ridge of the slide appears to be the principal area of lateritic soil, but it also



occurs under the lake sediments The laterites and saprolite development in the meadow slide deposit may be as deep as 50 feet or more in places; average depth is estimated to be 20 feet Estimated average depth of nickel enrichment in the Snow Camp Mountain patch is about 8 feet The calculated average grade of soil sampled in lake sediments is 0 63 percent nickel

SOURGAME - F-BOT-18

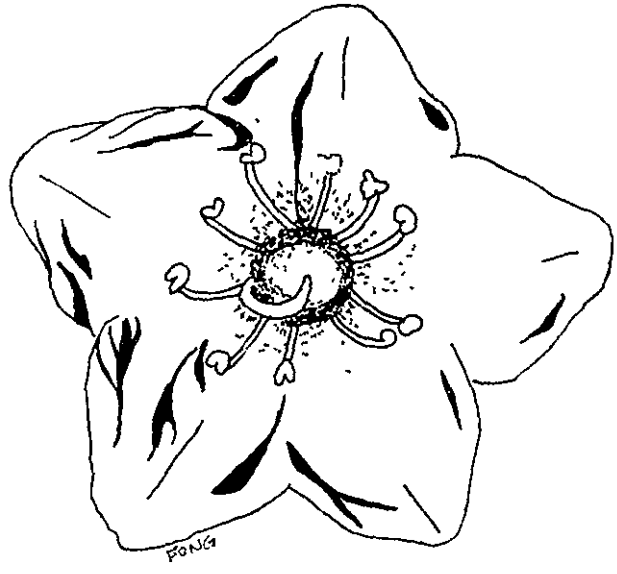
The 3,640 acre proposed Sourgame Botanical Area is located in the southwest corner of the Gold Beach Ranger District, it takes its name from Sourdough Camp and Game Lake. Other geographic points within the area are Saddle Mountain, Gray Butte, Horse Sign Butte, and Game Lake Peak (T 36S , R 12W and T 37S., R.12W) (Figure F-BOT-18, 3 parts). Elevation range is approximately 1,600 to 4,394 feet The Sourgame site has been divided into two sections; this provides flexibility to land managers who must make decisions on land allocations. For further information on these options see Figures F-1 and F-BOT-18 (3 parts)

The flora of the Sourgame area is unique The wide variety of soil types present have produced a number of contact zones which harbor a botanically rich species mix. At least three sensitive species are present (Table F-BOT-18). *Darlingtonia* bogs dot the area The Game Lake area harbors *Eriogonum pendulum*, *Allium bolanderi*, *Allium falcifolium*, *Lilium vollmeri*, *Frazera speciosa*, *Lewisia nevadensis*, unusual sedges, and four species of violets, including *Viola macloskeyi*. Sourdough Camp's complement of species includes *Darlingtonia*, *Bensoniella oregana*, *Castilleja elata*, and a large population of *Lilium vollmeri*. The population of Vollmer's lily here is one of the finest populations of this species existing, according to Orrel Ballantyne, a botanist from the Arcata, California area who has studied our native *Lilium* species extensively.

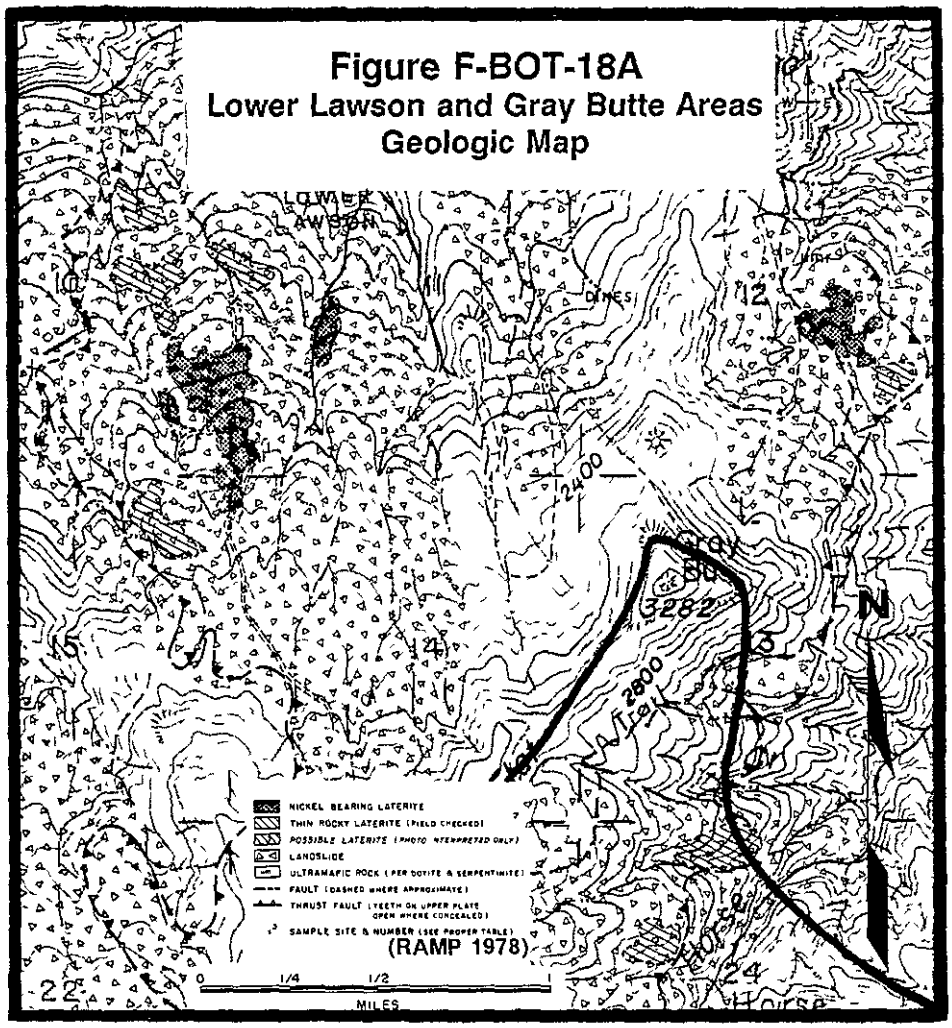
A few of the other interesting species in the Sourgame area are *Lathyrus delnorticus*, *Arabis koehleri* var. *stipitata*, *Mimulus cardinalus*, *Lilium bolanderi*, *Sanicula tuberosa*, and *Picea breweriana*.

About 3,640 acres in this proposed Botanical area are tentatively available and suitable for timber production; this land is capable of producing about 1,082 thousand board feet (MBF) of harvestable timber annually on long-term sustained yield (LTSY) basis (see Table F-3). Some laterite soils are present (Figure F-BOT-18A).

In the Preferred Alternative (S), two separate portions of the area are recommended as Botanical areas: Sourdough Camp (63 acres), Game Lake (508 Acres). Both areas are outlined in Figure F-BOT-18 (Page 3 of 3). These two sites have important botanical values, as attested to by Veva Stansell, a local Botanist from Pistol River:



> **Sourdough Camp**, rarely shown on current Forest maps, is named on USGS topographical maps. It consists of a small damp meadow with a thicket of *Rhododendron occidentale* below, and a *Darlingtonia californica* population above. The meadow is spangled in June and July with an abundance of *Lilium vollmeri*, a healthy and vigorous stand. Above the *Darlintonia* is a shaded grassy area where *Bensoniella oregana* is found. It is unusual for these two species to be found in the same drainage. The main road along the east side of Saddle Mountain supports another rare plant, *Lathyrus delnorticus*. This dainty legume is endemic to the Siskiyou Mountains *Castilleja elata*, a pink to lavender-flowered paintbrush, is another uncommon species found near the damp areas.
>
> The meadow area around **Game Lake** is surprisingly undegraded in number of species, in spite of heavy use as a camping site. The serpentine-peridotite hillside east of the lake provides a view of the mysterious Big Craggies, and a carpet of wildflowers in season. *Allium bolanderi*, *A. falcifolium*, *Eriogonum pendulum,* and *Frasera speciosa* are among those of interest. The trail to the old lookout site above the lake begins at Skinners Camp, a small cold shaded spring in a patch of *Darlingtonia californica*. Four members of the Orchid Family grow in or near this damp area (two *Habenaria*'s, and a *Listera* and *Coralorhiza*). *Lilium vollmeri*, *Castilleja elata*, and *Allium validum* are among a long list of species at this site. On up the trail large blocks of granodiorite provide a habitat contrasting with the wet area at Skinners Camp. A small grove of *Picea breweriana* sits on a slope near the top. The unusual spikes of the tall Green Gentian (*Frasera speciosa*) tower to 4 feet or so. Iris, columbine,



violet, and dwarf ceanothus are but a few of the colorful species lining the trail to the remains of the old lookout

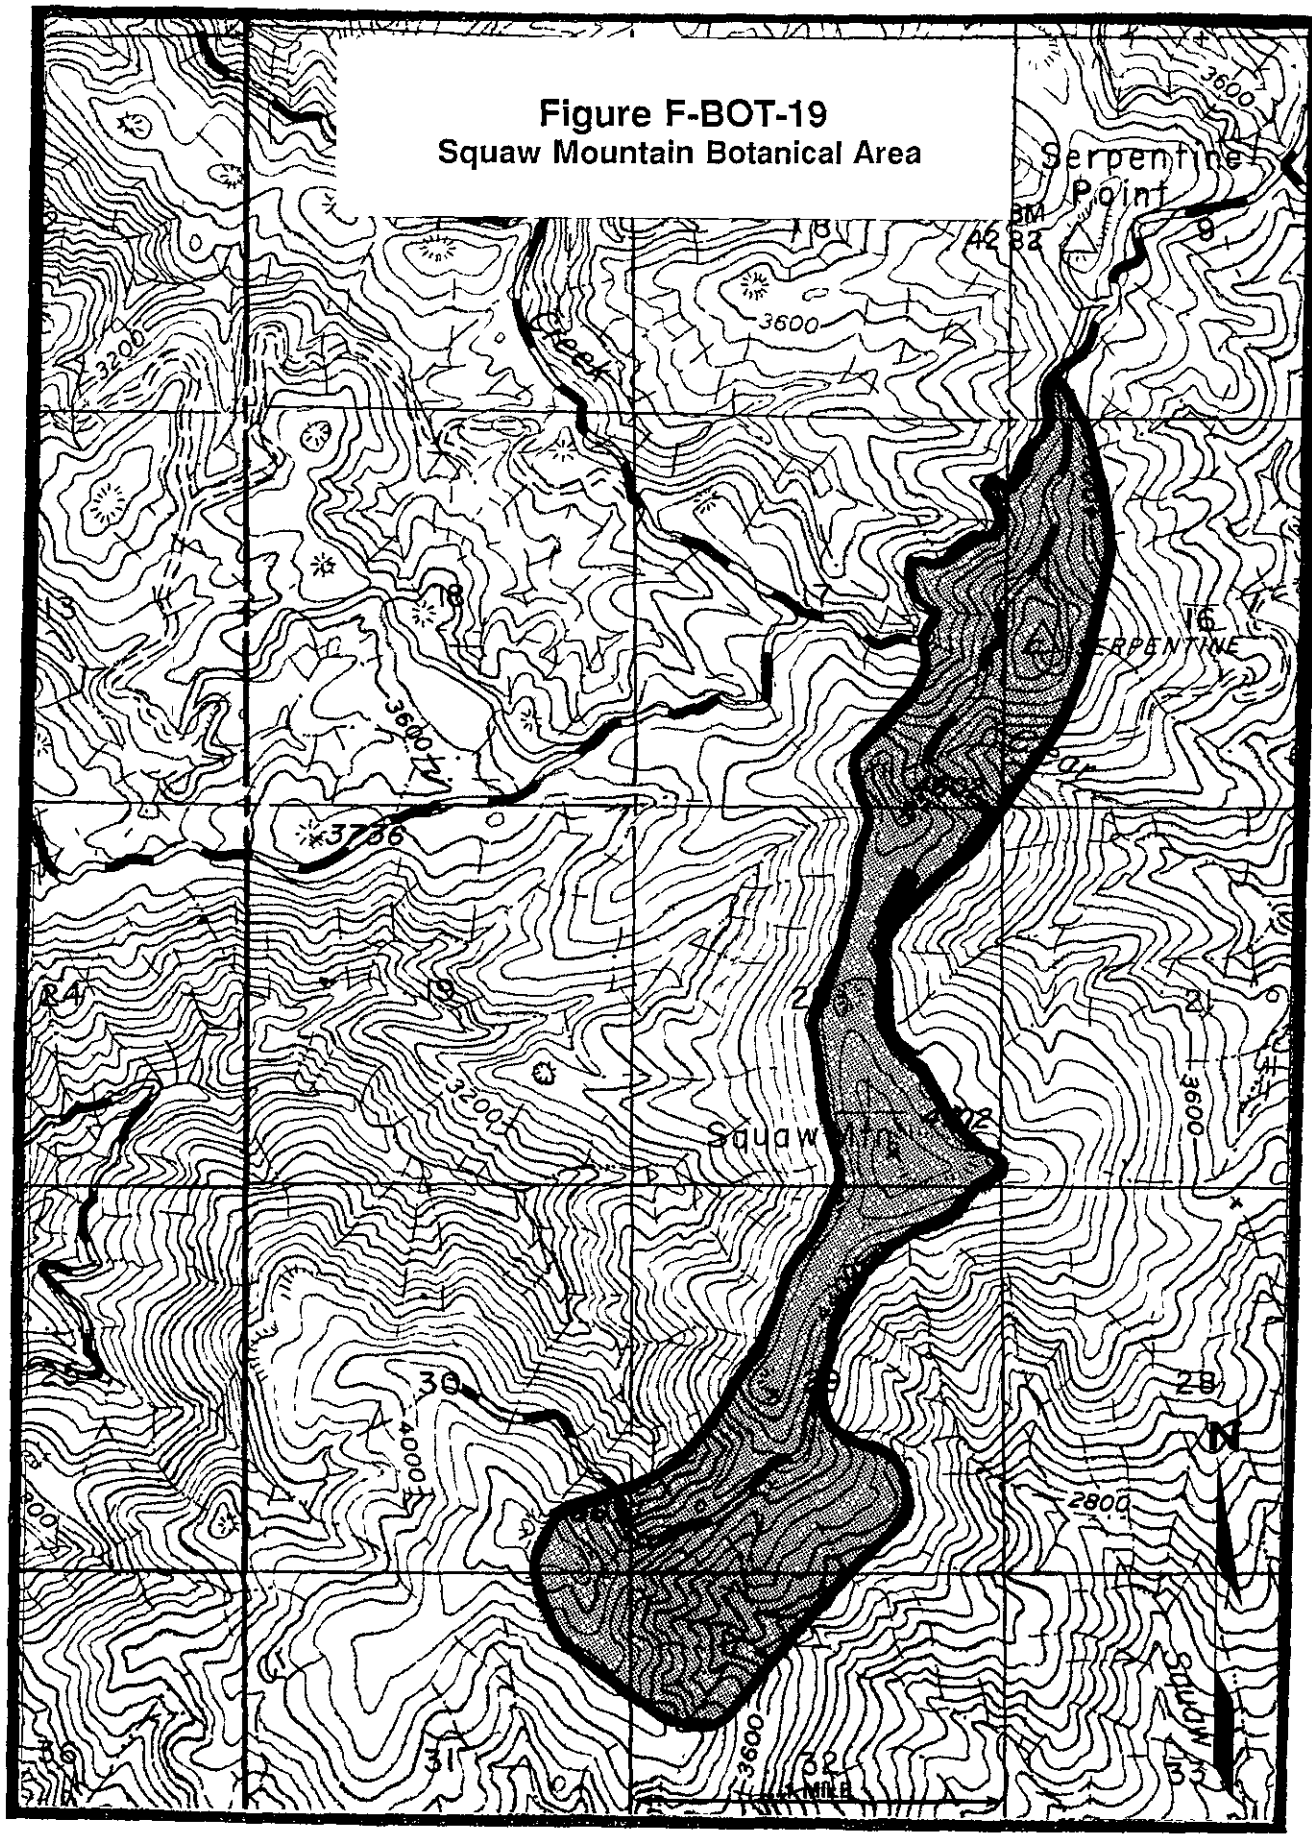


Table F-BOT-18 Unusual Plants in the Proposed Sourgame Botanical Area

Scientific Name	Common Name
Sensitive Species	
Allium bolanderi	Bolander's onion
Bensoniella oregana	bensonia
Erythronium howellii	Howell's fawn lily
Lupinus tracyi	Tracy's lupine
Watch/Review Species	
Arabis aculeolata	Waldo rock cress
Arabis koehleri ssp *stipitata* 1/	Koehler's rock cress
Castilleja elata	slender paintbrush
Darlingtonia californica	California pitcher-plant
Eriogonum pendelum	long-stalked eriogonum
Eriogonum ternatum 1/	Waldo eriogonum
Lathyrus delnorticus 1/	Del Norte pea
Lilium vollmeri	Vollmer's lily
Sedum laxum ssp. *heckneri* 1/	lax stonecrop

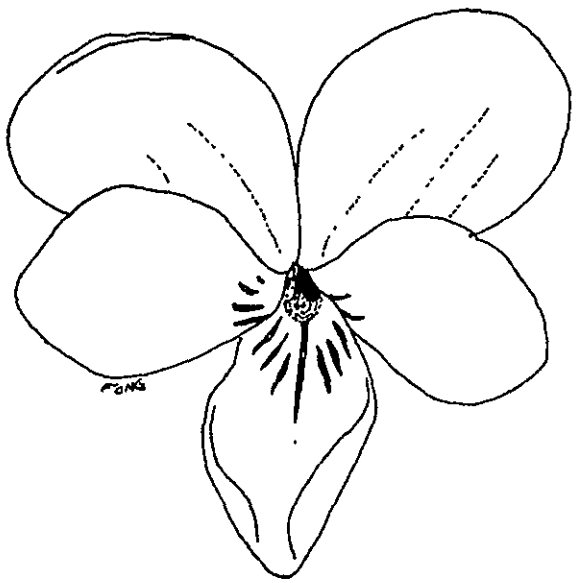
SQUAW MOUNTAIN - F-BOT-19

The 638 acre proposed Squaw Mountain Botanical Area is located on the Galice and Illinois Valley Ranger Districts, a few miles north of Eight Dollar Mountain (T 37S , R 8W., Sections 16, 17, 20, 29, 30, 31, 32) (Figure F-BOT-19). This proposed area occupies metavolcanic and ultramafic rock ridges and includes the Serpentine Lookout Site and Squaw Mountain. Elevation ranges from 3,500 to 4,702 feet.

The plant resources of the area have not been well inventoried, two sensitive species are known to be present (Table F-BOT-19).



About 252 acres in this proposed Botanical area are tentatively available and suitable for timber production, this land is capable of producing about 136 thousand board feet (MBF) of harvestable timber annually on a long-term sustained yield (LTSY) basis (see Table F-3). Two chromium prospects are located in the vicinity (Ramp and Peterson 1979).

This area is not recommended as a Botanical area in the Preferred Alternative (S).

Table F-BOT-19 Unusual Plants in the Proposed Squaw Mountain Botanical Area

Scientific Name	Common Name
Sensitive Species	
Lewisia leana	Lee's lewisia
Senecio hesperius	Siskiyou butterweed
Watch/Review Species	
Arabis koehleri var. *stipitata* 1/	Koehler's rock cress

1/ Potential candidate for Regional Forester's sensitive list.

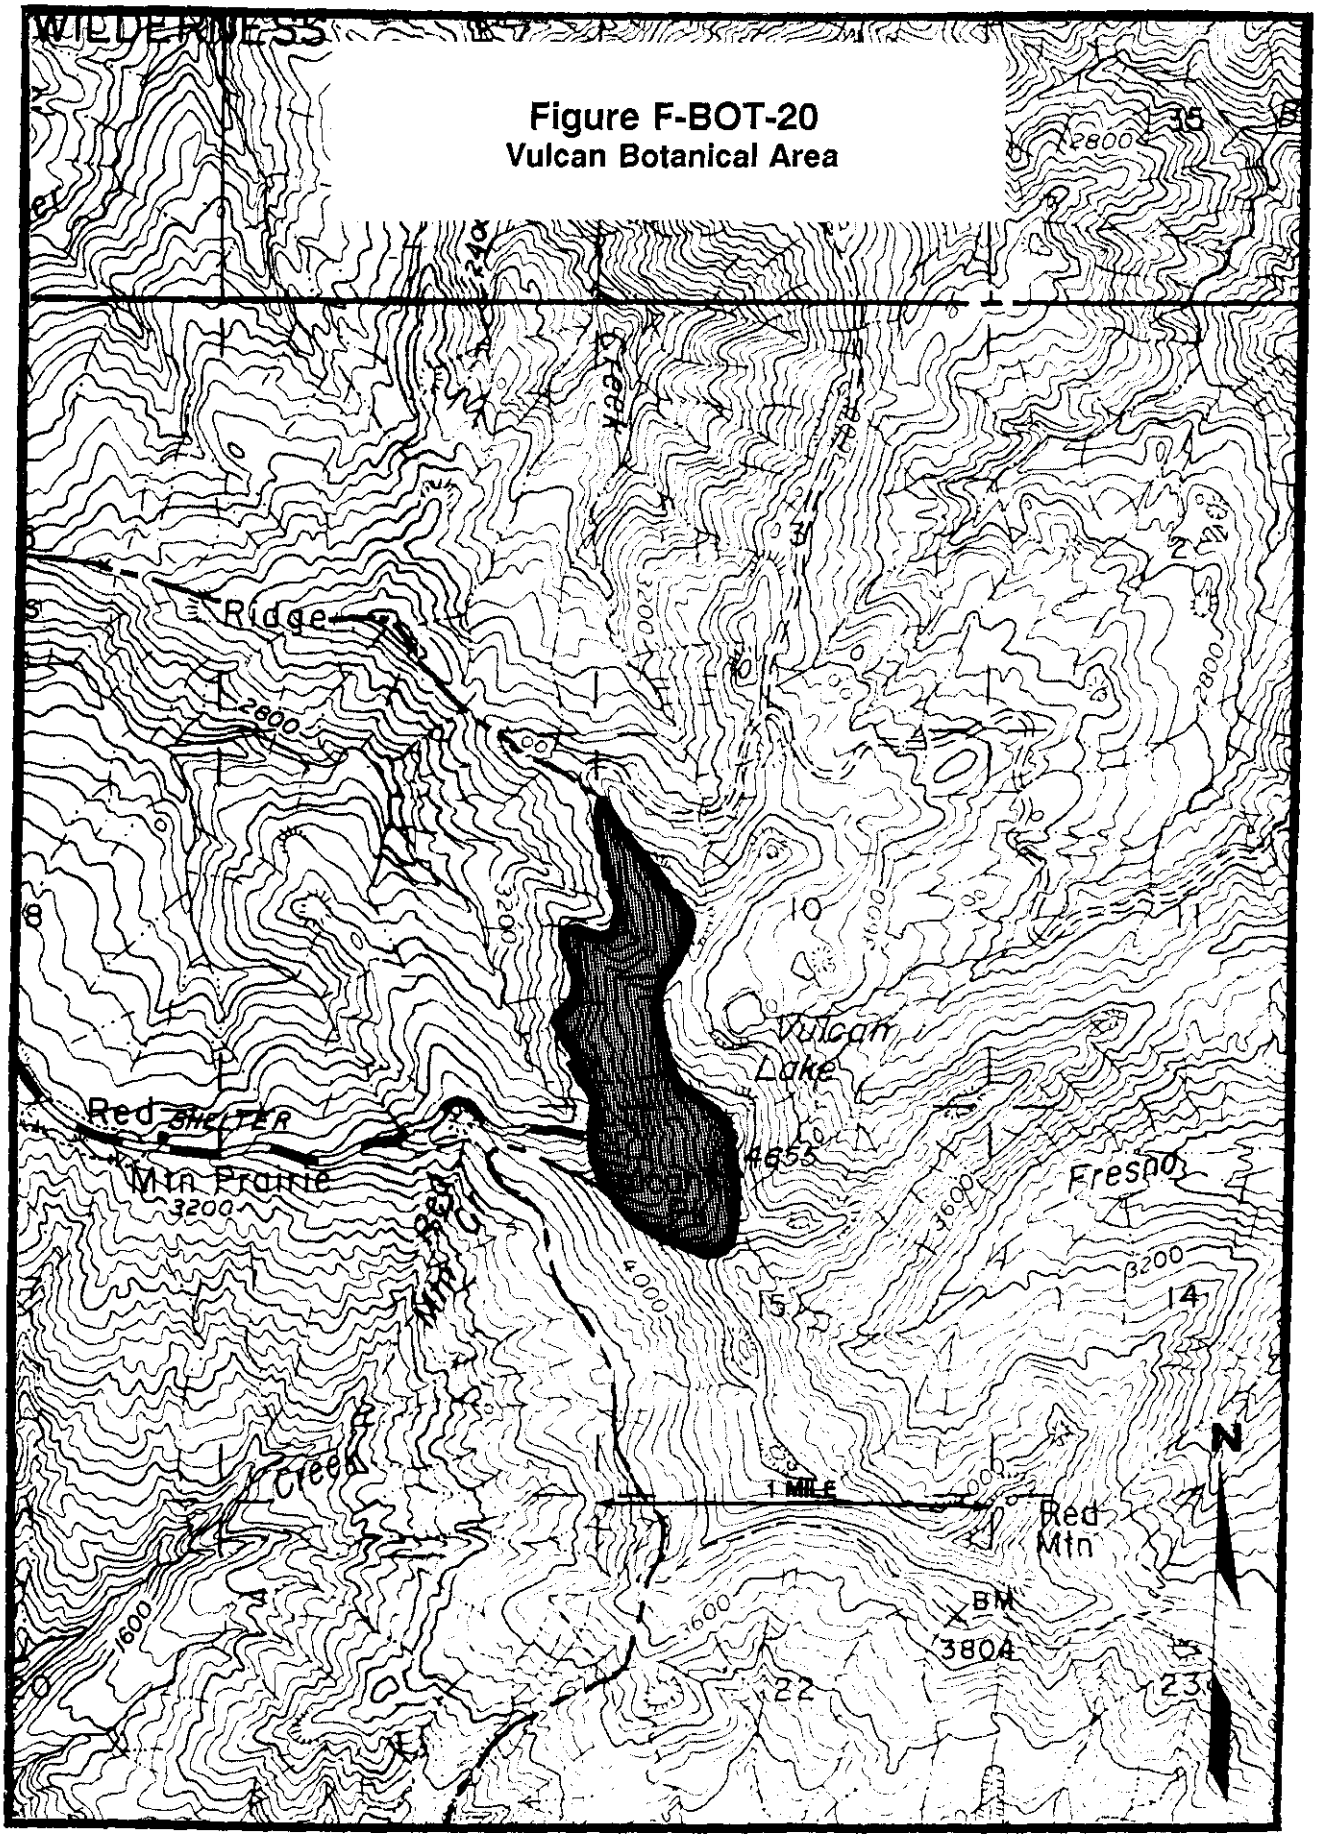


Figure F-BOT-20
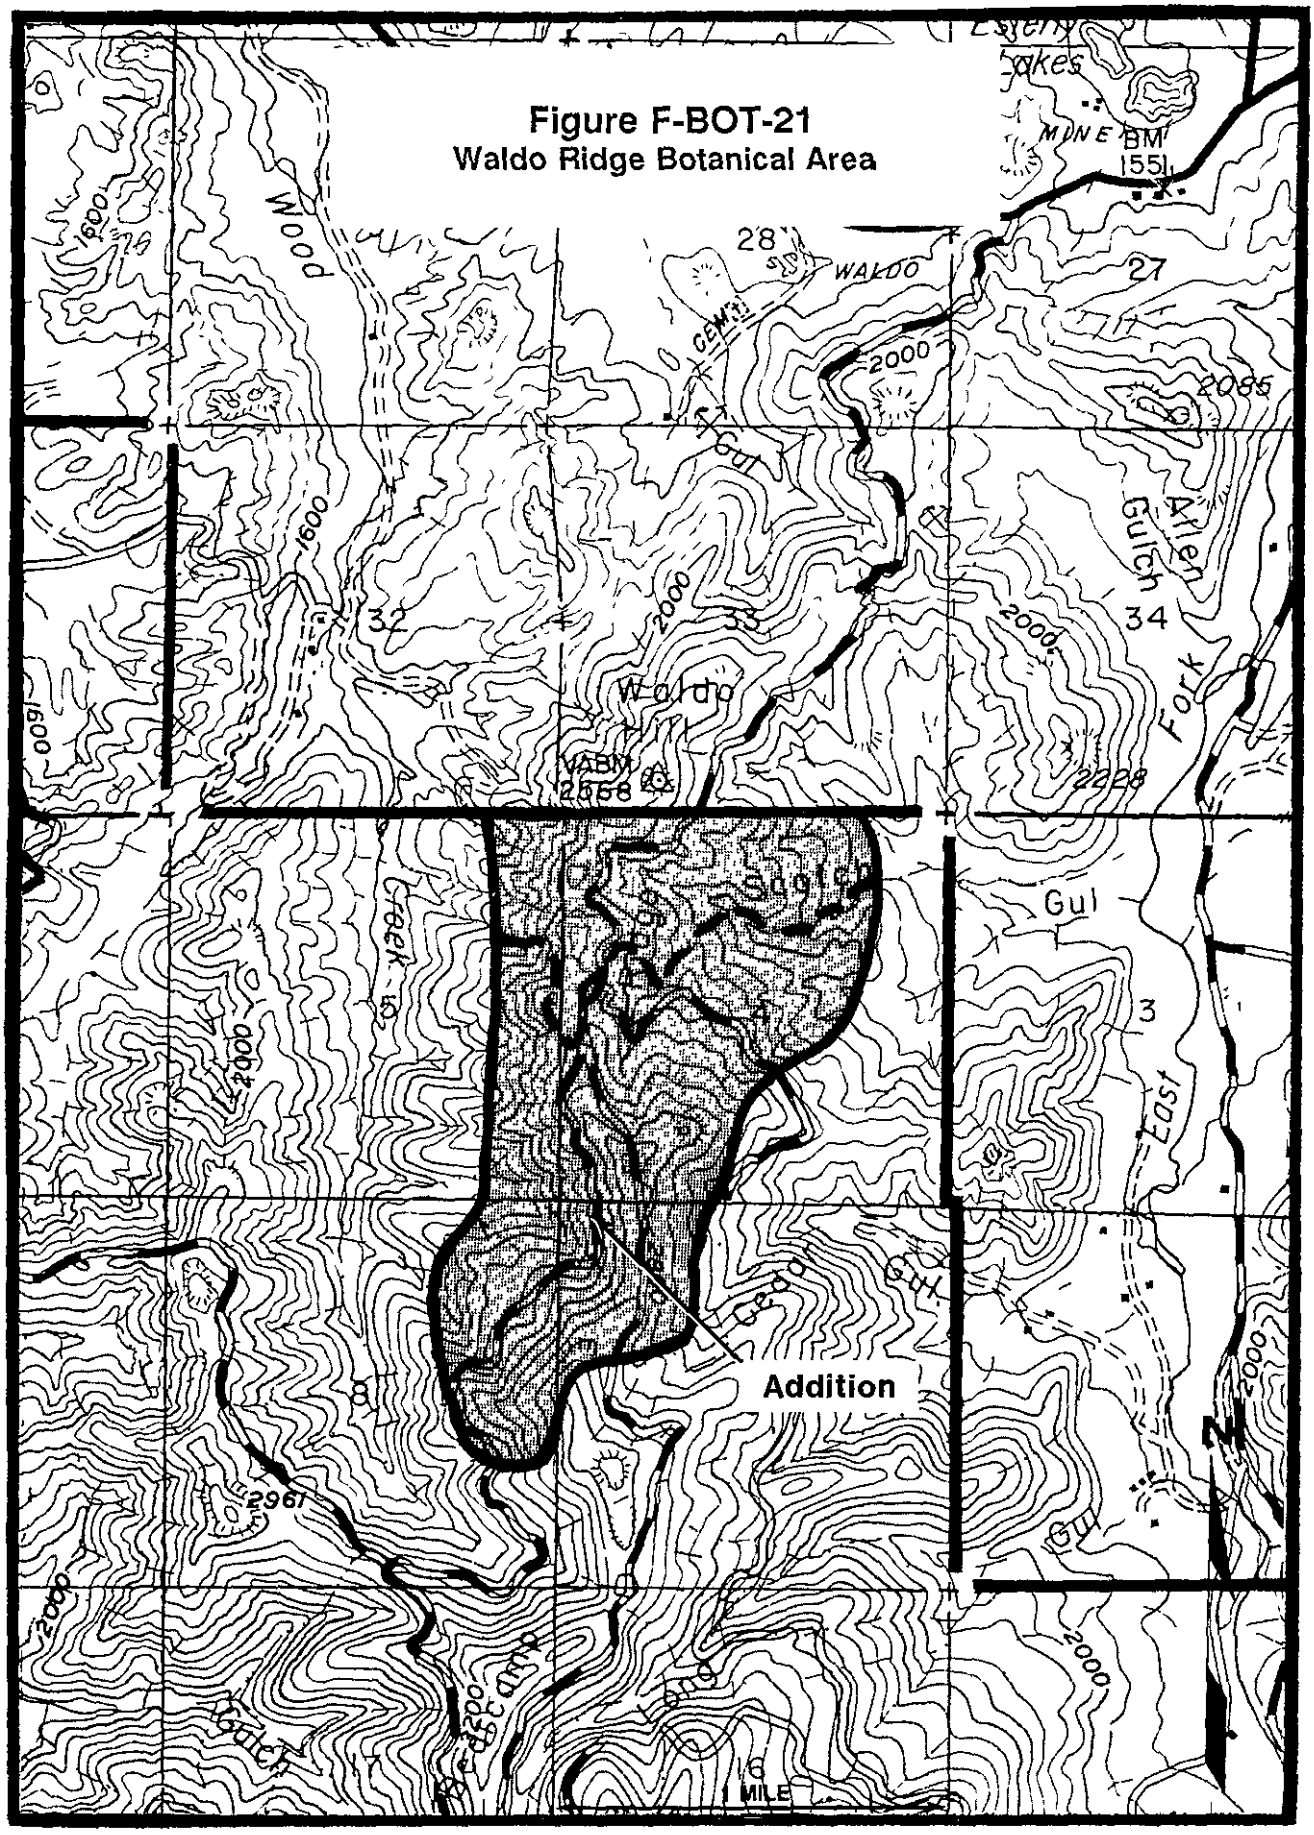
Vulcan Botanical Area

VULCAN - F-BOT-20

The 133 acre proposed Vulcan Botanical Area is located on the western boundary of the Kalmiopsis Wilderness, on the Chetco Ranger District (T.39S , R.11W., Sections 9, 10, 15) (Figure F-BOT-20) Elevation range is 3,600 to 4,655 feet (at Vulcan Peak). This area is recommended as a Botanical area in the Preferred Alternative (S)

Although not thoroughly inventoried, the known flora of the proposed Botanical area includes four sensitive species. *Epilobium rigidum* is present, along with other interesting species such as *Dentaria gemmata*, *Hieracium bolanderi* and *Horkelia sericata* (Table F-BOT-20).



The area has no lands tentatively available and suitable for timber production

Soils in the area are derived from ultramafic rock. No mineral deposits have been mapped within the area. The nearest significant nickel laterite deposits are located at the Cottonwood Camp Area, just south of Vulcan Peak. A chromite prospect is located in the northeast corner of the proposed Botanical area (Section 10 SE1/4 of the NW1/4 of the SW1/4) (Ramp and others 1977).

Table F-BOT-20. Unusual Plants in the Proposed Vulcan Botanical Area

Scientific Name	Common Name
Sensitive Species	
Dentaria gemmata	purple toothwort
Epilobium rigidum	rigid willow-herb
Hieracium bolanderi	Bolander's hawkweed
Streptanthus howellii	Howell's streptanthus
Watch/Review Species	
Cypripedium californicum 1/	California lady's slipper
Darlingtonia californica	California pitcher-plant
Eriogonum ternatum 1/	Waldo eriogonum
Lilium vollmeri	Vollmer's lily
Sedum laxum ssp *heckneri* 1/	lax stonecrop

WALDO RIDGE - F-BOT-21

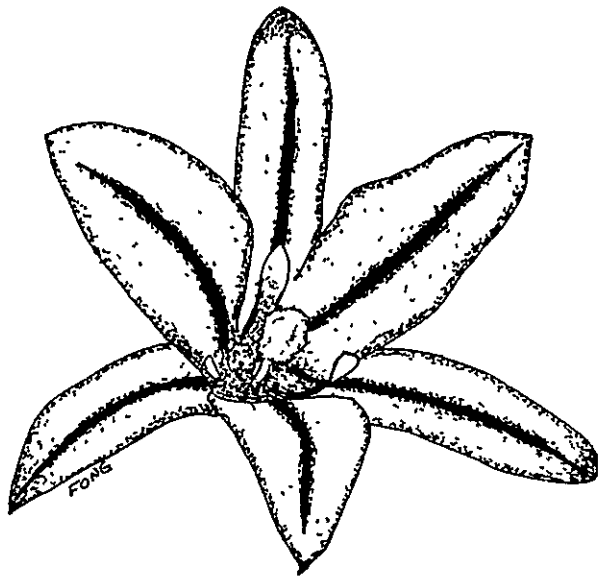
The proposed 707 acre Waldo Ridge Botanical Area is located on the Illinois Valley Ranger District, two miles south of the old mining town of Waldo (T 40S , R.8W., Sections 4, 5, 8, 9) (Figure F-BOT-21) Waldo Hill (2,568 feet) is just north of the proposed area; the headwaters of Scotch and Cedar Gulches drain the eastern half of the area Elevation range is 1,750 to 3,200 feet.

The Waldo Ridge site has been divided into two sections; this provides flexibility to land managers who must make decisions on land allocations. The primary area contains more sensitive plant resources than the addition. For further information on these options see Figures F-1 and F-BOT-21

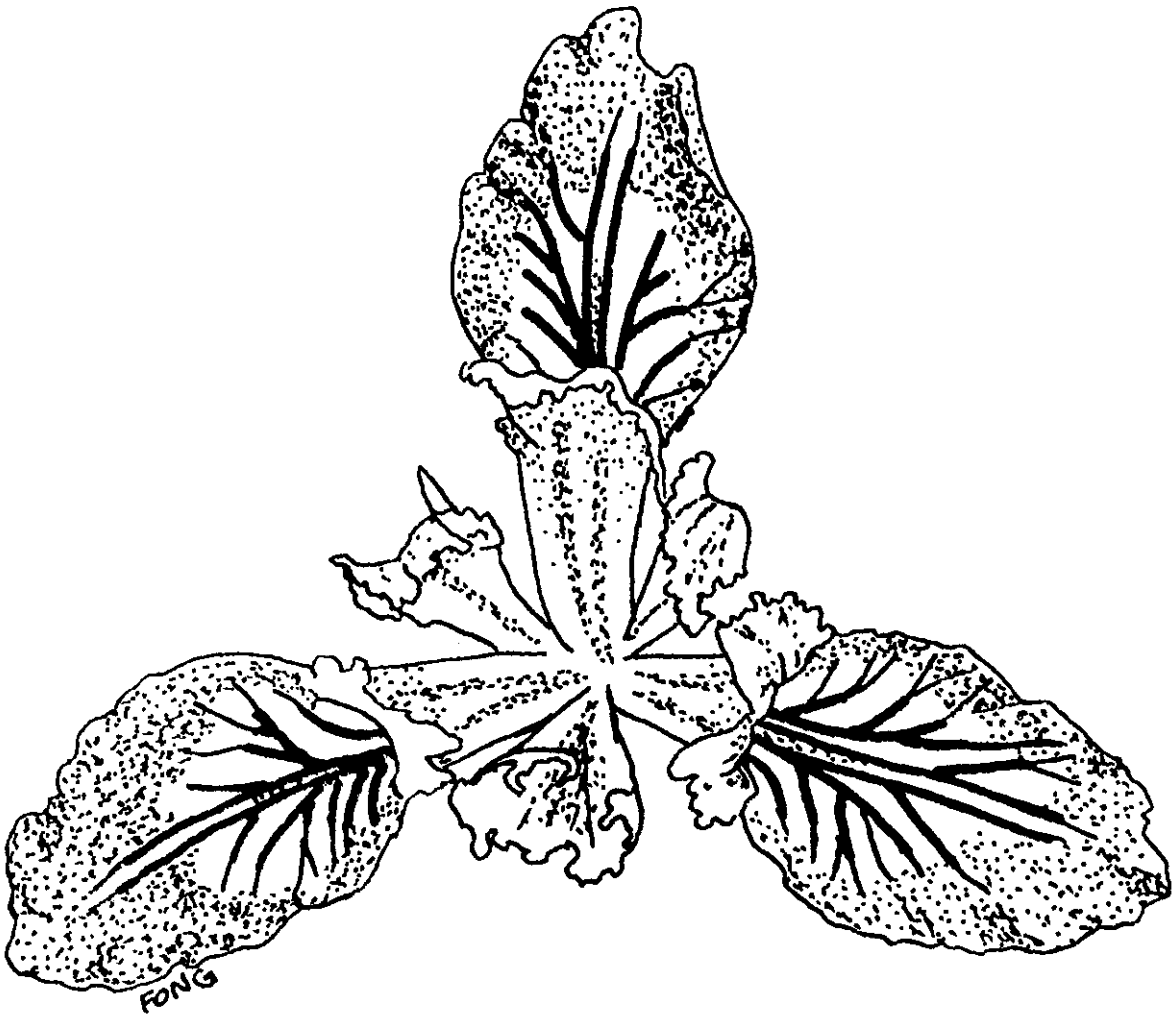
Although the plant resources of the proposed area have not been completely inventoried, ten sensitive species are known to be present. Included are *Monardella purpurea*, *Senecio hesperius*, and lilies such as *Calochortus howellii* and *Fritillaria glauca* (this may be the type locality for the last species). *Limnanthes gracilis* ssp. *gracilis* has been reported from the area, along with *Arabis suffrutescens* var. *horizontalis* These two sightings would be firsts for the Siskiyou National Forest (they need to be verified). Sensitive plants are concentrated in the northern portion of the area (see Figure F-BOT-21).

The old mining settlement of Waldo, just north of the proposed Botanical area, was an important center of interest for early-day botanists. Waldo is listed as the type locality for a number of rare plants endemic to southwestern Oregon and northwestern California Until recent years, labels on herbarium specimen-sheets rarely contained site-specific data. Although labels on older herbarium specimen-sheets may indicate that a plant was picked at a specific site, such as "Waldo", collecting may actually have taken place anywhere within a few miles. For example, on May 18, 1930, Tracy's sanicula (*Sanicula tracyi*) was collected at "Waldo" by Kildale. Conceivably, this specimen may actually have been collected within the Waldo Ridge proposed Botanical area, two miles south of the settlement of Waldo Recent botanical surveys of the Waldo townsite area have failed to turn up any specimens of *S. tracyi*; perhaps this species will yet be rediscovered on the Waldo Ridge area. Intensive plant inventories of the proposed area are needed before the full extent of the area's unusual plant resources can be established

The Waldo Ridge proposed area, as presently delineated, contains 516 acres of land tentatively suitable for timber production, mostly in the "Addition". These acres are capable of a long-term sustained yield (LTSY) of about 278 thousand board feet (MBF) annually of timber harvest (see Table F-3 for more detail).



Soils in the area are derived from two rock types: ultramafic (serpentine/peridotite) and metavolcanic (Applegate Group). Ultramafic rock is found mainly in the upper and lower third of the Botanical area; the middle third is metavolcanic. No known mineral deposits are within the Botanical area, but ultramafic rock does contain minor deposits of gold, and placer deposits of platinum originate in this rock type Gold-bearing quartz veins are characteristic of the metavolcanic rock within this proposed area (Ramp and Peterson 1979).



The Waldo Ridge area is not recommended as a Botanical area in the Preferred Alternative (S). More botanical inventory is needed to pinpoint important concentration sites for rare species; it is also thought by botanists that rare plant values are higher on adjacent land (to the north) managed by the Bureau of Land Management. The Bureau is presently involved in a comprehensive land management planning process; they will consider the land north of Waldo Hill for Botanical area status. If the BLM does classify the Waldo site as a Botanical area, at a future date the Forest Service could follow suit and designate the Siskiyou portion. The site could become a "joint" Botanical Area. In any event, the Forest Service portion of the area will be reconsidered at the next revision of the Forest Plan.

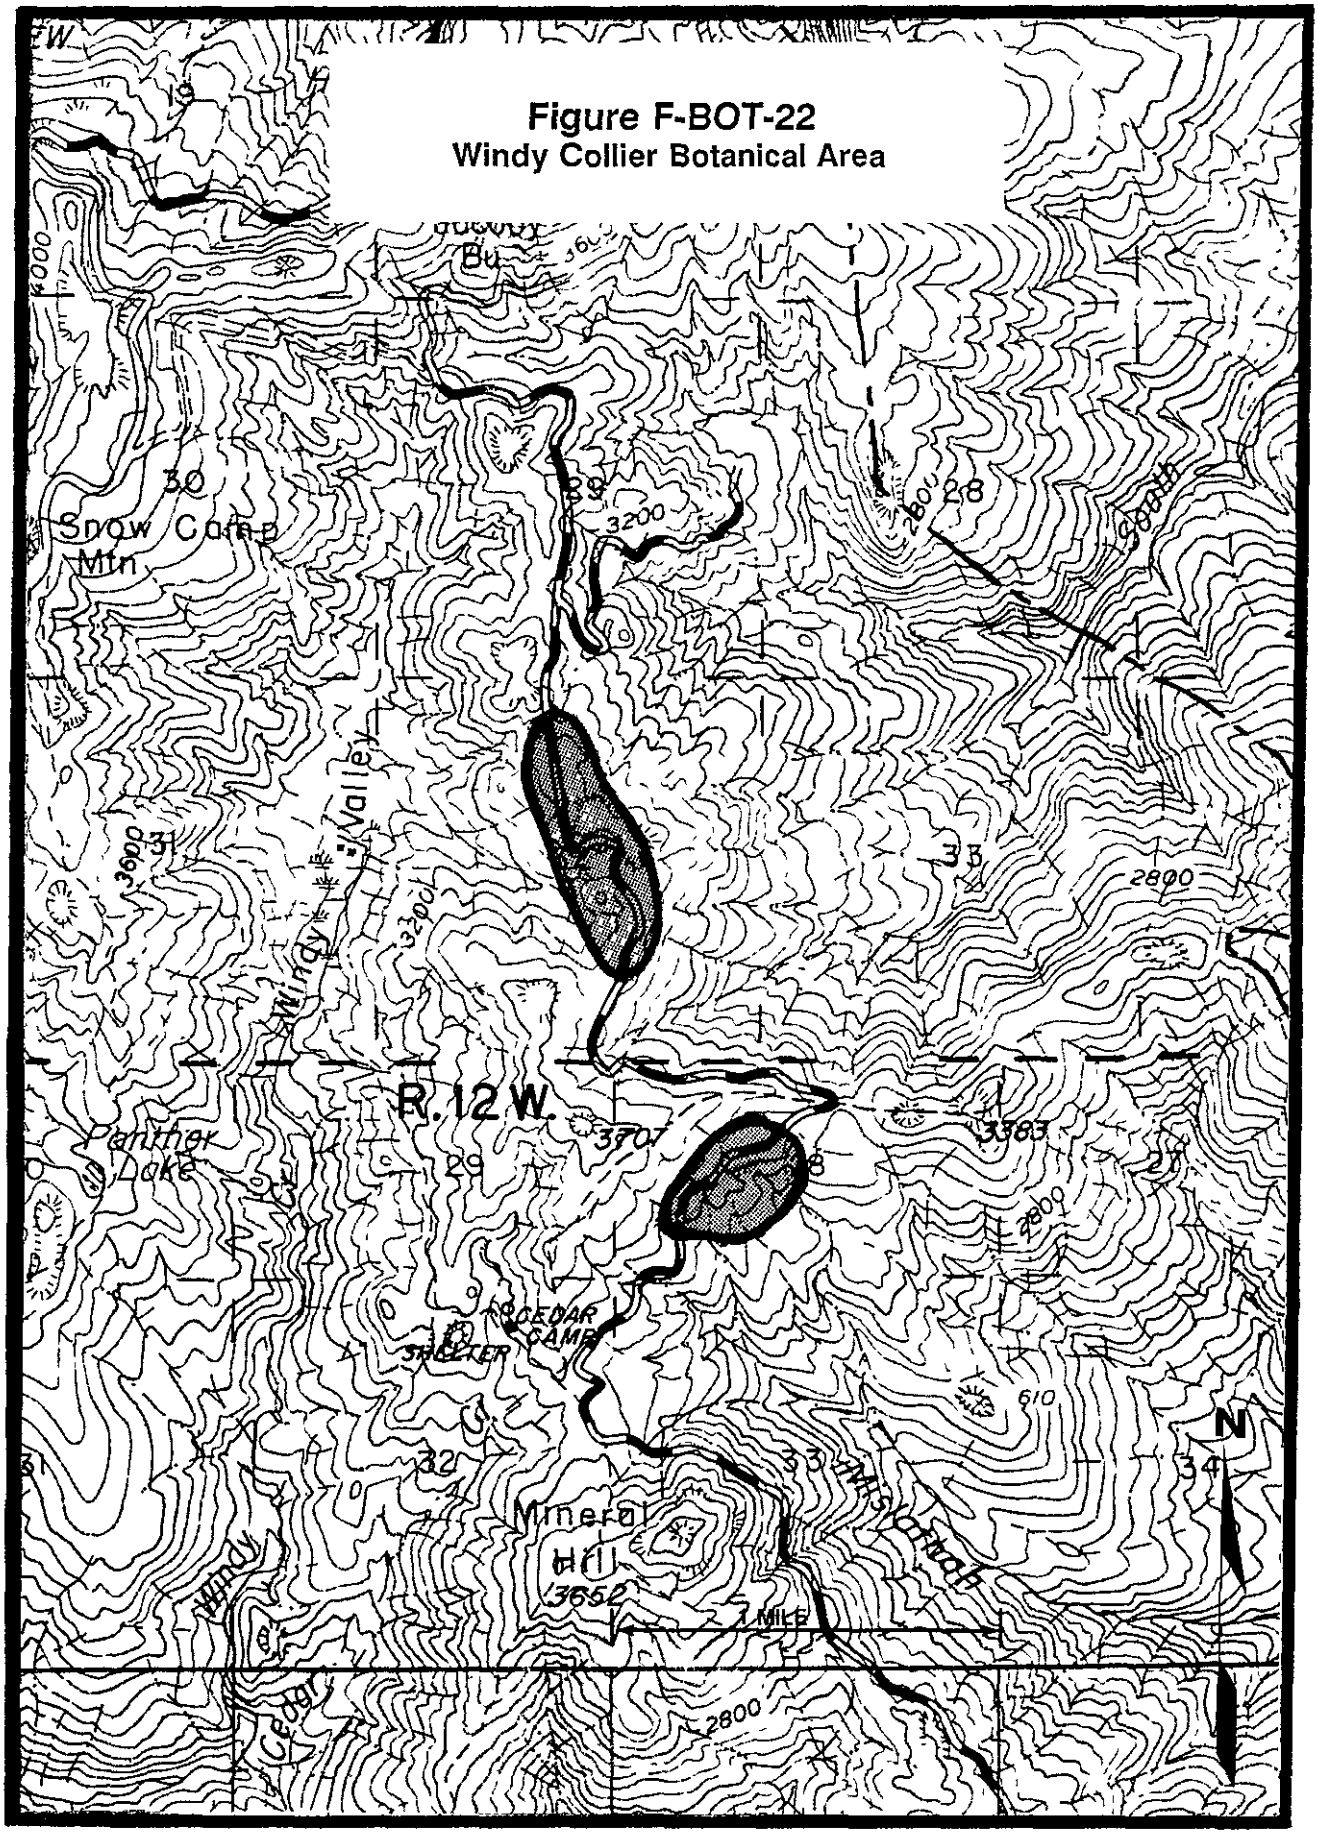


Table F-BOT-21 Unusual Plants in the Proposed Waldo Ridge Botanical Area

Scientific Name	Common Name
Sensitive Species	
Calochortus howellii	Howell's mariposa lily
Epilobium oreganum	Oregon willow-herb
Erythronium howellii	Howell's fawn lily
Fritillaria glauca	Siskiyou fritillaria
Lewisia oppositifolia	opposite-leaved lewisia
Microseris howellii	Howell's scorzonella
Monardella purpurea	Siskiyou monardella
Sanicula tracyi ?	Tracy's sanicula
Senecio hesperius	Siskiyou butterweed
Streptanthus howellii	Howell's streptanthus
Watch/Review Species

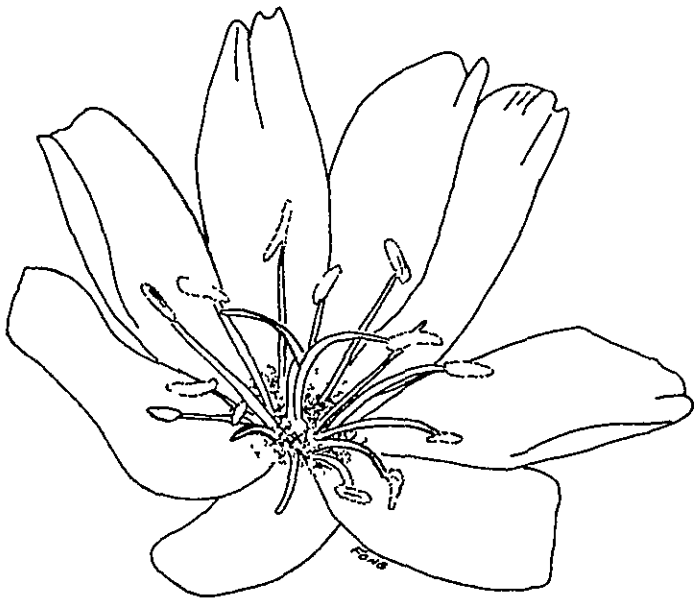
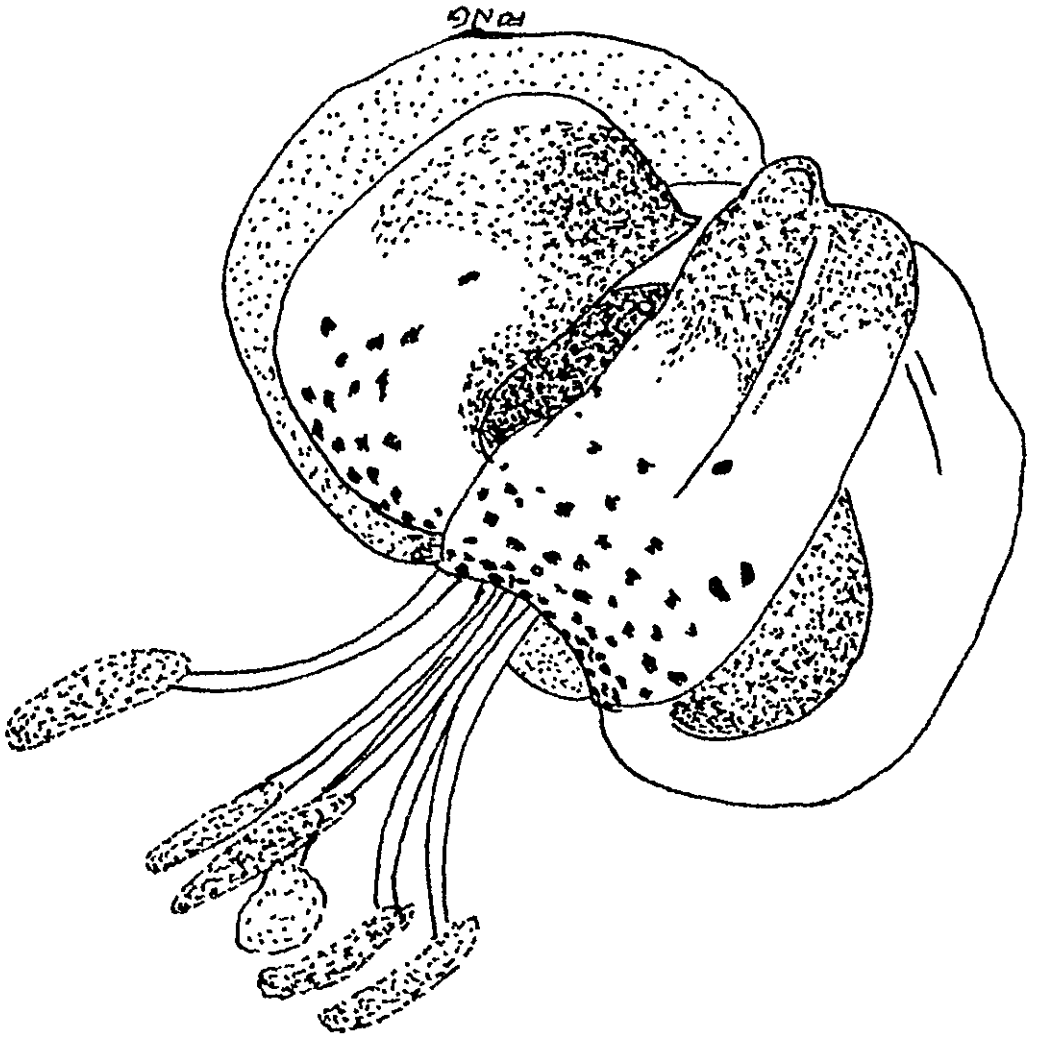
WINDY COLLIER - F-BOT-22

The 147 acre proposed Windy Collier Botanical Area is located on serpentine ridgetops in the northwestern corner of the Chetco Ranger District. The area is divided into two separate portions a mile apart, one in Section 32, T.37S , R.12W., and the other in Section 28, T.37 1/2 S., R.12W (Figure F-BOT-22) Elevation range is 3,050 to 3,450 feet. Windy Valley is approximately one mile to the west.

This area is an unusual assemblage of intermixed dry and wet sites. Scattered *Darlingtonia* bogs are juxtaposed with dry chaparral sites. Plants such as *Lilium vollmeri* (bog site) grow within 10 feet of *Lilium bolanderi* (dry site). *L.* bolanderi is especially common. Intensive plant inventories of this area will undoubtedly reveal the presence of sensitive species (Table F-BOT-22).



The Windy and Collier proposed area contains 115 acres of land tentatively suitable for timber harvest and could produce approximately 62 thousand board feet (MBF) per year of harvestable timber on a long-term sustained yield (LTSY) basis (see Table F-3).



Soils in this area are derived from ultramafic rock (serpentinite). Chromite prospects have occurred in both portions of the Botanical area; no other mineral deposits are known (Ramp and others 1977)

This area is not recommended as a Botanical area in the Preferred Alternative of the Forest Plan (S).

NARRATIVES
OLD-GROWTH BOTANICAL AREAS

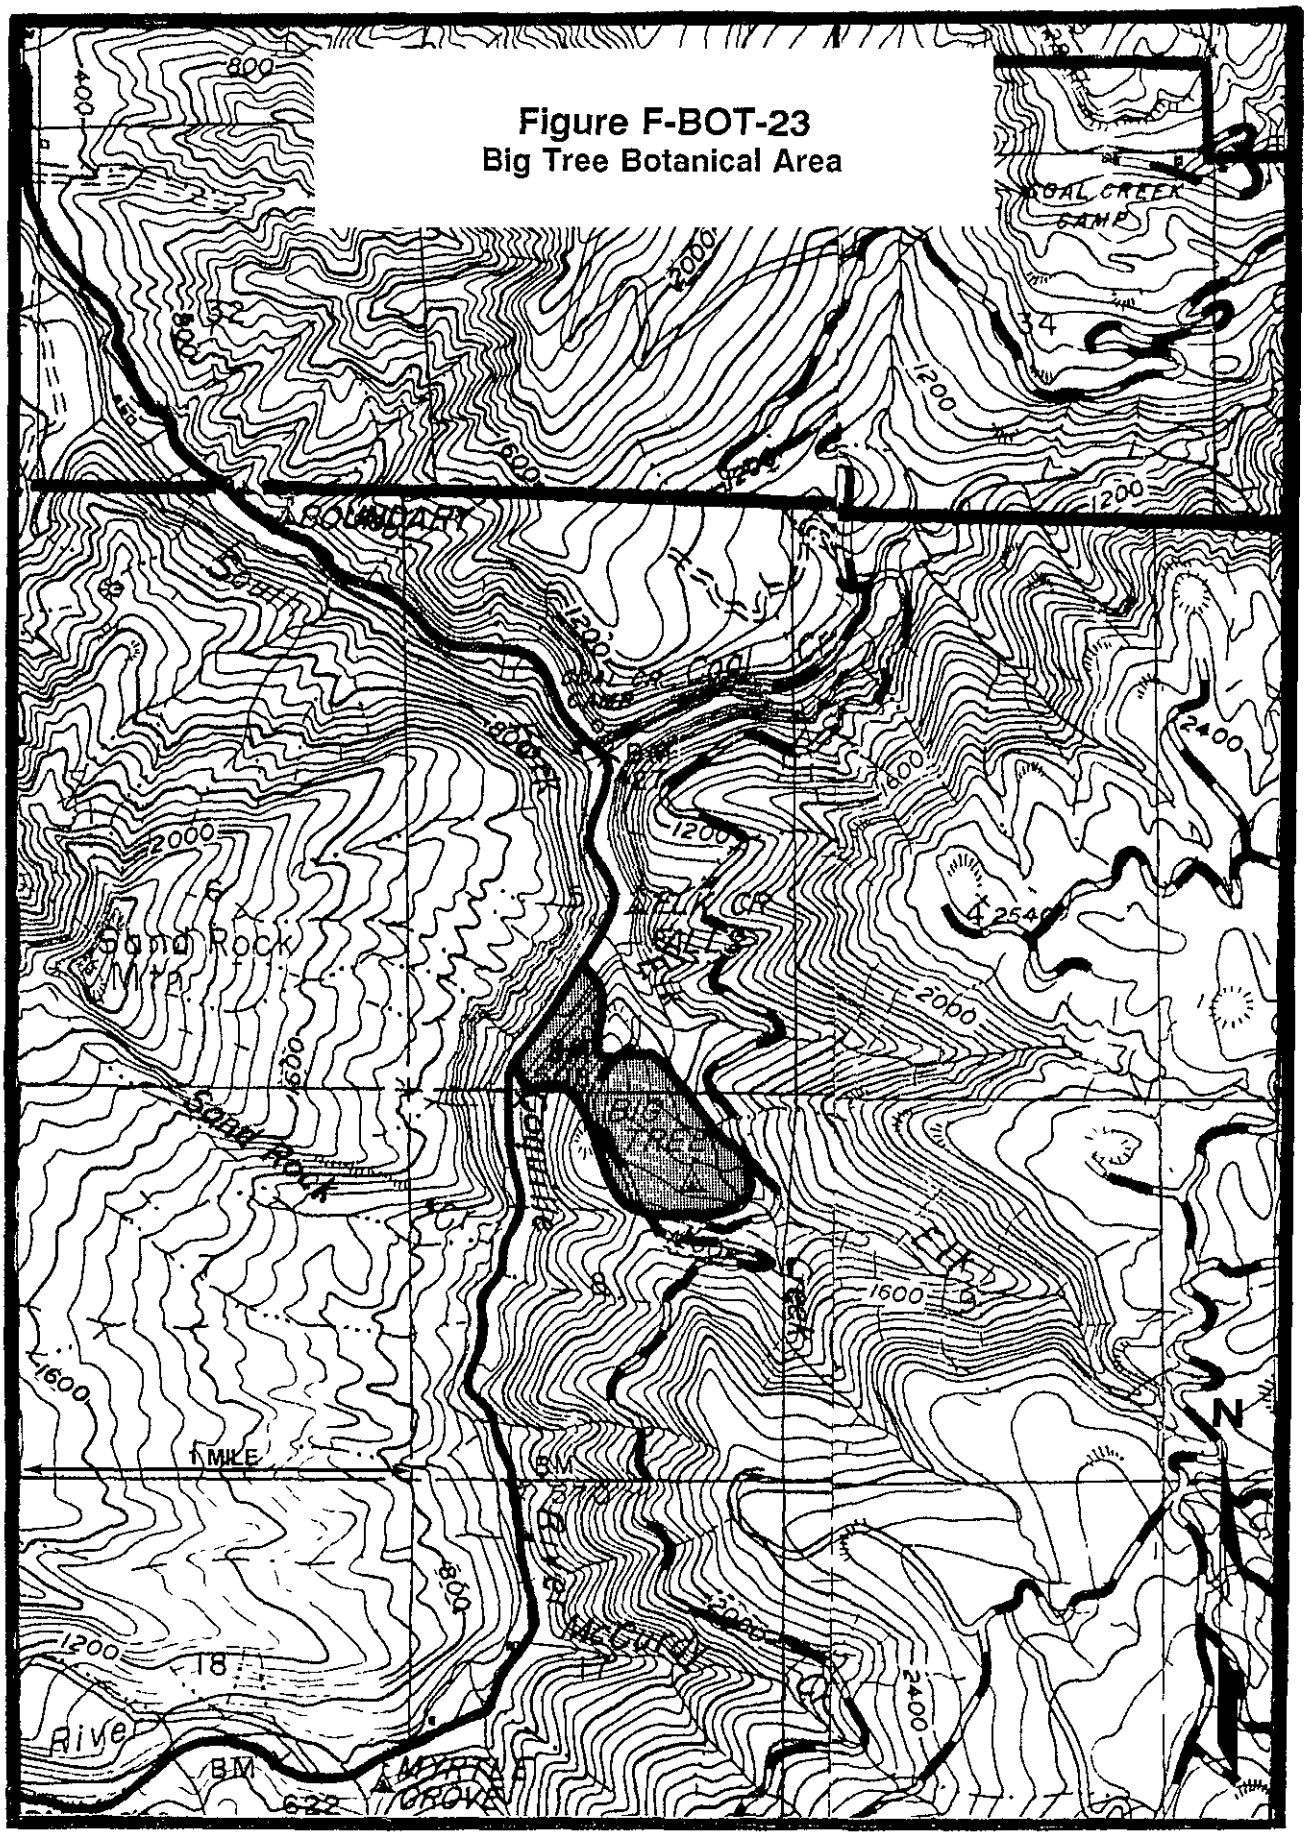

Figure F-BOT-23
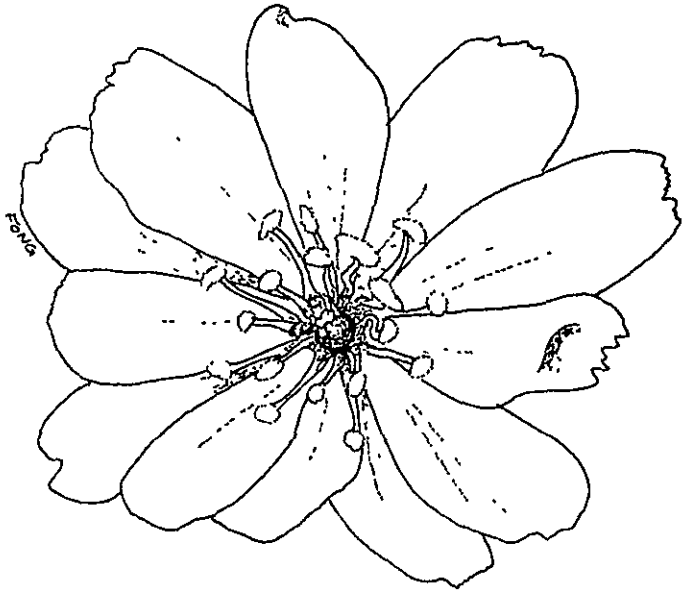
Big Tree Botanical Area

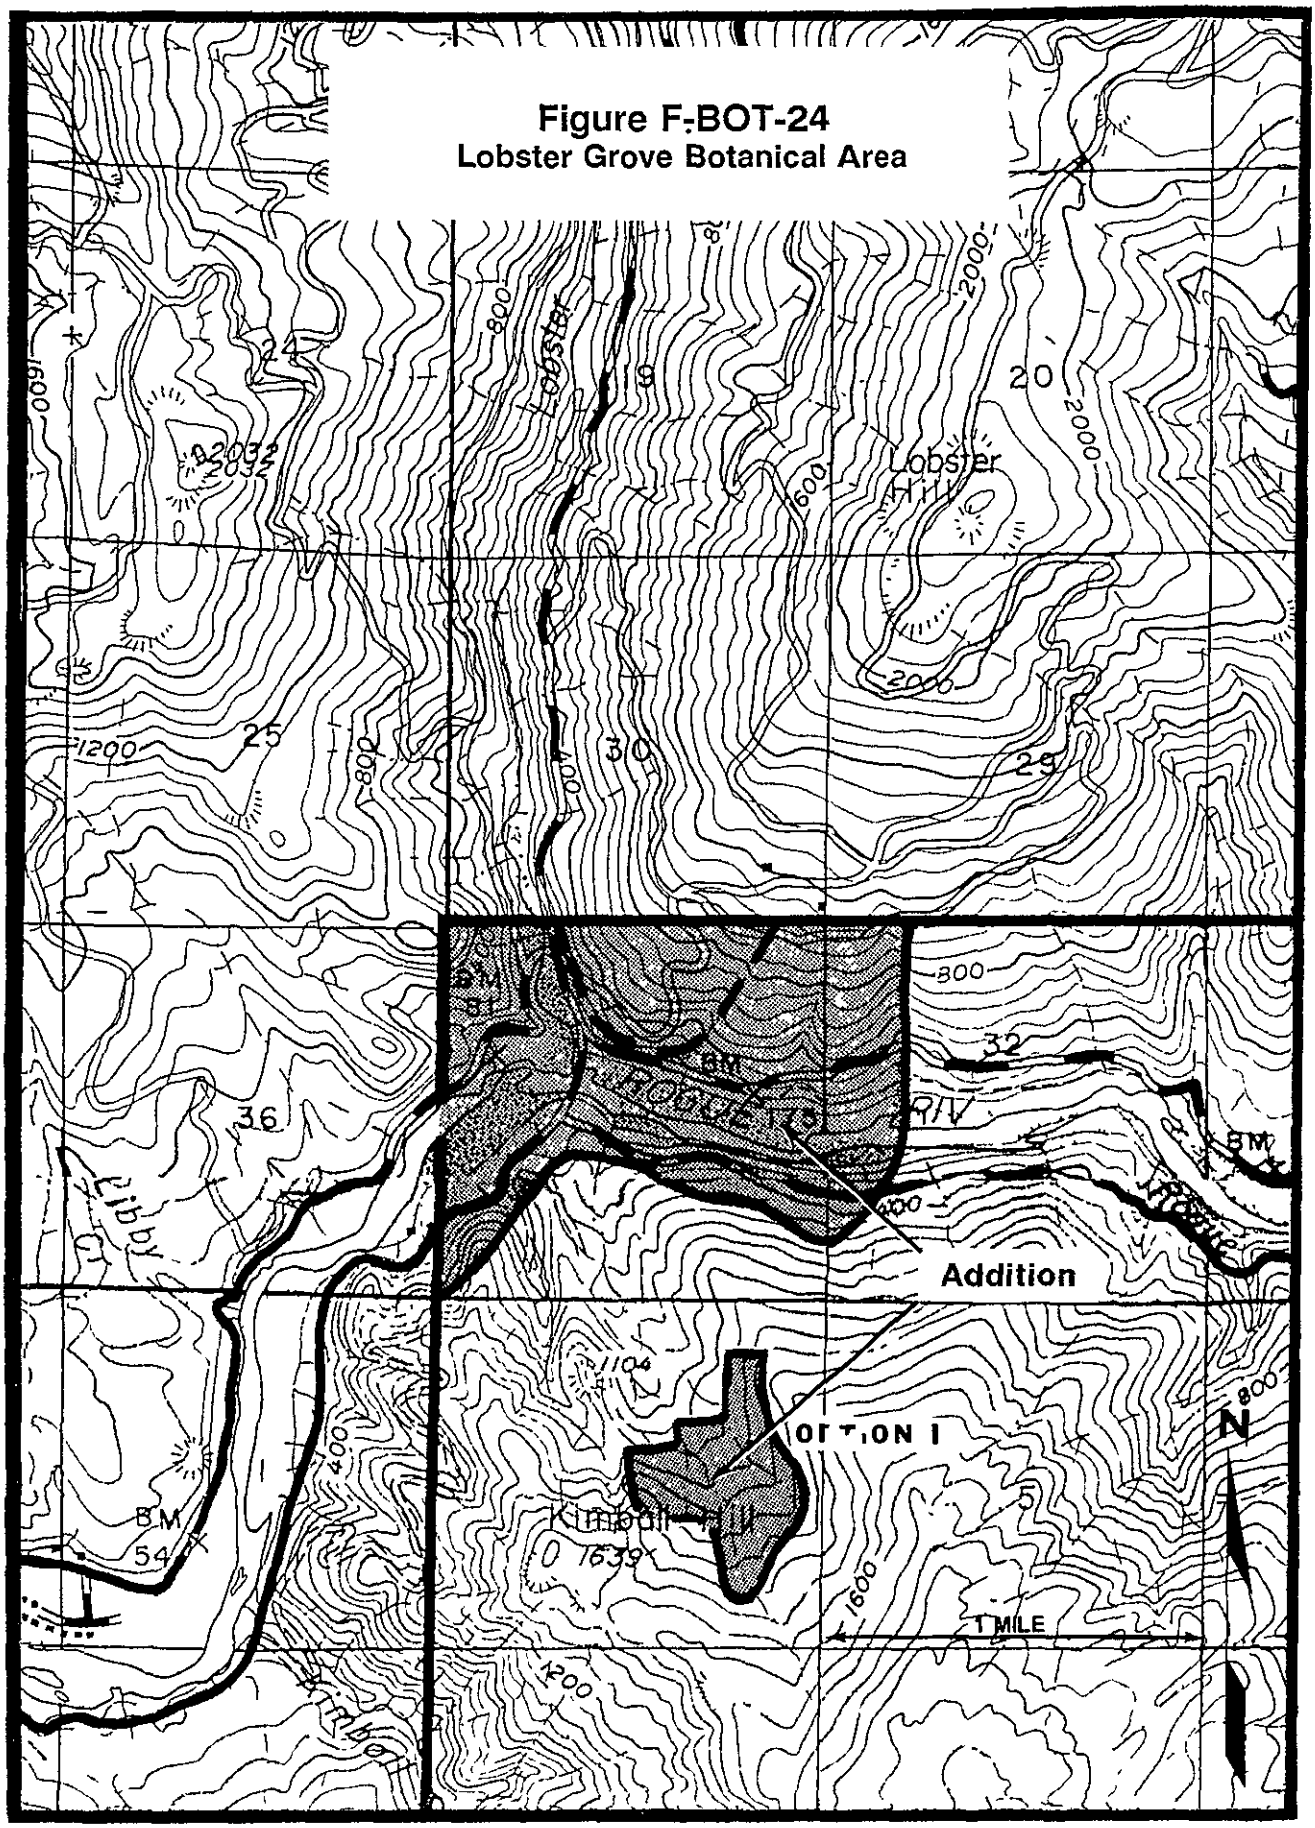
OLD-GROWTH BOTANICAL AREAS - PROPOSED

BIG TREE - F-BOT-23

The 127 acre proposed Big Tree Botanical area is located along the South Fork of the Coquille River south of the mouth of Elk Creek, on the Powers Ranger District (T.32S., R.11W., Sections 5, 8) (Figure F-BOT-23). Elevation range is 500 to 1,200 feet.



This is an old-growth site; no sensitive plants are known. The value of the site lies not with rare plants, but with its old-growth plant community. The world's largest Port-Orford-cedar is located within the area. Very large Douglas-fir are also present. Big-leaf maple and western hemlock dominate the subcanopy. The understory is composed of rhododendron, tanoak, alder, and sword fern.



Access to the area is a trail (1150) which connects Elk Creek Falls along road 42 to Big Tree Picnic Area on road 3358. The area is also partially accessible by spur roads 3358-090 and -091. The old-growth site is visible from road 42 and the South Fork of the Coquille River.

About 116 acres in this proposed Botanical area are tentatively available and suitable for timber production; this land is capable of producing about 63 thousand board feet (MBF) of harvestable timber annually on a long-term sustained yield (LTSY) basis (see Table F-3).

Soils in this area are derived from marine sedimentary rock, primarily siltstones and mudstones (Umpqua Formation) (Beaulieu 1971).

The site was listed as a Supplemental Resource area in the DEIS. In Alternative S of the FEIS (the Preferred Alternative) Big Tree is recommended as a Botanical Area.

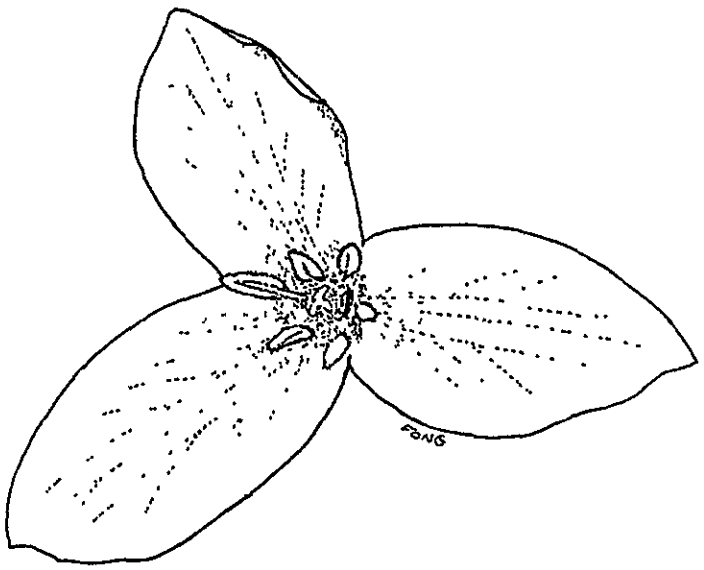
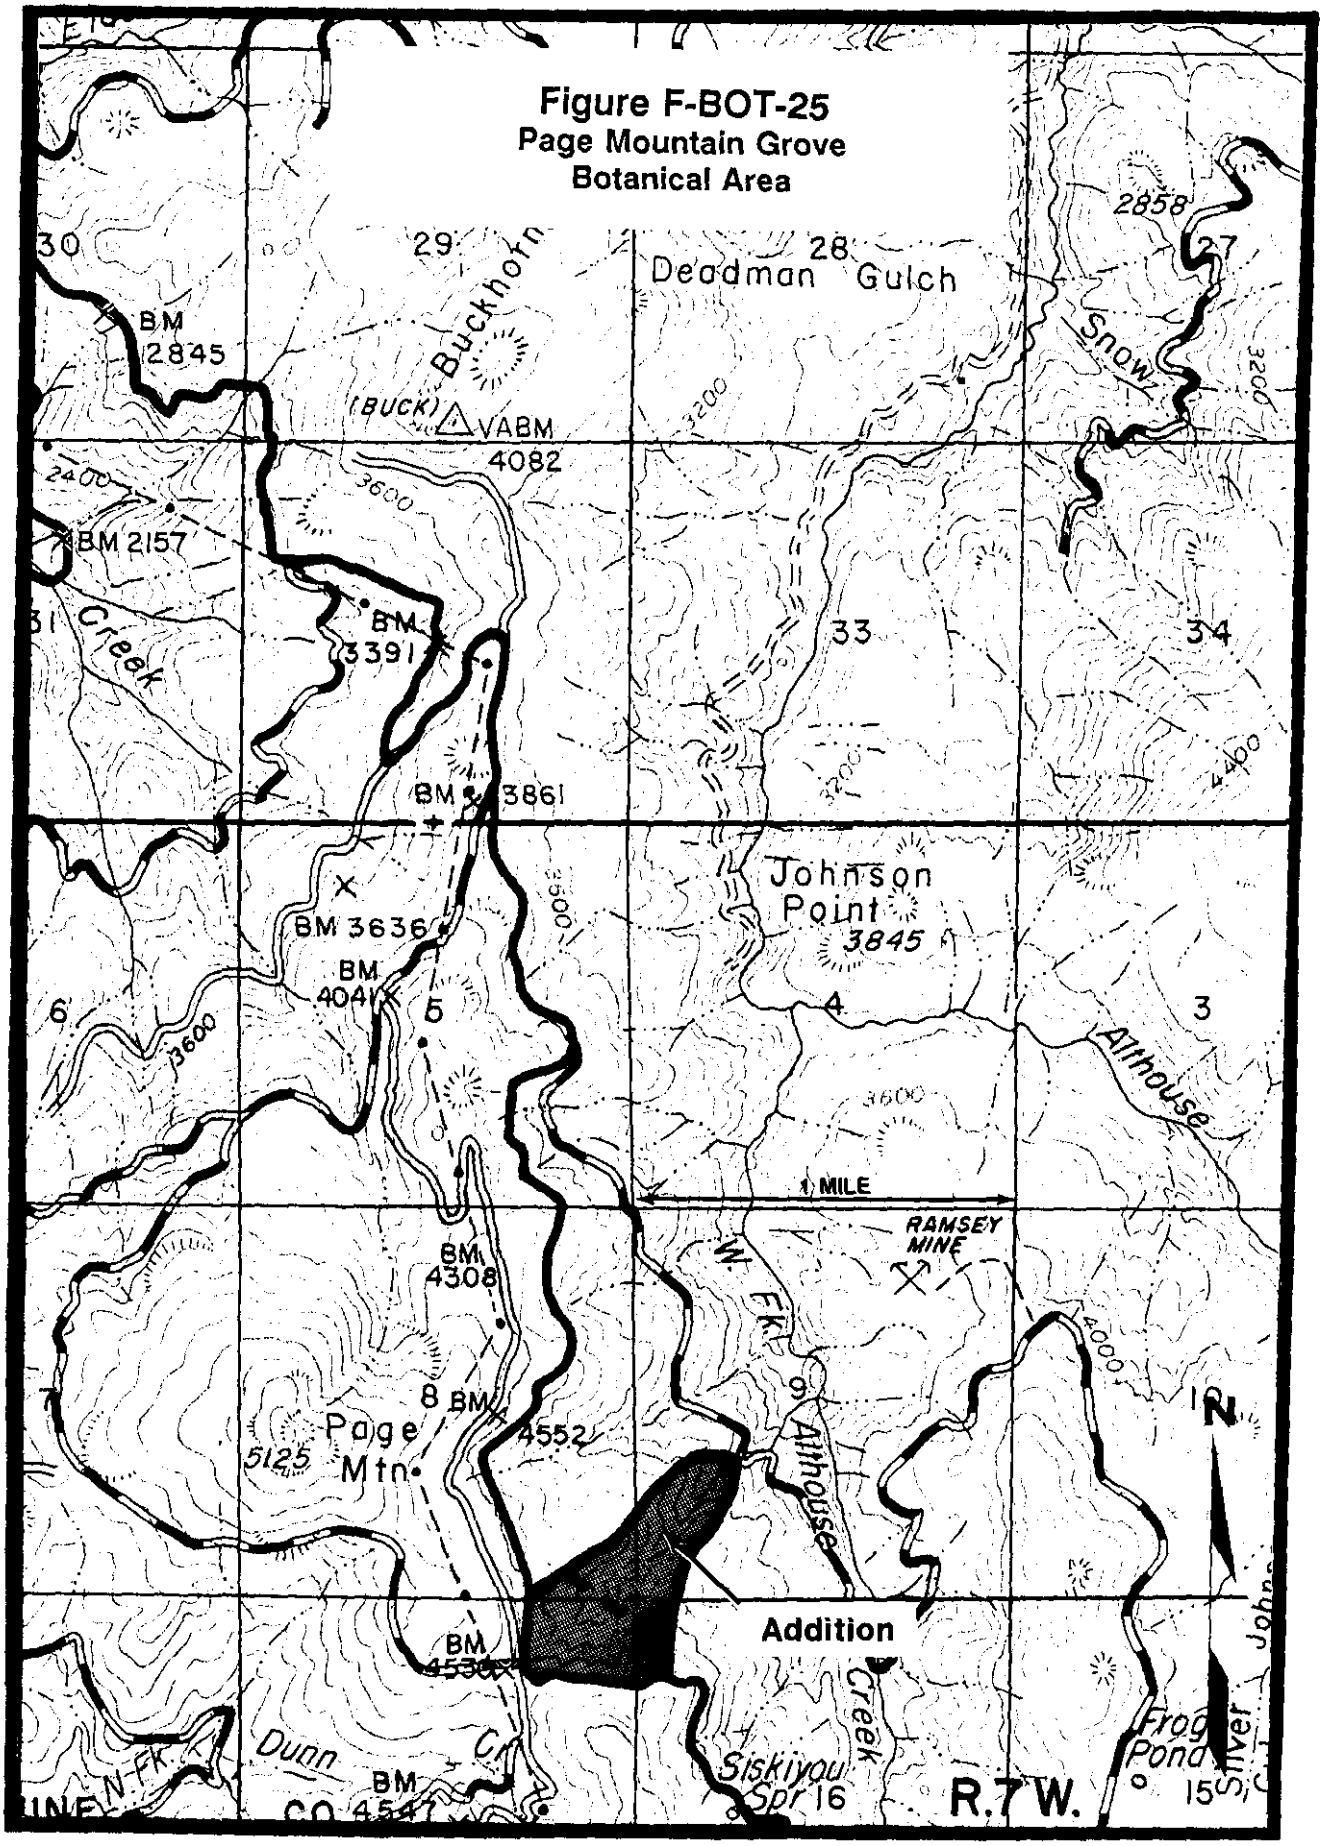
LOBSTER GROVE - F-BOT-24

The 534 acre proposed Lobster Grove Botanical Area is located on the banks of the Rogue River at the mouth of Lobster Creek, on the Gold Beach Ranger District (T.35S.,R.13W., Sections 31, 32, and T 36S ,R.13W., Section 6) (Figure F-BOT-24). Elevation range is 81 to 1,500 feet. The Lobster Grove site has been divided into two sections; this provides flexibility to land managers who must make decisions on land allocations. For further information on these options see Figures F-1 and F-BOT-24



This is an old-growth site; no sensitive plants are known. The value of the site lies not with rare plants, but with its old growth plant community. This is an area of very large Douglas-fir and Port-Orford-cedar; some individual trees approach 8 feet in diameter. The 10-15 large trees per acre dominate the site, the heavily shaded understory is composed of sword fern, willow (wet sites), tanoak, madrone, and Oregon-myrtle (the world's largest myrtle tree is located within the Grove).



In the steeper areas slopes average 50 percent. Access to a significant portion of the area north of the river is a jeep road through private land. Most of the old-growth site is visible from the Agness road, and a portion is visible to boaters on the Rogue River. Groves of large old-growth trees are increasingly rare, especially in an area visited by thousands of recreationists each year. In the future this site may receive considerable use by the public

About 312 acres in this proposed Botanical area are tentatively available and suitable for timber production; this land is capable of producing about 169 thousand board feet (MBF) of harvestable timber annually on a long-term sustained yield (LTSY) basis (see Table F-3).

Soils in this area are derived mainly from Colebrooke schist, with quaternary unconsolidated sediments present along the river No mineral deposits are known (Ramp and others 1977).

In response to public comments on the DEIS, an 89 acre parcel was "added" to the Addition, this site is south of the main area, near Kimball Hill. A loop trail though this outstanding old-growth site winds through groves of very large Douglas-fir, tanoak, and other species; sword fern and beargrass are common on the Forest floor. Access to the trailhead is via Road 090. The entire 534 acres is recommended as a Botanical Area in the Preferred Alternative (S).

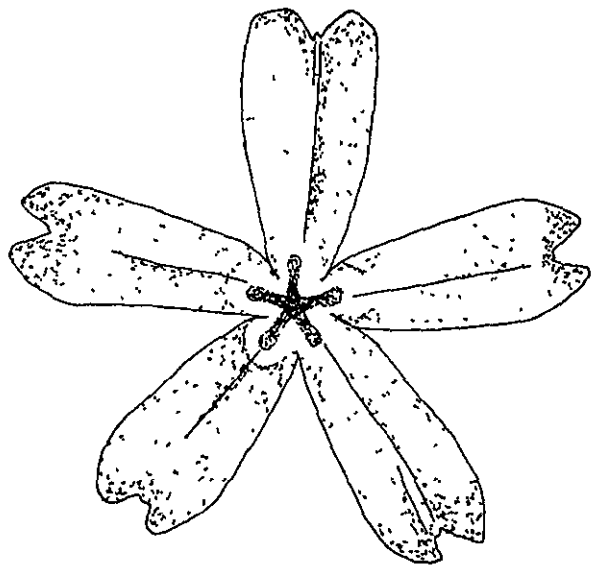
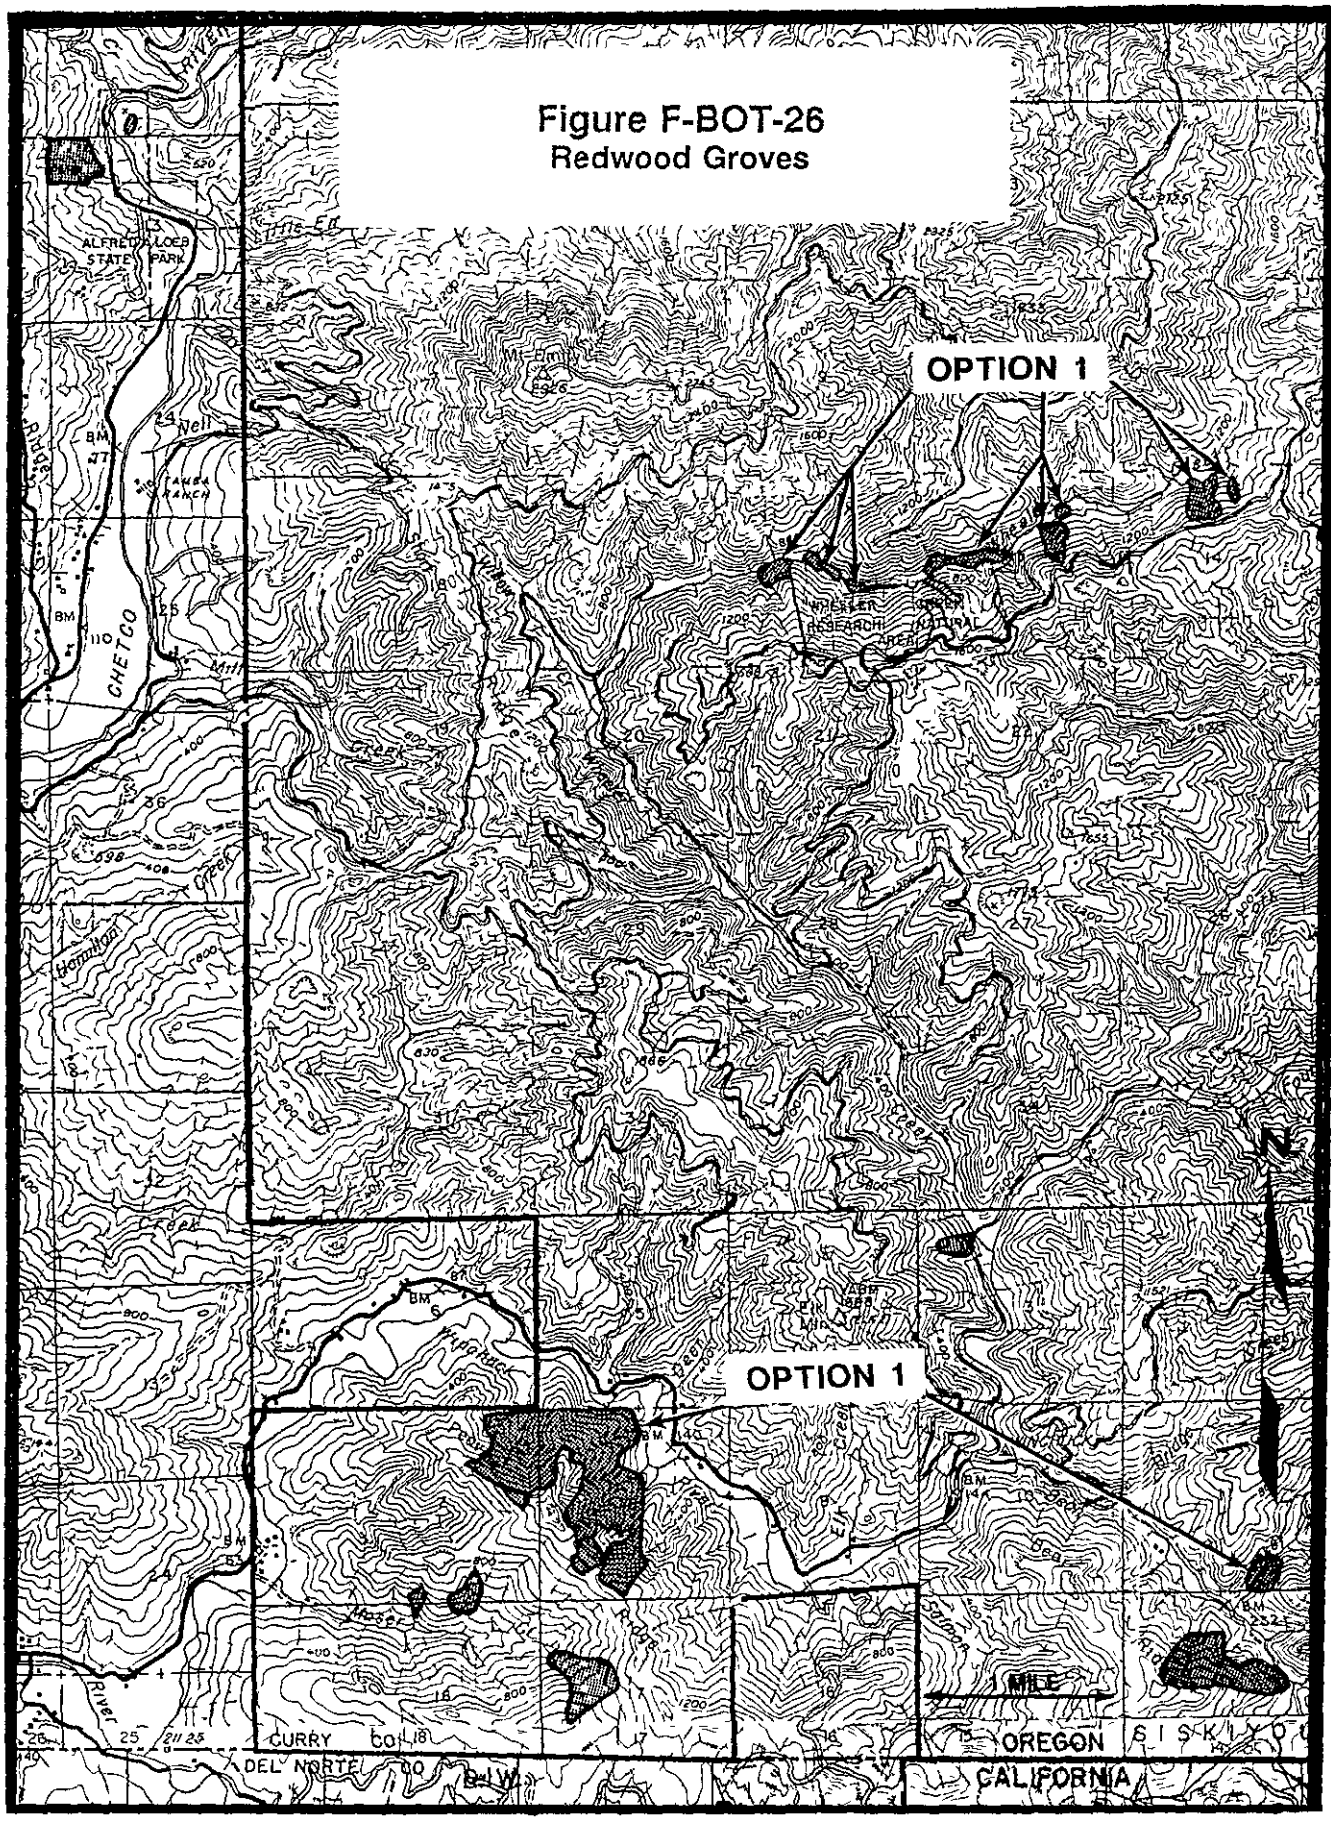
PAGE MOUNTAIN GROVE - F-BOT-25

The 128 acre proposed Page Mountain Grove Botanical Area is located in Oregon near Page Mountain, adjacent to the border of the Siskiyou and Klamath National Forests, and along Road 48 within the Illinois Valley Ranger District (T.41S., R.7W., at the corner common to Sections 8, 9, 16, 17) (Figure F-BOT-25). Elevation range is 3,800 to 4,530 feet. The Page Grove site has been divided into two sections, this provides flexibility to land managers who must make decisions on land allocations. The primary area contains the heart of the site. For further information on these options see Figures F-1 and F-BOT-25.



This is an old-growth site on benchy ground; no sensitive plants are known. The value of the site lies not with rare plants, but with its old growth plant community. The overstory consists mainly of Douglas-fir, with some white fir; Port-Orford-cedar is present in the draws. Tree diameters average 45 inches (diameter breast high), with individual trees as large as 90 inches. White fir is present in the understory, very little shrub growth is present, with the exception of scattered areas of Sadler's oak. Brewer spruce occurs outside the area at slightly higher elevations.



This old growth site is adjacent to the Happy Camp Road (48), and easily accessible to the public. A potential recreation trail in the upper end of the area was laid out on the ground ("flagged") in 1980. Groves of large old-growth trees are increasingly rare, especially at sites easily visited by the public. Potentially, in the future this site could receive considerable use by the public.

About 123 acres in this proposed Botanical area are tentatively available and suitable for timber production; this land is capable of producing about 67 thousand board feet (MBF) of harvestable timber annually on a long-term sustained yield (LTSY) basis (see Table F-3).

Soils in this area are derived from metasedimentary rocks of the Applegate group. A gold prospect (Ramsey mine) is located a mile to the southeast (Ramp and Peterson 1979).

The primary portion of the area (not the Addition) is recommended as a Botanical area in the Preferred Alternative (S) (see Figure F-3(b) for a summary of effects on timber harvest).

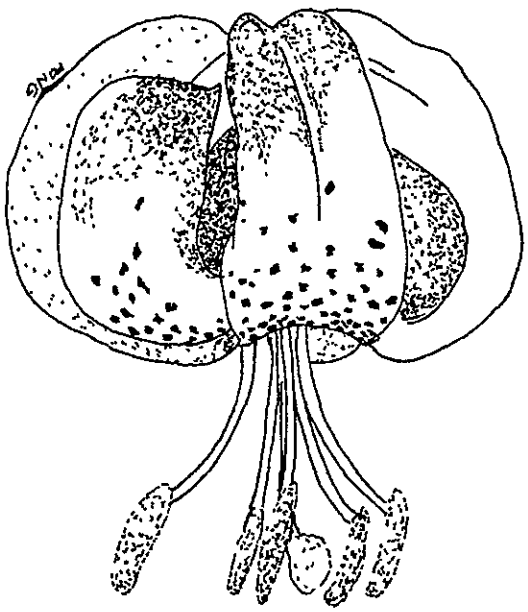
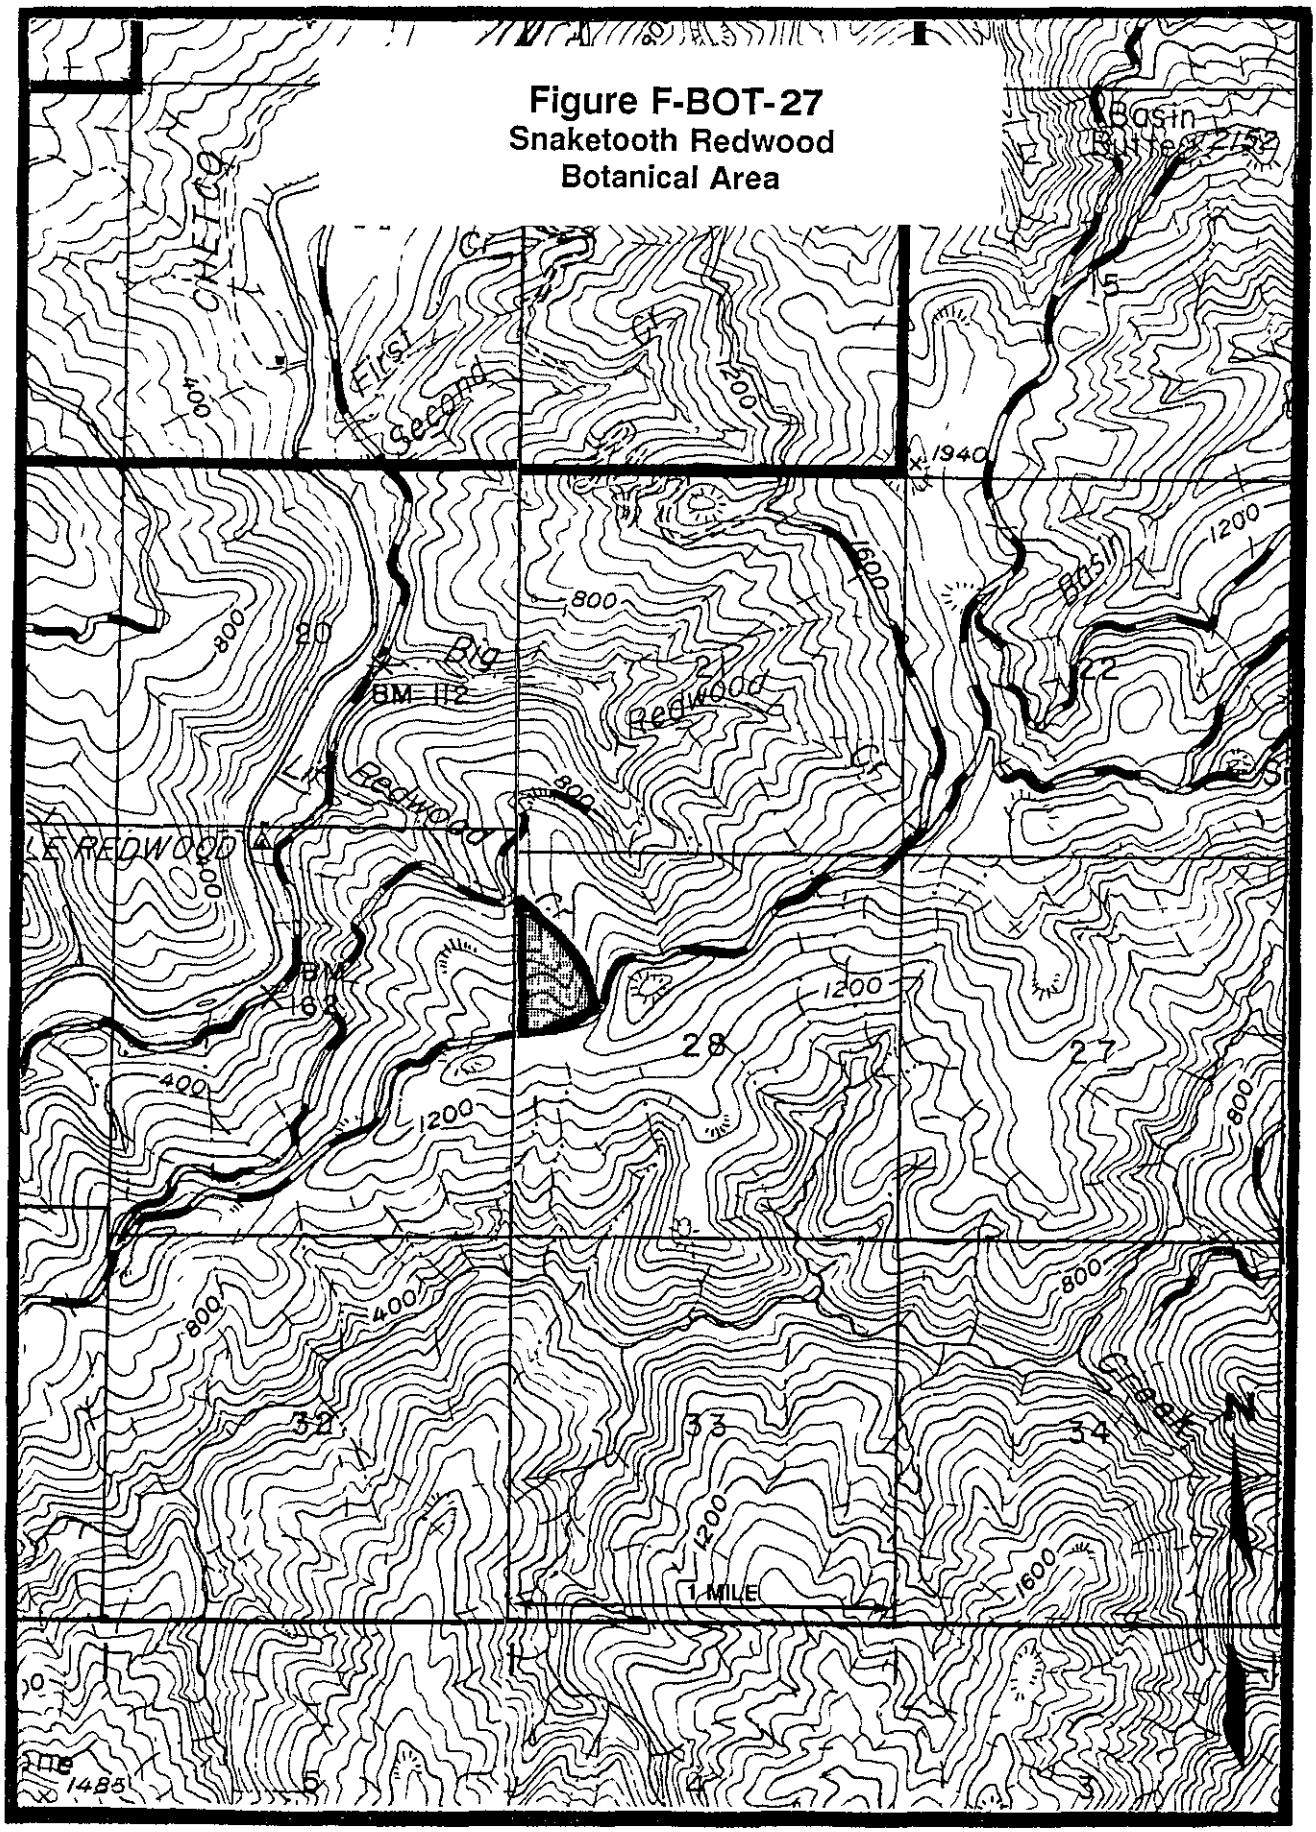
REDWOOD GROVES - F-BOT-26

The 511 acre proposed Redwood Groves Botanical Area has been identified as an outgrowth of a Redwood Management Plan written by personnel of the Chetco Ranger District. The management plan was written in response to public comments received on the DEIS. The area is a collection of the best remaining old growth redwood stands in Oregon. The stands are in the Winchuck River and Wheeler Creek drainages on the Chetco Ranger District. Thirteen stands ranging from about 4 to 280 acres in size are included. The stands are located in T.41S., R 12W., Sections 3, 7, 8, 11, 14, 17, and T 40S , R.12W., Sections 14, 15, and 16 Access to the stands is limited in many cases. Some trails are expected to provide access in the future For further information on Redwood Groves see Figures F-1 and F-BOT-26



About two-thirds of the acreage currently receives special management as Designated Habitat for pileated woodpeckers (Management Area 8). Several of the northerly stands are adjacent to the existing Wheeler Creek Research Natural Area.



Redwood is at the northern limit of its range in southwestern Oregon. It appears that redwood has extended its range north in the last several centuries. These stands have a characteristic lack of sprouting clumps. Trees are generally not older than 300 years and large downed redwood logs are absent. Redwoods in these stands share the overstory with Douglas-fir and tanoak and scattered western Hemlock. Understory trees are younger and suppressed individuals of the above species, plus myrtlewood, alder and madrone Huckleberry, rhododendron, sword fern, and salal are the most common understory plants.

About 496 acres in this proposed Botanical area are tentatively available and suitable for timber production; this land is capable of producing about 268 thousand board feet (MBF) of harvestable timber annually on a long-term sustained yield (LTSY) basis (see Table F-3).

Soils in this area are derived from sedimentary rocks of the Dothan Formation (Ramp and others 1977).

Public concern over preservation of remaining old growth redwoods has prompted the Forest to recommend this new Botanical area in the Preferred Alternative (S).

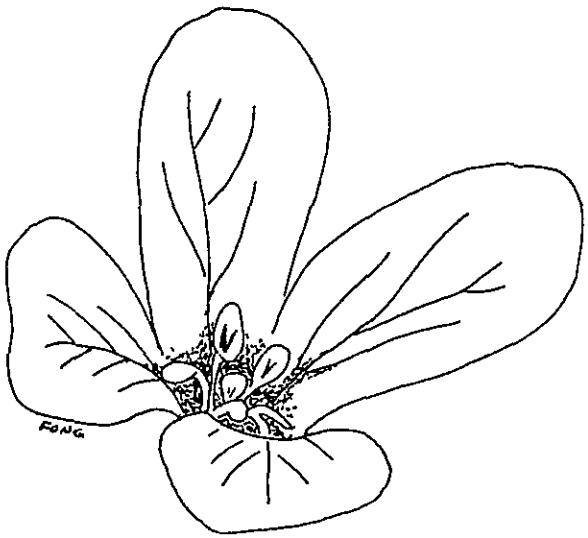
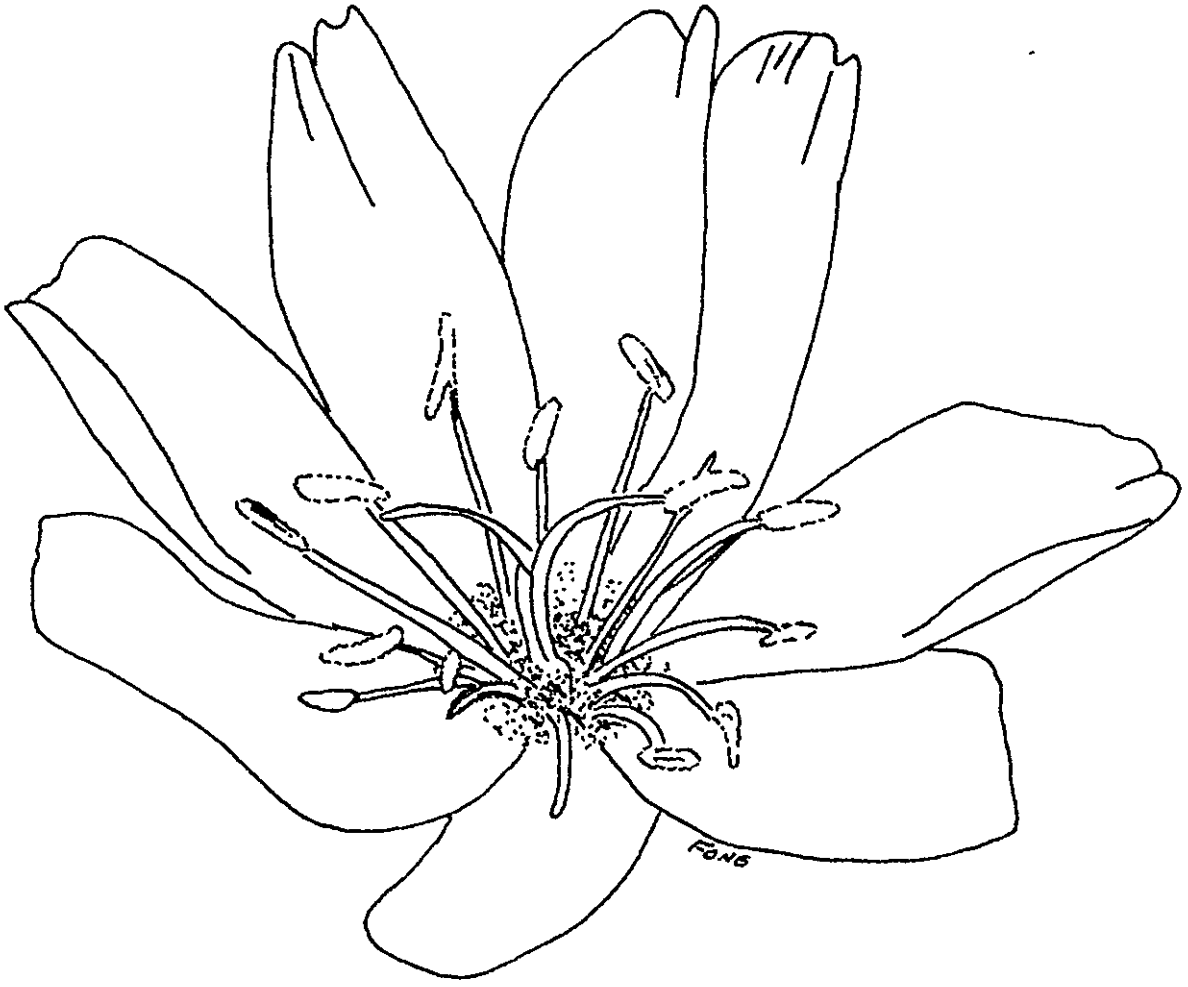
SNAKETOOTH REDWOOD - F-BOT-27



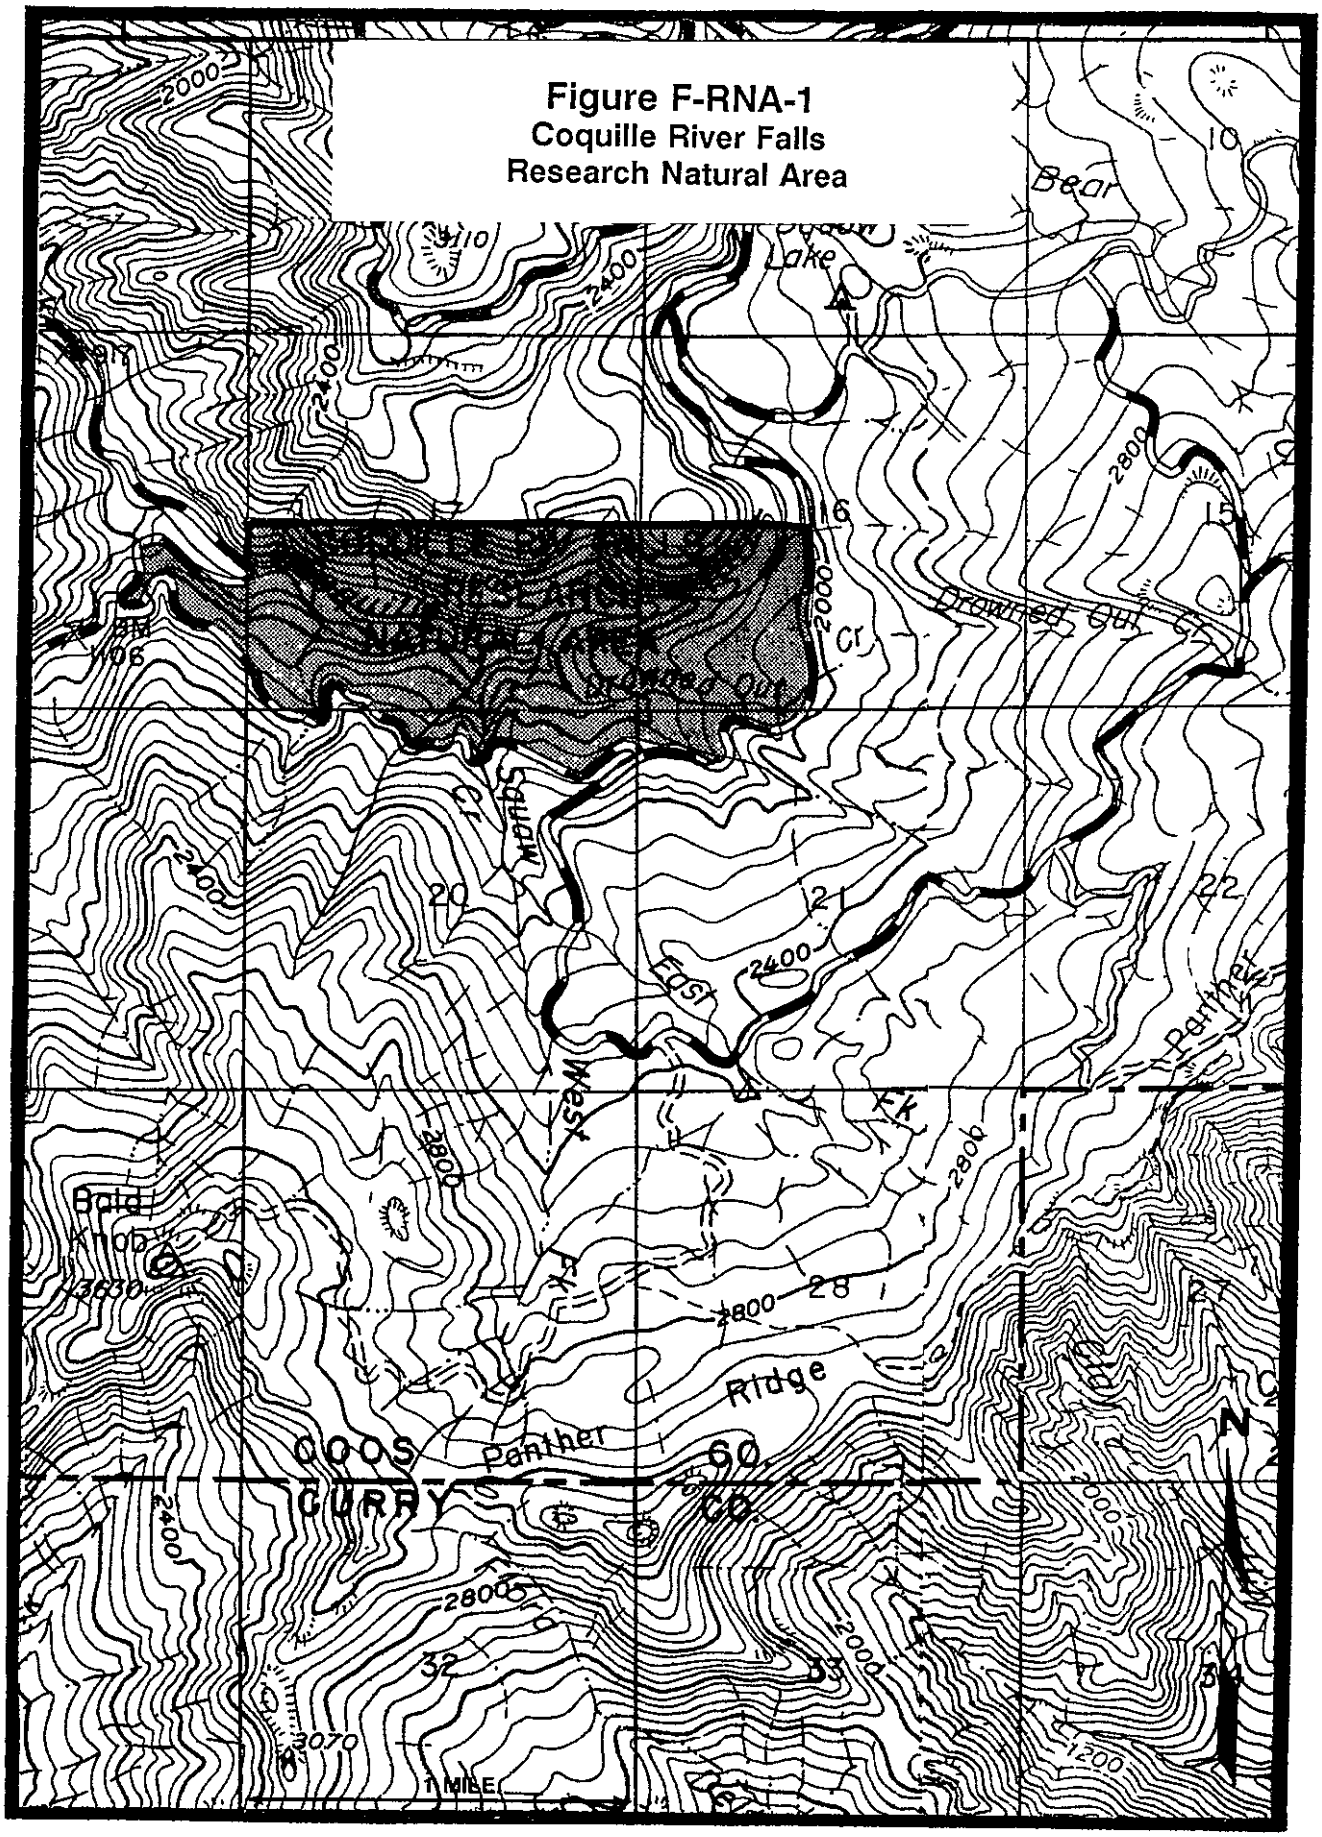
The 21 acre proposed Snaketooth Redwood Botanical Area is located on the Checto Ranger District a mile south of the Chetco River on Little Redwood Creek (T.39S , R 12W , Section 28 NW) (Figure F-BOT-27) Elevation range is 900 to 1,400 feet



This is the site of the northernmost naturally occurring redwood grove. Part of the grove was harvested in the early 1960's; the 21 acres proposed as a Botanical area is all that remains of the original grove. Douglas-fir is intermixed with coastal redwood; tree diameters are 36 to 40 inches or more.

About 20 acres in this proposed Botanical area are tentatively available and suitable for timber production; this land is capable of producing about 11 thousand board feet (MBF) of harvestable timber annually on a long-term sustained yield (LTSY) basis (see Table F-3).

Soils in this area are derived from Latest Jurassic sedimentary and volcanic rock (Ramp and others 1977).



This site is recommended as a Botanical area in the Preferred Alternative (S)

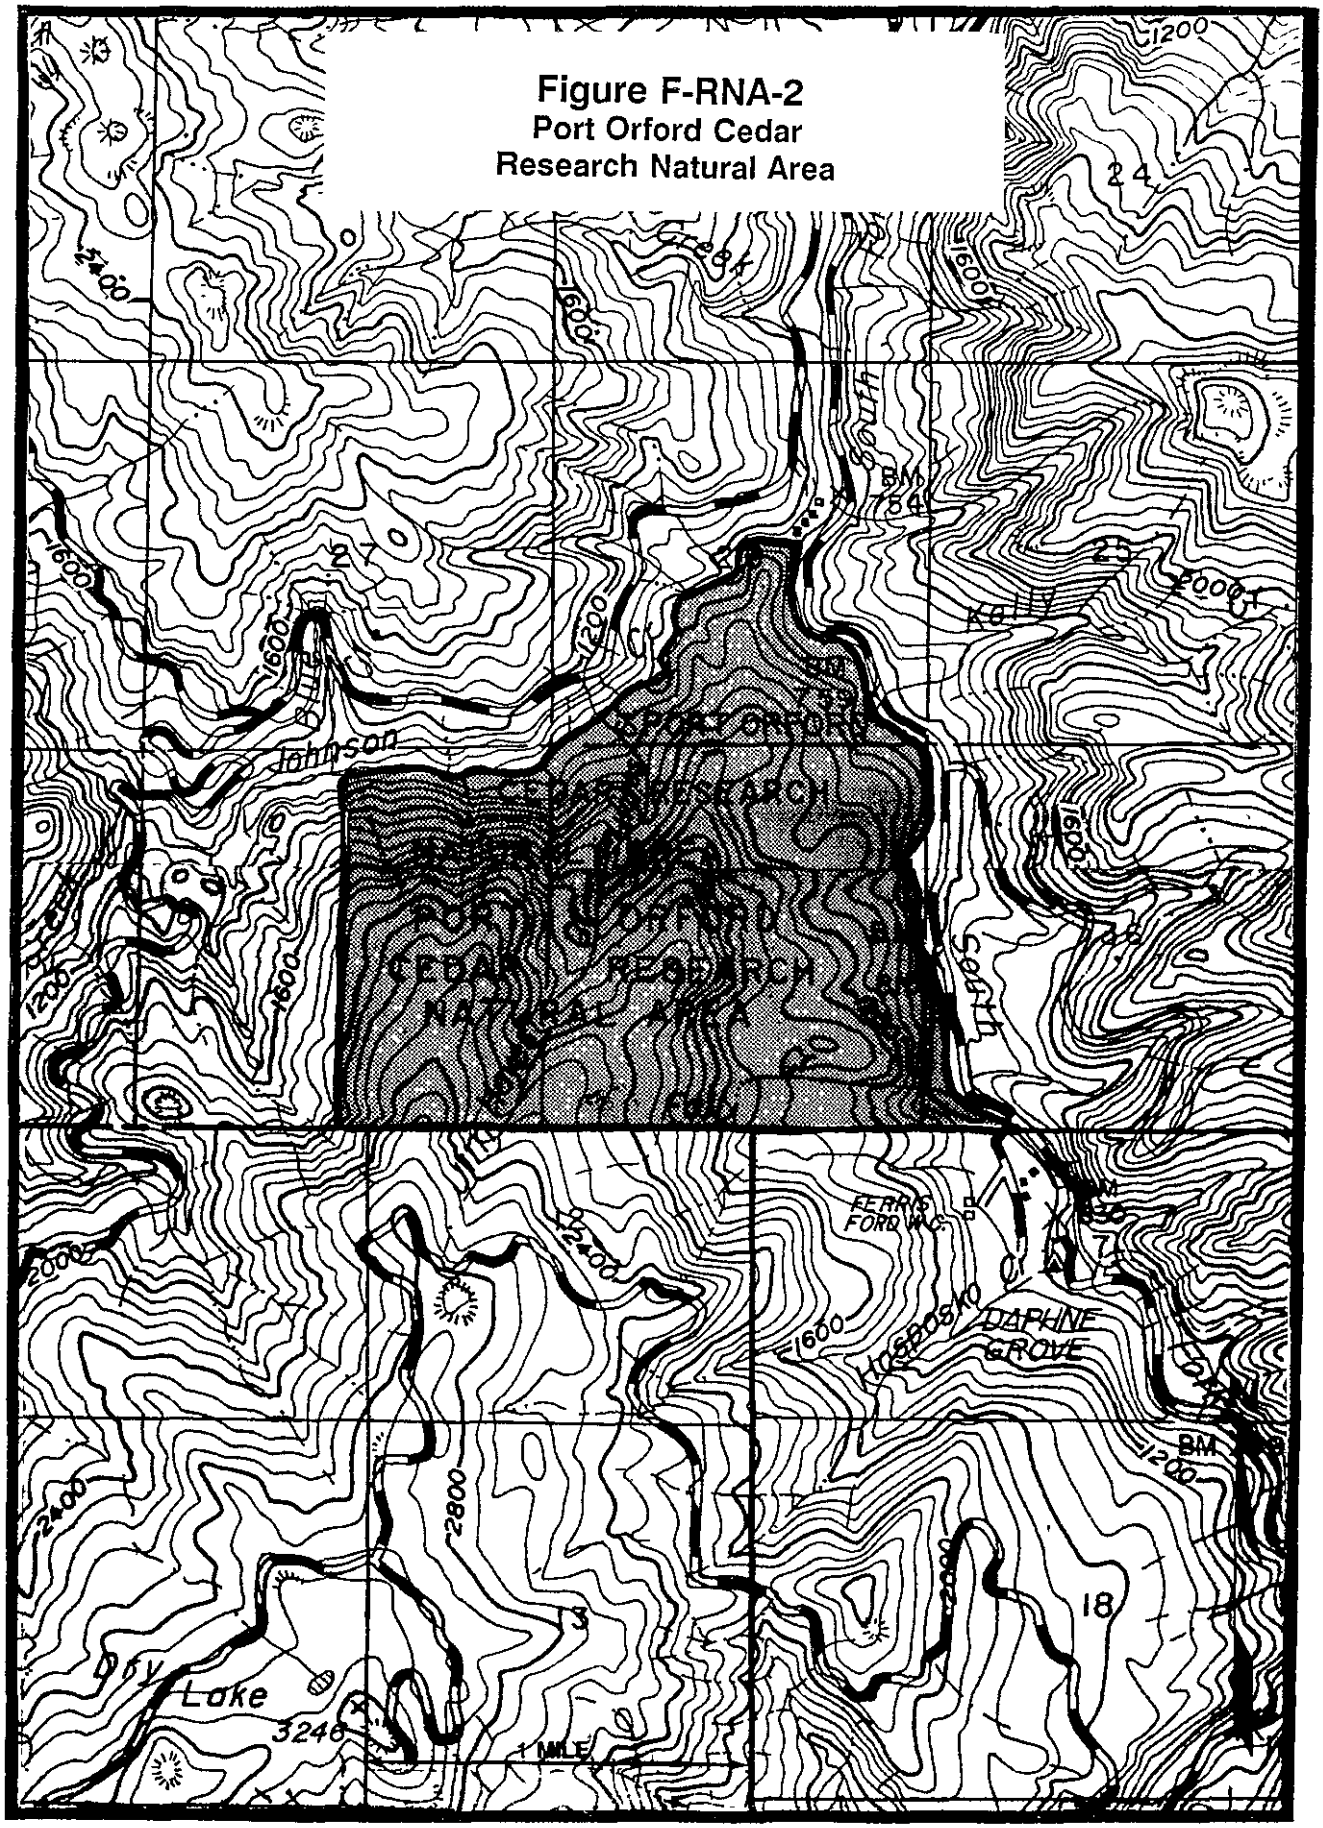
RESEARCH NATURAL AREAS - EXISTING

COQUILLE RIVER FALLS - F-RNA-1

The following is excerpted from Franklin and others (1972)



The Coquille River Falls Research Natural Area was established on January 31, 1945, to provide examples of virgin old-growth Port-Orford-cedar (*Chamaecyparis lawsoniana*) stands. The 500 acre tract is located in Coos County, Oregon, and is administered by the Powers Ranger District The Research Natural Area (RNA) occupies portion of Sections 16, 17, 18, 20, and 21, T 33S , R.11W (Figure F-RNA-1)

The Coquille River Falls Research Natural Area occupies a topographically rugged canyon area Except for a few benches along Road 3348, slopes are moderate to very steep Cliffs and rock outcrops are occasionally encountered and are very common along the river itself The South Fork of the Coquille River and numerous other streams such as Squaw and Drowned Out Creeks flow through the southern part of the RNA Spring and seep areas are also common. Elevations within the RNA range from 1,000 to 2,500 feet

The RNA is relatively simple geologically Bedrock is composed of sedimentary materials, primarily sand and siltstones, belonging to the Tyee formation of Eocene age. Soils vary greatly in depth throughout the area. The profiles typically are not strongly developed

The climate is wet and mild Precipitation is seasonal, with a peak in December and January and a minimum in July and August The summer drought period is more pronounced than in the northern Oregon and Washington coastal mountains. Annual precipitation is between 80 and 90 inches (Figure F-3)

Port-Orford-cedar and Douglas-fir (*Pseudotsuga menziesii*) are the most important tree species within the RNA, composing approximately 22 percent and 69 percent of the total timber volume There are particularly fine specimens of Port-Orford-cedar on the benches along Forest Road 3346 Western hemlock (*Tsuga heterophylla*), grand fir (*Abies grandis*), sugar pine (*Pinus lambertiana*), and Pacific yew (*Taxus brevifolia*) are other coniferous tree species found within the tract Hardwoods are well represented though not necessarily in the highest canopy levels These include red alder (*Alnus rubra*), tanoak (*Lithocarpus densiflorus*), golden chinkapin (*Castanopsis chrysophylla*), and Pacific madrone (*Arbutus menziesii*).

PORT ORFORD CEDAR - F-RNA-2

The following is excerpted from Franklin and others (1972):

The Port Orford Cedar Research Natural Area was established on October 26, 1937, as a sample of virgin old-growth Port-Orford-cedar (*Chamaecyparis lawsoniana*). The 1,122 acre tract is located in Coos County, Oregon, and is administered by the Powers Ranger District, Siskiyou National Forest The Research Natural Area (RNA) occupies Section 35, a portion of the E1/2 of Section 34 located south of Johnson Creek, that part of Section 26 located south of Johnson Creek and west of the Coquille River, and a small part of Section 36 which lies west of the Coquille River, all in T.32S , R12W., (Figure F-RNA-2)

The Port Orford Cedar Research Natural Area is topographically rugged except for occasional benches and some broad ridgetops. Slopes are particularly steep along Johnson Creek and the Coquille River. Elevations range from 850 feet along these streams to nearly 2,500 feet on the ridgetop in the southeast corner. Two small streams, Jim Hays and Fall Creeks, lie mostly within the RNA.

The RNA is complex geologically. Sedimentary materials (sandstones, siltstones and conglomerates) make up most of the bedrock. Soil profiles are not strongly developed in the area although soils are often deep.

The climate is wet and mild. Precipitation is seasonal, with a peak in December and January, and a minimum in July and August. The summer drought period is more pronounced than in the northern Oregon and Washington coastal mountains Annual precipitation is between 90 and 100 inches (Figure F-3).

Douglas-fir (*Pseudotsuga menziesii*) and Port-Orford-cedar are the most important tree species present, composing approximately 75 and 25 percent, respectively, of the old-growth forests which dominate the areas. Grand fir (*Abies grandis*), western hemlock (*Tsuga heterophylla*), western redcedar (*Thuja plicata*), sugar pine (*Pinus lambertiana*), western white pine (*Pinus monticola*), and Pacific yew (*Taxus brevifolia*) are also present. Hardwoods are well represented although not usually in the highest canopy level Tanoak (*Lithocarpus densiflorus*), golden chinkapin (*Castanopsis chrysophylla*), and Pacific madrone (*Arbutus menziesii*) are most abundant and widespread; occurrences of bigleaf maple (*Acer macrophyllum*), Oregon ash (*Fraxinus latifolia*), red alder (*Alnus rubra*), and Oregon myrtle (*Umbellularia californica*) are more localized. Most of the RNA is covered with forests of large, old trees. Although ages are not accurately known, many of the dominant specimens are undoubtedly 400 to 500 years old.

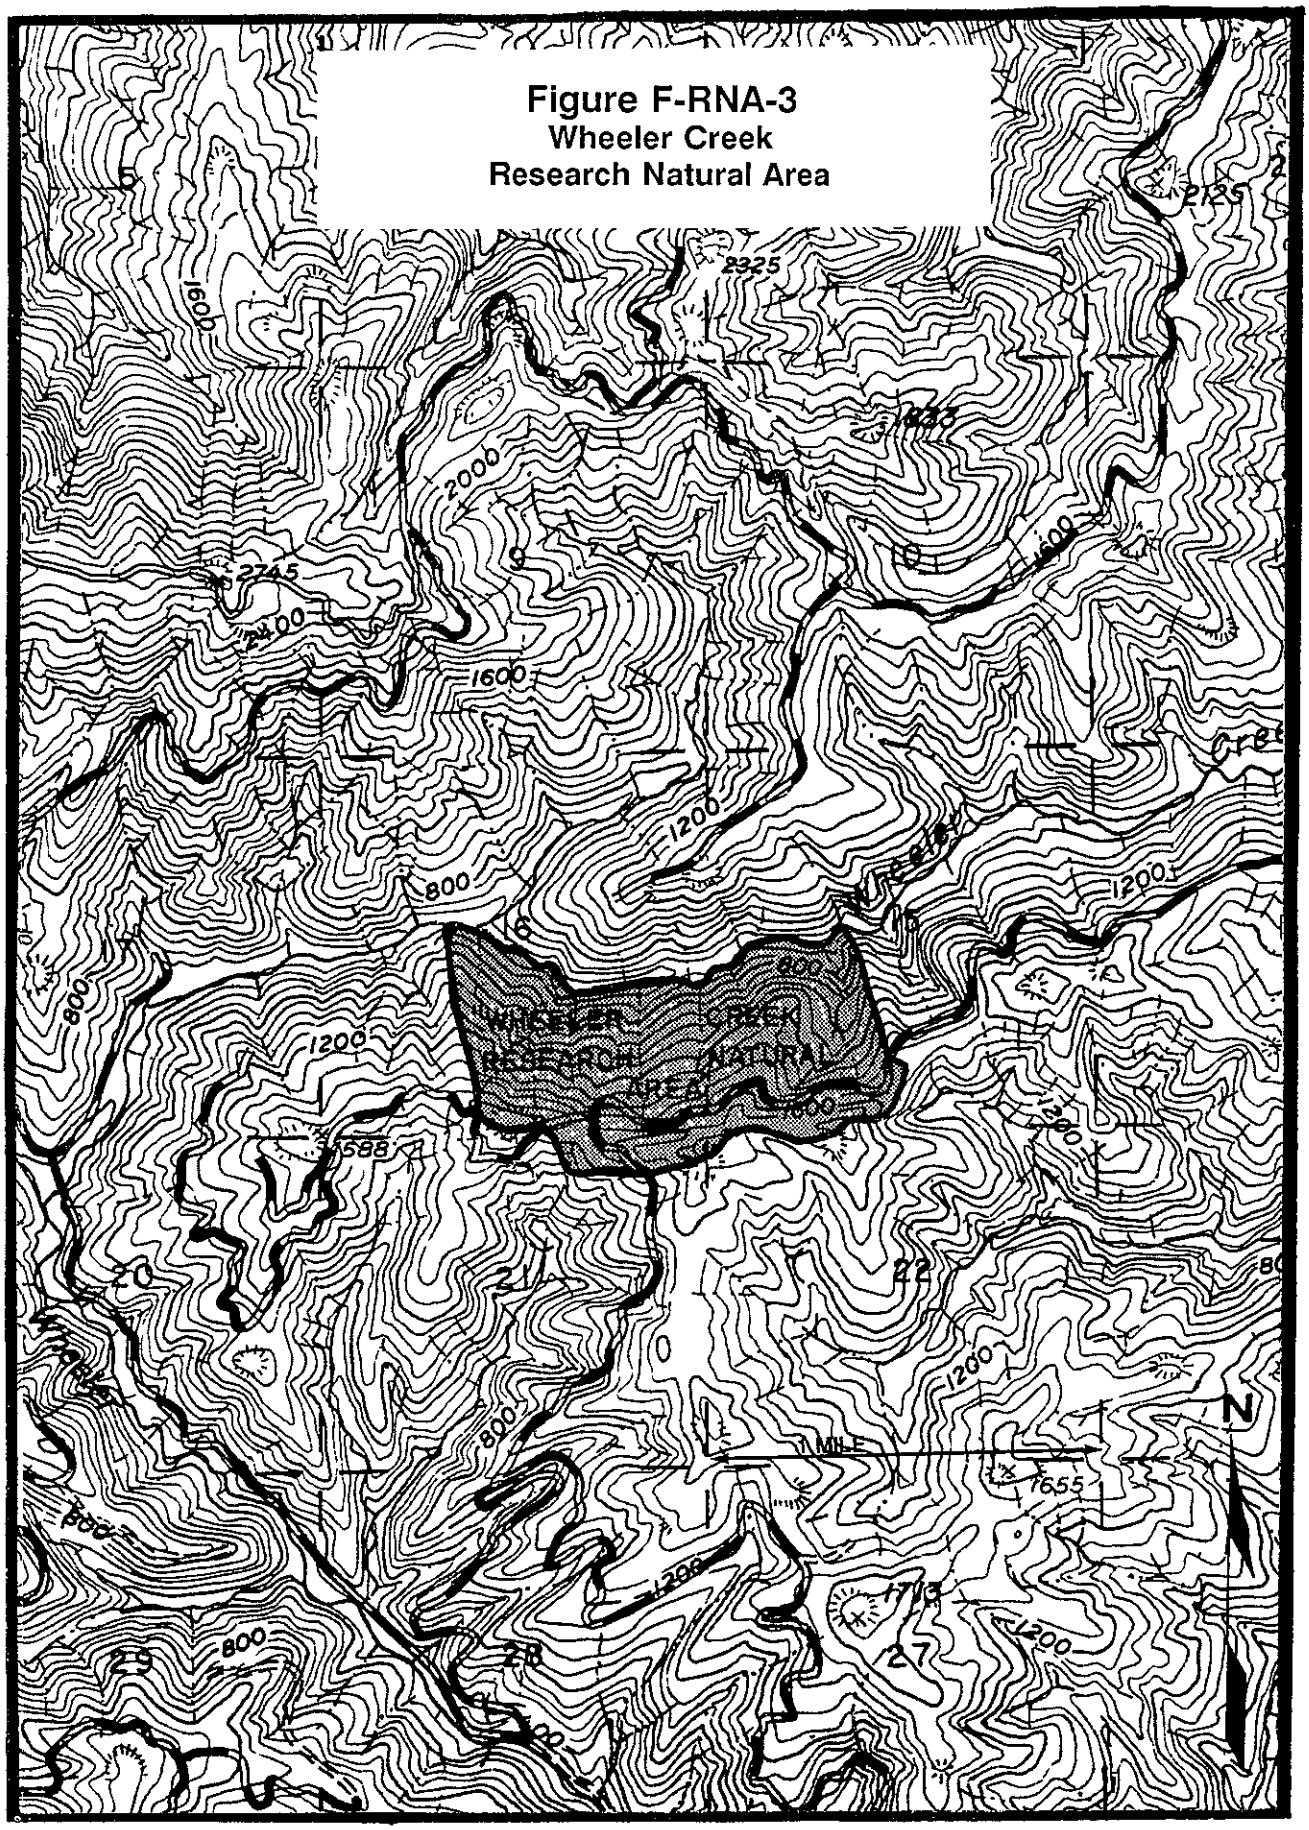

Figure F-RNA-3
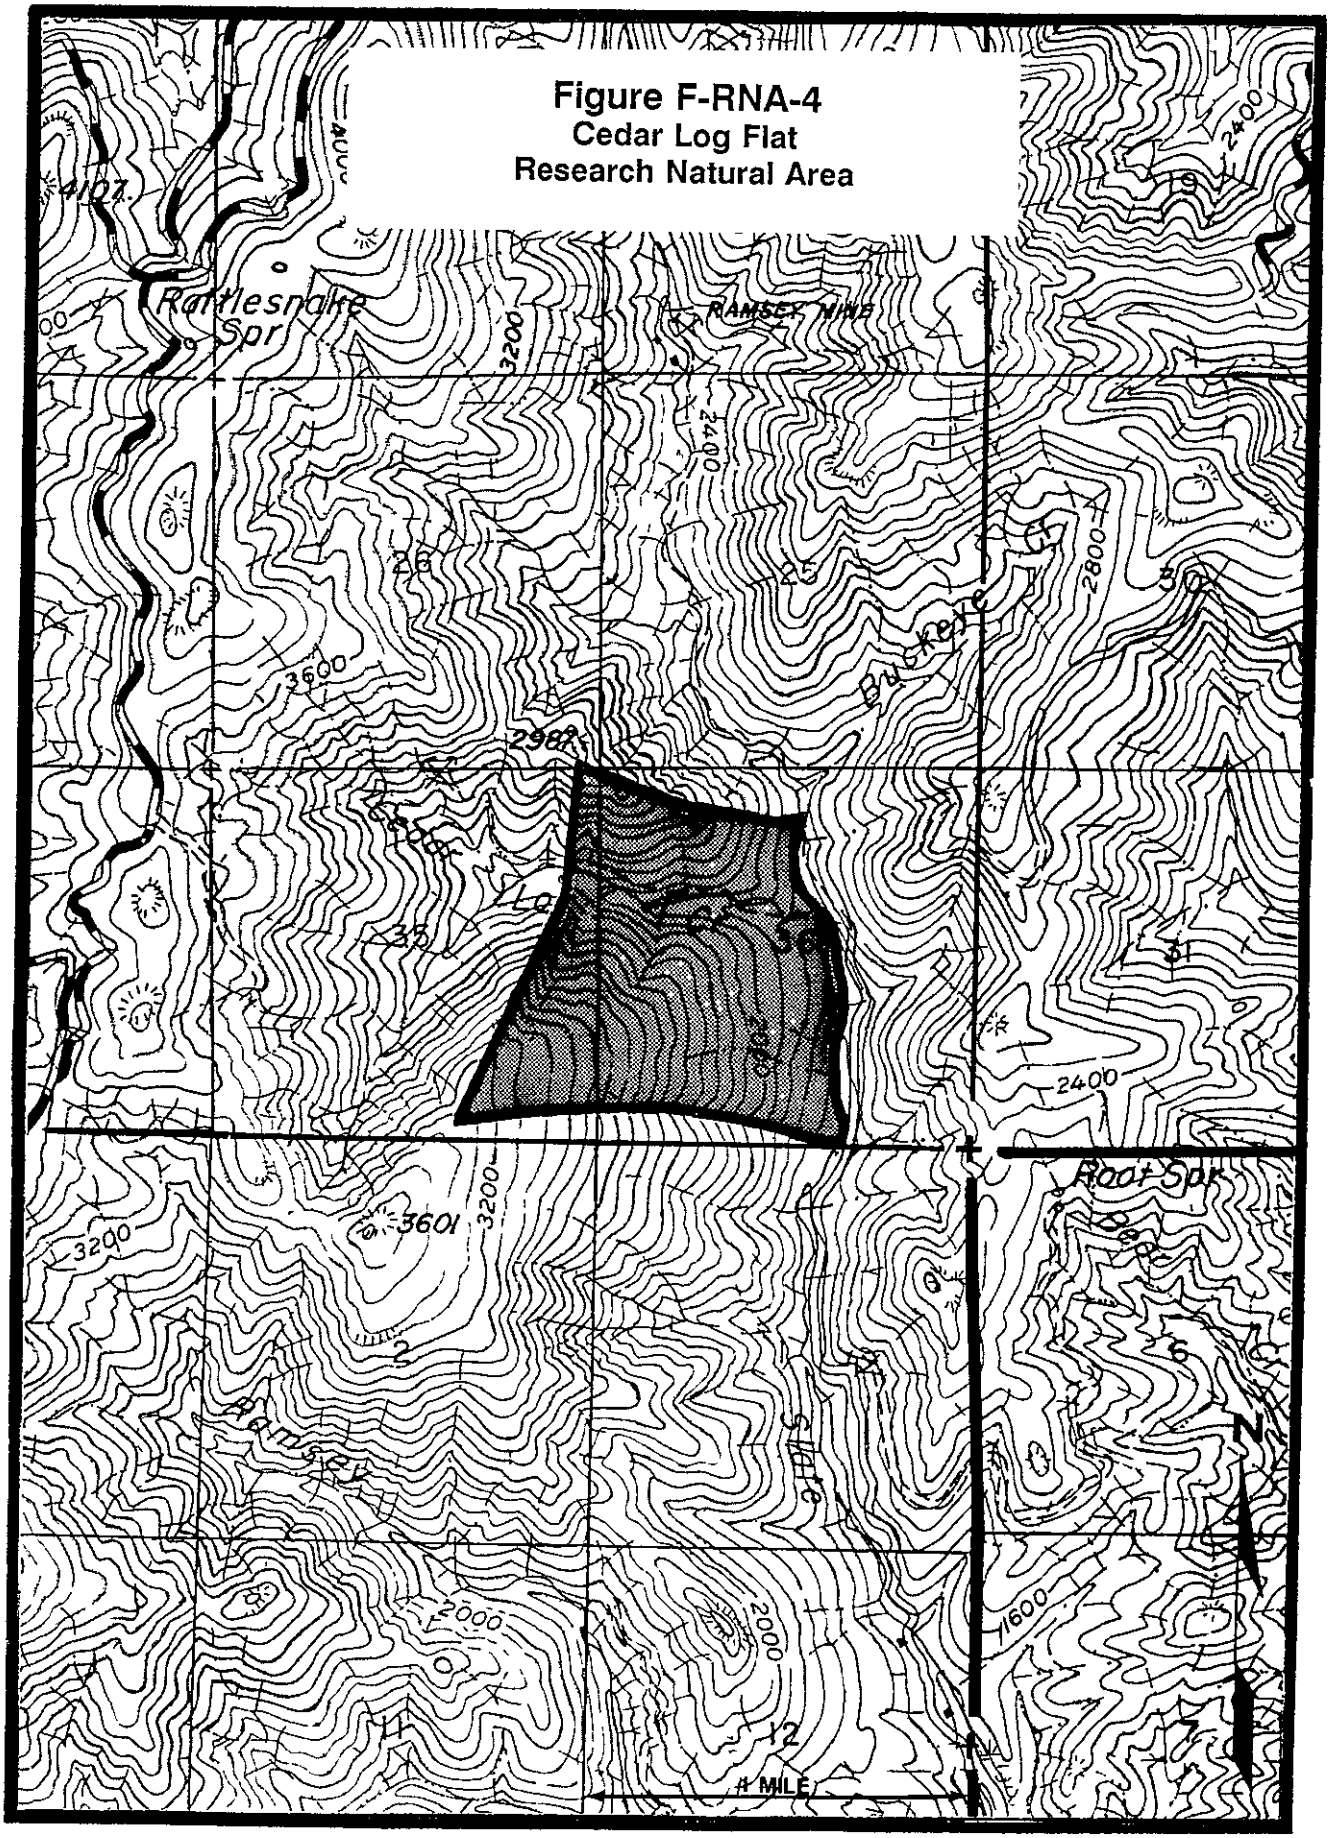
Wheeler Creek
Research Natural Area

WHEELER CREEK - F-RNA-3

The following is excerpted from Dyrness and others (1972):

The Wheeler Creek Research Natural Area was established on August 10, 1972, to preserve an example of redwood forest near the northern limits of its range. The 334 acre tract is located in Curry County and is administered by the Chetco Ranger District, Siskiyou National Forest. The Research Natural Area (RNA) lies principally in Sections 15 and 16, T.40S., R.12W., but includes small portions of Sections 21 and 22 in the same township The southern boundary of the RNA lies atop a major dividing ridge, the east and west boundaries are on subsidiary ridgetops, and the northern boundary parallels Wheeler Creek 200 feet to the north of the stream (Figure F-RNA-3).



The Wheeler Creek Research Natural Area occupies, for the most part, a steep north-facing slope extending from ridgetop to Wheeler Creek. With the exception of the saddle area near the southwestern corner and a few small benches, the slopes range from 60 to 80 percent and are smooth and uninterrupted. Six incised drainage channels, three of which contain perennial streams, drain the area. Elevations range from 550 feet along Wheeler Creek to 1,771 feet on the ridgetop constituting the southern boundary of the area.

Bedrock in the area is composed of massive beds of sandstone intercalated with relatively thin beds of shaley mudstone. Soils in the RNA generally exhibit poorly developed profiles derived from sandstone and mudstone colluvium.

The climate is typically wet and mild in the winter, with a dry summer season beginning in June and extending into September. The lack of rain in the summer is sometimes ameliorated by dense coastal fogs. The area is also characterized by strong southwesterly winds and infrequent snowfalls. Annual precipitation is between 140 and 150 inches (Figure F-3).

Except for about 30 acres of road clearing, the RNA is forested by a mosaic of redwood and Pacific Douglas-fir cover types, with the former predominating.

The major tree species within the RNA are redwood, Douglas-fir, and tanoak (*Lithocarpus densiflorus*). In moister habitats, e.g., in ravines, on lower slopes, and along Wheeler Creek, bigleaf maple (*Acer macrophyllum*), California laurel (*Umbellularia californica*), and red alder (*Alnus rubra*) are common. Western hemlock (*Tsuga heterophylla*) occurs sporadically throughout all but the driest portions of the tract. Pacific madrone (*Arbutus menziesii*) is occasional to common on drier habitats. Knobcone pine (*Pinus attenuata*) is found along some portions of the ridgetop which forms the southern boundary of the tract.

RESEARCH NATURAL AREAS PROPOSED

CEDAR LOG FLAT - F-RNA-4

The following report was written by Dennis Vroman (Galice Ranger District) in 1985 He gathered the data in 1984-1985 Cedar Log Flat has been recommended as an RNA in the Preferred Alternative (S)

The proposed Cedar Log Flat Research Natural Area covers 441 acres and is located near the center of the eastern boundary of the Siskiyou National Forest (T.36S., R 8W., Sections 35, 36, (Figure F-RNA-4). About 19 road miles from Grants Pass, the area is part of the Slate Creek drainage and flows into the Applegate River. Cedar Log Creek, a permanent stream, flows easterly through the area and is flanked by north and south aspects Located within the area is a large, grassy meadow on a gentle east-facing slope which is bound on the north by Cedar Log Creek and to the east by Slate Creek. The rest of the proposed RNA has easterly aspects and slopes are steeper. Elevation ranges from 1,700 to 3,300 feet within the area

Bedrock in the area consists of serpentine and peridotite; soils are shallow. Large areas exist of mostly bare parent material, with little or limited amounts of soil and vegetation. Some of these barren areas consist of a blend of massive boulders, rocks, rock fragments and strips of parent material. The deepest soils appear to be located on the gentle-sloping meadow area See Ramp and Peterson (1979) for more information on geology and mineral resources of the general area.

Vegetation of the area varies in type and amounts, depending upon the soil depth, slope, aspect and other site variables. Average rainfall within the proposed RNA is approximately 55 inches per year (Isohyetal Map, Oregon State University Extension Service). The older conifers are approximately 180 to 215 years. The larger conifers are approximately 40 inches Diameter Breast Height (DBH) and 130 feet in height. Among the more than 160 woody or herbaceous plants in the area are many sensitive plant species Other sensitive species may exist; more inventory work is needed.

Past evidence of wildfire is present throughout the entire area. Fire-caused basal scars are present on many of the older trees, even on the more barren south slopes. Along Cedar Log Creek are many blackened snags, some burned a great distance above the ground.

Ten sensitive plant species (USDA Forest Service designation) are found within the proposed RNA; some are otherwise not known outside of the Illinois Valley area. Five plants designated as watch or review species by the Forest Service are also present. Sensitive and Watch/Review list plants are included in the attached species list.

Cedar Log Flat Research Natural Area fills the following forest-type cell need in the Siskiyou Mountains Province (Dyrness and others 1975).

from Table 53

15. Jeffrey Pine-Grass on serpentine at low elevation

North of Cedar Log Creek. The area north of Cedar Log Creek has the most open ground, although dense brush can be found in the several side draws. The area has an average aspect and slope of 187 degrees and 48 percent respectively. The area averages 15 conifer trees/acre (50 percent *Pinus jeffreyi*, 33.3 percent *Calocedrus decurrens*, and 16.7 percent *Pseudotsuga menziesii* with a trace of *Pinus attenuata*). Hardwood trees average approximately three per acre and are 100 percent *Arbutus menziesii*. There are 5 conifer snags per acre (50 percent *P. jeffreyi*, 25 percent each of *C. decurrens* and *P. menziesii*). Lineal footage of downed conifer boles averages 201 feet per acre. Brush species cover 25.8 percent per acre on the average, with 36.5 percent *Arctostaphylos viscida*, 28.1 percent *Quercus vaccinifolia*, 14.1 percent *Quercus chrysolepis*, 7.8 percent *Garrya buxifolia*, 7 percent *Umbelluaria californica*, 3.5 percent

Ceanothus pumilus, 1 3 percent *Eriodictyon californicum*, 1 percent *Ceanothus cuneatus* and less than 1 percent of other species.

Four sensitive and two "watch or review list" species (USDA Forest Service designation), are known from the area Sensitive species present are *Thlaspi montanum* var. *siskiyouensis*, *Arabis koehleri var. stipitata*, *Fritillaria glauca* and *Eriogonum pendulum* (the last was confirmed by Dr. Kenton Chambers, Curator of the Oregon State University Herbarium, who noted that the discovery "is a very nice range extension from its known area"). Watch/review species are *Arabis aculeolata* and *Phacelia corymbosa*

Two distinct surface terrain types occur north of Cedar Log Creek. The eastern part has soils somewhat deeper, with more grass cover Also, fewer rocks and boulders are present; *Arabis aculeolata* populates the higher areas. The western part has soils somewhat shallower, with little grass cover. Also present are large amounts of rocks, boulders and long stretches of barren outcrops. Here *A. koehleri* var *stipitata* and *E. pendulum* are found *F. glauca* is found in the ravel at the base of the rock outcrops

Interesting birds and animals inhabiting this area include the canyon wren (*Catherpes mexicanus*), which appears to nest here. Mountain lion (*Felis concolor*) and black bear (*Ursus americanus*) sign has been found in this area.

Along Cedar Log Creek. Average estimated data for the 200 foot wide strip each side of Cedar Log Creek includes the following

Direction of stream flow is 98 degrees with slope of 7 percent. Conifer trees average 268 per acre (66 percent *Chamaecyparis lawsoniana*, 27.2 percent *P. menziesii*, 3.4 percent *Pinus lambertiana* and 1.7 percent each of *C decurrens* and *Taxus brevifolia*) There are 36 conifer snags per acre (83 3 percent *C. lawsoniana* and 16 7 percent *P. menizıesii*). Lineal footage of downed conifer boles averages 1859 feet per acre. Hardwoods per acre average 68 (46.6 percent *Q. chrysolepis*, 26.8 percent *Lithocarpus densiflorus*, 19 9 percent *A. menziesii*, 6.7 percent others). Brush species cover averages 39.7 percent per acre: 33.5 percent *Rhododendron occidentale*, 16 1 percent *Q. vaccinifolia*, 15.1 percent *U. californica*, 10.7 percent *L. densiflorus*, 9 3 percent *Ledum columbianum*, 7.7 percent *Q. chrysolepis*, 5.9 percent *Rhamnus californica*, and others of less than 0.5 percent each.

Two sensitive species found here are also in the meadow area: *Cypripedium californicum* and *Epilobium oreganum*. Two watch/review species occur here. *Lilium vollmeri* occurs here and in the boggy areas within the meadow; *Dicentra formosa ssp. oregana* occurs only here within the proposed RNA.

Native cutthroat trout (*Salmo clarki*) inhabit Cedar Log Creek. According to Don King (Fisheries Biologist, Siskiyou National Forest,) Pacific salmon species are impeded from reaching the upper regions of Slate Creek, and therefore Cedar Log Creek. Adult steelhead (*Salmo gairdneri*) were seen at the mouth of Cedar Log Creek in April 1985.

Ringtails (*Bassariscus astutus*), secretive nocturnal mammals, frequent the Slate Creek area near the mouth of Cedar Log Creek During the 1983-1984 trapping season, two of these animals were trapped here and released by a local fur trapper (G Sublette, personal communication, November 20, 1985). Ringtails may den near or within the proposed RNA.

Dense thickets of brush and trees, located both along Cedar Log Creek and at edges of bogs, provide nesting sites for numerous bird species requiring this habitat type. Such bird species include: Lincoln's sparrow (*Melospiza lincolnii*), MacGillivray's warbler (*Oporornis tolmiei*), black-headed grosbeak (*Pheucticus melanocephalus*) and western wood peewee (*Contopus sordidulus*).

South of Cedar Log Creek. The area south of Cedar Log Creek contains the densest amounts of brushy ground cover. Some massive boulders and large rocks are located here, interspersed with more open

areas of moss and herb cover. The species present reflect the cooler microclimate of the area, as illustrated by *Polypodium hesperium* growing from thick moss mats formed on the surface layer of rock. *Darlingtonia californica* is found here, on slopes ranging to 60 percent in some places. In the western section is a cool, northeast-facing side draw that has close to 100 percent brushy ground cover, with *Darlingtonia* dispersed throughout. Sensitive species which occur here (and within the meadow area) are *C. californicum* and *E. oreganum*

Average aspect and slope are 44 degrees and 45 percent respectively. Conifer trees average 279 to the acre (50 percent *C. decurrens*, 24.4 percent *P. menziesii*, 19.2 percent *P. jeffreyi*, 5 1 percent *P lambertiana*, 1.3 percent *C lawsoniana*). Conifer snags average 22 per acre (33 4 percent each of *P menziesii* and *C. decurrens*, 16.6 percent each of *C. lawsoniana* and *P. lambertiana*) Hardwoods average 25 per acre and are 100 percent *A. menziesii*. Lineal footage of downed conifer boles per acre averages 597 feet. Brush species cover an average of 50 percent of each acre, with 47.4 percent *Q vaccinifolia*, 15,3 percent *G. buxifolia*, 11 1 percent *U. californica*, 9.3 percent *Q. chrysolepis*, 4.6 percent *R californica*, 3 6 percent each of *L. columbianum* and *L. densiflorus*, 2.1 percent *Quercus breweri*, 1 4 percent *R occidentale*, and others with less than 0 5 percent each.

Meadow or "Flat". The meadow appears park-like with its open stand of conifers, dominated by *P. jeffreyi*. The major ground cover is made up of grasses (*Festuca* and *Poa*). A large variety of herbs occur; however, due to seasonal dominance, different species stand out when they are in bloom. Several bogs which remain wet throughout the year occur within the meadow or along the edge. Two sensitive species inhabit the bogs: *Cypripedium californicum* and *Epilobium oreganum*. The discovery of *E. oreganum* "is an important find" (Dr. Kenton Chambers). *L. vollmeri*, a watch/review species, also occurs here. Large populations of *Darlingtonia californica* inhabit the bogs. One bog along the southern edge runs through the entire length of the meadow. Two sensitive species occur on the meadow: *Microseris howellii* and *Senecio hesperius*. Prior to their recent discovery here, neither species had been found outside of the Illinois Valley area.

Many cavity nesting birds rear their broods in the meadow area. Species included are: western bluebird (*Sialia mexicana*), hairy woodpecker (*Picoides villosus*), northern flicker (red-shafted) (*Caolaptes auratus*) and red-breasted nuthatch (*Sitta canadensis*).

The meadow has an average aspect of 93 degrees and slope of 17 percent. Conifers average 50 per acre (100 percent *P. jeffreyi*, with traces of *C. decurrens*, *C. lawsoniana*, and *P. menizesii* near the edges. Conifer snags average 13 per acre (75 percent *P. jeffreyi* with 25 percent other species). Downed conifer boles average 334 feet per acre. Brush cover averages 7.1 percent per acre (71.5 percent *C. chrysolepis*, 19 6 percent *R. californica*, 4.2 percent *A. viscida*, 3.7 percent *C. pumilus* and small percentage of others).

Timber Resources. Timber resource values within the proposed RNA are low; existing stand volumes average approximately 6 thousand board feet (MBF) per acre. Site quality and management potential are poor, mainly due to low fertility of the serpentine and peridotite soils. Because of the rocky nature of the soils, stands with the larger volumes of harvestable timber are unplantable.

The Proposed RNA contains 441 acres; only 145 acres (mostly low site) is classified as tentatively suitable for timber harvest. For tentatively suitable land within the area, the Douglas-fir site index is approximately 75 and pine species is 50. Tentatively suitable for timber land within the RNA is capable of producing approximately 78 MBF per year on a long-term sustained yield (LTSY) basis (Table F-3).

Mineral Resources. Mining activity has occurred in the past outside the proposed RNA A chromite mine, located about one-half mile to the northwest, was in operation more than 25-30 years ago At that time the mine was operated under a government subsidy. One open shaft and the road to the mine are all that remain

There are numerous placer claims (gold-located 1980) and one lode claim (chrome-Del Norte Chrome-located 1980) existing within the area (Ramp and Peterson 1979). One of the placer claims is located on Cedar Log Creek None of the claims appear to have had any activity within the last one or two years.

A professional mineral examination of the area has not been conducted. This will be necessary if a decision is made to seek mineral withdrawal

The old mining road through the proposed RNA is still navigable by four-wheel drive vehicles; Slate Creek must first be forded. This path allows vehicle access to the meadow area, it may be necessary to control access in the future to prevent damage to the meadow

Research Project of Interest (within the proposed RNA). A bird banding project was conducted by Dennis Vroman during the 1985-1986 field seasons. Although smaller songbirds made up the bulk of species banded, records were kept of all bird species observed. This project provided the following information species occurrence, abundance, and seasonal trends. The study also provided basic information for long-term population trends

The following data (Tables F-RNA-4(a) and F-RNA-4(b) was compiled by Dennis Vroman During 1984-1985 (some data from Tom Atzet)·

Table F-RNA-4(a) List of Plant Species in the Proposed Cedar Log Flat Research Natural Area

Scientific Name	Documented Flowering Dates
Herbaceous Species:	
Achillea millefolium	6-2-80 (Atzet), 6-19-85
Adiantum pedatum var. *aleuticum*

Table F-RNA-4(b). Wildlife Species Identified or Known to be Present in the Proposed Cedar Log Flat Research Natural Area

Scientific Name	Common Name
Birds:	
Bonasa umbellus	ruffed grouse
Buteo jamaicensis	red-tailed hawk
Callipepla californica	California quail
Caolaptes auratus	northern flicker, red-shafted
Carduelis psaltria	lesser goldfinch
Carpodacus purpureus	purple finch
Cathartes aura	turkey vulture
Catharus guttatus	hermit thrush
Catherpes mexicanus	canyon wren
Certhis americana	brown creeper
Ceryle alcyon	belted kingfisher
Chamaea fasciata	wrentit
Columba fasciata	band-tailed pigeon
Contopus borealis	olive-sided flycatcher
Contopus sordidulus	western wood-pewee
Corvus corax	common raven
Cyanocitta stelleri	Steller's jay
Dendroica coronata	Yellow-rumped warbler, Audubon's
Dendroica nigrescens	black-throated gray warbler
Dryocopus pileatus	pileated woodpecker
Empidonax difficilis	western flycatcher
Falco columbarius	merlin
Glaucidium gnoma	pygmy owl
Ixoreus naevius	varied thrush
Junco hyemalis	dark-eyed junco, Oregon
Melospiza lincolnii	Lincoln's sparrow
Myadestes townsendi	Townsend's solitaire
Oporornis tolmiei	MacGillivray's warbler
Oreortyx pictus	mountain quail
Parus atricapillus	black-capped chickadee
Parus rufescens	chestnut-backed chickadee
Passerella iliaca	fox sparrow
Pheucticus melanocephalus	black-headed grosbeak
Picoides villosus	hairy woodpecker
Pipilo erythrophthalmus	rufous-sided towhee
Piranga ludoviciana	western tanager
Psaltriparus minimus	common bushtit
Regulus calendula	ruby-crowned kinglet
Regulus satrapa	golden-crowned kinglet

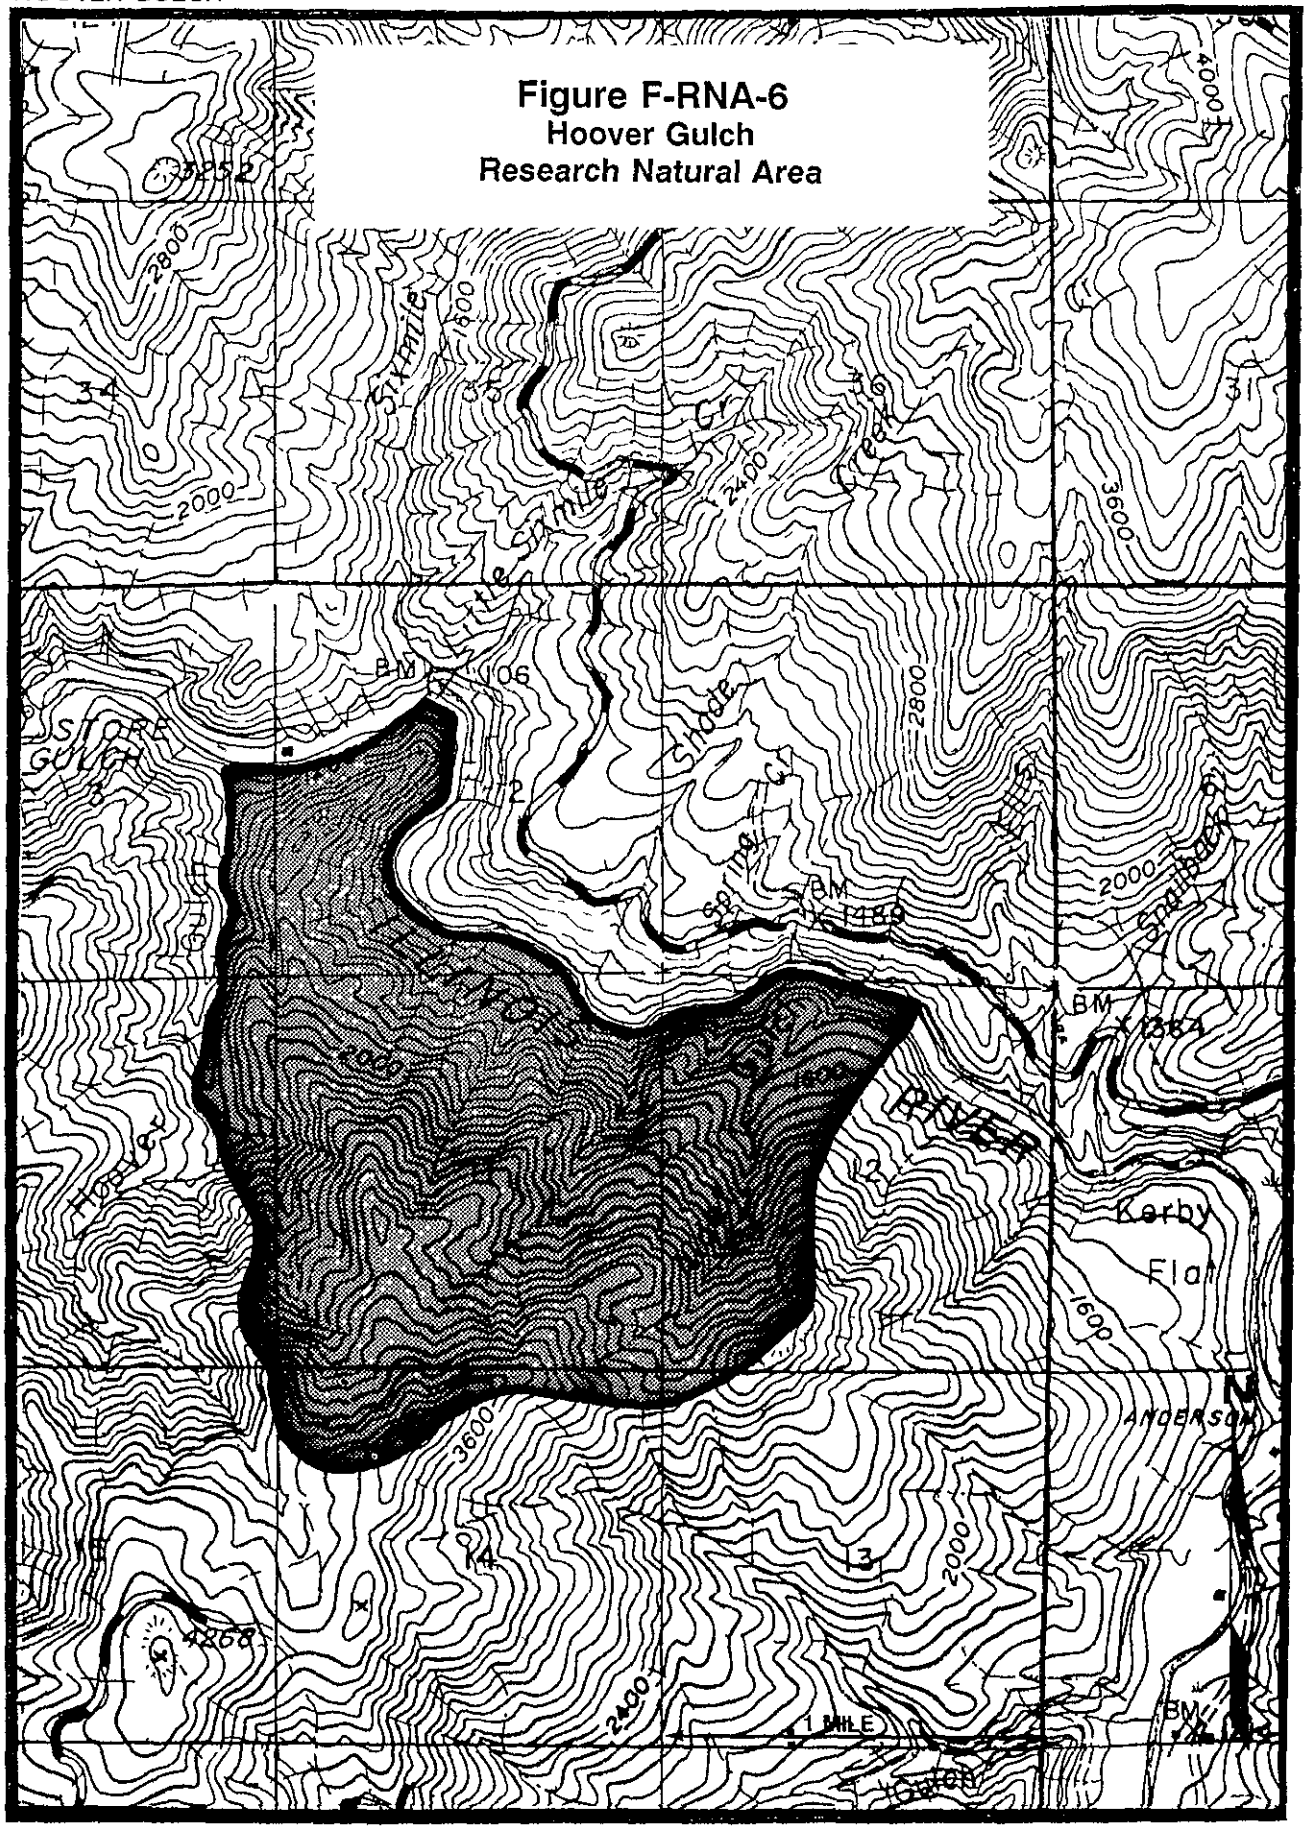
CRAGGY PEAK - F-RNA-5

The Craggy Peak area is on the Applegate Ranger District of the Rogue River National Forest and the Illinois Valley Ranger District of the Siskiyou National Forest, with the smaller part of the area (100 of 1,200 acres) on the Siskiyou (the portion on the Rogue River National Forest is called the Oliver Matthews RNA) The 1,200 acres lie in Sections 21, 28, 29, and 30 of T.40S , R.5W , and Section 25 of T 40S , R 6W The soils and ecology are varied. Most material is metavolcanic; however, there are small inclusions of granitic and ultrabasic materials Soils range from extremely shallow to deep. See Ramp and Peterson (1979) for more information on geology and mineral resources of the general area The Siskiyou National Forest portion of the area contains no land tentatively available and suitable for timber production (Table F-3). One unusual plant is known from the area (Table F-RNA-5); others will probably be discovered. Craggy Peak has been recommended as an RNA in the Preferred Alternative (S).

The Craggy Peak proposed RNA fills the need for six plant community "cells" (Dyrness and others 1975; Tables 53 and 54), (a) vernal pond at mid to high elevation; (b) cold springs; (c) Shasta red fir - white fir forest; (d) Brewer spruce showing maximum development; (e) Baker cypress in the eastern Siskiyous; and, (f) mountain herblands at high elevation. Cells b and f are on the Siskiyou portion of the area; the cold springs cell is especially important.

The range of vegetation is great but white fir/dwarf Oregon grape/prince's-pine is most common. Douglas-fir is common in the overstory but is definitely seral. Incense-cedar and white pine are sparsely represented.



The Baker cypress stand is within a north facing concavity between Miller Lake and the proposed eastern boundary. There are approximately 200 individuals with very little variation in age class and no regeneration. Brewer spruce is common in the north facing concavities and there are several areas with large individuals. On the ridge near the top, mountain hemlock dominates the north aspect. The south aspect has been burned more often and has several seral shrubs. The west end of the area has the only possible high elevation bald in the Siskiyous. It is extremely disturbed as is the surrounding area, and is dominated by green fescue (positive identification not made). However, it is suitable if grazing can be eliminated.

Alternatives to these cells are few. There are no other known Baker cypress stands in the Siskiyou Mountains. A site in the Cascade Mountains was considered, near Prospect, Oregon. The other mountain herbland sites considered, Elkhorn Prairie Site and the "meadows" along the "backbone" of the Siskiyous, have all been overgrazed and grazing continues today.

The Shasta red fir-white fir mix is more common; however, it would fit well within the proposed area rather than a separate RNA elsewhere.

HOOVER GULCH - F-RNA-6

The proposed Hoover Gulch Research Natural Area is a 1,292 acre area in the eastern portion of the Siskiyou National Forest, adjacent to the Illinois River (T.38S., R.9W., Sections 2, 3, 10, 11, 12, 13, 14), (Figure F-RNA-6). Hoover Gulch has been recommended as an RNA in the Preferred Alternative (S). The following description is excerpted from a April 1980 draft Establishment Report on file at the Supervisor's Office.

The proposed Hoover Gulch Research Natural Area occupies the Alder Gulch drainage, and an unnamed small stream basin between them. These streams are tributaries to the Illinois River. The Research Natural Area (RNA) contains approximately 1,200 acres of a variety of mixed-evergreen forest, some open forest types associated with ultrabasic parent materials, and two permanent small streams. The predominant rock type in the RNA is metavolcanic (greenstones of the Rogue and Galice Formations) The mixed-evergreen/canyon live oak (*Quercus chrysolepis*), tanoak (*Lithocarpus densiflorus*) Pacific madrone (*Arbutus menziesii*), Douglas-fir (*Pseudotsuga menziesii*), and sugar pine (*Pinus lambertiana*) forests vary from almost pure hardwood on the steep slopes of the Illinois River Canyon to nearly-pure closed canopy stands of Douglas-fir on benches or ridge tops. On rock outcrops, gnarled canyon live oak and Pacific madrone exhibit the effects of a hot, dry habitat on tree form Small outcrops of ultrabasic parent materials support distinctive open forests of Jeffrey pine (*Pinus jeffreyi*) and incense-cedar (*Calocedrus decurrens*) due to the special soils formed by these minerals.

The need for an RNA with plant communities such as those in the Hoover/Alder Gulch area was recognized by the Pacific Northwest Natural Area Needs Task Force. Hoover Gulch Research Natural Area can fill the following cell needs in the Siskiyou Mountains province (Dyrness and others 1975):

from Table 53

8 Mixed evergreen forest (Douglas-fir and evergreen hardwoods) (Major component)

10. Canyon live oak

from Table 54

2. Major stream drainage in mixed-evergreen forest.

The Hoover Gulch Research Natural Area fills two specific needs identified by the Pacific Northwest Natural Area Committee in 1973, and has several unique features which will contribute to scientific and educational needs in the future. It fills the identified need for an area with the mixed-evergreen forest type, which is recognized as a major community type in North America. This mixed-evergreen zone (Douglas-fir and evergreen forests) occupies large areas at low elevations in southwestern Oregon and northern California The Hoover Gulch Area contains representatives of both the relatively undisturbed and more recently burned mixed-evergreen forest of the Siskiyou Mountains. It provides a rich diversity of communities and habitat types of the mixed-evergreen zone on a wide range of slopes, aspects, elevations, and soils

The RNA would provide representative area of important tree species at the dry end of their environmental range, including Douglas-fir, sugar pine, and ponderosa pine (*Pinus ponderosa*). Douglas-fir dominates in the stands occupying rock mulch soils on the canyon walls. Sugar and ponderosa pine are found on deeper soils on benches and ridge tops. Tanoak, canyon live oak, and Pacific madrone occur in situations where they are part of the climax community, as well as in seral stages of community development On the driest rocky slopes, canyon live oak has the highest cover of any tree and tanoak is nearly absent. On better soils tanoak predominates. The diversity of landform, aspect, and elevation produce forest stands which vary not only in composition and structure, but in productivity, thus providing an excellent opportunity to study the factors which affect productivity in this Region.

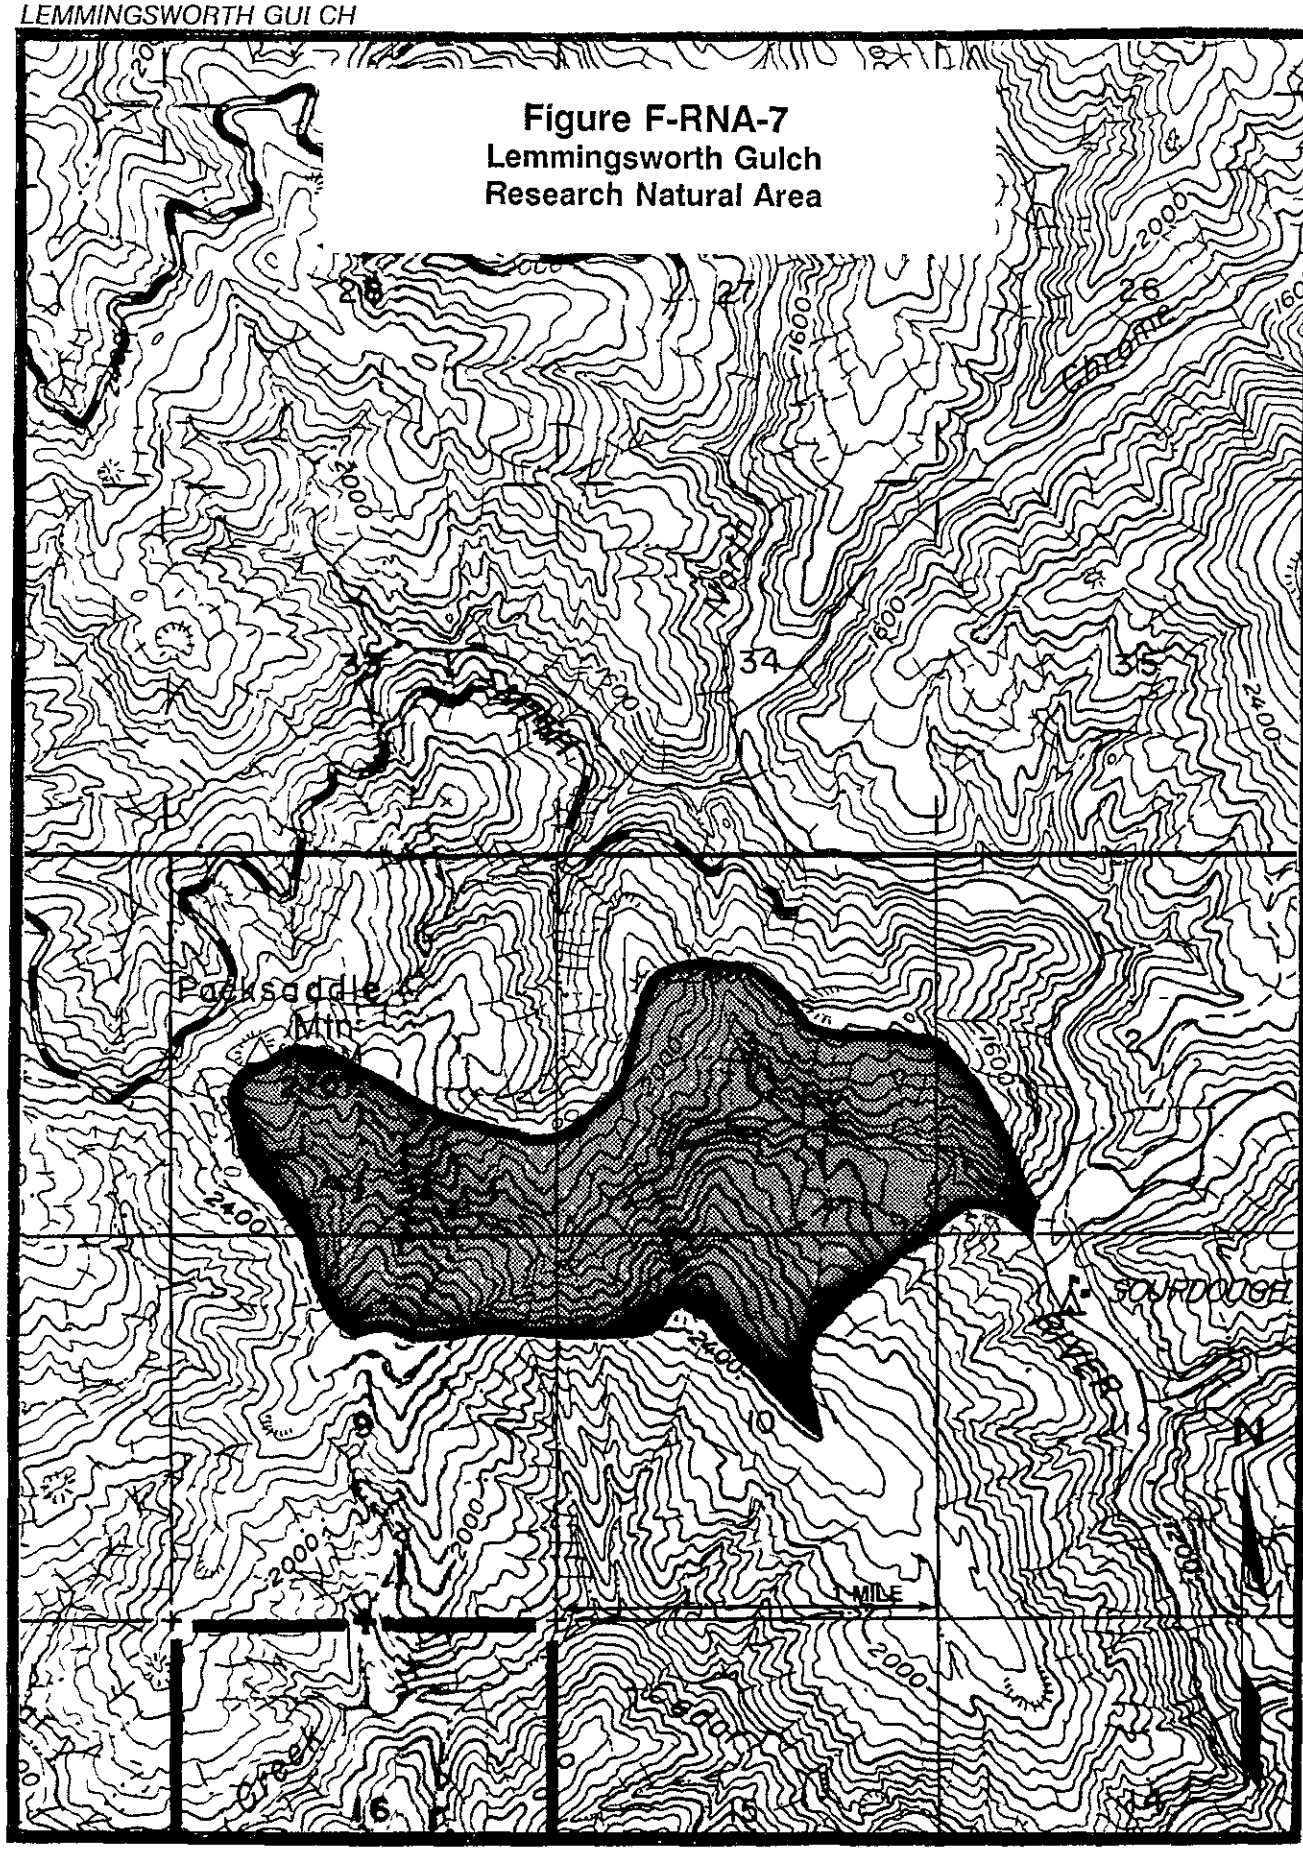
The proposed area also fills the identified need for a permanent stream in mixed-evergreen forest Since entire watersheds are included in the RNA, this would provide an ideal setup for watershed/nutrient cycling studies.

Several special features add to the value of this area as a research natural area The area contains several outcrops of ultrabasic (serpentine) parent material which supports distinctive plant communities where Jeffrey pine and incense-cedar are the major tree species. These outcrops provide an opportunity to compare these special communities on patches of serpentine with similar communities on the large land masses of the same parent material a few miles away. One unusual plant, *Darlingtonia californica*, is present within the RNA (Table F-RNA-6).

The proposed area is known to be inhabited by the northern spotted owl. Study of the owl in this area could provide better information about its habitat requirements.

The Illinois River Canyon is one of the most floristically rich areas of Oregon. Hoover Gulch would add diversity to the habitats now set aside in Botanical areas and other research natural areas.

Timber Resources. Timber management options for the area are limited. All timber within one-fourth mile of the Wild and Scenic Illinois River is excluded from harvest. In addition, Hoover Gulch serves as Spotted Owl Habitat Area (see the Proposed LRMP, Chapter IV, Management Area 8). Given these land allocations, none of the proposed RNA is available for timber management. However, if the Hoover Gulch site were not used to help meet minimum management requirements for spotted owls, and if no other land allocations were made for other resources (such as visuals), commercial timber land within the RNA would be capable of producing approximately 593 thousand board feet (MBF) per year on a long-term sustained yield (LTSY) basis (Table F-3).



Mineral Resources. A professional mineral examination of the proposed Hoover Gulch Research Natural Area was conducted on October 19-20, 1982 and July 26, 1983 (report on file at the Supervisor's Office). The mining engineer noted that gravels along the Illinois River and the ridgeline area in Section 14 are mineral in character. The lands drained by Alder Gulch and west to the ridge east of Hoover gulch are nonmineral in character. When an area is allocated for RNA purposes, an Establishment Report must be written and approved. The decision on whether or not to recommend a RNA for withdrawal from mineral entry would be addressed in the Establishment Report.

Five historical gold placer prospects are located within or near the edge of the RNA (Ramp and Peterson 1979). The future potential of these sites is considered low. A few placer claims presently exist at various locations in the RNA (Bureau of Land Management (BLM) records, as of May 27, 1982). Their validity has not been determined.

LEMMINGSWORTH GULCH - F-RNA-1

The proposed Lemmingsworth Gulch Research Natural Area is an 818 acre area in the southwest corner of the Siskiyou National Forest (T.41S., R 11W., Sections 2, 3, 4, 9, 10) (Figure F-RNA-7). Lemmingsworth has been recommended as an RNA in the Preferred Alternative (S). The following description is excerpted from a March 1980 draft Establishment Report on file at the Supervisor's Office

The proposed RNA is marked by a sharp contrast between geologic substrates, which results in a dramatic contrast in vegetation types. Peridotite substrates are sparsely forested with a mosaic of knobcone pine (*Pinus attenuata*) in nearly pure stands, Jeffrey pine (*P. jeffreyi*) woodlands, Douglas-fir (*Pseudotsuga menziesii*) forests, and mixed forests dominated by Douglas-fir and evergreen hardwoods. Tree cover drops to near zero in many areas, so that some portions are dominated by shrublands Normal substrates, on Dothan Formation, are more densely forested, with either older stands of Douglas-fir or younger stands of tanoak (*Lithocarpus densiflorus*) and Pacific madrone (*Arbutus menziesii*). The topography, typical of the western Siskiyou Mountains, consists of dissected drainages, steep slopes, and narrow ridges. The Research Natural Area (RNA) encompasses a single entire watershed that drains eastward into the North Fork of the Smith River Elevation range is from 1,100 to 2,707 feet.

Topographic variety, elevation range, and a variety of geologic substrates produce a highly diverse flora. The Siskiyou Mountains are noted for plant endemism, or extremely localized species. Many of these species are restricted to serpentine. The proposed Lemmingsworth Gulch Research Natural Area is noteworthy for its extremely high concentration of endemic and rare plant species. Lemmingsworth Gulch contains at least seven sensitive species and ten species on the Review or Watch lists (Table F-RNA-7).

The western Siskiyou Mountains contain the Josephine peridotite sheet, the largest continuous body of serpentine and peridotite in Oregon Along the margins of this sheet, at the point of contact with other substrates, there is often a dramatic and abrupt change in vegetation so that it is possible to step from one distinctive community type across the line to another. Peridotite is well known for its relatively depauperate tree strata and very diverse shrub and herb layers.

Research on stand structure, composition, and succession in forests on peridotite in the western Siskiyou Mountains is extremely limited. A research natural area which contains a peridotite area and a contact with "normal" substrates is a logical addition to a natural area system whose aim is to preserve examples of significant natural ecosystems for comparison with those influenced by man Comparative studies of the extreme conditions on peridotite should yield valuable information which will aid in understanding management of forests and adjoining "normal" substrates The need for such an area was recognized by the Pacific Northwest Natural Area Needs Task Force (Dyrness and others 1975). As a priority item, Table 58 of their report lists the need for a mid- to high-elevation area with serpentine vegetation matrix with normal soil contact.

Little study on stand dynamics, productivity, and nutrient flow has been done on forest types found on peridotite. Inclusion in the research natural area system of knobcone pine forests and Jeffrey pine forests is important so that their peculiar adaptation to the abnormal soil conditions found on peridotite can be studied. These forest type needs are identified as priority items in Table 58 of Dyrness and others (1975).

In addition to these needs forests found on normal soil in the western Siskiyous have received little study. The tanoak-madrone forests and mixed-evergreen forests of the western Siskiyous are both identified as priority needs by Dyrness and others (1975).

In summary, the RNA will preserve forest types found on serpentine in the western Siskiyou Mountains. The presence of an entire watershed and an excellent bedrock exposure at the point of exit of the stream

into the North Fork of the Smith River will allow comparative studies of nutrient outflow and water quality. Lemmingsworth Gulch Research Natural Area can fill the following **forest type cell needs** in the Siskiyou Mountains Province (Dyrness and others 1975):

from Table 53

8. Mixed-evergreen forest (Douglas-fir and evergreen hardwoods) (Minor component)
9. Tanoak/madrone forest
11. Knobcone pine
16. Jeffrey pine/grass on serpentine at high elevation
17. Port-Orford-cedar (*Chamaecyparis lawsoniana*)/Douglas-fir on serpentine soils
18. Serpentine vegetation matrix and normal soil island with good representation of contacts

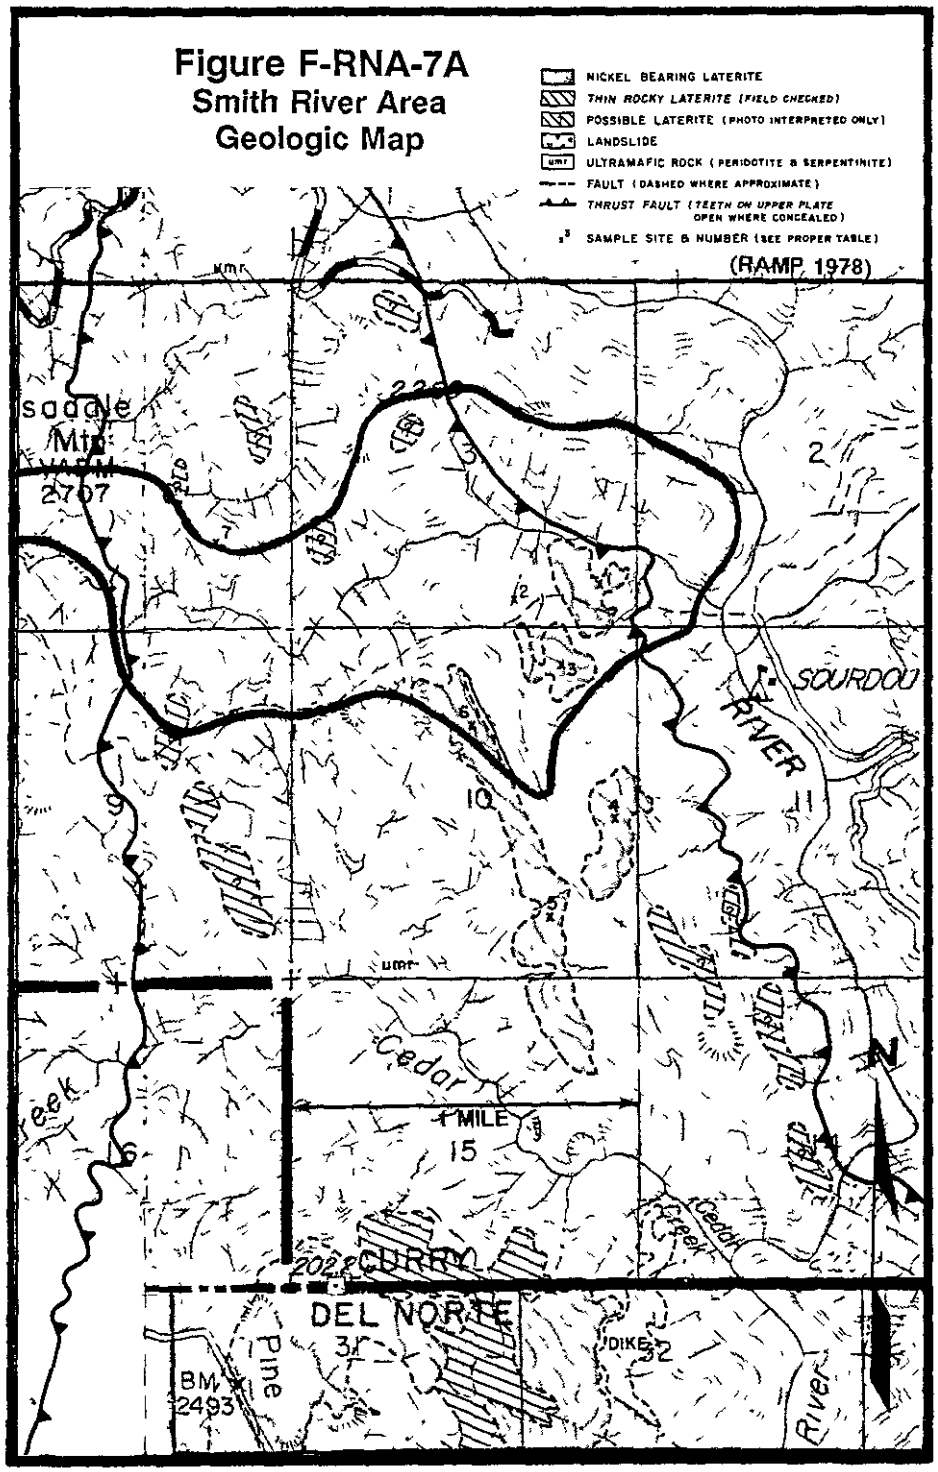
The following **aquatic cell needs** (Dyrness and others 1975) will also be filled:

from Table 54

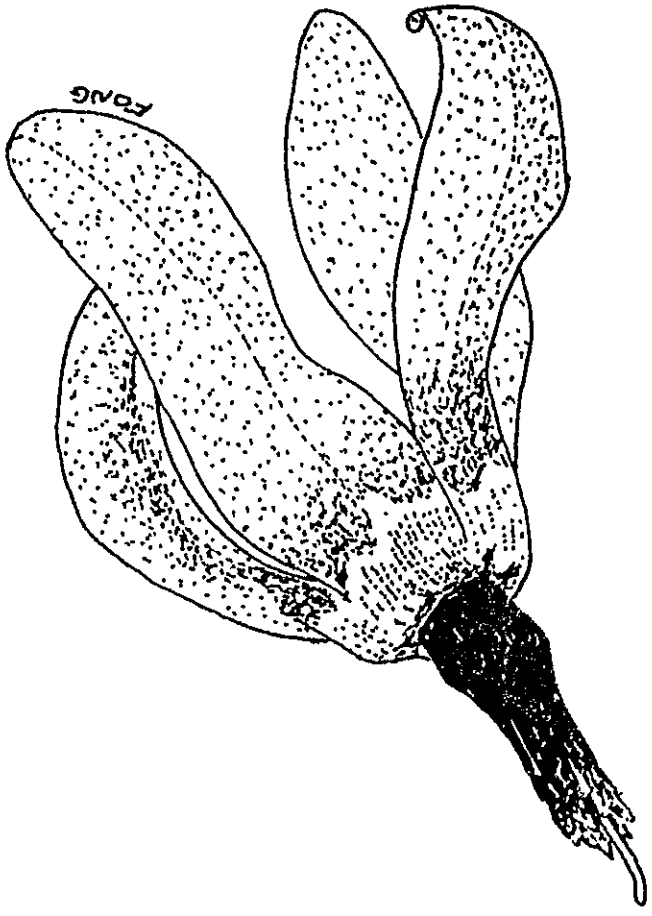
10. Stream drainage in serpentine at mid- to high-elevation
14. Mountain bog in serpentine area with *Darlingtonia*

Timber Resources. Timber resource values are low on this tract in terms of standing volumes or site quality and management potential, largely due to the poor serpentine soils. The area is generally covered with young stands of Douglas-fir, knobcone pine, Jeffrey pine, and associated species. Average volumes of tentatively suitable timber stands are estimated at 10 MBF per acre, but vary widely with the substrates. Average site index for tentatively suitable stands is approximately 75. Tentatively suitable timber land within the proposed RNA is capable of producing approximately 141 thousand board feet (MBF) per year on a long-term sustained yield (LTSY) basis (Table F-3). However, the site as a whole is basically noncommercial. The central portion of the proposed RNA has extremely steep, rocky soils, which are subject to rapid erosion and landslides. Past erosion following wildfires is evident. Establishment of the RNA would create no access problems to adjacent forest areas.

Mineral Resources. A Forest Service mining engineer examined Lemmingsworth Gulch on November 15, 1977. He found that the proposed site of the RNA was mineral in character. In a report dated January 5, 1978, he noted that laterites containing at least 0.7 percent nickel exist in the northwest portion of the area. The small laterite deposits in this area, by themselves, would not be of economic interest, but combined with other nearby deposits they could someday become valuable. Figure F-RNA-7A shows the laterite sites within the Lemmingsworth Gulch area.



There has been no known mineral production from within this area. Chromite has been mined within 1 mile of this area, and the geology is favorable for this mineral to be found within the proposed RNA



There are several mining claims in the area; they are not expected to cause any problems in the near future. The research natural area could be recommended for withdrawal from mineral entry. Mining action would nullify much of the value of the area for research. See Ramp and others (1977) for more information on geology and mineral resources of the general area.

Figure G-1 Silvicultural Systems Analysis	G-18

INTRODUCTION AND SUMMARY

The selection of silvicultural systems is a key element in the management of the Forest The systems used will strongly influence forest conditions and the ability to provide the outputs desired by society This facet of forest management has received considerable public attention in recent years, particularly in the form of concern over clearcutting and the application of even-aged systems in general This controversy escalated to a national issue, and Congress expressed that even-aged systems will be used only where determined to be appropriate to meet the objectives and requirements of the relevant plan, and more specifically, that clearcutting will be used only where determined to be the optimum method (Public Law 94-588).

It is often suggested that the Forest Service should consider alternatives comprised wholly of one type of system evaluated against another, implying that adoption of one type of system could provide the optimum management of the entire Forest This view ignores the tremendous variation found within this Forest and the multiple objectives that the Forest is managed to achieve. No single silvicultural system is applicable throughout the mixed conifer forests (Minore and Kingsley, 1983). In addition, adherence to the criteria for vegetative manipulation in the regulations (36 CFR 219 27(b)) will lead to selection of different systems for specific combinations of management objectives, site characteristics, and stand conditions In other words, the land itself often provides the best clues as to its appropriate management

This appendix describes the primary silvicultural systems available, the key site and stand conditions found on the Siskiyou National Forest, and the management goals and objectives associated with the alternatives of the Final Environmental Impact Statement (FEIS) for the Land and Resource Management Plan (LRMP). It provides a comparison of systems and anticipated results of each; then identifies the most appropriate systems for given combinations of the above factors. While the indicated systems should be those most often used, it is not intended that other systems should not be used when site specific conditions warrant Final selection of a silvicultural system and harvest method for a specific site is best left for the silvicultural prescription as provided for in Management Standards and Guidelines 1-1, selection criterion six of the Regional Guide for the Pacific Northwest Region, 1984 (USDA-FS, 1984).

Each of the systems described will be used to some extent. Uneven-aged systems will be used more frequently on sites that naturally tend toward uneven-aged structures (ultrabasic soils), or where they will best meet resource objectives. At a minimum, they will be tried in a few stands to gain experience on the Forest with uneven-aged management.

Due to the particular combinations of environmental conditions and management objectives, even-aged systems will be the most commonly used, with clearcutting the most common method of regeneration in this group The discussion presented here provides much of the rationale for the frequent selection of clearcutting as the optimum method Although many factors influence this decision, some have been over-emphasized. "Economics often bears the brunt of arguments for conversion to clear-cut systems In fact, these decisions originate in the practice of the art of forestry" (Brodie, 1981). Key factors in the determination of appropriate systems on this Forest are the intensity of vegetative competition commonly encountered, the difficulty of protecting residual trees through harvest operations on steep slopes, and the desirability of perpetuating high proportions of shade intolerant species.

DESCRIPTION OF SILVICULTURAL SYSTEMS

Silvicultural systems fall into two categories: Even-aged, and uneven-aged. With even-aged systems, all the trees in the stand are approximately the same age throughout most of the life of the stand. Uneven-aged systems produce stands with no beginning or end points in time, the trees within the stand are of distinctly different ages with at least three classes present.

Stand development and management options are strongly influenced by the regeneration cutting. The major silvicultural systems are known by the type of regeneration cutting employed Clearcutting, shelterwood, and seed tree are methods of regeneration within the even-aged system, single-tree selection and group selection are uneven-aged systems Each of these systems includes regeneration cutting, establishment of new seedlings or sprouts, and intermediate cutting or stand improvement treatments (commercial and precommercial thinnings) as needed to encourage the stand characteristics desired to achieve management objectives. The classification of silvicultural systems presented here is after Burns (1983), with additional descriptive information from Smith (1962)

EVEN-AGED SYSTEMS

Clearcutting involves harvesting of all the merchantable trees in a stand or large part of a stand to clear the way for the establishment of a new even-aged stand. The complete cycle of one generation from seedlings to final harvest is termed a rotation Virtually all of the trees are removed except those designated to fulfill resource needs or those which are unmerchantable and deemed not a hindrance to the establishment and growth of the new stand The new stand could be created by natural or artificial seeding, planting of seedlings, or sprouting from stumps or roots of cut trees. On the Siskiyou National Forest, most stands are regenerated by planting seedlings due to the unpredictable nature of the seed crops and the threat of falling behind the growth of less desirable vegetation if establishment of conifers is delayed. Most of the desirable timber species found here do not sprout readily, and the method of stump or root sprouting is generally not used (The Forest does contain a small amount of redwood which could be an exception)

The **shelterwood** method involves removal of the stand in a series of two or more harvests designed to establish a new crop before removal of the last of the mature stand These harvests span a relatively short period of time, only a fraction of the rotation, and the new stand produced is essentially even-aged The shelterwood method is used primarily to create a protected environment in which seedling survival and establishment may be enhanced, and in some cases to encourage the establishment of natural seedlings

The **seed-tree** method involves leaving a few trees at the time of the regeneration harvest to produce seed to reforest the cut-over area Depending on the amount of seed expected to be produced and the distance of dispersal from each tree, from three to ten trees per acre would be left. The seed trees may be removed in a second cutting or left indefinitely. This method differs from the shelterwood method in that the few trees left in seed-tree cutting do not significantly protect the seedling environment. Again, the new stand created would be essentially even-aged, varying only a few years or a small fraction of the rotation

UNEVEN-AGED SYSTEM

In the **single-tree selection** method, the mature timber is removed as single scattered trees. Such cuttings are repeated indefinitely at relatively short intervals (as often as every ten years on better sites) with the purpose of creating or maintaining an uneven-aged stand Removal of mature trees and thinning of the residual crop trees are both normally part of each harvest entry The regeneration of seedlings occurs in the spaces created by the removal of the individual trees

The **group selection** method is similar to the single-tree selection method except small groups of trees are removed at each harvest entry Openings created may vary from the width of a few tree crowns up to an acre or two in area and would resemble miniature clearcuts The uneven-aged stand created is a mosaic of very small even-aged groups or aggregations Many of the treatments used in the even-aged systems could be used except that any given treatment would be applied to small groups scattered through the stand

KEY SISKIYOU NATIONAL FOREST CONDITIONS

PLANT SERIES AND SOILS

Many site specific factors influence the selection of a silvicultural system The characteristics of the site itself are important to predict response to treatment and long-term effects of applying various systems The slope, aspect, elevation, soil, and climate, along with animals, pathogens, and sometimes fire, all interact to create the environment for vegetation response Plant communities (associations of particular plants) are an expression of the environment. A classification system covering the Forest defines environments according to their potential natural vegetation, or climax species, and site characteristics (Atzet and Wheeler, 1984). The smallest unit in the classification system is the plant association which can be used to resolve environmental differences for silvicultural prescriptions It can also be used to estimate productivity and extrapolate the response that could be expected under different conditions or following different management treatments Plant associations have been grouped into series with the same climax dominants The series lacks the resolution needed at the project level, but can be used for planning purposes and will be used here to indicate the long-term biological response expected under the various silvicultural systems.

PLANT SERIES

Although the mapping of plant associations or series has not been completed, an estimate of the relative occurrence of the individual series can be derived from the frequency with which the series was encountered in the ecology plot sampling There are seven commonly occurring series that represent most of the land area of the Forest. These series, their codes, and estimated proportion of the forest are displayed in the following table.

Series	Code	Percent Proportion
Shasta Red Fir	(ABMAS)	8
White Fir	(ABCO)	18
Western Hemlock	(TSHE)	8
Port-Orford-cedar	(CHLA)	5
Tanoak	(LIDE3)	41
Douglas-fir	(PSME)	13
Jeffrey Pine	(PIJE)	5

Shasta Red Fir Series (ABMAS). This series is found at elevations from 3,800 to 7,300 feet. It is most often found on northerly aspects and increasingly so at lower elevations. These sites generally have a heavy winter snow pack, and occur on all slopes and a wide variety of soil conditions. The predominate conifer species found in this series are Shasta red fir and white fir Other species occurring less frequently include western white pine, Douglas-fir, sugar pine, and mountain hemlock.

This series contains some of the coldest sites on the Forest and have extreme temperature fluctuations Exposed soil surface temperatures can fluctuate daily from 100 degrees Fahrenheit to freezing, creating an unfavorable environment for conifer regeneration The planting window is often very short as the soil condition goes from being too cold to support significant conifer root growth, to one of depleted moisture within a few weeks

Competing vegetation affects seedling establishment more than it affects long-term stand development and growth The species found on these sites are generally lower growing shrubs in contrast to the

hardwood trees more prevalent to warmer series However, vegetative competition may be significant If shrubs take over a site, they can dominate for two to three decades retarding regeneration and stand establishment.

White Fir Series (ABCO). This is the most prevalent series on the Forest It covers a wide range of environmental conditions and supports many species of conifers as well as other vegetation The most common conifers are Douglas-fir, white fir, Shasta red fir, ponderosa pine, incense-cedar, and sugar pine. The variation of this series encompasses a wide range of soils, elevations, and aspects Because of this variation it is difficult to make generalizations about regeneration potential, and management implications associated with regeneration. Important, however, is the relative absence of competitive hardwood tree species in the understories of stands in this series. This is not to say that these sites will not have vegetative competition, they often contain dormant seeds of shrub species, such as ceanothus, which may germinate following disturbance However, the competition from germinating seedlings is generally much less intense than that from hardwood stump sprouts

Western Hemlock Series (TSHE). This series is generally only found on the windward side of the coastal crest and north of the Rogue River It characteristically has deep soils, cool temperatures, and ample moisture. It is found more frequently on north aspects as distance from the coast increases Most common conifer tree species are Douglas-fir, western hemlock, and Port-Orford-cedar Red alder, tanoak, golden chinquapin, and California laurel (Oregon myrtle) are also common

With deep soils, ample moisture, and favorable temperatures, the most serious impediment to reforestation is competition from shrubs and hardwood trees. Even though conifers regenerate in disturbed areas quite readily from natural seedlings; species, such as, huckleberry, rhododendron, alder, and tanoak are often quite competitive

Port-Orford-cedar Series (CHLA). This series is scattered over broad areas on the extreme northwesterly portion of the Forest; however, it occurs principally along streams and in some areas with perched water tables east of the coastal crest. It is weakly associated with , but not limited to, ultrabasic soils It occurs over a variety of soil, slope, aspect, and elevation conditions. The major conifer species are Douglas-fir, Port-Orford-cedar, and white fir. Having ample moisture, this series supports a wide variety of species and is particularly important to riparian area management along streams where water, fish, wildlife, and recreation values are high.

Most of the sites in this series have favorable physical environments for establishment of conifer regeneration. The potential for vegetative competition is quite variable and could be severe on some sites.

Tanoak Series (LIDE3). This is the second most prevalent series on the Forest. It occurs on all slopes and aspects, often on deep soils, and is not found at higher elevations where it is limited by cooler temperatures. Although it supports a wide variety of conifer species, the most prevalent are Douglas-fir and sugar pine. Hardwood tree species common in this series include tanoak, madrone, golden chinquapin, and canyon live oak. Shrubs that often have a high percent cover are· salal, evergreen huckleberry, and rhododendron

Most of the sites in this series have favorable physical environments for the establishment of conifer regeneration However, the warmer and drier associations may not have enough moisture available to sustain seedlings into the growing season, resulting in poor survival The variety of shrub and hardwood species in this series tend to have high potential for prolific seeding and sprouting. Competition is encountered on most sites and is intense, with the potential to last well into the rotation if the site is not quickly reforested with conifers.

Douglas-fir Series (PSME). The Douglas-fir series is also common on the Forest It covers fairly wide range of elevations and all slope and aspects. It tends to occur on shallow to moderately deep soils and is the

driest series that supports commercial forest production Even on the more moist sites within the series, moisture is most often the limiting factor to conifer survival and growth. The most common conifers are· Douglas-fir, ponderosa pine, sugar pine, and white fir. Common shrubs or hardwoods are. madrone, tanoak, golden chinquapin, canyon live oak, and California black oak.

This series encompasses a variety of environmental conditions, but can be broken into three groupings of associations with similar management problems: Douglas-fir - white fir, Douglas-fir - tanoak, and those with no specific modifier. The **Douglas-fir - white fir group (PSME-ABCO)** is the coolest of the three, although it spans a range of moisture availability from dry to relatively moist. It has no characteristically dominating silvicultural problem; potential reforestation problems include competition, animal damage, moisture stress, and physical barriers

The **Douglas-fir - tanoak group (PSME-LIDE3)** has many of the reforestation characteristics as the Douglas-fir - white fir group. But, the potential for competition from tanoak is extremely high and is a dominating factor for this group. This competition not only influences reforestation, but also can influence conifer growth and production well into the life of a stand or even through the entire rotation Soils are generally deeper than the other groups, temperatures more moderate, and atmospheric moisture more plentiful.

The remaining group of associations has no modifier. They are simply the **Douglas-fir associations (PSME)**. In terms of plant growth, these are the least productive of the series. Shallow soils with low water holding capacity, high evaporative demand, and high radiation loads combine to significantly limit growth. High soil surface temperatures and drought make reforestation difficult on many sites in this group.

Jeffrey Pine Series (PIJE). This series only occurs on serpentinite/peridotite derived soils. These soils are both clayey and shallow, and are high in magnesium relative to calcium and in heavy metals such as nickel and chromium which have growth retarding effects on most conifers. These are the least productive forested sites in the Siskiyou mountains. The series is found over a fairly wide range of elevations and on all slopes and aspects. The vegetation is diverse both in the number of species present and the structure in terms of size and age. Incense-cedar and Jeffrey pine are the most common conifers, although western white pine, Douglas-fir, and Port-Orford-cedar occur frequently as well.

Sites in this series may be difficult to reforest due to the shallow soils with nutrient imbalance and heavy metals. They are also not very productive; therefore, substantial investments in silvicultural treatments may not be warranted Many of these sites have existing understories of conifer regeneration, or even several age classes comprising natural uneven-aged stands. Though artificial regeneration may be difficult to achieve, these sites tend to regenerate naturally to Jeffrey pine and Douglas-fir.

ULTRABASIC SOILS

The soils of the Forest are diverse, and no attempt will be made here to characterize individual soil types. There is a major dichotomy that is useful in understanding vegetation development, projecting treatment response, and assessing management opportunities. This division separates those soils characterized as ultrabasic from those with a more normal balance of minerals. Ultrabasic soils are derived from serpentinite/peridotite and gabbro parent materials. These soils tend to be both clayey and shallow, are high in magnesium relative to calcium, and often are high in heavy metals such as nickel and chromium. Productivity is generally low, and reforestation though artificial means may be difficult. Sites with these soils often have greater diversity of vegetation in both species and structure. On these soils there are often more species of conifers growing in mixed stands, and there is often a diversity of sizes and ages. They tend to have some natural conifer regeneration following disturbance and are less dominated by sprouting shrubs and hardwoods than other soils. Because of the lower productivity, the fuel loadings tend to be lower, and fires are seldom intense enough to eliminate the younger age classes of conifers

The management problems and opportunities are substantially different on ultrabasic soils than on other soils with even-aged stands and where sites are likely to be dominated by shrubs and hardwoods following disturbance The potential to meet short and long-term management objectives with uneven-aged systems is greater for many of these areas with ultrabasic soils. Regeneration is often present or predictable, and competing vegetation is less.

SUMMARY OF PLANT SERIES AND SOIL GROUPS

The important considerations from the plant series and soil types relating to this analysis are the level of vegetative competition expected, and the tendency toward natural conifer regeneration. Many of the plant series or associations have similar characteristics in terms of the general factors considered. To facilitate the analysis and avoid redundancy, the plant series and soils are grouped into the following three categories

Plant Series and Soil Group 1: High Competition. This group includes those sites where vegetative competition with young conifers is expected to be high The tendency is to produce hardwood trees, particularly tanoak, stump sprouts following logging and slashing for site preparation commonly outgrow conifer seedlings. Plant series in this group are·

LIDE3
TSHE
PSME-LIDE3
CHLA except CHLA/QUVA and CHLA/GABU associations
ABCO/LIDE3 and ABCO/CHLA associations

Plant Series and Soil Group 2: Moderate Competition. Sites in this group are expected to have less vegetative competition than Group 1, although it will still be significant. The competition is more likely to be from shrubs or forbs than faster growing hardwood sprouts. This group includes:

ABMAS
PSME-ABCO
ABCO except ABCO/LIDE3 and ABCO/CHLA associations

Plant Series and Soil Group 3: Low Competition - Ultrabasic Soils. This group includes sites where the vegetation is sparse, and there is less competition for sunlight (plant growth is more limited by the availability of moisture and nutrients). Stands tend to be fairly open and competition is more from low growing shrubs, forbs and grasses. Sites with ultrabasic soil generally have a variety of conifer species Although growth may be slow, these sites tend to produce natural conifer regeneration. This group includes·

PIJE
CHLA/QUVA and CHLA/GABU associations
PSME - all associations not in groups 1 and 2

EXISTING STAND CONDITIONS

The nature and condition of the existing vegetation are important to predict response to silvicultural treatments, and to evaluate the potential of the current stand to meet objectives under the various options for silvicultural systems. Forest-wide inventories currently available do not include the resolution in stratification needed to adequately assess the opportunities and effects associated with the different silvicultural systems Site specific stand conditions will be assessed intensively in the preparation of the silvicultural prescriptions for field implementation. The discussion here is somewhat general and is intended to provide a framework to aid in that site specific analysis. The existing conditions will be

discussed in the framework of a stratification into a few categories that have implications for the broad treatment of silvicultural systems presented here.

MATURE AND OVER-MATURE CONIFER STANDS

Many stands on the Forest initiated following natural disturbances, primarily wildfires, which destroyed the previous stand and opened the growing space for new seedings. These stands are essentially even-aged and often composed of trees of advanced age and declining vigor. Use of selection systems in such stands have consistently resulted in high mortality among the residual trees and are better suited to stands with more variation in age, size, and vigor (Burns, 1983). Some stands have had minor disturbances, such as low intensity fire or scattered windthrow, which did not completely destroy previous age classes, but opened growing space and created more than one age class. These stands contain more than one age class, but younger age trees are usually suppressed with low vigor. There are not enough vigorous seedlings with the growth potential to meet management goals and objectives.

IMMATURE STANDS

There are some pole and small timber size stands on the Forest, regenerated after fires or early logging, currently less than rotation age. These stands may or may not have excess stocking that would provide an opportunity for commercial thinning. Many of them are even-aged 60 to 90 years old, approaching rotation age.

The Forest now has approximately 135,000 acres of seedling and sapling stands, most of which are plantations created following timber harvests. These are predominately less than 30 years old The condition of these stands varies somewhat, but Forest-wide most are well stocked and many are growing rapidly following precommercial thinning treatments accomplished in the last two decades.

UNEVEN-AGED OR MULTI-AGED STANDS

There are stands occurring on sites with ultrabasic soils that have naturally developed uneven-aged structures. These stands have developed over a period of time as individual trees have slowly seeded in, often following low intensity fires or other minor disturbances. They tend to be quite slow growing and have not formed closed canopies that would suppress the further development of the younger age classes. These stands often have healthy stocking in a variety of age classes presenting a range of silvicultural options.

There are also a few stands occurring on more normal soils that have several age classes resulting from repeated low intensity disturbances, or from shade tolerant species seeding in under an established conifer overstory. In these cases it may not be feasible to perpetuate and reproduce multi-aged stand conditions under management. Short term silvicultural options for these stands may be different than the long term strategy suggested by the potential vegetation for the site.

MANAGEMENT GOALS AND OBJECTIVES

FOREST-WIDE

The goals and objectives most affecting the choice of silvicultural systems are those that relate to producing timber, and those that in some way conflict with or modify the way timber is produced. Most of the alternatives specify a fairly intensive level of management for those areas allocated to management emphasis that include programmed timber harvests. There are also goals for providing habitats to support all native wildlife species, protecting soil and water, and providing recreation opportunities. Resource values are to be protected or enhanced through fire and fuels management programs. Throughout all of the management programs and activities, implementation should be accomplished in an efficient and cost effective way

MANAGEMENT AREAS

Some of the management objectives relating to selection of silvicultural systems vary by the Management Areas defined for alternative land allocations Many of the 14 Management Areas do not have objectives for timber management and any incidental harvest done would be prescribed to achieve specific objectives for another resource. Management Areas with programmed timber harvest are 10, 11, 12, 13 and 14, Scenic/Recreation River, Riparian, Retention Visual, Partial Retention Visual, and General Forest, respectively. Although all of these areas are managed for multiple-use, the emphasis or priority changes by Management Area Management Area 10, Scenic/Recreation River, may have timber harvest, but any harvest must be designed to meet the Retention Visual Quality Objective (VQO) For purposes of selecting a silvicultural system, Management Area 10 can be considered the same as Retention.

MANAGEMENT AREA 11 - RIPARIAN

This is the area of riparian ecosystem along all perennial streams within areas selected for timber production. The width of this area will vary according to site specific conditions, although the minimum area of consideration is 100 feet measured horizontally from each side of the stream The primary goal for management is to maintain the integrity of the riparian ecosystem which includes streambank stability, vegetation, and terrestrial and aquatic habitats.

To accomplish the objectives of maintaining water temperatures through stream shade and providing large conifers for wildlife habitat, the proportion of conifers that can be removed through timber harvest is constrained Although hardwoods provide significant amounts of shade on many streams, conifers will also be left to meet multiple resource objectives The level of the constraint varies by stream class, and also by the Riparian Management Prescription option selected Riparian Management Prescriptions B and C provide for different levels of protection Different Planning Basins on the Forest may be allocated to one prescription or the other depending on the theme of the alternative. (Prescription A was also developed, but determined to not provide the minimum legal requirements for stream protection due to a projected increase in summer stream temperatures)

Prescription C allows minimal timber removal, primarily to facilitate harvest of adjacent stands. Harvest operations may not reduce the basal area of conifers below 80 percent of natural levels along Class I and II streams; or below 60 percent of natural levels along Class III streams

Prescription B provides a higher level of timber production while still emphasizing the protection and enhancement of riparian ecosystem values. The basal area of conifers should be maintained at or about 70 percent of natural conditions along Class I and II streams; and 30 percent along Class III streams.

MANAGEMENT AREA 12 - RETENTION VISUAL

Areas considered for allocation to the Retention VQO are generally immediately adjacent to and visible from major travel routes, rivers, and other high use recreation areas. The objective is to provide attractive scenery by maintaining the area in a natural or near natural condition. Multiple-use goals for these areas also include the production of wood products, maintenance of wildlife habitat diversity, and protection of watershed resources. Management activities will be conducted so they are completely subordinate to the character of the landscape and are not evident to the casual forest visitor (USDA-FS, 1962).

Implications for timber management include limits on the size and shape of openings, limits on the amount of area that can be in openings at one time, and the desire to retain and reproduce large trees in foreground areas It is expected that created openings will be less than five acres in size and that they will appear natural in the view area Not more than eight percent of seen areas are expected to be in visually perceived openings at one time. Harvest units are considered to be openings until the vegetation has reached a height of 20 feet, or for about two decades. This may result in rotations of up to 250 years. Some foreground

areas also have the objective of maintaining large trees for their aesthetic quality Producing large trees (36 inches Diameter Breast Height (DBH)) should not be of much concern with these long rotations, but practices such as precommercial and commercial thinning could result in meeting this goal over a greater portion of the rotation.

Important considerations for timber management involve the timing of the volume harvested from these areas Not only is the harvest of the existing volume contributing to current outputs, but the opportunities for commercial thinnings during the first rotation could contribute to timber production during a critical time in the Forest's schedule

MANAGEMENT AREA 13 - PARTIAL RETENTION VISUAL

Areas considered for allocation to the Partial Retention VQO are generally visible from major and secondary travel routes, rivers, and other high use recreation areas (often in the middle to background) The objective is to provide attractive scenery by maintaining the area in a near natural condition. Multiple-use goals for these areas also include production of wood products, maintenance of wildlife habitat diversity, and protection of watershed resources. Management activities will be conducted so they are subordinate to the character of the landscape (USDA-FS, 1962)

Implications for timber management are similar to those of Management Area 12, though less constraining. They include limits on the size and shape of openings, limits on the amount of area that can be in openings at one time, and the desire to retain and reproduce large trees in foreground areas. It is expected that created openings will be less than eight acres in size Not more than 16 percent of seen areas are expected to be in visually perceived openings at one time. Harvest units are perceived as openings until the vegetation has reached a height of 20 feet, or for about two decades. This may result in rotations of up to 130 years. Producing large trees (30 inches DBH) may require practices such as precommercial and commercial thinning in at least some of the stands.

Again, important considerations for timber management involve the timing of the volume harvested from these areas. The harvest of existing volume can contribute to current outputs, and the opportunities for commercial thinnings during the first rotation could contribute volume during a critical time in the Forest's schedule.

MANAGEMENT AREA 14 - GENERAL FOREST

This is the major timber producing area of the Forest. The primary goal is to obtain a full yield of timber within the capability of the land and the management requirements of other resources. Timber harvest is programmed on suitable lands throughout the area In addition, this area provides many recreation opportunities. It also provides habitat for many species of wildlife and is particularly important for those using openings and early seral stages.

To meet short and long term timber production goals, the majority of the existing available volume will be harvested in the next seven to nine decades. Young stands will be managed to capture the growth potential of the sites in usable wood volume. Managed stands should be relatively free of significant vegetative competition, and should contain stocking in sufficient number and quality to near fully utilize the site's tree producing capacity Losses to destructive agents such as wind-throw, animal damage, and disease should also be minimized

COMPARISON OF SYSTEMS

This comparison is provided to facilitate the understanding of the thought processes and considerations behind the selection of a silvicultural system. Where definitive results from research or experience are not available, the discussion relies on knowledge of silvicultural characteristics and experience in forest

management to extrapolate the expected results of the different systems. The comparison is organized by resource or program, and consists of those elements most important to, or most affected by, the choice of systems. The comparative evaluation focuses on factors specific to the Siskiyou National Forest Differences between even-aged and uneven-aged management are emphasized more than the intricacies of variations within them The discussion is general in nature, many exceptions would be expected in specific situations

VEGETATIVE DIVERSITY

Vegetative diversity can be broken into three parts for discussion species diversity, genetic diversity, and structural diversity over time and space

SPECIES DIVERSITY

Species diversity will depend on the specific environment and how the stands are managed On the moderate to highly productive lands, uneven-aged management would tend to result in a shift toward more shade-tolerant species (Gordon, 1978, Franklin, 1978) This would be more true for single-tree selection as group selection would create some holes in the canopy which could provide sun light for shade-intolerant species. Stands previously dominated by pines and Douglas-fir would shift toward hemlock, white fir, incense-cedar, and tanoak. The grasses, forbs and shrubs that normally flourish in openings following fires or harvests would be less prevalent in deference to shade-tolerant forbs and hardwoods. On many sites with ultrabasic soils, uneven-aged management would not greatly alter the species composition These sites are relatively open and slow growing, regeneration would not be under the influence of a closed canopy.

Even-aged systems have the potential to increase or decrease the species composition on a specific site, depending on the selection of species for planting, the success of the plantings, and the success and variety of natural regeneration Often when one or two major species are selected for planting, minor species can be regenerated from natural seeding. Management can influence this by leaving seed trees of selected species, designing for seeding from adjacent stands, or by prescribing for species consideration during precommercial thinning treatments. If regeneration fails, diversity may be reduced and species that were minor components of previous stands may predominate on some sites.

GENETIC DIVERSITY

Genetic diversity could be adversely influenced by any of the silvicultural systems if improperly applied When regeneration is successful, either natural or artificial, from a local seed source with a large number of parents, the diversity of the gene pool is not significantly changed There are a number of ways in which the genetic diversity or quality may be reduced. Regeneration failures with any of the systems could result in a loss of diversity for those species that fail Harvest methods that remove the largest and highest quality trees (i.e highgrading) could result in the regeneration being produced by the remaining lower quality, and possibly slower growing trees If regeneration is produced from a small number of parents or isolated trees, there is increased risk of reducing genetic quality or increasing inbreeding Natural or artificial regeneration from a large number of parents exhibiting desirable characteristics of growth and form can maintain a broad genetic base, and move the genetic composition toward a higher frequency of desirable traits Regardless of the system, management will strive to maintain genetic diversity

STRUCTURAL DIVERSITY

Structural diversity will be strongly influenced by the selection of silvicultural systems and management practices. Diversity varies both horizontally (spatially) and vertically Even-aged systems have little vertical diversity. They tend to have a single dominate layer of seedlings, saplings, or larger trees Older stands may or may not develop understories of shrubs or young trees Managed stands will tend to have less understory as stocking is kept at or near closed canopy levels, permitting insufficient sunlight to reach the

ground to promote shrub and tree growth Spatial diversity would be great as stands of all ages and stages of development would be interspersed across the Management Areas where timber management is practiced

Uneven-aged systems would create the reverse situation, there would be great vertical diversity within each stand, but there would be less spatial diversity between stands. Within each stand there would be an array of sizes and ages from seedlings or young saplings to trees near rotation age. If large areas were managed with uneven-aged systems, all the stands would have similar structure and differences between stands would be minor. Group selection could have somewhat greater spatial diversity as group removals would create some small even-aged clumps

VISUAL RESOURCE

Any of the systems may be appropriate to achieve the desired character depending on the circumstances Uneven-aged systems may be better for creating or maintaining naturally appearing landscapes, particularly when the viewer is close to the area Although the activities may be widespread, the change in character is more subtle and not as obtrusive to the casual forest visitor as even-aged openings might appear.

On the other hand, vast areas in uneven-aged stands would have little diversity Even-aged systems may facilitate the creation of designed openings or the reshaping and enhancement of existing ones The differences between clearcut and shelterwood are short term. Initially they may appear quite different, but the shelterwood trees left at the first entry will need to be removed when the regeneration is quite small to minimize damage to the seedings. Following removal of the shelter trees, there will be little difference in the visual character from that of a recently harvested clearcut Shelterwood units should be designed to meet VQO's when the shelter trees are removed.

WILDLIFE HABITAT

All forest conditions provide habitat for some type of wildlife. Management that favors one species group will be unfavorable for some other group. Most wildlife species are adapted to thrive under conditions of specific structure and species composition For example, a mosaic of openings and cover, such as that created by even-aged systems, is optimum for species such as deer and elk that forage on herbaceous and shrubby vegetation produced in openings (Witmer and others, 1985). Uneven-aged or multi-layered stands with substantial vertical diversity would favor species such as tree squirrels and spotted owls Yet others, such as soaring hawks, require large openings and would do poorly without this habitat.

The selection of silvicultural systems will influence the proportions of species and when and how they could use the stands as habitat Even-aged systems with a mosaic of diverse stands would provide habitat for a large number of species as stands progress through various seral stages (Logan and others, 1985, Thomas and others, 1975). If large contiguous areas are managed with uneven-aged systems, habitat diversity could be significantly diminished (Hall, McComb, and Ruediger, 1985) A mix of silvicultural systems, with the vertical diversity of uneven-aged stands and the spatial diversity created by even-aged blocks, might well produce the balance of habitat that would best achieve wildlife management objectives.

FISHERIES

The Riparian Management Area Prescription is designed to protect and enhance the fisheries and watershed values. To accomplish the objectives for these areas, continuous vegetative cover is needed along perennial streams for shade and streambank stability Even-aged systems would not provide this continuous cover. The single-tree selection or group selection methods are more appropriate for managing these areas while maintaining protective cover. Entries in these riparian "strips" will generally need to be coordinated with entries on adjacent areas Uneven-aged prescriptions with regular cutting cycles and intensive

cultural treatments would not be feasible The only feasible timber management may be modifications of systems; designing prescriptions to take advantage of opportunities as they occur over the long term

SOIL AND WATER

The risks of soil and water impacts are often more a function of the watershed characteristics and the logging and roading methods used, than the silvicultural system Possible adverse effects are erosion, sedimentation, landslides, soil compaction, and loss of productivity through soil or nutrient loss

The risk of erosion and landslides increases with the amount of protective vegetation and surface litter removed This risk is generally greatest with the clearcutting method because more cover is removed at one time Other even-aged methods may be as high depending on the amount of clearing done to prepare the sites for seedling establishment The risk would be lower for the selection systems for any one treatment entry; however, the loss of soil by erosion may be offset by the increased frequency of entries. Repeated logging at ten to twenty year intervals could keep soils of landings and skid roads exposed a high percentage of the time and result in more erosion over the long term than the even-aged systems with one or two thinnings and the final harvest for each rotation

The risk of soil nutrient loss also increases with the amount of vegetation and litter removed Again, the *risk for any one entry is greater from the even-aged systems because of the greater degree of clearing* Clearcutting with yarding of cull material and burning of residue has the greatest potential for significant *nutrient reduction However, the effects on long term cycles of nutrient capital that might result from any* of the systems is not well understood.

Frequent and extensive use of heavy equipment has the potential to cause significant compaction of some soils This is predominately a function of the logging method used, timing of activity, and soil types rather than the silvicultural system. However, if large stands are managed with uneven-aged systems, there may be incentive to use more ground based logging systems to accomplish the selection harvests, and the risk of soil compaction would be increased.

Applying uneven-aged management to extensive areas on this Forest would also result in the need for higher road densities to effectively access the timber. With the greatest soil and water impacts coming from roads, any on site advantages of uneven-aged systems would be more than offset.

FIRE AND FUELS

Considerations for fire and fuel management fall in two broad categories, ability to control or manage wildfires, and ability and efficiency of treating fuels to manage risk of large wildfires A mosaic of stands *managed under the even-aged systems would contain breaks in the spatial fuel patterns that would* provide opportunities for management or control of wildfires. Uneven-aged systems would produce contiguous areas with fairly high fuel loadings and continuous vertical fuel ladders. These fuel ladders created by multiple tree layers carry ground fires into the crowns of the large trees. Under these conditions, crown fires could be expected more frequently, and fires would tend to be larger and burn at higher intensities. Control would be more difficult and costly and resource damage would likely be increased

Treatment of activity created residue fuel is easier and more cost efficient with the even-aged systems, particularly clearcutting Treatments following final harvests can be prescribed without the added complication of protecting residual crop trees. This facilitates the creation of breaks in the fuels complex as described above. Effectively treating residue fuels in areas managed with the uneven-aged systems would be more difficult and expensive. Providing the necessary protection for the younger residual crop trees would severely restrict treatment options Because of the greater difficulty and higher cost, increased accumulation of fuels should be expected if significant acreages are managed with the uneven-aged systems

TIMBER

Several important aspects of timber management are influenced by the selection of silvicultural systems The implications for forest regulation, the mode of operations, the complexity of administration, and yield that can be produced are important considerations.

REGULATION

A fully regulated forest has a balance of stands capable of supporting continuous production and harvesting at the long-term sustained capacity. Ideally, approximately the same number of acres would be harvested each period With uneven-aged systems, all acres would be harvested at ten to twenty year intervals with approximately equal yield from each harvest. With even-aged systems, stands would be harvested around the Forest to produce an equal yield in all periods. The Siskiyou National Forest currently has a substantial imbalance toward older aged stands, several decades will be needed before regulation is achieved. Production will be below the long-term sustained yield capacity for approximately the next eight decades, or until existing mature and understocked stands are regenerated and the first of the managed stands begin to reach rotation age

Regulation can be achieved most easily with even-aged systems for several reasons. Inventory information with the resolution that would be necessary to plan and schedule selection harvests is not available for much of the Forest; detailed information about the trees available for cutting would be needed on a stand by stand basis. Most of the existing mature stands do not have the crop tree stocking that would be needed to get them into a productive condition, regeneration would be needed to realize significant growth in these stands To achieve the equivalent growth of even-aged systems, several times more acres would need to be treated. Attempts to move these stands toward uneven-aged structures would result in major portions of the sites being occupied by very slow growing trees for several decades as regeneration of various ages is incrementally added through repeated treatments. The transition of essentially even-aged stands to balanced uneven-aged form might well require several rotations (Smith, 1962) Another factor that can affect regulation is the occurrence of wildfires or other natural events which result in the regeneration of even-aged stands. It would be difficult to regulate a forest under a selection system when significant acreages of unplanned even-aged stands occur

OPERATIONS

The choice among silvicultural systems strongly influences several aspects of harvesting and other treatment operations. Uneven-aged systems tend to be much less efficient with many more acres harvested to yield the same volume and a wide variation in tree size which precludes matching harvesting equipment for maximum efficiency. In contrast, whole stands of even-aged trees with a narrow range of sizes allow equipment to be utilized that provides for the efficient handling of the particular tree size.

The shelterwood method has the advantage of uniform tree size, but some efficiency is lost due to the needed second operation to remove the shelter trees left in the first entry. This splits the available volume into two operations essentially doubling many of the cost items. In addition, there is the added risk of mortality or damage to the seedlings from removing the residual shelter trees after the regeneration has become established. This is a critical step in the shelterwood method and often is the most difficult to achieve. This is particularly true on this Forest where many slopes are steep and convex; poor deflection for cable logging poses a difficult situation to protect established seedlings from moving logs and cables.

Treatments of uneven-aged stands are even more complex. Crop trees must be individually selected from a variety of sizes, ages, and species; and their care and protection integrated in all operations This applies to activities such as fuel treatment, site preparation, release, and precommercial thinning as well as timber harvests. Again, with uneven-aged systems, large acreages would need to be covered to achieve a modest gain due to the interspersing of treatment opportunities throughout larger stands In many cases the

treatments needed to achieve optimum production may not be feasible For example, treating residue fuels may subject residual crop trees to unacceptable risk if fire is part of the treatment prescription, or treating competing vegetation to release individual crop trees may be too expensive to consider.

ADMINISTRATION

There is a significant difference in the record keeping, inventory, and project administration required for uneven-aged systems versus even-aged systems The detailed information needed to plan and carry out treatments, as well as the frequency of treatments, make the uneven-aged systems more costly to manage (Alexander and Edminster, 1979). More accuracy is needed in the inventory information to prescribe harvest from several tree classes To achieve this resolution in data collection, stand stratification must be done to finer detail resulting in many more stands to inventory, keep records on, and administer Even with computers for data management, the level of complexity would quickly become unmanageable.

YIELD

Research studies to compare the long-term wood production associated with the different silvicultural systems have not been completed, although some studies are under way in other forest types Theoretically, the total production may be greater for the selection systems because continuous stocking of trees is maintained on the site; however, many operational and managerial factors influence the actual production of merchantable stand growth and timber yield (Curtis, 1978) Several factors affecting yield have been mentioned in previous sections, the feasibility of cultural treatments such as release and precommercial thinning, the shift in species composition toward more shade tolerant species, and the risk of logging damage to the crop trees planned for retention

There is also the complication of increased risk from disease as a result of logging damage and the carry over of disease from one generation to the next associated with uneven-aged systems In contrast, even-aged systems create a break in many disease cycles not unlike the natural events (fires) that created even-aged stands in the past While some diseases may carry over through inoculum in the soil, others, such as dwarf mistletoe, would be effectively eliminated or controlled by a break in the presence of conifers

Generalizations about the risks from insect or wildlife pests associated with the choice of silvicultural systems are difficult. Healthy vigorous trees are usually less susceptible to pests than those that are wounded or stressed Well managed stands under any of the systems, with a diversity of species and vigorous trees, will have less risk of significant pest damage. The risk of logging damage to residual crop trees with the uneven-aged systems is a critical factor on many sites. With steep slopes and long yarding distances, it is difficult to remove large trees without damaging leave trees Wounds become the entry points for insects and fungal diseases which cause decay and loss of wood volume. This is particularly critical with susceptible species, such as white fir and western hemlock, which may be favored during regeneration by the environment created by uneven-aged systems There is also risk of logging damage to crop trees during commercial thinnings in even-aged systems. However, the risk of damage is not as great since harvest trees would not be substantially larger than the crop trees; and the effect of damage is not as significant because crop trees need to last only the remaining part of the rotation from thinning to final harvest.

Release treatments to control competing vegetation will be needed in some cases regardless of the silvicultural system used if regeneration survival and growth is to be assured It has been suggested that the need for control of competing vegetation would be less with methods other than clearcutting There are no scientific studies to demonstrate this and the theoretical basis for the assertion does not seem to hold true on this Forest. Maintaining a continuous tree canopy would reduce the number of grasses, forbs, and shrubs, but this is because less of the sites plant producing resources (i.e , nutrients, moisture, light) are available These are the same resources needed by the young conifers Many of the most serious competitors are present in the stands and are capable of maintaining good vigor in shade or partial shade

(tanoak, madrone, canyon live oak, etc) The competition for the available site resources would be just as severe under the methods that retain part of the older stand. In addition, the operational feasibility of treatment would be diminished

The operational feasibility of other treatments designed to maintain or increase growth would also be diminished with uneven-aged systems Scattered needs for precommercial thinning or planting to achieve optimum production would likely not be treated Genetic gains through planting of genetically improved seedlings would not be realized to the same extent

The implications for the Forest's ability to provide timber outputs in the short-term are related to the current inventory structure. The Siskiyou National Forest is characterized as a "deficit inventory forest"; the current inventory must be metered out until second-growth stands become available for harvest, at which time the harvest level is projected to increase The period of time over which this existing volume must be metered out (the critical scheduling period) is approximately eight or nine decades for most alternatives. Even though the FORPLAN analysis is done with even-aged yield tables, the scheduled short-term Forest-wide outputs would not be affected by application of uneven-aged management on some stands, as long as harvest of the standing volume in these areas occurs during the critical scheduling period.

ECONOMIC IMPLICATIONS

Many of the factors affecting operational efficiency have economic implications. The size of the treatment area is a major factor in cost determination and efficiency Costs per acre for management treatments generally increase as the unit size decreases. This is true for logging costs as well as most cultural treatments Logging costs are also increased for uneven-aged systems due to the added complexity of harvesting needed to protect residual crop trees that are small and vulnerable to damage. Administration costs would also be much higher for uneven-aged systems for the reasons addressed above.

Within the even-aged systems, clearcutting is the most economically efficient in most cases The need for removal of the shelter trees in a second operation with the shelterwood method, or the potential loss of wood volume with the seed-tree method if seed trees are left on the site, make these methods more costly Exceptions would include those sites where regeneration would be difficult and more expensive to achieve with the clearcut method However, this should be evaluated carefully for each site, it may be cheaper to invest in artificial shading for seedlings than to use the shelterwood method (Tesch, 1984).

Theoretically, the cost of natural regeneration would be less than that of artificial regeneration favoring the uneven-aged systems or the shelterwood and seed-tree methods The costs of seed collection, nursery operations, seedling handling, and planting are significant However, the uncertainty of natural regeneration for much of the Forest make depending on naturals a risky proposition and brings up several complications. The sporadic seed crops and the variation of extreme weather team up with the competition of sprouting shrubs and hardwoods to delay or prevent natural regeneration. After sites are taken over by shrubs and hardwoods, it becomes much more difficult and expensive to achieve reforestation Often additional site preparation and planting are needed to accomplish the reforestation objectives. In the mean time, potential production from the site has been lost due to the period of inadequate stocking In addition, the opportunity to improve the genetic composition of future stands through the use of seedlings from selected parents is lost if natural regeneration is depended on exclusively.

In general, and without regard to special resource objectives, the cost efficiency of the methods falls into the following order from least cost to most cost· Clearcut, shelterwood, seed-tree, group selection, and single-tree selection.

SOCIAL IMPLICATIONS

Many of the concerns people express over the effects of the silvicultural systems are addressed by the discussions in the various sections above A large number of people seem to have a general dislike for clearcutting The concerns expressed include: clearcuts are visually unattractive, are difficult to reforest, adversely impact wildlife habitat, increase risks to soil and watershed values, require the high cost of artificial regeneration, cause loss of vegetative diversity, and increase vegetative competition and thus the use of herbicides. The implications of these specific concerns have both pros and cons as discussed, often satisfying one may involve intensifying another For example, reduction of even-aged openings to avoid visual impacts may reduce the forage available for big game, adversely affecting the habitat quality and recreation opportunities for some segments of the population. Also, use of less efficient systems to achieve different environmental effects may result in higher costs or lower outputs with accompanying adverse effects on local or national economies and employment.

The land allocations of the alternatives address these concerns to some degree The application of the silvicultural systems may be constrained or altered in the different Management Areas in response to these concerns and the various resource needs The social values derived from the use of the different systems remains somewhat a function of personal preferences; each of the described systems has a sound scientific basis when applied appropriately and matched to the management objectives and site specific conditions.

DIRECTION AND GUIDELINES

REGIONAL GUIDE CRITERIA

The Regional Guide for the Pacific Northwest Region, May 1984, provides selection criteria to guide the choice of silvicultural systems. These criteria will guide the selection of silvicultural systems and harvest cutting methods for site specific prescription. The final selection of harvest method for any specific site will be part of the silvicultural prescription as provided for in Management Standards and Guidelines 1-1, as provided for in selection criterion six. The selection criteria are:

1. The selected harvest cutting method must permit the production of a volume of marketable trees sufficient to utilize all trees that meet utilization standards and are designated for harvest

2 The selected harvest cutting method must permit the use of an available and acceptable logging method that can remove logs and other products without excessive damage to the identified desirable residual vegetation

3. The selected harvest cutting method must be capable of providing special conditions, such as a continuous canopy or continuous high-density live root mats, when required by critical soil conditions or as needed to achieve particular management objectives, such as streamside protection, wildlife needs, and visual enhancement

4 The selected harvest cutting method must permit control of vegetation to establish desired numbers and rates of growth of trees, as well as vegetation needed to achieve other management objectives identified in site-specific silvicultural prescriptions

5. The harvest cutting method selected will promote a stand structure and species composition that minimizes serious risk of damage caused by mammals, insects, disease, or wildfire, and it will allow treatment of existing insect, disease, or fuel conditions

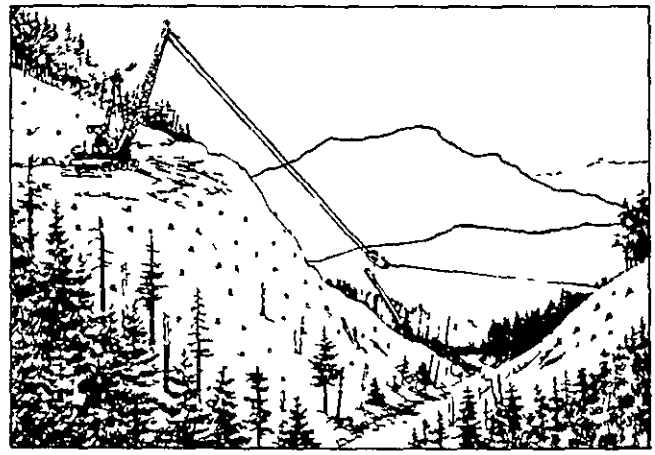
6. The harvest cutting method selected must meet resource and vegetation management objectives identified in the Regional Guide and Forest Plans Harvest cutting methods to be used on specific

areas may be identified in Forest Plans, in Environmental Assessments (EA's), or in silvicultural prescriptions that are written or reviewed by a certified silviculturist

RECOMMENDED SYSTEMS

The remaining part of this section pulls together the implications from the previous sections and provides suggested applications of the various silvicultural systems. The rationale for the recommendations and guidelines to use in the site specific decision process are displayed here The intent is to consider the combinations of management objectives, site conditions, and silvicultural systems; arriving at specific recommendations based on the comparison of systems in the previous section and the selection criteria above The harvest cutting methods identified for the combinations are generally the most appropriate, however, there is no intent that other methods should not be used when site specific conditions warrant (e g., considerations for slope stability may modify prescriptions) Combinations of site and stand characteristics that have similar recommendations are grouped in this section The results are summarized in Figure G-1.

The determination of where clearcutting is the optimum method will also be based on site specific factors (environmental, biological, esthetic, engineering, and economic) related to the selection criteria above and the objectives and requirements of the Forest Plan The comparison of systems from the previous section provides rationale relevant to the selection of clearcutting. Where clearcutting is among the appropriate methods identified, it will typically be advantageous in terms of engineering and economics Other systems may have advantages in terms of biologic or esthetic factors for some sites Shelterwood should generally only be used where regeneration goals could better be met with this method, although it may be used to accomplish short term mitigation of visual impacts in specific cases. The identification of clearcutting as the optimum method for sites on the Siskiyou will often be influenced by the key factors mentioned earlier in this appendix: the intensity of vegetative competition, the difficulty of protecting residual trees through harvest operations on steep slopes, and the desirability of perpetuating high proportions of shade intolerant species.



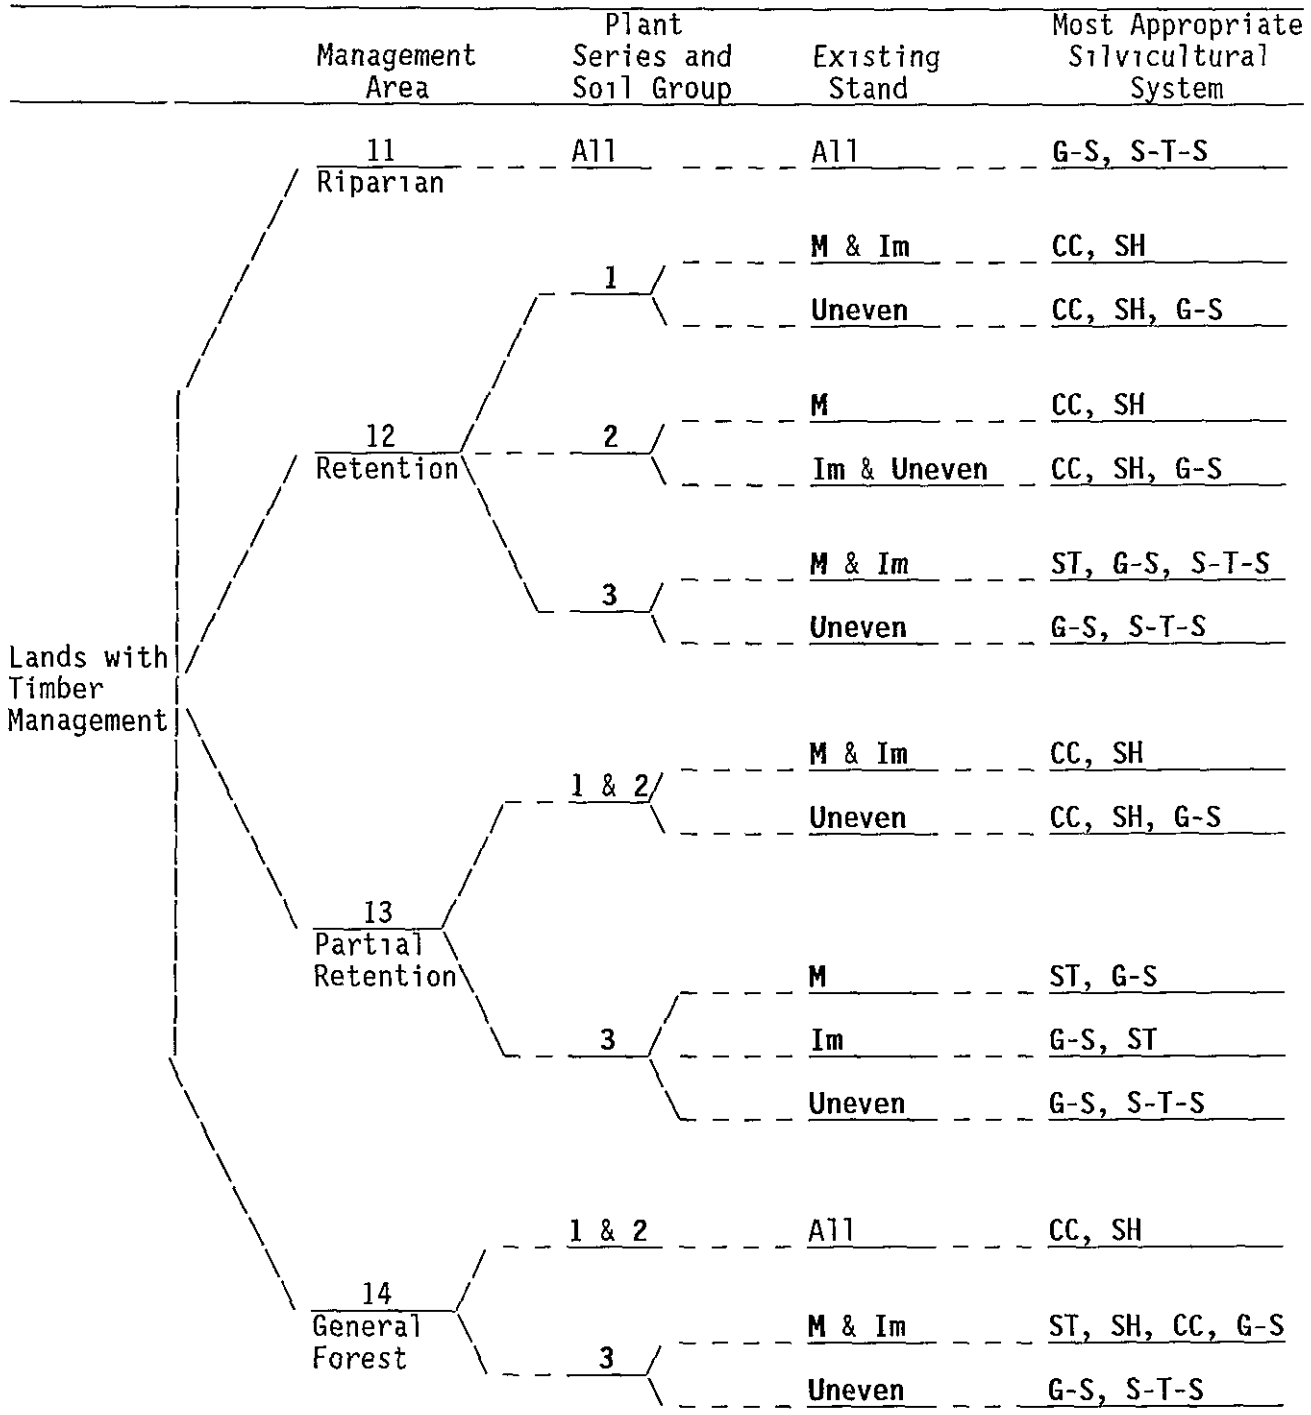


Figure G-1. Silvicultural Systems Analysis

Symbols Used: SH = Shelterwood, CC = Clearcut, ST = Seed-tree, G-S = Group Selection, Uneven = Uneven-aged, S-T-S = Single-tree Selection, M = Mature Stand, Im = Immature Stand

Plant Series and Soil Groups: 1 = High Vegetative Competition - Balanced Soils
2 = Moderate Competition - Balanced Soils
3 = Lower Competition - Ultrabasic Soils

MANAGEMENT AREA 11 - RIPARIAN

All Plant and Soil Groups
All Existing Stand Conditions
Most Appropriate Methods group selection, single-tree selection

The objectives for this management area generally can not be met with even-aged systems. Maintaining the continuous canopy cover can be accomplished with the single-tree selection method, or in some cases, the group selection method Along smaller streams (Class III), group selection may be most appropriate when regeneration of small clumps is desirable. Stands in the riparian areas are not likely to follow the classical uneven-aged distribution These narrow strips of land along the streams are generally some distance down a steep slope from the closest road. Management of these areas will be constrained by the need to coordinate timing of activities with entries in adjacent stands. In many cases it may only be feasible to do occasional salvage or overstory removal Stands will generally have a few widely spread age classes as harvest entries are made infrequently as opportunities occur. Initially many stands may have only two age classes and significant amounts of hardwoods and noncommercial species may occupy part of the growing space; yield projections are substantially reduced for this Management Area.

MANAGEMENT AREA 12 - RETENTION VISUAL *

Plant Series and Soil Group 1
Mature and Immature Stands (even-aged)
Most Appropriate Methods: clearcut, shelterwood

* (also Management Area 10, Scenic/Recreation River)

With intense vegetative competition expected, it is unlikely that the the combined objectives for this Management Area would be met with the uneven-aged systems. If uneven-aged management were applied to this area, the results would probably be a shift in stand composition toward a higher proportion of shrubs and hardwoods and neither visual or timber objectives would be met. The seed-tree method could be used, but with the expected competition and the uncertainty of rapid natural regeneration, it would involve considerable risk and would probably need to be augmented with planted seedlings. Shelterwood should be prescribed when it optimizes the regeneration goals for the site In some cases where it may provide some mitigation of short term visual impacts, a modification of the shelterwood method could be used, leaving trees for esthetic value rather than shelter for seedlings.

The implications for the immature stands in this group are similar to those for the the mature stands It is unlikely that immature stands in this group could be reasonably moved toward uneven-aged structures. Areas could be commercially thinned if excess stocking is available. Treatments should be designed to maintain the stands in healthy condition until they would be scheduled for regeneration harvest.

Plant Series and Soil Group 1
Uneven-aged Stands
Most Appropriate Methods· clearcut, shelterwood, group selection

Occasionally, stands may be found on this site group that have several age classes present. They generally also have large numbers of shrubs and hardwoods. It is unlikely that uneven-aged structures could be perpetuated with a reasonable level of management activity due to the propensity toward intense vegetative competition, even though natural events have resulted in sporadic replacement in the past. It may be possible to manage some of these stands to produce the desired benefits utilizing the potential crop trees already on the site; removing existing overstories and excess stocking to provide space for the crop trees In many cases it be may more efficient and as productive to regenerate with even-aged seedlings. In any event, the general trend for stands on these sites would be to move toward even-aged stands or groups

Plant Series and Soil Group 2
Mature Stands
Most Appropriate Methods: clearcut, shelterwood

Vegetative competition is expected to be a significant factor in this group, although not as severe as in Group 1. It is unlikely that mature stands could reasonable be moved toward uneven-aged structures in a acceptable period of time, consistent with meeting the goals of this Management Area Again, shelterwood could be prescribed when it optimizes the regeneration goals for the site In some cases where it may provide some mitigation of short term visual impacts, a modification of the shelterwood method could be used

Plant Series and Soil Group 2
Immature and Uneven-aged Stands
Most Appropriate Methods: clearcut, shelterwood, group selection

Considerations here would be similar to the mature stands, however immature and uneven-aged stands provide some opportunities to manage the existing crop trees and move into uneven-aged management. Group selection may be appropriate for some stands.

Plant Series and Soil Group 3
Mature and Immature Stands
Most Appropriate Methods: seed-tree, group selection, single-tree selection

With this plant and soil group's propensity to produce natural conifer regeneration, the seed-tree method or uneven-aged systems would be most appropriate for meeting the Management Area objectives Mature stands could be regenerated through the seed-tree method to produce another even-aged stand, or the future stand could be moved toward uneven-aged management

Plant Series and Soil Group 3
Uneven-aged
Most Appropriate Methods: group selection, single-tree selection

With an existing uneven-aged structure and the tendency to produce natural conifer regeneration, this combination would lend itself to uneven-aged management

MANAGEMENT AREA 13 - PARTIAL RETENTION VISUAL

Plant Series and Soil Group 1 and 2
Mature and Immature Stands
Most Appropriate Methods· clearcut, shelterwood

The rationale is similar to that presented under Management Area 12 With moderate to high levels of vegetative competition expected and the need to efficiently treat fuels and achieve regeneration, it would be difficult to meet the objectives for this area with uneven-aged systems In this Management Area where visual objectives are reduced below Management Area 12 and timber objectives are increased, adaptations of the shelterwood or selection methods to meet visual objectives would be less appropriate

Plant Series and Soil Group 1 and 2
Uneven-aged Stands
Most Appropriate Methods: clearcut, shelterwood, group selection

Occasional stands with several age classes may present opportunities to manage the existing crop trees through application of the group selection method. The difficulty and inefficiency associated with uneven-aged management of these sites will make clearcut or shelterwood more favorable in most cases.

Plant Series and Soil Group 3
Mature Stands
Most Appropriate Methods. seed-tree, group selection

Mature stands could be regenerated with the seed-tree method in this group where natural conifer regeneration is common. Future stands could be managed as even-aged or moved toward uneven-aged structures with future entries.

Plant Series and Soil Group 3
Immature Stands
Most Appropriate Methods group selection, seed-tree

Groups of existing immature trees capable of acceptable growth could be managed to produce future uneven-aged stands. Where objectives can be better met with even-aged stands, the seed-tree method would be appropriate to regenerate stands in this category.

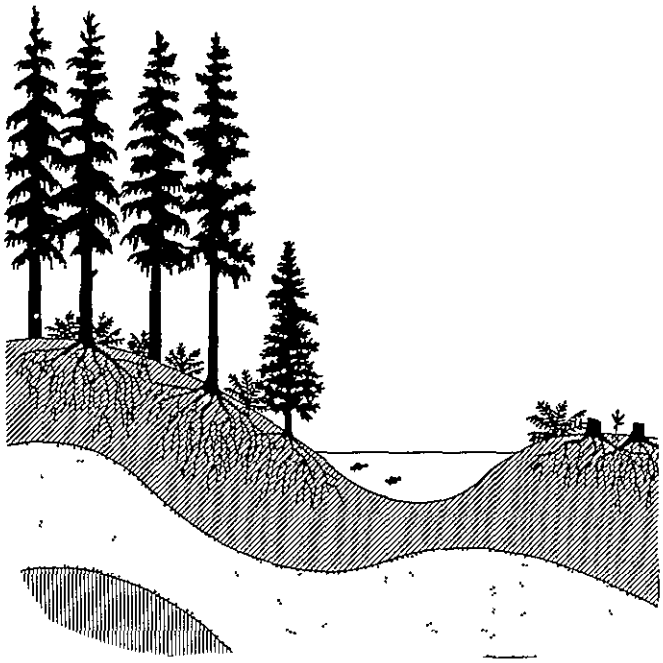
Plant Series and Soil Group 3
Uneven-aged Stands
Most Appropriate Methods: group selection, single-tree selection

On these sites that lend themselves to uneven-aged systems, and which currently support uneven-aged stands, the most appropriate methods are the uneven-aged selection methods

MANAGEMENT AREA 14 - GENERAL FOREST

Plant Series and Soil Group 1 and 2
All Stand Types
Most Appropriate Methods: clearcut, shelterwood

In this Management Area with emphasis on timber production and in the plant series and soil groups that are not particularly conducive to the uneven-aged systems, the most appropriate prescriptions will be clearcut or shelterwood. Many of the reasons for this conclusion have been stated in the comparisons of the systems and in the discussions under Management Areas 12 and 13 above. In general, the even-aged systems offer the greatest combination of benefits at the least cost. The shelterwood method should be used where it optimizes the regeneration goals for the site Where regeneration can be achieved without shelter, clearcutting will most often be the optimum method.



Plant Series and Soil Group 3
Mature and Immature Stands
Most Appropriate Methods. seed-tree, shelterwood, clearcut, group selection

This category may appropriately be managed with a number of methods depending on site specific conditions. Regeneration of even-aged stands may be accomplished by seed-tree, shelterwood, or clearcut methods as needed to assure adequate restocking and efficiently accomplish management

objectives. Immature stands (existing or future) may present opportunities to move toward uneven-aged management on sites that are specifically suited to it.

Plant Series and Soil Group 3
Uneven-aged Stands
Most Appropriate Methods. group selection, single-tree selection

On these sites that lend themselves to uneven-aged systems, and which currently support uneven-aged stands, the most appropriate methods are the uneven-aged selection methods

Note: Just before printing this FEIS, the Chetco, Elk and North Fork Smith were designated Wild and Scenic Rivers. Under the Omnibus Oregon Wild and Scenic Rivers Act, Alternative S fully represents the newly designated Wild and Scenic Rivers. Other alternatives presented different management options to assess Wild River and Scenic/Recreation River allocations. If another alternative is selected, it would have to be brought into conformance with the new Act.

INTRODUCTION

This appendix contains the tables referenced in Chapter II of the FEIS Organized by Alternative, each table demonstrates how Management Areas contribute to the resolution of Planning Problems

PLANNING PROBLEM 1

Table I-1. Acreage Selected as Suitable for Timber Production by Management Area

INTRODUCTION

This appendix is included in the Final Environmental Impact Statement for the Forest Plan in response to decisions of the Chief of the Forest Service and the Deputy Assistant Secretary of Agriculture regarding appeal No 1770, brought by the Northwest Forest Resource Council on September 18, 1986. The appeal centered on direction from the Regional Forester to incorporate "minimum management requirements" (MMR's) in forest plan alternatives. The appellant requested that the appropriateness of the MMR's be examined through the environmental impact statement process. The information in this appendix also responds to comments about Management Requirements that were raised during the review of the Draft Environmental Impact Statement.

A summary of Management Requirements is provided in Chapter II, "Management Requirements" section. Additional information is in Appendix B "Development of Management Requirements " The Standards and Guidelines (or specifications) for implementation of the management requirements are found in the Forest Plan.

This appendix addresses the issue raised by the appellant: For those management requirements which cause significant reductions in allowable sale quantity (ASQ) or present net value (PNV), alternate ways of meeting the management requirements are examined and their opportunity costs (reductions in ASQ and PNV) are compared.

Appendix J of the Draft Environmental Impact Statement, "Sensitivity Analysis for Minimum Management Requirements" has been completely replaced by the material presented here. The Appendix J of the Draft is part of the planning record.

BACKGROUND OF MANAGEMENT REQUIREMENTS

WHAT ARE MANAGEMENT REQUIREMENTS?

Many laws and regulations guide Forest Service activities. One law in particular, the National Forest Management Act of 1976 (NFMA), and its implementing regulations provide direction for the Forest planning process. The direction for National Forest Systems Land and Resource Management Planning, in Section 36 of the Code of Federal Regulations, Part 219 [36 CFR] specify. (1) the minimum specific management requirements to be met in accomplishing the goals and objectives of the National Forest System [36 CFR 219 27] and (2) the minimum requirements for integrating individual forest resource planning into the Forest Plan [36 CFR 219.14 through 219.26]. The term "management requirements (MR's)" will be used in this appendix to refer to these NFMA regulations instead of "minimum management requirements (MMR's) which were used in the Draft Environmental Impact Statement and Proposed Forest Plan.

Some management requirements are procedural in nature and need not be dealt with here. Some requirements were analyzed and were available for review during the Regional Guide Environmental Impact Statement process and are not dealt with here. See Appendix B for a more complete discussion. The management requirements which have not been fully dealt with elsewhere, and which require additional analysis due to significant opportunity costs associated with implementation are:

1. Maintenance of habitat to assure viable populations of fish and wildlife populations particularly mature and old growth habitat and,

2. Protection of water resources, particularly water temperatures.

These management requirements are described in greater detail in later sections of this appendix MR's for dispersal of created openings, other wildlife habitats and other requirements noted in 36 CFR 219 27 which

have not been addressed in other Environmental Impact Statements do not cause significant opportunity costs when implemented.

LEGAL REQUIREMENTS VERSUS IMPLEMENTATION METHODS

The management requirements from NFMA and its implementing regulations are legal requirements. They represent "ends" which must be met during forest plan implementation. For example, the NFMA implementing regulations require that "fish and wildlife habitat shall be managed to maintain viable populations of existing and desired non-native vertebrate species in the planning area." It is mandatory that, whatever implementation methods are chosen, the management requirement be met.

Specifications or standards for achievement for each management requirement are established at the national level or through analysis at the regional level for most of the management requirements. These are listed in the regulations or as Standards and Guidelines in the Regional Guide Additional specifications identified on the Forest are listed as Standards and Guidelines in the FEIS, Appendix D, and the Land and Resource Management Plan, Chapter IV. The specifications must be based on knowledge of the resources involved For example, in meeting the management requirement for viable populations of vertebrate species it is necessary to define the type of habitat required by the species, the maximum distance between habitats which will still provide reasonable assurance of genetic interaction, and the size of habitat area needed to support a breeding pair.

Often, the pool of scientific knowledge is insufficient to provide the entire basis for defining the specific conditions or standards that will satisfy or meet a management requirement. When this happens it is necessary to rely on the field experience and the professional judgement of knowledgeable professionals and to establish monitoring and research that will provide better information for future planning efforts.

Implementation methods are the "means" or "ways" in which the management requirements will be met. Usually there is more than one way in which a management requirement can be met. Determining the most appropriate means of meeting the specifications for each management requirement involves careful analysis at the Forest level. Considering and analyzing different means or ways of meeting a specific management requirement are particularly important if there are potentially significant reductions in present net worth (PNV) or allowable sale quantity (ASQ) involved

HOW IMPLEMENTATION METHODS TO MEET THE MANAGEMENT REQUIREMENTS ARE DEVELOPED

The selection of means sufficient to meet management requirements is based on effectiveness in meeting resource protection and on minimizing reductions to PNV or ASQ. The general process used in evaluating alternative ways of meeting the management requirements is as follows:

1 Identify the desired "end" for each management requirement

2 Assemble existing information about the resources addressed by the management requirement.

3 Analyze the existing information to determine what conditions or specifications need to exist on-the-ground to assure meeting the "ends" of the management requirement. (See Table J-1.)

4. Develop various ways or means to meet the management requirement. (See Table J-2)

5. Evaluate the effectiveness of the alternative means in meeting the management requirements Estimate the environmental effects of each set of means.

6 For each set of means, estimate the effects on economic efficiency (as measured by changes in present net value) and the effects on timber availability (as measured by allowable sale quantity)

7 Where opportunity costs of meeting a management requirement exceed two percent of PNV or ASQ of the present net value benchmark, the analysis used to select the means are presented Two percent was used because differences less than two percent would not be significant in terms of opportunity costs of alternative means. A higher threshold would preclude evaluation of many alternatives.

For discussion purposes, opportunity costs are reductions in present net value (PNV) and reductions in allowable sale quantity (ASQ) that result from implementing resource protection measures (means or ways) to meet the management requirements set forth in NFMA regulations. In order to provide protection for water quality and wildlife habitat on Siskiyou National Forest land, some opportunities to maximize present net value or to maximize timber production must be foregone.

Discussions are grouped by water quality management requirements and by wildlife management requirements in separate sections. In each section, the management requirements are displayed along with relevant specifications from national and regional guidelines, and alternative implementation methods (means or ways) are analyzed.

Table J-1 summarizes each of the management requirements (ends) subject to analysis of opportunity costs on the Siskiyou National Forest and summarizes the specifications or standards of achievement for those ends. Table J-2 shows the alternative means considered for implementing each management requirement where the opportunity costs exceeded two percent.

Table J-1. Summary of Management Requirements and Associated Specifications.

Ends	Summary of Specifications
Protect water quality	Temperature increases of two degrees Fahrenheit or less.
Habitat provided that maintains viable populations of existing native and non-native vertebrate species	
- Pileated Woodpecker and Pine Marten	Maintain mature conifer stands (for nesting and feeding) of adequate size and distribution to permit interaction among breeding pairs of dependent species. [See Tables J-6 and J-7.]
- Northern Spotted Owl	Maintain old growth conifer stands (for nesting and feeding) of adequate size and distribution to permit interaction among breeding pairs of dependent species

Table J-2 Summary of Alternative Means Considered for Implementing Each Management Requirement

Management Requirements	Alternative Means
Protect streams and streambanks	Set-aside stream side streambanks vegetation (no scheduled timber harvest) Selective harvest of streamside vegetation (scheduled timber harvest)
Provide for adequate habitat to maintain viable populations of existing native and desired non-native vertebrate species	
- Pileated Woodpecker and Pine Marten	Dedicate habitat sites for no timber harvest Manage habitat sites on 140-year rotations
- Northern Spotted Owl	Dedicate habitat sites for no timber harvest Manage habitat sites on 300-year rotations

In analyzing the effects of the alternative means of meeting the MR's on present net value (PNV) and allowable sale quantity (ASQ), FORPLAN runs were made with and without constraints designed to simulate meeting the management requirement. The PNV benchmark was used for this analysis. This benchmark is a FORPLAN run which identifies the mix of management activities which would result in the highest level of economic efficiency (i.e., the highest PNV) in managing Siskiyou National Forest resources. It also identifies the ASQ associated with the most economically-efficient mix of management activities

A benchmark was chosen to use in the with and without constraint comparison, rather than an issue-based Forest Plan alternative, because management practices necessary to meet other objectives of the issue-based alternatives may partially or fully meet the MR, thus clouding any analysis of opportunity costs induced by the management requirement. The true effect when measured against a fully developed alternative is significantly less because the objectives of that alternative may satisfy the management requirements to a large extent.

IMPLEMENTATION METHODS WITH HIGH OPPORTUNITY COSTS

Table J-3 displays the opportunity costs of the implementation measures selected for meeting management requirements on the Siskiyou National Forest. Only those implementation measures with opportunity costs of two percent or larger are shown: water quality, mature conifer (for pileated woodpecker and pine marten) and old-growth conifer (for spotted owl)

IMPLEMENTATION METHODS WITH LOW OPPORTUNITY COSTS

Management requirements for other wildlife habitat requirements for threatened and endangered species, sensitive species (except spotted owl), special habitats, and dead and defective tree habitat are not addressed in this analysis because opportunity costs of providing sufficient habitat to maintain viable populations are less than two percent.

IMPLEMENTATION METHODS THAT MEET MORE THAN ONE MANAGEMENT REQUIREMENT

Implementation methods selected to meet water quality management requirements also provide fish habitat in streams and riparian habitat adjacent to streams to assure the maintenance of viable populations of species dependent on these habitats. In addition, the water quality implementation methods meet the harvest dispersion management requirement. Alternative implementation methods for meeting water quality management requirements will also meet fish habitat and riparian habitat requirements No additional discussion or analysis is displayed in Appendix J for these management requirements.

WATER QUALITY MANAGEMENT REQUIREMENTS

SOURCE OF THE WATER QUALITY MANAGEMENTS REQUIREMENTS

Management requirements for water quality are based on NFMA which states: Forest planning shall provide for compliance with requirements of the Clean Water Act, the Safe Drinking Water Act, and all substantive and procedural requirements of Federal, State, and local governmental bodies with respect to the provision of public water systems and the disposal of waste water [36 CFR 219.23(d)].

Special attention shall be given to land and vegetation for approximately 100 feet from the edges of all perennial streams, lakes and other bodies of water. This area shall correspond to at least the recognizable area dominated by the riparian vegetation. No management practices causing detrimental changes in water temperature or chemical composition, blockages of water courses, or deposits of sediment shall be permitted within these areas which seriously and adversely affect water conditions or fish habitat [36 CFR 219 27 (e)].

The Clean Water Act seeks to control nonpoint sources of water pollution To comply with Section 208 of the Act, Forest Service Region Six, the states of Oregon and Washington (which manage implementation of the Act in the respective states), and the Environmental Protection Agency agreed on a process whereby each state reviews Forest Service management practices to determine if they meet or exceed state water quality standards. Practices that are judged to meet or exceed the standards are certified as Best Management Practices (BMP's) which the Forest Service then agrees to continue

Table J-3. Opportunity Cost of Meeting the Management Requirements with the Selected Implementation

Selected Implementation Method	First Decade ASQ MMCF/Year (MMBF/Year)	Change in ASQ 1/ Percent	PNV MM $	Change in PNV Percent
PNV Benchmark with No Protection Measures	39 8 (215 3)	–	1,814 6	–
Opportunity Cost of Water Quality	5 2 (28 1)	13	228 0	13
Opportunity Cost of Mature Conifer for Pileated Woodpecker and Pine Marten	1 0 (5 5)	3	54 7	3
Opportunity Cost of Mature Conifer and Old Growth for Spotted Owl	1 7 (9 1)	4	89 3	5

1/ Percent change calculated on cubic foot basis

SPECIFICATIONS FOR THE WATER QUALITY MANAGEMENT REQUIREMENTS

State of Oregon water quality standards (Oregon Administrative Rules 340-41-205 through 325) provide specifications to be met by implementation methods selected by the Forest. They are summarized below:

1. Dissolved oxygen concentration shall not be less than 90 percent of saturation at the seasonal low, or less than 95 percent of saturation in spawning areas, during spawning, incubation, hatching, and fry stages of salmonid fishes.

2. No measurable increases shall be allowed ..when stream temperatures are 58 degrees Fahrenheit or greater .or more than two degrees Fahrenheit increase due to all sources combined when stream temperatures are 56 degrees Fahrenheit or less...

3. No more than a 10 percent cumulative increase in natural stream turbidity shall be allowed, as measured relative to a control point immediately upstream of the turbidity-causing activity

4. pH values shall not fall outside.. 6.5 to 8 5.

On the Siskiyou National Forest, most of the activities which affect water quality are related to timber harvesting. They include removal of trees, road construction, and burning of brush and organic debris (For more discussion, see FEIS, Chapter IV, "Soil and Water" section)

The primary approach to maintaining water quality on Siskiyou National Forest lands is to. (1) limit or prohibit timber harvest on certain unstable slopes (by designating such lands as unsuitable for timber production), (2) disperse timber harvest through time and space to avoid potential for cumulative impacts, and (3) on lands designated suitable for timber production, maintain sufficient shade producing vegetation along stream banks to maintain stream temperatures within acceptable limits.

Scheduling harvest from unsuitable lands would not be consistent with NFMA. Timber harvest is dispersed to meet the Management Requirement by limiting harvest in each planning basin to no more than 20 percent of the area; opportunity costs are negligible at this level. Maintaining sufficient vegetation to meet temperature requirements is the subject of additional examination here.

In the FEIS, the specifications established by the Forest are called Standards and Guidelines. The required watershed condition, and the standards that indicate achievement of the water quality management requirement, are described in the Land and Resource Management Plan, Chapter IV. The following specifications are addressed in this appendix.

Riparian Area Standard and Guideline: Maintain stream temperatures. (Any increase in summer stream temperatures would violate Oregon State Water Quality Standards.)

ALTERNATIVE WAYS OF MEETING THE MANAGEMENT REQUIREMENTS FOR WATER QUALITY

Alternative ways for the meeting specifications shown above could be modeled in FORPLAN to simulate the required end conditions. These become alternative constraints in the model that set limits on how FORPLAN schedules timber harvest to maximize PNV. (FORPLAN constraints are discussed in the FEIS, Appendix B, "Development of Management Requirements ") The following alternatives were considered:

ALTERNATIVES CONSIDERED IN DETAIL

Alternative 1: Set-aside Shade Producing Streamside vegetation (no scheduled timber harvest).

This alternative is designed to minimize vegetation disturbance and schedules no timber harvest in riparian areas No shade providing vegetation would be removed by timber harvest in riparian areas.

Alternative 2: Selective Harvest of Shade Producing Streamside vegetation (scheduled timber harvest).

This alternative allows a moderate level of removal of shade producing vegetation from the riparian area. A maximum of 70 percent and 30 percent removal of the basal area from Class III, and Class I and II streams are allowed. The actual average harvest used for the FORPLAN model was 50 percent and 20 percent removal because the maximum amount of timber could not be removed in all cases. This alternative is designed to maintain existing water temperatures in streams within a planning basin as regrowth of shade producing vegetation (previously removed as a result of past activities) balances removal associated with new projects. These prescriptions are applied to a basin as a whole and the expected results are viewed as a net change over time. This riparian management option is designed to produce zero net change over time.

EVALUATION OF IMPLEMENTATION METHODS TO MEET WATER QUALITY MANAGEMENT REQUIREMENTS

Either of the alternative means or implementation methods noted above would meet management requirements and warranted more detailed analysis

OPPORTUNITY COSTS

The opportunity costs of implementation methods for meeting water quality management requirements were estimated by comparing the differences in PNV and ASQ that would occur with and without the constraints that simulate the means for accomplishing the required condition

Table J-4 compares the PNV and ASQ opportunity costs of the alternative implementation methods (means) for water quality protection.

Table J-4 Opportunity Costs Associated with Alternative Means for Meeting the Water Quality Management Requirements

	First Decade ASQ MMCF/Year (MMBF/Year)	Change in ASQ 1/ Percent	PNV MM $	Change in PNV Percent
PNV Benchmark with no Protection Measures	39 8 (215.3)	–	1,814 6	–
Opportunity Cost of Meeting Management Requirements with Alternative 1 (No Vegetative Removal)	27 3 (39 3)	18	320 0	18
Opportunity Cost of Meeting Management Requirements with Alternative 2 (Moderate Vegetative Removal)	5.2 (28 1)	13	228 0	13

1/ Percent change calculated on cubic foot basis

CONSEQUENCES OF ALTERNATIVE WAYS OR MEANS OF MEETING WATER QUALITY

The opportunity costs of the option of removing no vegetation from the riparian areas is approximately five percent greater than the moderate shade removal alternative. This alternative would go beyond meeting the requirement of protecting stream temperatures; over time, the temperature would be enhanced (lowered) as more shade would be provided. In those basins where past activities have removed substantial shade producing vegetation along streams, the no vegetative removal alternative could enhance fish habitat

RATIONALE FOR THE SELECTED IMPLEMENTATION MEANS

Implementation methods (means) for meeting the management requirements for water quality are based on practices that existed before the NFMA regulations. Consequently, interpretations and processes for meeting these requirements are already established on the ground.

Alternative 2 represents current practices consistent with the Siskiyou Riparian Policy This policy has evolved over a number of years incorporating results of scientific research as methodology and expertise become available. The stream temperature modeling has been facilitated by work pioneered on this Forest using a solar pathfinder to correlate changes in the vegetation (growth or removal) with changes in actual stream shade during critical times of the year The riparian policy has developed with the involvement of experienced resource professionals from all disciplines and has been the object of numerous field reviews attended by professionals from all levels of the Forest Service, as well as university faculty members, representatives from the timber industry, the State of Oregon, and other interested publics The Siskiyou's riparian policy and

streamside management are considered state-of-the-art in multiple-use management in an area with high resource values and conflicting interests.

By implementing Alternative 2 the Forest would meet state water quality standards throughout the planning period while minimizing PNV and ASQ opportunity costs.

IMPLICATIONS FOR FOREST PLAN ALTERNATIVES

FEIS Chapter II and Appendix B discuss the effects of this alternative way of meeting water quality requirements in FEIS alternatives. The analysis of opportunity costs of selected means of water quality protection shown in Table J-4 shows the maximum PNV and ASQ effects. Actual Plan alternatives will have somewhat less opportunity costs as overlaps from lands withdrawn for wildlife, scenery, recreation or other nontimber objectives will help to provide shade producing vegetation

ROLE OF MONITORING AND RESEARCH

The assumption that leaving shade producing vegetation on riparian areas in necessary to maintain viable populations of fish is based on extensive research that describes the importance of water temperature for water quality and habitat

Continued monitoring will be done on water temperature fluctuations due to removal and growth of stream shade producing vegetation. See the Forest Plan monitoring program

MANAGEMENT REQUIREMENT FOR VIABLE POPULATIONS OF EXISTING NATIVE VERTEBRATE SPECIES

SOURCE OF THE MANAGEMENT REQUIREMENT

The NFMA regulations require that:

"Fish and wildlife habitat shall be managed to maintain viable populations of existing native and desired non-native vertebrate species in the planning area. For planning purposes, a viable population shall be regarded as one which has the estimated numbers and distribution of reproductive individuals to insure continued existence in the planning area In order to insure that viable populations will be maintained, habitat must be provided to support, at least, a minimum number of reproductive individuals and that habitat must be well distributed so that those individuals can interact with others in the planning area." (36 CFR 219.19)

DESCRIPTION OF THE MANAGEMENT REQUIREMENT

All vertebrate species in Region Six were assessed with regard to population numbers and/or distribution that could result in either Forest or Regional extinction during the next five decades. Management requirements were developed for species whose viability would be at risk if no management actions were taken to protect their habitats.

The focus was on habitats that were likely to be limiting in the future (in short supply either in total acreage or in distribution) and on identification of particular species that could be used to represent all species dependent on those habitats. This identification was done on a subregional basis, recognizing the variability of situations within the Region. Once these species were identified, the Region defined their habitat requirements and biological characteristics The species are included in the list of Management Indicator Species (MIS) that the Forests address in forest planning and subsequent monitoring

Table J-5 displays current Regional management requirement direction regarding limited habitats and wildlife species by sub-regional zones The Siskiyou National Forest is in Zone II (mountain goat not included)

Northern spotted owl, pileated woodpecker and pine marten are the only species for which alternative ways of meeting management requirements are evaluated. Management requirements for threatened and endangered species, sensitive species (except spotted owl), special habitats, and dead and defective tree habitat are not addressed in this analysis because opportunity costs associated with providing sufficient habitat to maintain viable populations are less than two percent. The management requirements for fish are met with the same management practices which provide the requirements for water quality and riparian area management, therefore further analysis is not provided.

Table J-5. Species Matrix for Addressing Management Requirements for Wildlife and Threatened and Endangered Species.

Zone Habitat	Zone 1 North Coastal	Zone 2 Westside Cascades	Zone 3 Eastside Cascades	Zone 4 Blue Mountains
Mature and Old Growth (Seral Stages V and VI)	*Northern Spotted Owl Pine Marten Pileated Woodpecker	*Northern Spotted Owl Pine Marten Pileated Woodpecker	*Northern Spotted Owl Pine Marten Pileated Woodpecker Northern three-toed Woodpecker	Pine Marten Pileated Woodpecker Northern three-toed Woodpecker
	*The Final Supplemental Environmental Impact Statement and subsequent Record of Decision provide direction for management of spotted owl habitat in Region Six

Riparian	The Forest determined and documented as part of the planning records, whether it needed to address wildlife in addition to fish, and if so which wildlife species would represent the riparian habitat Coordination of this process with adjacent Forests was necessary to determine consistency			
Big Game		Mountain Goat	Mountain Goat (Wenatchee)	
Threatened and Endangered Species	Bald Eagle Peregrine Falcon Brown Pelican Aleutian Canada Goose	Bald Eagle Peregrine Falcon	Bald Eagle Peregrine Falcon Grizzly Bear Woodland Caribou (Colville)	Bald Eagle Peregrine Falcon

HABITAT NEEDS

Once the species needing management requirements were identified, the Region defined habitat requirements and biological characteristics These are the basis for providing habitat and also for deciding how best to represent the species' needs in the planning process and in the FORPLAN Model

Habitat needs were defined using information from existing research whenever possible (see bibliography). This information was used to define the habitat conditions, habitat dispersal, and habitat size necessary to meet the management requirement. When information was available, but did not fit exactly the management requirement context, professional judgement was used to apply the information in estimating habitat needs. When information was not available, habitat needs were developed using professional judgment of a number of the more knowledgeable biologists on the subject Information from existing research was used whenever possible (Note: Habitat needs of spotted owls are described in the Final Supplement to the Environmental Impact Statement for an Amendment to the Pacific Northwest Regional Guide, USDA Forest Service 1988).

Specific information on habitat needs, specifications for meeting habitat requirements, and alternative ways of meeting the management requirements for pine marten, pileated woodpecker, and spotted owls are presented in the following sections For each species, information is provided for these three habitat factors:

Principal Habitats Used

Information about the seral stages and Kuchler vegetation types which are used by the various species is documented in many research papers for individual species. Information as to which Kuchler type and/or seral stage are primary or secondary habitat, and the amount of dependency upon each habitat, is based mostly on professional judgment (Guenther and Kucera 1978, Phillips and others, 1981).

Dispersal Distance Between Habitats

Usually no research information is available for optimum dispersal distance between habitats As a result, dispersal distance is often determined on the basis of observations, experience, and professional judgment Dispersal distance is based on the ability of an individual species to travel to the next habitat often enough to prevent isolation of sub-populations Distances are adjusted to consider the network and overlap of habitat formed by the species (e.g , pileated woodpecker and pine marten).

Size of Habitat Areas

The size of individual habitat areas provided for each wildlife species is based on the habitat acreage needed to support the basic social or reproductive unit of the species, i.e., breeding pairs. Both home range and species density information are used to estimate the needed size of habitat area. This was supplemented with professional judgement where no data were available for the specific habitat types being managed

SPECIFICATIONS FOR MEETING HABITAT REQUIREMENTS FOR PILEATED WOODPECKER AND PINE MARTEN

Approximately 40-50 wildlife species are known to depend on or prefer mature conifer habitat during some part of their life cycleon the Siskiyou National Forest. By providing a dispersion of mature conifer habitat sites for the pileated woodpecker and pine marten, we are assuming that the other species preferring mature conifer habitats will have adequate habitat to maintain viable populations throughout the planning period

Regional specifications for pileated woodpecker and pine marten are discussed in the following sections The specifications are summarized from "A Report on Minimum Management Requirements for Forest Planning on the National Forests of the Pacific Northwest Region, USDA Forest Service" (USDA Forest Service, June 1986). In developing the report, various habitat sizes and dispersal distances were considered. Based on that analysis, minimum habitat sizes and maximum dispersal distances were identified for each species. This information is based on the best available data. Alternatives which addressed changes to size or distribution were not considered in developing the Forest Plan for the Siskiyou National Forest.

Habitat specifications for pileated woodpecker and pine marten are summarized in Tables J-6 and J-7.

PILEATED WOODPECKER SPECIFICATIONS

Principal Habitats Used

Pileated woodpeckers need mature or old growth stands of timber for nesting and feeding Habitats were identified in Bull and Meslow (1977), Guenther and others (1978), and Thomas (1979).

Dispersal Distance Between Habitats

An initial five-mile maximum dispersal distance between habitats resulted from professional judgment documented in Phillips and Roberts (1985). In June of 1986, the distance between habitats was modified to one habitat area for every 12,000 to 13,000 acres (about five miles apart) to allow greater flexibility in application.

Size of Habitat Areas

The size of nesting areas in Region Six for the pileated woodpecker has been identified as a range of 100 to 540 acres. To meet the needs of pileated woodpeckers both east and west of the Cascades, 300 acres of old growth or mature timber for nesting area, plus 300 acres of feeding area was defined as a Region-wide requirement. Three hundred acres of nesting area appears to be an average for different habitats As more data specific to westside and eastside habitats (eastside may be further subdivided) become available, the size of the nesting area may be adjusted (Bull and Meslow, 1977; Bull, 1975; Mannan, 1982; Mellen, 1986). A 1,000-acre unit was established as the minimum size territory that a pair of woodpeckers would defend. This was determined from research data. Snag size and density were taken from Thomas (1979), and acreage figures from Bull (1975), and Bull and Meslow (1977) See Table J-6 for summary of habitat specifications,

Table J-6 Pileated Woodpecker Habitat Requirements.

	Principal Habitats Used	Dispersal Distance Between Habitats	Size of Area to which Wildlife Prescriptions Apply	Habitat Requirements to be Used in Analyses
	Zone II (West Cascades)1/	One habitat area for every 12,000 to 13,000 acres	600 acres/pair	Within a 1,000-acre unit
A	Reproducing Seral Stages V and VI of Kuchler types K2, K5, K6, K29, and riparian			Maintain 300 acres of conifers in seral stages VI and/or V, per pair for reproducing Maintain a minimum average of two hard snags per acre greater than or equal to 12 inches dbh within the 300-acre reproductive area Forty-five of these 600 snags should be greater than or equal to 20 inches dbh
B	Feeding All seral stages of Kuchler types listed for reproducing habitat, provided snags are present			When possible, maintain reproductive area in 300 contiguous acres If not possible, habitat may be arranged in blocks no less than 50 acres and no more than 1/4 mile apart. Maintain a minimum average of two hard snags per acre greater than or equal to 10 inches dbh on an additional 30 acres for feeding

1/ Siskiyou National Forest is in Zone II, Westside Cascades Principal habitats used vary by zone in the Region

PINE MARTEN SPECIFICATIONS

Principal Habitats Used

The pine marten uses seral stages III-VI--closed sapling-pole, large mature, and old growth (Thomas, 1979; Guenther and Kucera, 1978, Phillips and others, 1981). The Kuchler types used are from Guenther and Kucera (1978) The principal habitat for pine marten is seral stages V and VI (mature and old growth).

Dispersal Distance Between Habitats

Burke (1982) recommends that the maximum dispersal distance between habitat areas for pine marten should be two miles. In 1984 the Regional Forester changed the dispersal distance from two miles to three miles. This change was made because it was felt where more than one adjacent habitat is available for dispersal, the dispersal distance can be extended to three miles for pine marten This change has been reviewed by a number of biologists within and outside the Forest Service and most agree that it would appear not to create a population viability problem for represented species. In June of 1986, the dispersal distance specification for pine marten habitat was changed to one habitat for every 4,000 to 5,000 acres (about three miles apart) to allow greater flexibility in application.

Size of Habitat Areas

In the professional judgment of the biologists listed in Phillips and Roberts (1985), a breeding female pine marten can be supported on 160 acres of quality habitat Research is variable as to the size of area needed, but the female pine marten home range is estimated to be 160 acres (Campbell, 1979). The biologists listed in Phillips and Roberts (1985) judged that this area should be contiguous to ensure that there would be enough habitat within the home range of the female. They also judged that crown closure should equal or exceed fifty percent Research papers indicate that areas with a low percent crown closure receive little or no use by pine marten Therefore, to ensure an adequate crown closure, a minimum requirement of 50 percent closure was selected.

Research shows that pine marten require dead and down material for foraging, cover, and denning. Six down logs/acre (Burke, 1982) was selected as the minimum down material requirement. The number and size of snags required was selected to ensure that the amount of down material was achieved. The specifications for pine marten habitat are summarized in Table J-7.

ALTERNATIVE WAYS OF MEETING THE MANAGEMENT REQUIREMENT FOR PILEATED WOODPECKER AND PINE MARTEN

On the Siskiyou National Forest, mature conifer habitat is defined as a stand of predominantly conifers which are over 100 years old.

Habitat areas for pine marten and pileated woodpeckers were mapped using Regional spacing, size, and habitat suitability criteria. Pine marten sites are to be located every 4,000 to 5,000 acres and pileated woodpecker sites every 12,000 to 13,000 acres.

Whenever possible, sites were placed within Wilderness, Wild Rivers, RNA's, other areas unsuitable for timber production, and in areas of reduced harvest levels, wherever these met habitat quality and distribution requirements.

Table J-8 summarizes the number of mature conifer sites for pileated woodpecker and pine marten located by unsuitable and tentatively suitable timber land. The total areas for pine marten include taking credit for pine marten habitat in pileated woodpecker and spotted owl areas; the total for pileated woodpecker also counts the pileated habitat in the owl areas

Table J-8. Mature Conifer Habitat Sites.

Species	Every M Acres Distribution Requirements	Sites Unsuitable Timber Land	Sites Suitable Timber Land
Pine Marten	4-5	136	73
Pileated Woodpecker	12-13	79	45

Once the minimum number of habitat sites was determined using Regional spacing and habitat suitability specifications, the Forest considered two options for providing mature conifer habitat. One was to dedicate the required number of acres of suitable habitat in each site. These areas would not be managed for timber production and would be expected to remain in suitable habitat condition for several decades The second option was to manage timber stands on a larger area in order to harvest timber and produce replacement stands over time.

Alternative 1: Dedicated Sites

Under a dedicated mature conifer strategy, the required amount of mature conifer is withdrawn from timber production. Dedication of mature conifer sites has the advantage that the location of the stand does not change over time, making implementation less complicated. Dedication also assures that desired structural characteristics will be available for wildlife. There may be some risk of loss of individual stands through catastrophe.

Alternative 2: Managed Sites

This option involves the projection of long rotations on enough acres to maintain the necessary habitat through time, with all areas being rotated. The "normal" rotation age for stands in General Forest is projected to be about 100 years Production of mature conifer habitat is expected to take around 100 years, rotations

of 140 are used to model a managed regime providing mature habitat from age 100 to 140 This means that for every acre of suitable habitat, 2-1/2 acres would be managed as replacement stands when the original acre is harvested.

Management of mature conifer sites assumes that existing stands can be harvested as other stands grow into a mature conifer condition to replace them. If replacement stands fail to develop desired structural characteristics (ie large diameter snags and down material) as predicted, mature conifer habitat would either be lost for a period of time or further delay in harvesting the existing mature conifer stands would occur.

Analysis of Opportunity Costs

The opportunity costs of designating the habitat areas (selected method) are displayed in Table J-3 The examination of opportunity costs and efficiency of the option for providing mature forest habitat through managed rotated stands is accomplished though an evaluation of per-acre timber production and economic efficiency of the possible regimes. The analysis if based on a Forest-wide evaluation, however, specific FORPLAN runs were not used to make a comparison (Forest-wide ASQ and PNV effects are not computed) This analysis has been explained in detail in Appendix B, Development of Management Requirements, and is summarized briefly here

The minimum time required to produce mature forest habitat is 100 years. At that time the average replacement area would contain more volume than the original habitat area. Rotating the areas would result in less timber yield than harvesting the replacement area and leaving the original area to continue providing habitat Table J-9 compares the empirical yield table volumes after 100 years with the volumes from the intensive managed yield tables at age 100

Table J-9 Comparison of Volumes After 100 Years.

Site	Volumes After 100 Years (MCF)	
	Empirical	Managed
High	9 226	11 830
Medium	5 049	9 704
Low	3 687	3 225 1/

1/ Low site would not provide mature Forest habitat at this age

Consequences of the Different Ways of Meeting the Management Requirements

Populations of pileated woodpeckers and pine marten would not be expected to differ significantly under either alternative Both would maintain the same amount and distribution of habitat. There are, however, differences in the opportunity costs as dedication of habitat areas would have the least impact on timber outputs and therefore PNV.

Rationale for the Selected Method

The Siskiyou National Forest chose to provide mature conifer habitat by dedicating sites where needed on tentatively suitable timber land. This alternative achieves the desired habitat with the least effect on timber outputs and is an economically efficient way of meeting the management requirement Modeling these areas as designated for this planning period does not preclude future planners from designating replacement areas as substitution opportunities can be identified (i e., some existing pole stands could be substituted for originally designated area by the 5th decade). Whether areas are modeled as designated or rotated, there would be little difference in implementation for the first planning period

Implications for Forest Plan Alternatives

Plan alternatives were designed to address public issues. As a result most alternatives, including the preferred, incorporate objectives for retention of mature and old growth timber for a variety of reasons, such as wildlife, scenery, and recreation. Pine marten and pileated woodpecker areas overlap with areas selected for other purposes (such as unroaded recreation areas and special interest areas) wherever these sites meet habitat suitability and distribution requirements Methods resulting in the opportunity cost shown in Table J-3 would benefit other resource uses as well.

Role of Monitoring and Research

The Forest Monitoring Plan (Forest Plan Chapter V) calls for monitoring populations and habitats of pileated woodpeckers and pine marten. At scheduled plan reviews, monitoring data will be considered in determining the suitability and effectiveness of the selected method for meeting the management requirement for viable populations This will be an important test of the appropriateness of the selected modeling assumptions.

Information needs for both pine marten and pileated woodpecker include·

1. Dispersal distances:
   a. How far can juveniles successfully disperse?
   b. As habitat becomes increasingly fragmented, what is the ability of dispersing individuals to locate habitat islands?
   c What effect does the size of habitat areas have on the ability of dispersing individuals to locate these sites?

2 Size of mature conifer habitat sites·
   a. Occupancy and use of habitat sites, particularly as the sites become more isolated.
   b. Reproductive success within habitat sites.
   c. Home range size in fragmented forests.

3. Utilization and reproductive success of pine marten and pileated woodpeckers in mature conifer sites managed on a 100 year rotation (ie. are managed sites meeting habitat needs as compared to natural stands).

4. Population density, home range size and distribution of pine marten in southwest Oregon

SPECIFICATIONS FOR MEETING THE HABITAT REQUIREMENTS FOR NORTHERN SPOTTED OWL

Specific Regional direction for the northern spotted owl is found in the Final Supplement to the Environmental Impact Statement (FSEIS) for an Amendment to the Pacific Northwest Regional Guide released in August, 1988. In response to an appeal of the R-6 Regional Guide, the Supplement was prepared to address planning direction for spotted owl habitat management Standards and guidelines adopted as a result of the Supplement will be used by National Forests in the Region to meet the management requirement to maintain viable populations of spotted owls.

The Final SEIS was prepared after a series of public meetings and study of the nearly 42,000 comments received on the Draft Supplement issued in the summer of 1986. A summary of the analysis of public comments, substantive comments, and copies of letters received from government agencies and elected officials can be found in Appendix G of the FSEIS.

The Forest Service Preferred Alternative (F) directs that the amount of suitable habitat at each designated SOHA will vary by physiographic province. Specific criteria were followed in locating designated SOHA's on

the Siskiyou Current distribution of owl habitat on lands unsuitable for timber production was evaluated for adequacy of distribution SOHA's were designated on lands suitable for timber production only where necessary to meet distribution standards Standards and Guidelines for the Forest Service preferred alternative (F) are briefly summarized in the following discussion Chapter II of the Final Supplement should be reviewed for a detailed description of the direction. These Regional Standards and Guidelines provide specifications or standards for achievement of management requirements for northern spotted owls

1. **Amount of suitable habitat in designated habitat areas.** Designated habitat areas shall contain the following amount of suitable habitat in the Klamath Mountain physiographic province. 1000 acres within 1.5 miles of the nest site... Habitat shall occur as one contiguous stand if possible or, as a 300-acre stand containing the known or suspected nest site with the remaining habitat as contiguous as possible. Each stand shall be larger than 60 acres.

2 **Spacing of Designated Habitat Areas:** Designate habitat areas where· greater than six miles separates areas which occur in reserved lands or in lands unsuited for timber production, and which are capable of supporting less than three breeding pairs of spotted owls; or where greater than 12 miles separates such areas capable of supporting three or more pairs.

3 **Threatened and Endangered Species:** No spotted owl habitat management activities shall adversely effect Federally listed threatened or endangered species or their habitat.

4. **Identification of Suitable Habitat** Suitable habitat shall be identified in Forest Plans according to the *general definition in the spotted owl Final Supplement and with concurrence by the Regional Forester*

5. **Management of Habitat.** Spotted owl habitat can be provided through prescriptions using even-aged or uneven-aged silvicultural systems, or no scheduled harvest. Prescriptions to be used and where they will apply shall be specified in the Forest Plans.

6. **Location of designated Habitat Areas:** Designate habitat areas only on lands suitable for timber production as needed to meet spacing standards.

7 **Priority for Locating Designated Areas:** Priority for locating designated areas follows status of occupancy by spotted owls The highest priority is given to locations with verified occupancy by spotted owl pairs; next highest to locations with confirmed sightings of owls; lowest priority to locations where the presence or absence of owls is unknown.

The Final Supplemental Environmental Impact Statement (FSEIS) to the Regional Guide (for spotted owl habitat management guidelines) does not include the number of designated habitat areas as part of any alternative. The number of habitat areas are not specified in the Regional Guide, but will be a consequence of applying standards and guidelines in Forest Plans.

ALTERNATIVE WAYS OF MEETING THE MANAGEMENT REQUIREMENTS FOR NORTHERN SPOTTED OWL

The Forest considered two ways or means for providing spotted owl habitat One is to dedicate the required number of acres of suitable habitat in each site These areas would not be managed for timber production and would be expected to remain in suitable spotted owl habitat over time. The second way is to manage timber stands through long rotations in order to produce replacement stands over time. The Siskiyou National Forest chose to provide spotted owl habitat by dedicating the required amount of habitat.

Alternative 1: Dedicated Sites

Under a dedicated habitat strategy, each acre of spotted owl habitat is withdrawn from timber production. Dedication of existing stands assures that desired structural characteristics will be available, but may risk loss of individual stands through catastrophe or decay Recent literature on old-growth suggests this risk is much less than once thought.

Alternative 2: Managed Sites

Management of sites assumes that existing old growth stands can be harvested as they are replaced by other stands that grow into an old-growth condition Delay in harvesting the existing old-growth stands would occur if replacement stands fail to develop desired structural characteristics on schedule Management of old growth on a harvest basis and replacing it removes structural characteristics important to old-growth and may hasten the decline of the residual stand (Franklin 1981).

Analysis of Opportunity Costs

The opportunity costs of designating the habitat areas (selected method) are displayed in Table J-3. The examination of opportunity costs and efficiency of the option for providing mature forest habitat through managed (rotated) stands is accomplished though an evaluation of the per-acre timber production and economic efficiency of the possible regimes The analysis summarized briefly here is similar to that described for mature forest habitat above and is explained in detail in Appendix B, Development of Management Requirements.

The minimum time required to produce old-growth forest habitat is 200 years. At that time the average replacement area would contain more volume than the original habitat area. Rotating the areas would result in less timber yield than harvesting the potential replacement area and leaving the original area to continue providing habitat. Dedicating the habitat minimizes the opportunity costs of ASQ and PNV.

Consequences of the Different Ways of Meeting the Management Requirements

Populations of spotted owls would not be expected to differ significantly under any of the options available to meet the management requirement. There are, however, differences in the opportunity costs.

Rationale for the Selected Method

The Siskiyou National Forest chose to provide spotted owl habitat by dedicating habitat sites. This alternative maintains necessary habitat, and has the least effect on timber outputs; it is an economically efficient way of meeting the management requirement with the least opportunity costs

The dedicated habitat approach has the advantage that the location of the habitat site does not change over time, making implementation less complicated than continuously relocating the habitat site as the stands are harvested and replaced.

Implications for Forest Plan Alternatives

Plan alternatives were designed to address public issues. As a result most alternatives, including the preferred, incorporate objectives for retention of old-growth and mature timber for a variety of reasons, such as wildlife, visual, and recreation To the extent possible, spotted owl habitat areas overlap with areas selected for other purposes (such as Wilderness, unroaded recreation areas, special interest areas and other lands determined as not appropriate or unsuited for timber production), wherever these meet habitat suitability and distribution requirements. The analysis of opportunity costs of selected means of spotted owl protection displayed in this appendix are gross PNV and ASQ effects caused by the selected implementation methods.

The costs do not take into account any overlap that may occur among implementation methods where lands selected for spotted owl habitat may also meet other wildlife, scenery or recreation objectives on lands suitable for timber harvest.

Role of Monitoring and Research

The Forest Monitoring Plan (Forest Plan Chapter V) calls for monitoring populations and habitats of spotted owls.

The Final Supplemental Environmental Impact Statement to the Regional Guide (Appendix D) identifies specific monitoring and research needs and describes how the information will be obtained. Intensive inventory, monitoring, and research being conducted by the Spotted Owl Research, Development, and Application Program will provide new information This should allow an opportunity to re-evaluate and possibly adjust management direction within five years.

RELEASE AND DISTRIBUTION TO THE PUBLIC

On August 28, 1987, the Draft Environmental Impact Statement (DEIS) and Proposed Land and Resource Management Plan (Proposed LRMP) were formally released to the public. An initial 350 copies of the document were mailed to government agencies, local libraries, and interested members of the public. A total of 750 copies were printed, all of which have been distributed In addition, a 40-page Reviewer's Digest was distributed to hundreds of individuals and a slightly condensed version titled "An Invitation to Comment" was printed and circulated to 62,000 through the local newspapers.

The comment period was originally scheduled to end on November 27 Two days after the DEIS and Proposed LRMP were released, dry lightning storms ignited fires which lasted for several months and burned over 110,000 acres of the Siskiyou National Forest. The Forest and local communities were unable to carry out the review of the DEIS as resources were committed to the fire-fighting effort Regional Forester Jim Torrence immediately extended the comment period to December 24 In response to members of the public who maintained that even more time was needed to fully analyze the draft documents and formulate comments on the proposal, the Regional Forester extended the formal review period an additional 30 days. After 150 days of review, the close of the public input period came on January 25, 1988.

During the review period, the Proposed LRMP was the featured topic at 37 open meetings attended by more than 600 people. Forest personnel attended each meeting to describe how the DEIS was prepared and to answer questions from the public. They presented an introduction to the Forest Planning process, an overview of the DEIS and the range of alternatives examined, and detailed information on the Current Direction Alternative and the Preferred Alternative. Briefings were also held in Washington, D C for Congressional aides, professional societies, and lobby groups

The Forest received a total of 16,983 responses during the review period, containing 17,277 signatures. The majority of the responses (97 percent) carried one signature One hundred fifty-one responses were unsigned Six petition responses carried 101 signatures.

Responses were received from 49 states (only North Dakota was missing), the District of Columbia, and five foreign countries (Canada, Australia, Germany, Greece, and Yugoslavia) Oregon was responsible for the greatest number of responses (10,469), followed by Illinois (1,601), Texas (1,592), Wisconsin (877), and California (649)

The majority of the responses were from individuals acting for themselves (99 percent). The second, third, and fourth largest groups of respondents were environmental/conservation groups (36 responses), timber industry (27 responses),and city/municipal officials (13 responses). Seven county officials, six state officials, and four Federal officials also responded (see Table K-1).

Campaigns initiated by interest groups resulted in the majority of responses Southern Oregon Timber Industry Association (SOTIA) generated 5,479 form letters in support of their proposed Evergreen Alternative Most of these (97 percent) came from the Pacific Northwest, with less than 14 responses coming from 8 other states. Their input accounted for 49 percent of Oregon's total response, 31 percent of California's, and 1 percent of Washington's.

Table K-1. Synopsis of Responses Received

Total Number of Responses	**16,983**
Total Number of Signatures	**17,277**
Form of Responses	
Form Letters and Coupons	15,524
Letters and Postcards	1,219
Forest Mailers	221
Resolutions	8
Petitions	6
Other	5
Who Responded	
Federal Agencies and Elected Officials	4
State Agencies and Elected Officials	6
County Agencies and Elected Officials	7
City/Municipal Governments/Officials	13
Academia	11
Professional Societies	2

Civic Groups	9
Businesses	12
Timber Industry	27
Timber Resource Groups	12
Associations/Unions	5
Recreation Groups	9
Indian Tribes	1
Other	3
Individuals/Families	16,826

The most popular form of response was the form letter (91 percent), followed by the letter or post card (7 percent). Resolutions, petitions, and Forest mailers made up the remainder of the responses (see Figure K-1).

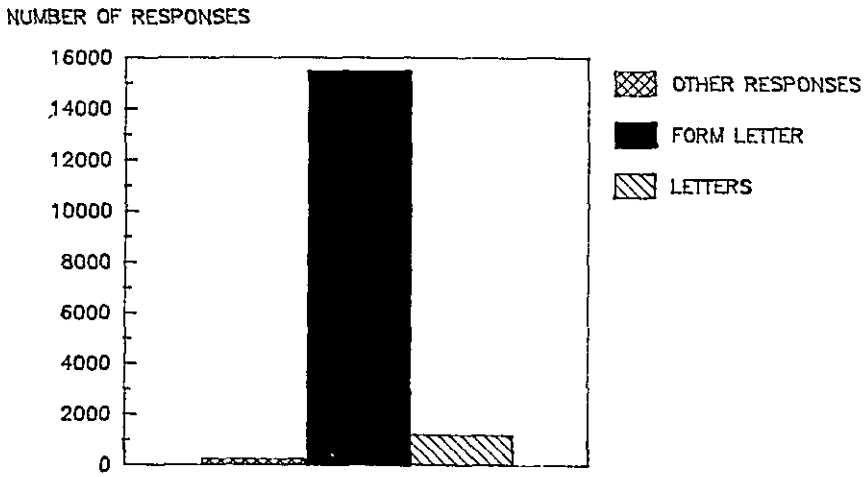

Figure K-1 Responses Received

Form letters (9,155) in response to a campaign proposing a Siskiyou National Park, on the other hand, came from nearly every state in the Nation, and constituted 33 percent of Oregon's total response, 99 percent of Illinois', 97 percent of Texas', 99 percent of Wisconsin's, and 51 percent of California's. Most of the Park campaign responses came from a few university towns in these states; the concentrated mailings are attributed primarily to one individual who made the speaking engagements on selected campuses

The number of responses received from states with the most response, and the portion of responses resulting from the campaigns by SOTIA and Siskiyou National Park proponents, are graphically depicted in Figure K-2. Similar information for the cities with the largest number of responses is depicted in Figure K-3

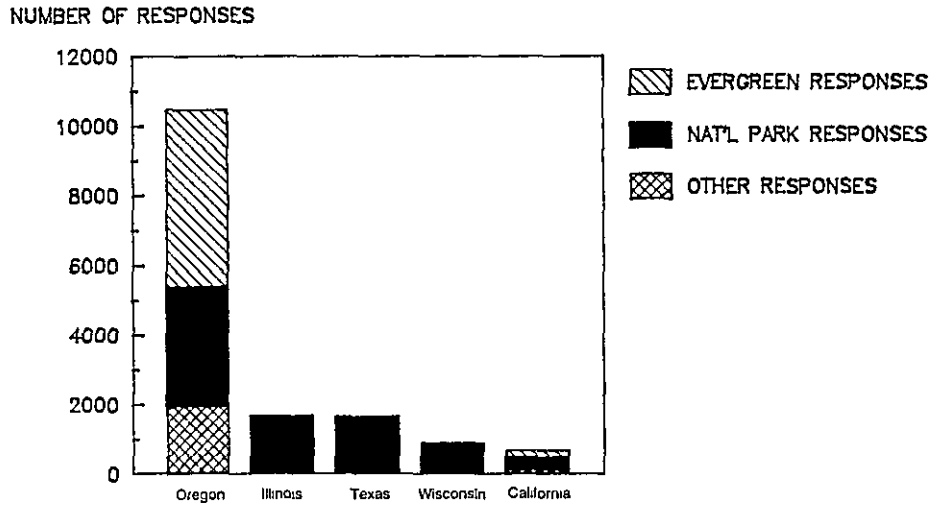

Figure K-2. States With Highest Number of Responses

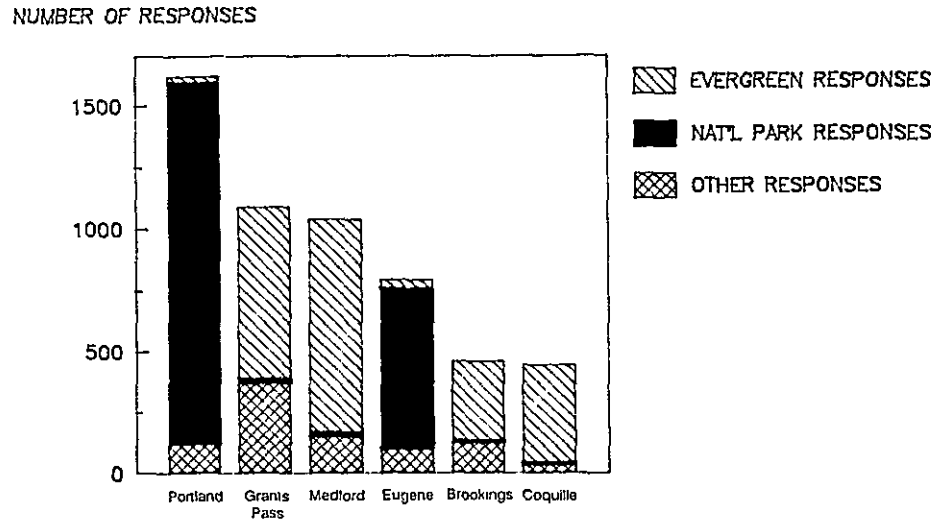

Figure K-3. Oregon Cities With Highest Number of Responses

SUMMARY OF PUBLIC COMMENT ANALYSIS

Appendix K includes a summary of the analysis of public comments, substantive comments summarized by subject matter, and copies of letters received from government agencies and elected officials.

All comments received by January 25, 1988 (the end of the 150 day formal review period) were reviewed, analyzed, and considered in preparing the Final Environmental Impact Statement (FEIS) All responses to the DEIS are available for review at the Supervisor's Office, Siskiyou National Forest, 200 N E Greenfield Road, Grants Pass, Oregon.

The largest group of respondents (23 percent) commented on the broad area of socioeconomics There was a direct correlation indicated between jobs and timber harvest levels and, as a result, community stability. This subject area also included social considerations, such as the effects on people, families, and communities, not directly economic in nature. Respondents are concerned with maintaining lifestyles and occupations consistent with family tradition.

The second largest group of respondents (18 percent) commented on timber management, an issue which continues to be highly polarized and emotionally charged. Many respondents asked that old-growth forests be protected, and unroaded areas preserved. Some feel that the level of harvest is over-optimistic, reforestation is inadequate, and yield tables project unrealistic growth Many objected to clearcutting, suggesting that monocultures are being created. Others point out the dependence of local communities on the supply of timber to maintain jobs and social and economic stability. They maintain that the Forest is capable of significantly higher timber outputs than projected in the DEIS.

Sixteen percent of respondents commented on the roadless issue, which was also very polarized. Timber and mining interests perceive a critical need to maintain a land base The environmental community feels the unroaded tracts of low elevation, coastal old-growth Douglas-fir are the last large vestiges of a rapidly vanishing ecosystem.

A large group of respondents (10 percent) commented on the issues of fisheries and water quality. They are concerned about basin constraints, riparian prescriptions, water temperature, and cumulative effects of sedimentation. Some think that the Forest is not doing enough to protect the fishery and water quality values; others think there is too much being done, resulting in less timber production.

The issues of tourism and recreation were commented on by 8 percent of the respondents Many want to develop and enhance the recreational use of the Siskiyou National Forest. Local counties have chosen tourism as their "Oregon Economic Comeback Strategy," and look for support and participation by the National Forests in this strategy. Thousands of comments urge the development of a National Park alternative, emphasizing the natural beauty and recreational opportunities on the Forest.

There was broad support for designation of the inventoried Chetco and North Fork Smith Rivers as Wild and Scenic Comments went beyond the present scope of the DEIS to include suggestions that other rivers, such as the Elk, Pistol, Winchuck, South Fork Coquille, South Fork Chetco, and South Fork Sixes Rivers be added to the National Wild and Scenic River System as well.

RESPONSE TO PUBLIC COMMENT

A substantive comment is defined as: "A comment that provides factual information, professional opinion or informed judgement germane to the action being proposed" (Forest Service Handbook 1090 5). The comments in this Appendix contain not only "substantive" comments, but also many that expressed a "resource preference" or value These were included to give the reader a feeling for the broad range of comments the Forest received.

Comments to the DEIS are grouped by general subject matter, as outlined below, and summarized because the public response has been exceptionally voluminous (see 40 CFR 1503 4(b)). Comments were extracted from the letters and may be paraphrased. Every attempt has been made to accurately capture each substantive comment and display them. The comment is presented in uppercase; the Forest Service response follows each comment. There is direct tie between the responses to the public comments and the content of the FEIS and Forest Plan. Whenever possible, a reference is made in the response to the exact location in the documents wherein the reader may find changes and (or) supporting information. Abbreviations have been used throughout the appendix; a list of acronyms can be found in the FEIS.

Many local responses expressed concern that since the Forest Plan affects local jobs and lifestyles, more emphasis should be given to those responses that came from the Pacific Northwest. Responses received from outside the Northwest held the opposing viewpoint; they stressed that the national forests belong to all Americans, thus, responses from across the nation should be considered as well.

Comments in this Appendix were included without regard to the author's location, occupation, or lifestyle. Each comment is valuable whether "substantive" or not; opinions, feelings, suggestions, and observations were all read carefully and considered. Use of public comments is not merely a vote-counting process. Each comment was weighed on its own merit against legal, technical, and resource capability constraints. Using professional judgement, the Forest assessed and considered all of the public comments, individually and collectively. The Forest will be different as a result of the comments. The issues, concerns and opportunities for the Forest were given a new emphasis as described in Chapter I of the FEIS. Many suggestions were incorporated and changes were made to the plan, as evidenced by the Preferred Alternative. Numerous suggestions were detailed and specific; many of these are not summarized in this Appendix of comments but were, nevertheless, used in making changes and improvements

The Forest responsed to comments in a variety of ways, which involved:

(1) Modifying alternatives including the proposed action.
(2) Developing and evaluating alternatives not previously given serious consideration by the agency.
(3) Supplementing, improving, or modifying the analyses.
(4) Making factual corrections.
(5) Explaining why the rationale, authorities and sources were used in the DEIS and why the Forest's position is maintained in the FEIS.

The comments and responses are further steps in a continuing dialogue with the public. Extensive public participation has been extremely valuable in improving the future of the Forest. We hope this interest will continue with participation in Forest management planning as we amend, revise, and improve the Forest Plan as new information becomes available.

LAND MANAGEMENT

ALLOCATIONS

1 *COMMENT*· ACQUIRE ALL INHOLDINGS ON ALL PUBLIC LANDS.

Response: Non-federal lands which are within the Siskiyou National Forest boundary are identified and classified according to desirability of acquisition (See LRMP, Chapter IV, "Standards & Guidelines 9-3"). Where management goals indicate that the ownership of a tract should be public, the Forest will try to acquire the tract. Our primary means of acquisition is through land exchange, which means that the Forest Service trade public land of equal value in another location in order to acquire the key tract.

2. *COMMENT*: CREATE A NATIONAL PARK ALTERNATIVE, CREATE A SISKIYOU NATIONAL PARK

Response: Several National Park proposals were considered, but eliminated from detailed study for several reasons as described in Chapter II of the FEIS ("Alternatives Considered but Eliminated from Detailed Study"). Alternatives which place lands currently administered by the Forest Service into the hands of other jurisdictions were not reasonable considering the scope of this Environmental Impact Statement for preparation of the Forest Plan The purpose of the Forest Plan, as explained in the planning regulations, is to "provide for multiple use and sustained yield of goods and services from the National Forest System in a way that maximizes long term net public benefits in an environmentally sound manner" (36 CFR 219.1(a)) National Parks are, by law, not managed under the principles of multiple use and sustained yield.

Consideration of possible inclusion in the National Park system has been specifically assigned by Congress to the Secretary of Interior; designation of a National Park requires Congressional legislation. The National Park Service has stated it has no intent to pursue additional studies regarding a National Park (letter from National Park Service, Pacific Northwest Regional Director, to Siskiyou National Forest Supervisor, 10/2/87). It is remote and speculative that Congress would designate a National Park in the very near future. Additionally, Congress has repeatedly urged the completion of Forest Plans. Nothing would preclude the National Park Service from preparing a legislative environmental impact statement with Forest Service cooperation, just as nothing precludes Congress from designating a National Park in the future.

In response to public comments, several aspects of what National Parks offer the public were seriously considered by the Forest. Suggestions for increased emphasis in tourism and recreations have resulted in increased cooperative efforts with local county and other Federal agencies. A number of capital investment projects were developed (LRMP, Appendix B). Two of the alternatives developed for detailed study (Alternatives E and G) include land allocations to the Backcountry Recreation Management Area; when combined with existing Wilderness, they resemble the boundaries of several of the National Park proposals. Environmental consequences associated with those alternatives are disclosed in the FEIS, Chapter IV. Complementary to Park proponents' interests, considerably more unroaded area would be allocated to the Backcountry Recreation Management Area in the new Preferred Alternative S. In addition, attention was given to visual allocations along high recreation travel routes (FEIS, Chapter II, "Alternative S")

3. *COMMENT*. PROTECT THE PROPOSED SISKIYOU NATIONAL PARK AREA BY SELLING IT OFF. LET ORGANIZATIONS BUY SUCH PARTS OF FORESTS FOR THE PRESERVATION OF OREGON'S OLD GROWTH.

Response: Under existing law, the Forest Service is not allowed to sell land that it administers The agency can transfer lands through an exchange process that allows exchange of parcels of land of equal value if it is in the interest of the Government to do so None of the alternatives in the FEIS consider exchange or transfer of the lands in the area proposed by some individuals for a National Park (FEIS, Chapter II, "Alternatives Considered, But Eliminated From Detailed Study").

4 *COMMENT*: INCREASE THE ALLOCATION OF MANAGEMENT AREA 7 APPLIED TO MORE STREAMS AND PUSHED UPSTREAM ON SOME OF THE STREAMS TO WHICH IT IS ALREADY APPLIED.

Response: The alternatives include a full range of options for Supplemental Resource Management Areas. More protection of fisheries and water quality was a consideration in developing the new Preferred Alternative S. Alternative S would allocate additional areas to Supplemental Resource than the Preferred Alternative K in the DEIS

5 *COMMENT*: THE SUPPLEMENTAL RESOURCE CATEGORY SHOULD BE ELIMINATED FROM THE PLAN BECAUSE THESE AREAS WERE CONSIDERED FOR PERMANENT ROADLESS DESIGNATION UNDER RARE II AND SUBSEQUENTLY RELEASED FOR MULTIPLE USE.

Response. The use of Supplemental Resource Management Areas has been in existence for over a decade. The first application of this designation was in the current Mt. Butler-Dry Creek Unit Plan (FEIS, 1976). This designation has been carried forward in the Forest Plan because it best meets the management goals established for those areas listed in Management Area 7, Chapter IV, LRMP. Restated, these goals are to protect or enhance key fish and wildlife habitats, protect sensitive watershed areas, and provide for the recreation values, all of which are multiple-use purposes.

6. *COMMENT*· THERE SHOULD NOT BE ANY MORE LARGE SET-ASIDES FOR VARIOUS TYPES OF WILDLIFE. LANDS NOT SUITABLE FOR TIMBER PRODUCTION AND THOSE NECESSARY FOR THE PROTECTION OF PLANT AND ANIMAL LIFE CAN AND SHOULD BE RESERVED OTHER THAN FOR THOSE PURPOSES, THE LAND SHOULD BE AT WORK GROWING TREES.

Response: Growing trees is an important role for the Siskiyou National Forest However, the Forest has other roles, too, such as maintenance of viable populations of all wildlife species existing on the Forest The National Forest Management Act directs the Forest Service to provide for "diversity of plant and animal communities." Lands not suitable for timber production, but meeting habitat requirements for certain plant or animal species were selected wherever possible as potential Botanical Areas or as Designated Wildlife Areas (FEIS, Appendix F and J)

7. *COMMENT*. ALTHOUGH THE EIS DOES ADDRESS ENERGY TRANSMISSION CORRIDORS, IT DOES NOT MENTION THE PLANNING CORRIDOR THAT WOULD CONNECT THE ELECTRICAL TRANSMISSION SYSTEM NEAR MURPHY AND WILDERVILLE TO THE SYSTEM NEAR AGNESS AND GOLD BEACH THIS CORRIDOR, WHICH PROVIDES A FUTURE CORRIDOR OPTION ACROSS THE COAST RANGE IN SOUTHWESTERN OREGON, IS LISTED IN THE THE 1980 WESTERN REGIONAL CORRIDOR STUDY. PLEASE REFER TO THE STUDY FOR CORRIDOR INFORMATION. INCLUDE A MAP IN THE EIS SHOWING THE ABOVE-MENTIONED FUTURE CORRIDOR ALONG WITH THE EXISTING CORRIDORS THAT WERE MENTIONED IN THE DRAFT EIS.

Response: This corridor was originally included to tie in a hydroelectric project at the proposed Buzzard Roost Dam on the Illinois River. The dam site has since been removed from consideration following the designation of the Illinois River as a Wild and Scenic River. The corridor mentioned in the 1980 Western Regional Corridor Study is not feasible since the Act prohibits licensing water-related projects such as dams (FEIS, Chapter III, "Utility and Transportation Corridors"). Secondly, the corridor is very speculative relative to a proposed route across areas of extremely steep and unstable ground, this is coupled with a multitude of conflicting resource values. Last, the proponents of such a venture have remained somewhat silent as to the specifics of need and location. Therefore, without a concrete proposal, little of substance existed for analysis.

8. *COMMENT*: THE ILLINOIS RIVER SHOULD BE REOPENED TO SMALL DREDGES FROM DEER CREEK TO McCALEB RANCH, BUT WITH A SEASON SO THAT IT WOULDN'T BOTHER THE RAFTERS OR THE FISHERMEN.

Response: This issue was considered in the Illinois Wild and Scenic River Management Plan. The DEIS did not attempt to open management decision issues for the Illinois Wild and Scenic River, but simply incorporated the existing River Management Plan. The Illinois Valley Ranger District will solicit and consider public input when the River Management Plan is due to be revised.

9. *COMMENT*: THE AREA BETWEEN BOLAN LAKE, RED BUTTES, AND GRAYBACK MOUNTAIN HAS TREMENDOUS RECREATION POTENTIAL. IT IS HIGH ALTITUDE WITH ATTENDANT REFORESTATION PROBLEMS. THAT TIMBER HARVEST BE RESTRICTED IN THIS AREA, AND THAT FURTHER ROADS NOT BE BUILT WHILE THE COUNTIES DEVELOP TOURISM AND RECREATION PLANS. THIS IS A RELATIVELY SMALL AREA, PERHAPS 5,000 ACRES IN ALL, THAT IS BETTER SUITED TO NON-TIMBER MANAGEMENT.

Response: The alternatives examine a range of allocations for this area, including allocations to Supplemental Resource, Research Natural Areas, Botanical, and Backcountry Recreation Management Areas. The Preferred Alternative S would allocate approximately 3,000 acres of this area to the Backcountry Recreation and other Management Areas with no programmed harvest.

10. *COMMENT*: THE FOREST MUST EXPLAIN TO THE PUBLIC WHY IT HAS ALREADY MADE THE LAND MANAGEMENT DECISION WITHOUT PUBLIC INPUT. A SIGNIFICANT PORTION OF THE PLANNING PROCESS PRESCRIBES THE LAND ALLOCATIONS BEFORE THE PUBLIC HAS HAD AN OPPORTUNITY TO REVIEW THE LIKELIHOOD OF SUCH LAND ALLOCATIONS.

Response: Extensive public participation has characterized the development of the Siskiyou National Forest LRMP and the accompanying FEIS. Public input influenced land allocations to the Management Areas (14 areas). These allocations vary greatly by alternative and strongly reflect public preferences. See the FEIS, Chapter II, for the acreage in Management Areas by alternative. The final decision regarding land allocations will consider the significant public involvement; the Record of Decision be the instrument which provides explanation relative to the decision and response to public input.

11. *COMMENT*: SILVER CREEK FALLS IS OMITTED AS A UNIQUE INTEREST AREA UNDER THE PROPOSED PLAN, BUT THIS MUST BE A GENUINE MISTAKE. THE PROPOSED BUDGET, FOR EXAMPLE, INCLUDES PROJECTS AT THE FALLS.

Response: In the DEIS, Silver Creek Falls was allocated to the Supplemental Resource Management Area It has been reclassified as a Unique Interest Area in the Preferred Alternative S of the FEIS (Table II-3, "Special Area Assignments").

12. *COMMENT*: THE STANDARDS FOR MANAGEMENT AREA 5 (UNIQUE INTEREST AREAS) MEET SOME IMPORTANT PROTECTION CRITERIA. ALL UNIQUE INTEREST AREAS SHOULD BE ALLOCATED TO MA 5.

Response: All inventoried Unique Interest areas are allocated to Management Area 5 in the Preferred Alternative S.

13. *COMMENT*: THE MA 7 (SUPPLEMENTAL RESOURCE) ALLOCATIONS IN DEIS ALTERNATIVE "K" IS SUPPORTED ALSO, THE ADDITION OF ALL RIPARIAN AREAS IN THE ELK/SIXES PLANNING BASIN TO MA 7 IS RECOMMENDED. THE HIGH FISH VALUES OF THE ELK/SIXES PLANNING BASIN WARRANT THE PROTECTION LEVEL OF THE SUPPLEMENTAL RESOURCES PRESCRIPTION THE MA 7 ALLOCATION WOULD ALSO HELP PROTECT THE STATE OF OREGON'S ELK RIVER HATCHERY

Response: The additional protection proposed by overlaying Supplemental Resource Management Areas on the existing, Congressionally designated, and proposed Management Areas in Alternative S is considered unnecessary for enhancement of fish and water quality. More restrictive land allocations to complement the resource values in Elk/Sixes Planning Basin have been installed by Congress (Grassy Knob Wilderness of 1984, Omnibus Oregon Wild and Scenic River Act of 1988). The Forest Plan land allocations move beyond this with additional protection which includes, in part, the following: Supplemental Resource Areas on the North Fork Elk, South Fork Sixes, and along a small reach of the mainstem of Elk River, Partial Retention Visual in the Elk River corridor, the large Iron Mountain Botanical Area; and several Designated Wildlife Habitat areas). In addition, Riparian Prescription C has been applied to all rivers and streams in the basin Management for visual quality will also be applied to both the upper reaches of the North and South Forks of Elk River as a result of the recent (November 1988) addition of the State Scenic Waterways system.

Standards and Guidelines and associated Best Management Practices have also been strengthened to protect fish and water quality (LRMP, Chapter IV, "Management Prescriptions"). The benefits to fisheries in the Elk/Sixes Planning Basin are expected to accrue simultaneoulsy with the current trends of improving water quality (particularly temperature). Adding the extensive network of very constraining Supplemental Resource areas on the main rivers and tributaries of the basin serve little purpose other than severely constrain other compatible, multiple-use opportunities

14 *COMMENT*: THE ALLOCATION OF MA 8 (DESIGNATED WILDLIFE HABITAT) IN DEIS ALTERNATIVE "K" IS SUPPORTED THIS MANAGEMENT PRESCRIPTION, ALONG WITH MORE RESTRICTIVE MANAGEMENT AREAS AT RECOMMENDED LEVELS, SHOULD MAINTAIN A SATISFACTORY LEVEL OF OLD-GROWTH ECOSYSTEMS.

Response. Allocations in the FEIS Preferred Alternative S are slightly greater than Alternative K to meet the Standards and Guidelines in the Amendment to the Pacific Northwest Regional Guide (Spotted Owl Guidelines, 1988b)

15. *COMMENT*. ALL SPECIAL WILDLIFE SITES (24,004 ACRES) NOT ALLOCATED TO MORE RESTRICTIVE MANAGEMENT AREAS SHOULD BE ALLOCATED TO MA 9 THE LIMITED AMOUNT

OF MEADOWS IN THIS MANAGEMENT STRATEGY REPRESENT THE ONLY PERMANENT BIG-GAME FORAGE SITES OFFERED IN THE ALTERNATIVES.

Response: In response to public comments to provide connecting habitat, allocations of Special Wildlife Sites in the FEIS Preferred Alternative S are somewhat higher than Alternative K

TRANSPORTATION

Development

16. *COMMENT*. NO ROAD CONSTRUCTION ON BALD MOUNTAIN OR SILVER PEAK SHOULD OCCUR. THE TREES ARE NOW MUCH LESS VALUABLE FOR LUMBER THAN BEFORE THE FIRE, WHILE THE ENVIRONMENTAL DAMAGE WOULD BE COMPOUNDED BY LOGGING.

Response: The interaction between road construction, economic values, and fire effects on Bald Mountain and Silver Peak have been analyzed in detail in the Silver Fire Recovery Project FEIS which includes the site-specific analysis required for projects The Silver Fire Recover Project FEIS and Record of Decision is incorporated by reference into the Forest Plan FEIS and LRMP (FEIS, Chapter I, "Introduction").

17. *COMMENT*. AT PRESENT, A LARGE PART OF THE SISKIYOU NATIONAL FOREST IS NOT AVAILABLE FOR ENJOYMENT BY THE RETIRED ELDERLY AND DISABLED AMERICANS. BUILD A ROAD SYSTEM INTO ALL OF THE SISKIYOU NATIONAL FOREST WILDERNESS AREAS ALLOWING ALL AMERICANS ACCESS TO THEIR RESOURCES

Response: We recognize the need to provide facilities that accommodate the needs of retired elderly and disabled Americans and seek to provide those opportunities throughout the Forest. While there is road access to trailheads that lead into Wilderness, construction of these types of facilities and a road system within the Wilderness is specifically precluded in the Wilderness Act. The intent of the Wilderness Act is to retain vestiges of Wild America. Wilderness values are overriding and recreation is an activity that may occur, but is subordinate to the maintenance of wilderness character Road construction is not allowed under any circumstances except in situations where a valid mining claim (pre-dating the Wilderness designation) may require access. These situations are strictly regulated and are intended to provide access only to the miner Motorized access to the public is not permitted in Wilderness. Many other scenic areas of the Forest are accessible by road, however (See FEIS, Chapter III).

18. *COMMENT*: THE ESTIMATE OF ROAD MILES/SECTION SHOWN IN APPENDIX B (PAGE B-36) SEEMS VERY HIGH FOR UNROADED AREAS IN MANY PLANNING BASINS RELATIVE TO THE ACTUAL MILEAGE PER SECTION IN ROADED AREAS. THIS WOULD TEND TO OVERESTIMATE COSTS OF DEVELOPMENT. THE TABLES OF ROAD CONSTRUCTION SHOULD HAVE INCLUDED ALL POTENTIAL ROADS, PERMANENT OR TEMPORARY.

Response· The DEIS displayed the new road construction miles per acre harvested coefficients used in the FORPLAN model for each Planning Basin and its miles per square mile equivalent The "roaded area" values represent an estimate of only those new roads needed in the presently roaded area to access timber not economically within reach from present roads. The text in the FEIS preceding this table has been strengthened to emphasize that these were new mileage factors and not area total factors as for the unroaded areas The text in the "Improvements" section of FEIS (Chapter III) has also been strengthened to indicate the same If the existing road system were embodied with these "roaded area" coefficients, the total for the "roaded areas" would generally exceed the "unroaded area" factors by from one to two miles per square miles

It is nearly impossible to estimate all potential temporary roads Temporary roads are normally discouraged, and those constructed should be obliterated as part of the work for a particular project. The Forest-wide Standards and Guidelines (LRMP, Chapter IV) give direction for appropriate use and mitigation of temporary roads

19. *COMMENT*· BUILD A PUBLIC HIGHWAY FROM GRANTS PASS TO GOLD BEACH OR O'BRIENTO BROOKINGS.

Response: Various studies on the desirability of a public highway, other than the existing U S. Highway 199 and State Route 42, from the inland valley areas to the southern Oregon coast indicate the favored route to be along the Grants Pass to Merlin to Galice to Agness to Gold Beach corridor. The road management agencies along this route include· Oregon State Highway Division, Josephine County Public Works, USDI-Bureau of Land Management, USDA-Forest Service, and Curry County Road Department The Forest Service section is primarily double-lane paved standard on the west half and single-lane paved standard on the east half. From the standpoint of managing the National Forest, these standards are adequate at this time The Forest Service would support State and County proposals to provide a public highway through this corridor.

20. *COMMENT*: THE ILLINOIS RIVER ROAD IS IN NEED OF IMPROVEMENT FROM SELMA TO OAK FLAT AND ON DOWN TO THE TRAILHEAD AT BRIGGS CREEK.

Response: Agree The first 2.5 miles of this road out of Selma is a Josephine County road. From that point on the road is managed by the Forest Service. The next 4 6 miles to Six Mile Road has a bituminous surface treatment on it The balance of the road (11 3 miles) is on the capital investment program for improvement (See LRMP, Appendix B, "Road and Bridge Capital Investments"). The schedule for improvement identifies the first 4.2 miles of this latter segment for capital investment reconstruction in Fiscal Year 1989, the rest of the road to be improved in 1992. This will bring that segment up to a standard suitable for passenger car travel

21. *COMMENT*: THE OLD MINING ROAD FROM SELMA TO BRIGGS CREEK SHOULD NOT BE UNIFORMLY IMPROVED THROUGHOUT THE ENTIRE LENGTH. DEVELOPMENTS, IMPROVEMENTS, AND CAMPGROUNDS SHOULD BE PLACED NEAR THE SELMA END. MAJOR CHANGES WILL DESTROY THE LANDSCAPE AND CHARACTER OF THE CANYON AND DEGRADE THE EXPERIENCE OF BEING THERE.

Response. This route provides access to a long section of the Illinois Wild and Scenic River. The anticipated scale of public use along this route supports making safety improvements. Facilities to support the recreational use (campgrounds, trailheads, boating sites, etc.) will be provided and maintained to enhance their experience The loss of landscape character and degradation of experience is not anticipated as a result of improving the access road There will be a change in use, however land allocations, capital investments, maintenance of facilities, and monitoring are provided to complement the scenic and recreation attributes of the Illinois River canyon (FEIS, Chapter IV; LRMP, Chapter IV, V, and Appendix B).

22. *COMMENT*: GOOD, WELL-MAINTAINED ROADS TO SERVE THE AREA BETWEEN AGNESS AND CAVE JUNCTION WOULD SEEM TO BE IMPERATIVE TO GET THE GREATEST BENEFIT FOR THE GREATEST NUMBER IN RELATION TO SCENIC AND RECREATIONAL RESOURCES, WILDLIFE HABITAT AND TIMBER PRODUCTIVITY.

Response: There are several roads serving the area between Cave Junction and Agness, but no direct road linkage The Illinois River Trail completes the direct link between these two communities Three collector roads serve as access to the Illinois Wild and Scenic River, five or six collector and local roads access trail heads to the Kalmiopsis Wilderness, and at least six collector and numerous local roads access the area for recreational, mineral, and timber management purposes.

At present, only some of the collector roads and few of the local roads in this area would be considered suitable for passenger car use Some improvements are scheduled for one of the roads (Collector Road 4103). As future projects are planned for this area, road management objectives will be developed and revised to provide a transportation system capable of supporting anticipated multiple uses However, no plans exist for a direct linkage between these two areas.

23. *COMMENT*: THERE SHOULD BE ACCESS ROADS INTO ALL AREAS OF THE FOREST, FOR PROTECTION, FIRE FIGHTING, OR TOURISM. ALL FORESTS SHOULD HAVE GATED FIRE ROADS FOR PROPER MANAGEMENT WHAT IS THE DIRECTION FOR MANAGING THE 135 (PLUS) GATES ON THE FOREST?

Response It is not physically, environmentally, or economically feasible to construct access to every part of this Forest Road construction is expensive. Timber sales are the primary means of funding, but these funds have limits. Helicopter access is possible for fire fighting purposes to most areas of the Forest where sufficient lateral clearances can be maintained.

Very few roads have been built specifically for fire management purposes. Those that have are primarily to lookout sites As the Forest road system developed over time, initial administrative roads became multiple-use roads On this Forest, roads that have gates are usually closed for a multitude of resource reasons such as protection of wildlife, soil and water, and occasionally to protect areas during periods of extreme fire risk. Road management objectives are set for specific areas as part of the road management planning process. Depending on the objectives, gates may be routinely closed. This will be one of the topics addressed in the deer and elk management plan to be prepared within three years of implementation of the Forest Plan (LRMP, Chapter I and IV, "Forest-wide Standards and Guidelines).

Closures

24. *COMMENT*. NO NEW ROADS SHOULD BE BUILT ON THE SISKIYOU NATIONAL FOREST. NEW ROADS SHOULD BE CONSIDERED ONLY AFTER ALL OTHER ALTERNATIVES HAVE BEEN EXAMINED. NEW ROADS SHOULD BE EXCLUDED FROM RIPARIAN AREAS AND FLOODPLAINS TO PREVENT EROSION, SILTATION AND SEDIMENTATION ANY SALVAGE LOGGING SHOULD BE DONE BY AERIAL TRANSPORT

Response: Land allocations in the alternatives considered in the FEIS (Chapter II) identify the proposed uses of the Forest land areas When such designation is for commercial timber or developed recreation uses, roads are the present method of access. Costs usually determine the means for harvesting timber and hauling the product to the mill. All present economical harvesting methods require roads for haul; even helicopter logging has an economic flying distance of only one mile. Until the economic situation changes or technology is improved, or the land allocation is changed, roads are the only economic method of access Alternative M was specifically developed to evaluate the consequences of managing the Forest with no new road construction.

Standards and Guidelines for Riparian Management Areas (LRMP, Chapter IV) include instructions to exclude roads from riparian zones unless justifiable reasons exists Whereas avoidance is the first option evaluated, such justification might pose an unacceptable or unrealistic hardship or expense on other

resource opportunities (LRMP, Chapter IV, "Management Prescriptions"). At the project level, site-specific environmental analysis would be used to make such a determination, and appropriate mitigation measures would be specified Several of the Forest-wide Standards and Guidelines and associated Best Management Practices (LRMP, Chapter IV and Appendix F) are designed to minimize or prevent erosion, stream siltation, and to protect water quality for its established beneficial uses Any necessary crossings of wet areas would use methods that minimize impacts to water quality and fisheries However, it is unreasonable to assume that a road system would not require at least some degree of stream crossing in areas of the Forest heavily laced with channels. Therefore, with the expected road construction and drainage density experienced on the Siskiyou, impacts on the soil and water resource have been evaluated for each alternative (FEIS, Chapter IV).

25 *COMMENT*: MORE ROADS SHOULD BE CLOSED.

Response· The FEIS considered a range of alternatives that included various levels of road closures. Tables II-11 and II-12 (FEIS, Chapter II) give estimates of mileage for each alternative The "Significant Interactions" section (FEIS, Chapter IV, "Improvements") contains the purposes for road closures Direction and restrictions relating to road closure and road obliteration are included in the "Facilities Transportation System" section of the LRMP, Chapter IV ("Forest-wide Standards and Guidelines"). Road closures may be implemented to meet a number of economic and resource objectives, including protection of soil, water, and wildlife.

26. *COMMENT*: EXISTING ROADS SHOULD BE SURVEYED, AND THOSE FOUND TO BE ENVIRONMENTALLY HARMFUL SHOULD BE CLOSED AND ALLOWED TO RETURN TO A NATURAL STATE. RECENT FIRE ROADS, OR "CAT TRACKS" OR "FIRE BREAKS" NEED TO BE RESTORED TO THEIR NATURAL CONDITION IN AREAS THAT WERE PREVIOUSLY ROADLESS. NEW ROAD CONSTRUCTION SHOULD BE LIMITED UNTIL THE COST OF ALL LOGGING ROADS IS COVERED BY A MINIMUM REQUIRED BID FOR TIMBER.

Response· Existing roads are reviewed on a regular basis for road maintenance planning. Those roads causing environmental damage are identified and programmed for mitigation. Closure may be used as a mitigation procedure. Only roads determined not to be needed again, or those causing unacceptable resource impacts that cannot be mitigated, are returned to a natural state (deconstructed or "put to bed").

Access routes and other areas disturbed in the suppression of the recent fires were reviewed for rehabilitation needs during or immediately following the fire. Temporary roads and other disturbances were water barred, seeded with grass and covered with straw where needed to reduce the effects of erosion These mitigation measures and direction for use and obliteration of temporary roads are discussed in the Forest-wide Standards and Guidelines (LRMP, Chapter IV).

Where the need for new road construction is required to provide access to a timber sale, the cost of construction is part of the sale appraisal. There are situations where overall access needs exceed the value of one sale, and future sales will use the planned network. In this type of situation, capital investment funds are used to build the basic road network Appendix B (LRMP) gives an estimate of the road and bridge capital investments planned for the first half of the decade

27 *COMMENT*· ROAD MANAGEMENT AND SELECTIVE CLOSURE HAVE GAINED PROMINENCE IN RECENT YEARS AS A CRUCIAL ELEMENT IN MAINTAINING HABITAT FOR BIG GAME. YOU SHOULD WORK WITH OREGON DEPARTMENT OF FISH AND WILDLIFE AND OREGON STATE DEPARTMENT OF FORESTRY TO DEVELOP SPECIFIC CRITERIA FOR ESTABLISHING ROAD CLOSURES TO MEET WILDLIFE OBJECTIVES THAT ARE FAIR TO FOREST USERS. THESE

STANDARDS ARE ESPECIALLY IMPORTANT FOR ROADLESS AREAS YOU PROPOSE TO DEVELOP

Response: Road management is an important aspect of habitat management for big game Standards and Guidelines (LRMP, Chapter IV) provide for road closures to meet objectives for wildlife as well as other resource protection. A number of roads, such as those into Horse Creek Meadows, have been closed to vehicle traffic The roads and big game topic will be addressed in a comprehensive deer and elk management plan to be prepared after implementation of the Forest Plan. Appropriate State agencies have been involved in preparation of the FEIS and Forest Plan, and will be among those involved in preparing the deer and elk management plan.

28. *COMMENT*· THE PLAN STATES THAT RIGHT-OF-WAY GRANTS FOR ROADS WILL BE DENIED UNLESS NO OTHER ACCESS IS AVAILABLE. THE FSM STATES (4063.3.6) "DO NOT PERMIT ROADS, FENCES, OR SIGNS ON AN ESTABLISHED RESEARCH NATURAL AREA UNLESS THEY CONTRIBUTE TO THE OBJECTIVES OR TO THE PROTECTION OF THE AREA." THE STATEMENT IN THE PLAN SEEMS TO LEAVE THE DOOR AJAR FOR ROAD BUILDING; THIS SEEMS TO RUN COUNTER TO THE MANUAL INTENT.

Response. Standards and Guidelines concerning roads in RNA's do not run counter to FSM 4060 (LRMP, Chapter IV).

Effects

29 *COMMENT*· ROADS SHOULD BE PAVED TO REDUCE SILTATION.

Response: It is physically feasible to pave many roads, it may or may not be economically feasible Asphalt paving materials incorporate oil products, and are expensive. Where feasible and appropriate, asphalt (roads) and concrete (boat ramps) paving have been utilized on this Forest This practice will likely continue in the future Of 19 prioritized road projects for the capital investment program (see LRMP, Appendix B, "Road and Bridge Capital Investments"), six are paving projects involving over 20 miles of road.

Siltation is one of the factors considered in paving decisions. Siltation can be derived from several sources associated with roads; these include the road surface itself, the cut and fill slopes, and ditch lines. Grasses, shrubs, and trees are planted or permitted to grow on the exposed areas to reduce the soil erosion

Generally, maintenance costs for paved roads are significantly higher than for graveled roads, except where the graveled roads require substantial dust abatement or use is exceptionally high With limited maintenance funds, paving of roads is not practical unless there is an economic advantage (e.g., users fees pay for the maintenance), or resource damage such as stream siltation is a serious problem. Soil and water protection are important factors in planning construction, reconstruction and maintenance of roads (See LRMP, Chapter IV, Standards and Guidelines)

30. *COMMENT*: WHEN ROAD CUTS AND FILL ARE REVEGETATED, NATIVE PLANTS NEED TO BE USED WHAT IS THE POLICY FOR THE USE OF NATIVE PLANTS FOR REVEGETATION ON THE SISKIYOU NATIONAL FOREST?

Response. In response to increased public concern regarding use of native species and biological diversity, Forest-wide Standards and Guidelines (LRMP, Chapter IV) have been strengthened to emphasize establishment or protection of native plants on road cuts and fills A variety of plants and inert materials are used for erosion protection immediately following road construction Depending on availability, native herbs, shrubs, and trees make up a part of those materials and are used for erosion

control and stability protection Natural invasion of road cut and fill slope soil by native herbs, shrubs, and trees may take several years following construction, whereas annual grasses, legumes, and mulches may provide the needed first winter protection in some situations.

31. *COMMENT*: WHAT TYPE OF ENVIRONMENTAL ASSESSMENT IS DONE PRIOR TO ROAD CONSTRUCTION? EROSION RESULTING FROM POOR ROAD LOCATION AND CONSTRUCTION IS ONE OF THE BIGGEST THREATS TO OUR RIVERS AND STREAMS USE OF EROSION AND MASS WASTING RISK MAPS SHOULD BE REQUIRED.

Response. All road proposals are evaluated by an interdisciplinary team during the project environmental analysis to assure that erosion, mass wasting, and stream sedimentation are mitigated (LRMP, Chapter IV, "Forest-wide Standards and Guidelines"). Erosion and adverse impacts associated with poor road location and construction does pose a major threat to the slopes and streams of the Forest and downstream uses. Therefore, engineers, hydrologists, foresters, soil scientists, geologists, and biologists who are trained in erosion and mass wasting processes perform these evaluations These evaluations include a risk assessment for impacts associated with erosion and mass wasting potential, and may include maps. The process of evaluation includes input and feedback at all stages of location, design, construction, operation, maintenance, and monitoring Following the environmental analysis and before construction, a "plan-in-hand" field review of the proposed road is made to further refine the project plans and eliminate or reduce potential problems

Other Transportation Comments

32 *COMMENT*· TOO MUCH OF OUR ACCESS IS DEPENDENT UPON THE TIMBER HARVEST TO BE BUILT BY THAT INDUSTRY, AND THEN USED BY THE GENERAL PUBLIC OPEN GRAVEL ROADS TO PROVIDE RECREATIONAL HUNTING, WILDLIFE VIEWING AND SIGHT SEEING.

Response. Much of the access to and within the Siskiyou National Forest has resulted from timber harvest activities The timber resource will continue to provide access in most areas until the road system to commercial timber lands is complete. Portions of the road system originated as administrative roads built by the Civilian Conservation Corps or for mining access, which replaced trail access. Most of these early roads have been upgraded to standards which accommodate timber harvest traffic. This improved system offers added recreational and other access opportunities for Forest users

In some cases, timber harvest access has "opened" areas to recreational activities, which subsequently placed limitations on the potential timber harvest Some roads, however, are built with capital investment funds primarily for recreation opportunities and other management needs. Several roads are planned to be built or upgraded for recreation as identified on the "Road and Bridge Capital Investments" in Appendix B, LRMP.

Some roads are graveled with just enough aggregate to protect the surface from rainfall and water runoff, yet not enough to permit wet weather traffic. Recreational access is one of the considerations in determining the road management objectives that decide the maintenance level (surfacing) and if a road should be closed to vehicle traffic Road management objectives are continually reviewed and revised to meet changing demands and resource protection requirements. Other factors considered in designing roads are described in the LRMP (Chapter IV, "Forest-wide Standards and Guidelines").

33. *COMMENT*: NOWHERE IN THE PLANNING DOCUMENTS IS THERE MENTION OF THE POSSIBILITY OF OBTAINING TIMBER ACCESS BY RAILROAD AS OPPOSED TO ROAD, EVEN THOUGH IT IS A LONG-ESTABLISHED TECHNOLOGY WHICH CREATES MUCH LESS SOIL DISTURBANCE.

Response. A small portion of the Siskiyou National Forest in the Powers area was harvested using railroad-based logging systems. This occurred on lands acquired by the National Forest from private ownership. A significant portion of the railway network utilized cut and fill construction, producing the same level surface as used for roadways, many long sections of railway grades were converted to roadways when log trucks became more efficient. Long gentle grades to climb or descend were required to safely transport logs by rail. Where cut and fill construction was not possible, bridges (commonly called railroad trestles) were used to span to areas which permitted cheaper cut and fill construction Rotting remains of some of these railroad trestles are still present in a few locations. Only in areas of trestle would the environmental impacts be less. The logging techniques from railways may include the same techniques available from roadways, and likely produce similar impacts on the environment. However, areas accessed by rail is generally far more gentle than the balance of the Forest terrain.

Alternative access methods for timber harvest are considered on a site-specific project level basis If rail access was feasible and economical for an area, this method could certainly be considered.

34. *COMMENT* A BETTER SYSTEM OF MONITORING THE ENTIRE ROAD AND SKID TRAIL NETWORK NEEDS TO BE DEVELOPED SO THAT PROBLEMS CAN BE IDENTIFIED AND CORRECTED. MAINTENANCE COSTS DO NOT REFLECT TRUE COSTS, INCLUDING THOSE INCURRED FROM FLOOD AND STORM DAMAGE. A WINTER ROAD MAINTENANCE PROGRAM NEEDS TO BE DEVELOPED.

Response. The road maintenance program is an integral part of the Road Management Plan, which gives additional and more specific guidance to land managers. The Road Management Plan is a dynamic document which changes from year to year. Condition surveys for road maintenance are a monitoring tool which identify and track problem areas as they develop. The maintenance portion of this plan establishes the framework for who, what, and when actions will be performed.

Due to flood, storm damage, or the lack of regular maintenance, roads can deteriorate to where normal maintenance activities cannot bring the road back to the original standards. Such restoration requires construction equipment and techniques, so it is usually handled as reconstruction. Reconstruction costs, rather than maintenance costs, include these additional expenses due to floods and storms.

Winter use is made possible only by requiring those using the roads to do the necessary maintenance A part of the Road Management Plan deals with extended timber-haul seasons. This extra-normal haul requires performance of maintenance during wet conditions on roads which have been strengthened to accommodate extended season of use.

35. *COMMENT*: ROADS NEED TO BE BETTER SIGNED SO THE PUBLIC KNOWS WHERE EACH ROAD ON THE FOREST WILL TAKE THEM.

Response: Road management objectives establish the intended use and users for a particular road. Many single-use roads are managed to discourage general public use, and therefore would not be signed in a way to attract passenger car use Many roads traverse short distances (less than a mile) to project activity areas, and not all roads have identifiable destinations.

Destination signing on each road would be very expensive to purchase and to maintain. Reflective-type signs have an effective life of three to seven years. Like many things that are not under constant surveillance, signs tend to be subject to the full gambit of vandalism -- destruction, mutilation, or theft.

It is the Forest Service objective to provide adequate signing for the public Adequacy may vary depending on the above conditions Forest recreation maps which clearly display the road system are available at Forest Service offices

MULTIPLE USE

36. *COMMENT*: SINGLE USE OR RESTRICTED USE CLASSIFICATIONS CAN AND SHOULD BE COMPLETELY ELIMINATED FROM THE PLAN.

Response. All fourteen Management Areas described in Chapter II of the FEIS and Chapter IV of the LRMP provide for multiple uses. Management Areas 1 through 9, however, do restrain or prohibit some uses (activity) considered incompatible with the values associated with these sites Much of the acreage assigned to Management Areas 1 through 9 has been either designated by Congress (Wilderness and Wild Rivers) or is considered an NFMA management requirement (Designated Wildlife Habitat). The balance, such as new Botanical, Unique Interest, and Backcountry Recreation Management Areas, are discretionary allocations evaluated through the range of alternatives and subject to public and other agency input and review in this current planning effort.

The connotation often associated with the term "Multiple Use" is that every acre of the National Forest should contain its full array of uses, including wood products, wildlife, recreation, and so forth. The Multiple Use-Sustained Yield Act of 1960 provides a slightly different interpretation; "In the administration of the national forest, due consideration shall be given to the relative values of the various resources in particular areas." The establishment of Wilderness is given as an example that is considered consistent with the purposes and provisions of this Act. The Act further states that under multiple use, ".. some land will be used for less than all of the resources; ...with consideration being given to the relative values of the various resources, and not necessarily the combination of uses that will give the greatest dollar return or greatest unit output."

37. *COMMENT*: TRAIL AND RECREATION SITES SHOULD HAVE ADEQUATE UNLOGGED BUFFERS TO ENSURE THE "MULTIPLE-USE" NEED OF QUIET AND SOLITUDE

Response: Most, if not all, of the Forest's developed recreation sites are located in areas of the Forest managed for Visual Quality Objectives in all alternatives considered. Forest-wide Standards and Guidelines (LRMP, Chapter IV) have been modified to ensure adequate protection to trails and related recreation experiences. Some of the sites, however, may have been constructed after occurrence of activities not now compatible with the site, or are located within view of other ownerships which do not share the same objectives.

TIMBER MANAGEMENT

HARVEST

Harvest Levels

38 *COMMENT*: FULLY ACCOUNT FOR REDUCTIONS IN TIMBER YIELD DUE TO REDUCED HARVEST AND EXTENSIVE MANAGEMENT OF STREAMSIDE MANAGEMENT UNITS

Response: The relationship between allocations to Riparian Management Areas (Streamside Management Units) and timber yield was discussed in DEIS, Appendix J, "Summary of Relationship between Timber and MR's" which is now part of the process record. This linear relationship can be

summarized as a reduction in ASQ of 180 MBF (six-tenths of the 300 MBF effect under full yield) per 1,000 acres of land otherwise suitable for timber production allocated to Riparian Prescription B for the average alternative. The reduction for Riparian Prescription C would be about eight-tenths of the potential, or about 240 MBF per 1,000 acres. These formulas may be applied to the total suitable land allocation to Riparian management in any alternative, including the Preferred, to calculate the approximate reduction in potential timber harvest (FEIS, Appendix I, "Management Area Contributions to the Resolution of Planning Problems").

39. *COMMENT*. ANY REDUCTIONS IN ASQ SHOULD BE PHASED IN OVER A TEN-YEAR PERIOD.

Response: The projected Forest outputs, including ASQ, are average annual values for the first decade (LRMP, Chapter IV, "Proposed Outputs"). Actual outputs for individual years may vary. The administrative option exists to phase in a reduction in ASQ, provided that the total for the decade remains the same Congressional direction on funding and priorities would ultimately determine whether that option can be implemented

40 *COMMENT*· THE PROPOSED PLAN WILL CREATE A SHORT-TERM OVERSUPPLY OF TIMBER, CAUSING ARTIFICIALLY LOW PRICES (NOT REFLECTING THE TRUE VALUE) AT THE EXPENSE OF ROADLESS AREAS AND THE ENVIRONMENT.

Response. The analysis of current and future timber supply and demand does not indicate that implementation of the Preferred Alternative S will create a short-term oversupply of timber The Preferred Alternative would cause a slight decrease in ASQ from the Siskiyou National Forest compared to the situation prior to Forest Plan implementation No compensating increases in harvests from other ownerships are predicted in the first decade During this time, a slight increase in demand for local wood products is anticipated. The combination of these trends does not indicate a short-term oversupply of timber.

41. *COMMENT*: COMPARE PROPOSED ASQ TO THE HARVEST LEVEL IN THE EXISTING PLAN, AND TO RECENT ACTUAL HARVEST LEVELS

Response: The ASQ proposed for Preferred Alternative S is located in the description of alternatives The harvest level of the prior plan corresponds to the harvest level for Alternative No Change, also located in the description of the alternatives (FEIS, Chapter II, "Alternatives Considered in Detail"). Recent actual harvest levels are displayed in the table titled, "Siskiyou National Forest Timber Harvest Record 1963 to 1986" (FEIS, Chapter III, ""Economic and Social")

42. *COMMENT*: THE FEIS PREFERRED ALTERNATIVE SHOULD BE DEVELOPED WITH A MAXIMUM TIMBER PRODUCTION OBJECTIVE AND NOT BE OVERRIDDEN BY A MAXIMUM PNV OBJECTIVE

Response. The Preferred Alternative (and others) use a maximum timber objective function with a PNV "rollover." This does not override the timber objective function, but produces an economically efficient solution that achieves the maximum level of timber output derived with the timber objective. To do this, the model is solved with the timber objective function. Then a value equal to 99 percent of the maximum ASQ achieved is used to set a minimum ASQ constraint, and the model is solved with a PNV objective function.

43. *COMMENT*· THE NEED FOR OLD GROWTH FOR BIOLOGICAL OR AESTHETIC REASONS CAN ALSO BE SATISFIED TO SOME DEGREE WITHOUT SACRIFICING WOOD PRODUCTS IN LARGE

STANDS OF DECADENT OLD GROWTH IT WOULD APPEAR TO BE PRUDENT TO GET THE MAXIMUM WOOD PRODUCT FROM THE RESOURCE BASE WITH THE LEAST INTERFERENCE WITH OTHER USES, AND WITH THE LEAST SACRIFICE OF INCREASED FUTURE PRODUCT.

Response: Efficient allocations of land can satisfy biological or aesthetic needs with a minimum effect on allowable sale quantity As an example, the design of the Designated Wildlife Habitat Management Area had examined lands unsuitable and unavailable for timber harvest prior to evaluating suitable lands for their appropriate allocation as an old-growth habitat Management Requirement. Other allocations were also examined to consider their efficiency for competing and compatible uses to ensure no opportunities were overlooked.

44 *COMMENT*: THE SISKIYOU'S PREFERRED ALTERNATIVE IS UNACCEPTABLE BECAUSE IT VIOLATES THE FOREST SERVICE'S MANDATE TO PRACTICE SUSTAINED YIELD IN ITS TIMBER HARVEST PROGRAM NATIONAL FORESTS ARE TO BE MANAGED SO AS TO PRODUCE A HIGH LEVEL OUTPUT OF TIMBER. OTHER RESOURCES MAY BE CONSIDERED ONLY INSOFAR AS THEY DO NOT CONFLICT WITH THE STATUTORY DIRECTIVE TO MANAGE THE FORESTS FOR MULTIPLE-USE SUSTAINED-YIELD. SUSTAINED YIELD MEANS THE ACHIEVEMENT AND MAINTENANCE IN PERPETUITY OF A HIGH-LEVEL ANNUAL OUTPUT OF THE VARIOUS RENEWABLE RESOURCES.

Response: A "high-level" output of various renewable resources has to be viewed in context of all the resources of the Forest including, recreation, range, watershed, timber, wildlife and fish. A "high-level" of all these resources necessarily requires an appropriate blend; it does not dictate that one resource will be given undue preference over another The Multiple-Use Sustained-Yield Act of 1960 directs that the several products and uses of the National Forests be administered with due consideration given to the relative values of the various resources in a particular area. The various renewable resources are to be managed "so that they are utilized in the combination that will best meet the needs of the American people, making the most judicious use of the land for some or all of these resources...; that some land will be used for less than all of the resources; and harmonious and coordinated management of the various resources.. with consideration being given to the relative values. ., and *not necessarily the combination of uses that will give the greatest unit output.*" While some alternative themes in the FEIS may weight one or several resources far heavier than others, they still appear consistent with the Organic Administration Act of 1897, the Multiple-Use Sustained-Yield Act, and NFMA The critical point is the decision which has as its basis numerous laws and regulations applicable to the future direction and management of the National Forest. None of these laws and regulations mandate the achievement and maintenance in perpetuity of a high-level annual output of timber at the expense of other resources. The Preferred Alternative S best accomplishes this appropriate blend

45. *COMMENT*. YOUR PLAN K, MANAGEMENT AREAS #1-#14, ALMOST ALL CONTEMPLATE TIMBER LANDS REDUCTIONS WHY? WE ARE LOSING TWO CROPS OF TIMBER UNDER PLAN K WHICH RUNS COUNTER TO REAL FORESTRY PRACTICE.

Response: The Forest Service is required by Congress to "include coordination of outdoor recreation, range, timber, watershed, wildlife and fish, and wilderness" (National Forest Management Act of 1976). The different Management Areas are lands which provide for coordination of the different uses of your National Forest (FEIS, Chapter II, "Management Areas"). Specific reductions in land suited for timber production vary widely by alternative and are mainly due to the addition of Backcountry Recreation and Supplemental Resource areas. The Backcountry Recreation areas are primarily adjacent to the Wild and Scenic Illinois River where timber management is expensive and potential impact on river users high. The Supplemental Resource Areas are primarily include steep, inner gorge areas with very productive fisheries.

Congress has given the Forest Service direction that rotations will not be less than 95 percent of the culmination of mean annual increment (CMAI). The rotation length used on the Siskiyou National Forest varies by site class and management intensity from 80 to 140 years within the General Forest Management Area.

46. *COMMENT* ALTERNATIVE K SEEMS TO CONTINUE LOGGING AT CURRENT LEVELS AND DAMN THE CONSEQUENCES. ANNUAL TIMBER SALE QUANTITY IS BASED ON 150 MMBF WHICH IS THE HIGHEST VOLUME HARVESTED SINCE 1979 THIS SHOULD MAKE THE LOGGERS HAPPY BUT IT IS NOT GOING TO HELP PROTECT THE ENVIRONMENT.

Response: Harvest levels in 1987 and 1988 have exceeded 150 MMBF The different land allocations, Standards and Guidelines, and capital investments for recreation, watershed, wildlife and fisheries, range, and timber will provide environmental protection under a number of resource opportunities The environmental consequences associated with each alternative are presented in Chapter IV of the FEIS

47. *COMMENT.* OUR OPPOSITION IS ALSO BASED, IN PART, ON THE FACT THAT THE MAXIMUM POTENTIAL OF THE TIMBER PRODUCING LANDS IN THE SISKIYOU NATIONAL FOREST NOT LEGALLY WITHDRAWN FROM TIMBER PRODUCTION ARE NOT BEING MANAGED AS INTENSIVELY AS THEY SHOULD BE, AND AS A CONSEQUENCE DO NOT PROVIDE THE MAXIMUM HARVEST POTENTIAL OF THESE LANDS.

Response· Many of the alternatives, including the Preferred, do not produce the maximum amount of harvests on lands available and suitable for timber production for two reasons. First, it is not cost efficient to produce the maximum amount of timber Some hardwood conversions, fertilizations, commercial thinning opportunities, and other activities will not pay for the costs of implementation (FEIS, Chapter II). Second, the Forest Plan must "provide for multiple use and sustained yield of the products and services... and include coordination of outdoor recreation, range, timber, watershed, wildlife and fish, and wilderness" (NFMA, 16 USC 1604)

48. *COMMENT*· PRODUCTIVE CAPACITY AND EFFECTS OF INTENSIVE MANAGEMENT ARE UNDERESTIMATED OR OVER-ESTIMATED, NOT ADEQUATELY DISCUSSED, AND/OR UNSUBSTANTIATED. GROWTH OF IMMATURE TIMBER (PLANTATIONS) IS OVERSTATED.

Response: Forest growth and yield ("productive capacity") and the growth effects of intensive management were both projected from 1979 Siskiyou National Forest inventory data as modeled by DFSIM. The relationships used within the DFSIM computer model to project stand growth and development were statistical regressions developed from data collected from many stands grown under different conditions throughout the Pacific Northwest Douglas-fir region. The collected data included many stands with different treatments and management intensities, which provided a basis for projections of the effects of intensive management practices. The model is considered to be "state-of-the-art", and permits further refinement for local conditions. Local tree height/age relationships were used in growth functions, and output was modified for stockability limitations of low productivity sites (Managed Yield Tables for the Siskiyou National Forest, pp. 1-19; Craig, D., 1984).

49. *COMMENT*· SOME REVIEWERS REQUEST A DEPARTURE FROM NON-DECLINING TIMBER FLOW; OTHERS STATE THAT DEPARTURES ARE NOT JUSTIFIABLE.

Response: Two alternatives are presented both with and without a departure in ASQ from non-declining timber yield constraints: Alternatives A and A-Departure, and Alternatives D and its departure, Alternative

B. Alternative A-Departure was designed to maintain current harvest levels for at least the first decade, with a temporary decline in harvest levels in later decades. Alternative B would achieve the RPA goal for ASQ in the short term with a sharp decline in later decades In the DEIS there was also a departure variation on the Preferred Alternative This alternative received little public support and offered little in terms of the range of alternatives being considered, and was subsequently eliminated from detailed study in the FEIS. The matrix of alternatives with and without departure schedules facilitates comparison of the effects of departure on selected alternatives (see FEIS Chapter II).

50 *COMMENT.* THE PREFERRED ALTERNATIVE VIOLATES SUSTAINED YIELD PRINCIPLES (HARVEST LEVELS ARE TOO HIGH TO BE SUSTAINED)

Response· The analysis process used current inventory information of adequate statistical reliability to group areas of similar biological and physical characteristics (Capability Areas). These Capability Areas were then grouped by common management opportunities and response to management activities (Analysis Areas). Timber prescriptions and yield projections were developed by the DFSIM model for various combinations of site quality and management intensity associated with these Analysis Areas (see FEIS Appendix B) DFSIM projects future timber yields based on stand data from a large number and variety of managed stands in the Pacific Northwest Douglas-fir Region. The FORPLAN linear programming model identified the most efficient set of prescriptions and schedules within the objectives and allocations of each alternative. A constraint for nondeclining yield was applied in FORPLAN for all alternatives except alternatives where a departure was specifically being analyzed. Thus, the alternatives were developed using valid inventory data, a sound, state-of-the-art analysis process, and a rigorous set of constraints so that each alternative (except identified departures) would ensure a sustained, nondeclining yield of wood products. The process is discussed in detail in FEIS, Chapter II, "Description of the Analysis Process".

51. *COMMENT*: PROVIDE FOR SUSTAINED YIELD OF PRODUCT QUALITY AS WELL AS QUANTITY.

Response: Product quality, interpreted as lumber grade, was a factor in the economic evaluation of all alternatives. Product quality was positively related to the average diameter of harvested timber. An increasing timber value was assigned in economic calculations as projected average harvested diameter increased (FEIS, Appendix B, "Determination of Economic Values"). These data were used in the economic efficiency analysis of various rotation/thinning regimes by the DP-DFSIM model. Thus, DP-DFSIM recognized a product quality value premium when it identified those regimes with the highest net benefits (*Managed Yield Tables for the Siskiyou National Forest*, "DP-DFSIM"; Craig, D , 1984) These regimes were then applied in FORPLAN alternative analyses.

The optimal rotation and thinning regimes for high and medium sites predict an average tree diameter at final harvest of approximately 17 inches (*Managed Yield Tables for the Siskiyou National Forest*, "Analysis of Thinning Regimes", Craig, D , 1984) These prescriptions would be applied to sites in the General Forest Management Area. However, prescriptions developed for other Management Areas would provide limited amounts of larger diameter timber for harvest over extended rotations. These Management Areas are Riparian, Partial Retention Visual, Retention Visual, and Scenic/Recreation River (LRMP, Chapter IV, "Management Prescriptions")

52 *COMMENT.* INCREASE AVAILABLE, SUITABLE LAND BASE TO INCREASE SUSTAINED YIELD (EITHER REDUCE NON-TIMBER ALLOCATIONS, OR INCREASE REFORESTABLE LAND BASE BASED ON FIR RESEARCH RESULTS)

Response. Land suitability is determined by the physical capability of the lands to comply with legal requirements if managed for timber production. These requirements are described in FEIS, Appendix B,

"Suitability Analysis." All available data sources were compiled and evaluated by knowledgeable District personnel (silviculturists and soil scientists) to determine and map suitable lands on a site-by-site basis The latest reforestation technology, including applicable results from Forestry Intensified Research (FIR) program in southwest Oregon, was considered when determining the potential of various sites for prompt reforestation without irreversible resource damage. Suitability determinations are based on inherent characteristic of each site.

Two potential circumstances could modify the suitable land base in the future. Further field examination of sites may refine the existing information base, and indicate that changes in suitability classification are necessary on a site-specific basis. Changes in reforestation or soil erosion control technology may permit some additional lands to be promptly reforested without irreversible resource damage. These changes will be monitored for the significance of their aggregate effect on Forest Plan projections as described in LRMP, Appendix D, "Monitoring and Evaluation Program Background "

After reductions are made to the suitable land base to meet legal requirements, a wide range of potential allocations to the various Management Areas is still possible. Alternative C, which is similar to the Maximum Timber Benchmark, represents the upper bounds of potential legal timber production The other alternatives considered a wide range of possible General Forest allocations, and associated ASQ (FEIS, Chapter II, Table II-5).

53. *COMMENT*: REDUCE TIMBER HARVEST (ASQ) TO IMPROVE ENVIRONMENTAL VALUES, PRESERVE ROADLESS AREAS.

Response: ASQ is determined for Forest Plan alternatives by the FORPLAN model based on timber yield tables for assigned prescriptions and intensities, guided by the land allocations particular to that alternative. For each alternative, land is allocated to Management Areas based on the theme and objectives for that alternative. Land areas are assigned based on how well they meet the objectives and respond to the issues while minimizing effects on other resources (FEIS, Chapter II, "Description of the Analysis Process"). This allocation process most directly influences the interaction of ASQ with environmental effects and roadless area management.

The alternatives considered in detail are well-distributed through a wide range of potential allocations to the various Management Areas. The alternatives evaluate specific combinations of resource objectives which result in various ASQ levels (FEIS, Chapter II, Table II-5). The ASQ is one of the important parts of each alternative presented for the decisionmaker.

54 *COMMENT*: INCREASE TIMBER HARVEST (ASQ) OVER PREFERRED ALTERNATIVE (WITH OR WITHOUT MAINTAINING MMR'S AND/OR DISPERSION CONSTRAINTS).

Response· The timber harvest level interacts with almost every other issue. A range of alternatives is evaluated to provide information relative to the balance of benefits that might be achieved under different options. Each alternative is designed to efficiently meet a unique set of objectives. The basic potential of the Forest is limited by the amount of suitable land available for timber production. Management Requirements (MR's) of law and regulation must be satisfied. The Forest Service has attempted to identify the most efficient (least tradeoff) methods for accomplishing the MR's (FEIS, Chapter II "Management Requirements," and Appendix J). In response to comments on the DEIS, the Forest has re-analyzed the timber harvest dispersion constraints when developing the FEIS Preferred Alternative S These constraints have been refined in this alternative to accomplish dispersion objectives with less opportunity cost to ASQ (FEIS, Chapter II " Alternatives Considered in Detail").

55. *COMMENT*: FURTHER STUDY AND DOCUMENTATION ARE NEEDED OF THE IMPACT OF REDUCED ASQ ON LOCAL/REGIONAL MILLS AND INVESTMENTS.

Response: The effects of changes in ASQ by alternative were analyzed for the four-county region which consumes nearly all timber produced by the Siskiyou National Forest (Jackson, Josephine, Curry, and Coos counties) The effects on aggregate supply and demand among all ownerships were used for the comparison of alternatives for this topic (FEIS, Chapter IV, "Economic and Social"). This analysis was updated using the latest data between the Draft and Final EIS

Salvage

56. *COMMENT*. FIRE-KILLED TIMBER SHOULD BE REMOVED AS SOON AS POSSIBLE TO AVOID GREATER DAMAGE

Response: For the 1987 fires, this issue has been decided in decisions for the Silver Fire Recovery Project (FEIS, 1988), and several Environmental Assessments for the Longwood and Galice fires. For future fires, a site-specific analysis will be completed which will consider the removal of fire-killed timber in accordance with the Forest's Standards and Guidelines.

57. *COMMENT* PRESERVATION OF STANDING TIMBER IN BURNED AREAS MUST BE CONSIDERED TO BE EQUAL TO THE PRESERVATION OF THE OLD-GROWTH AREAS.

Response: Salvage will occur only in a portion of the areas burned in the 1987 fires Most live trees will not be cut, significant areas of dead trees will be left standing. See the Silver Fire Recovery Project FEIS and Record of Decision for more detail

58. *COMMENT*: WITH THE "BLACK FOR GREEN," I'M CONCERNED ABOUT THE USES OF THE GREEN FURTHER DOWN THE ROAD, IF IT WILL JUST BE POSTPONED CUT OR COMPLETELY TAKEN OUT OF THE TIMBER YIELD OF THE FUTURE.

Response: The amount of green timber to be sold is one of the major decisions of the Forest Plan. Some green timber is postponed and others are taken out of the timber base as identified in the FEIS

59. *COMMENT*. SALVAGE LOGGING COULD OCCUR IN DESIGNATED WILDLIFE HABITAT UNDER THE EXCEPTIONS LISTED UNDER TIMBER MANAGEMENT (MA8-7) HOW WILL THIS BE REGULATED, IF A SMALL PERCENTAGE OF THE STAND ACTUALLY BLOWS DOWN?

Response: The direction has been rewritten to tighten restrictions on salvage logging in these areas (LRMP, Chapter IV, "Management Prescriptions"). It would seldom, if ever, occur.

Silvicultural Methods

60. *COMMENT*: THE BASE PERIOD USED TO ESTABLISH TIMBER VALUES OVERESTIMATES VALUES BECAUSE IT INCLUDES THE INFLATIONARY OVERBIDDING OF THE LATE 1970'S.

Response The base period of 1973-1982 was used to establish timber values It includes both high and low stumpage values, typical of timber economic cycles

61. *COMMENT*· REQUIRE RECOVERY AND RESTOCKING OF A HARVESTED AREA BEFORE HARVEST IN ADJACENT STAND IS PERMITTED.

Response· The Forest-wide Standards and Guidelines (LRMP, Chapter IV) require that a harvested stand shall be considered a created opening until reforestation meets these criteria· Crop trees are well distributed and meet acceptable stocking levels; Crop trees average at least 4-1/2 feet tall and are free to grow.

It is permissible to harvest timber stands adjacent to a created opening. However the total size of the combined harvest areas is limited to a maximum of 60 acres, with exceptions for catastrophic events and certain specified circumstances (LRMP, Chapter IV, "Timber Management").

62 *COMMENT*. EMPHASIZE NATURAL RESISTANCE TO PATHOGENS AND FIRE IN REFORESTATION PRACTICES.

Response: Forest Standards and Guidelines require that silvicultural treatments should reduce susceptibility to insect and disease damage (LRMP, Chapter IV, "Fire and Pest Management"). Where natural resistance mechanisms are identified, they would be incorporated into reforestation and stand management prescriptions (e g., blister rust resistance mechanisms in sugar pine are selected for in seed collection, and resistant seedlings are planted on hazardous sites.) Where genetic ("natural") diversity mechanisms are not known or effective, control of age class distribution, stocking levels, and species mix can best minimize both the risk and hazard of losses to pathogens. One pathogen of particular concern is Phytophthora root disease of Port-Orford-cedar. No natural resistance has yet been identified Measures have been identified to reduce the risk of introducing the disease in reforestation activities, including: emphasis on natural regeneration in uninfected areas, exclusive use of disease-free Port-Orford-cedar planting stock, and control of planting operations to minimize the risk of introducing disease spores to uninfected stands ("Port-Orford-Cedar Control Strategies", POC Consensus Group, 1988)

Forest Standards and Guidelines also require that fire hazard be managed and reduced to appropriate levels, considering all resource values (LRMP, Chapter IV, "Fire and Pest Management"). Treatment of fuels prior to reforestation is a principal means of reducing hazard for the future stand Factors that influence fire risk and hazard which are considered in prescribing stand management activities include: spatial and temporal arrangement of treatment areas, and treatment methods and specifications. Although there is variability in fire resistance among species used in reforestation on the Siskiyou National Forest, the overall adaptation of a species to site-specific conditions and resource objectives are the principal criteria by which species are prescribed for reforestation.

63. *COMMENT*. USE A VARIETY OF ROTATION AGES, INCLUDING LONGER ROTATIONS, TO PROVIDE MORE MULTIPLE USE BENEFITS AND/OR GREATER TIMBER QUALITY.

Response· A variety of rotation ages, including longer rotations, were considered and analyzed in the development of both alternatives and Management Area Standards and Guidelines.

Most Alternatives that were considered in detail analyzed environmental and economic effects using rotations that approximated CMAI (average 100 years). Alternatives D-1 and K-1 analyzed the effects of shorter rotations (average 80 years). Alternative M analyzed the effects of longer rotations (average 250 years). Reference FEIS, Chapter II, "Alternative Descriptions "

In the General Forest Management Area, the minimum stand ages for final harvest range from 80 to 140 years, depending on site quality and management intensity. These rotations are presented as minimums, and longer rotations may occur on a site-specific basis to better meet multiple resource objectives and scheduling constraints. Three Management Areas have Standards and Guidelines which include longer rotations for multiple resource benefits (LRMP, Chapter IV)

64. *COMMENT.* SUBSTANTIALLY INCREASE THE MONEY FOR RESOURCE ELEMENT TIMBER E5 (ADEQUATE REFORESTATION)

Response. The reforestation budget is a function of the amount of acres harvested. The Siskiyou National Forest has reforested areas harvested in the past and will continue to reforest future areas The funding level is adequate to achieve reforestation.

65. *COMMENT·* GENETICS, USE OF HERBICIDES, THINNING, AND FERTILIZATION SHOULD BE USED INTENSIVELY TO INCREASE GROWTH.

Response: Timber harvest outputs disclosed in the FEIS are based on the assumption that all silvicultural techniques are available to be used. Chapter IV of the LRMP discusses the timber management practices that may apply on all lands selected for timber production Commercial thinnings, fertilization, release, and use of genetically improved seedlings are examples of some of the management practices that are recommended in the FEIS However, before any cultural activities are undertaken, site-specific environmental analyses and/or silvicultural prescriptions will be prepared. In the case of herbicides, the site-specific environmental analyses will be tiered to the 1988 Regional vegetation management FEIS ("Managing Completing and Unwanted Vegetation").

66 *COMMENT·* RESEARCH IN FOREST ENTOMOLOGY BY TIM SCHOWALTER, OREGON STATE UNIVERSITY, INDICATES THAT CONVERSION OF OLD-GROWTH FORESTS TO EVEN-AGED SINGLE SPECIES STANDS INCREASES THE PROSPECTS OF SERIOUS DISEASE AND INSECT INFESTATION

Response: The Siskiyou National Forest does not manage for single species stands The choice of even- or uneven-aged management (both systems have been used on the Forest) is dependent on site potential and stand conditions. Possible insect infestation is considered in resource prescriptions.

Waring indicates that carbohydrate reserve is one of the most important factors affecting the tree's ability to resist insect attacks The even-aged stands of lodgepole pine on the east side of the Cascade Range were much more resistant to western pine beetle when fire regularly thinned the stands, keeping the survivors with a high carbohydrate reserve. On the Siskiyou, we plan to produce healthy stands through stocking level control and providing for a diversity of species.

67. *COMMENT* PLANT MORE TREES

Response: The Siskiyou National Forest's objective for reforestation is to promptly reforest all nonstocked lands which are suitable for timber management to acceptable stocking levels. In addition, certain nonstocked lands unavailable for timber production may be reforested to produce other resource benefits. The silviculturist prescribes the number of seedlings to be planted based on site productivity and anticipated seedling survival. The success in meeting reforestation objectives is monitored through periodic plantation surveys until the plantation can be certified as established and free to grow. Summaries of historic reforestation success displayed in the FEIS Chapter III indicate that current reforestation

practices meet our stocking and timeliness objectives with a very high degree of success. There is no apparent benefit to be derived from planting more trees at additional cost.

68 *COMMENT*. LEAVE ADDITIONAL TREES AND RELY MORE ON NATURAL REGENERATION.

Response: Forest-wide Standards and Guidelines require the consideration of natural regeneration potential in silvicultural prescriptions (LRMP, Chapter IV, "Timber Management"). The Siskiyou National Forest is currently studying correlations between plant associations and observed natural regeneration over time. The objective of this study is to better predict sites where natural regeneration could be expected to supplement planted stock or completely reforest a site. With reliable predictive tools available, the silviculturist must then weigh the cost savings of natural reforestation against the risks of costly site reclamation in cases of failure in prescribing for natural regeneration. Long-term costs/limitations of natural regeneration include a reduction in potential yield as compared to genetically-selected stock and, ironically, a potential reduction in genetic diversity due to the high degree of interrelatedness among potential seed trees in a single stand ("Natural Regeneration--Genetic and Seed Aspects," Friedman, Sharon T., USDA-Forest Service, Region Six Tree Improvement Paper #64, 1985).

Where natural regeneration is planned as part of a silvicultural prescription for reforestation, both seed source and site conditions would be considered. If site conditions are unfavorable for prompt natural regeneration, or if tree vigor and seed production is low, leaving additional seed trees would have little effect. Under favorable site and stand conditions, relatively few trees (3 to 10 per acre) are required to produce abundant seed In certain circumstances, more trees would be left to ameliorate harsh site conditions (heat, moisture stress, frost) for seedling establishment (shelterwood harvest).

69 *COMMENT*. REDUCE DEPENDENCE ON NURSERY STOCK FOR REFORESTATION DUE TO THE POTENTIAL REDUCTION OF GENETIC DIVERSITY

Response: Forest-wide Standards and Guidelines require the consideration of natural regeneration potential in silvicultural prescriptions (LRMP, Chapter IV, "Timber Management"). The Siskiyou National Forest is currently studying correlations between plant associations and observed natural regeneration over time. The objective of this study is to better predict where natural regeneration could be expected to supplement planted stock or completely reforest a site.

However, increased reliance on natural regeneration may actually result in a reduction in genetic diversity on a particular site. Studies have found a high degree of interrelatedness among the dominant, seed-producing trees within a small area such as a single stand. When a stand is opened up for regeneration, these trees are most likely to be left and the degree of self- and cross-pollination among related individuals would be relatively high. ("Natural Regeneration--Genetic and Seed Aspects," Friedman, Sharon T., USDA-Forest Service, Region Six Tree Improvement Paper #64, 1985.)

Guidelines for seed collection for artificial reforestation include provisions to maintain genetic diversity in nursery stock. Each seedlot groups collected seed from individual parent trees that are broadly distributed over a specified geographic area and elevation band. A minimum number of parents is required for grouping into a seedlot, and distribution requirements ensure that relatedness among parent trees is minimized (Siskiyou National Forest Ten-Year Tree Improvement Plan; Tibbs, T , Brady, G., and Vagle, N ; Rev. 1988)

70. *COMMENT* ROTATIONS AND FOREST MANAGEMENT PRACTICES SHOULD BE DEVELOPED AND USED TO MAINTAIN/REPLACE OLD-GROWTH FORESTS ON AT LEAST SOME HARVESTED LANDS

Response: Silvicultural systems and rotations have been planned for two Management Areas which will provide some degree of old-growth character. For the Retention Visual Management Area, objectives include maintenance of natural landscape character with a large tree component, and minimizing perceived openings over time Techniques are recommended to produce trees in the range of 36 inches DBH prior to final harvest The scheduling constraints for the Retention viewsheds are anticipated to result in rotation lengths of up to 250 years (LRMP, Chapter IV, Management Area 12).

For the Riparian Management Area, objectives for maintaining canopy cover and large conifer habitats will encourage the development of multi-layered stands with an old-growth component. For Class I and II streams (larger streams and rivers), at least 70-80 percent of the preexisting conifer basal area should be maintained after harvest operations. Entries should not occur more frequently than at 20-year intervals (LRMP, Chapter IV, Management Area 11).

The Forest Plan recognizes that old-growth wildlife habitat areas set aside in this Plan will not provide suitable habitat indefinitely The forest is a dynamic, rather than static, ecosystem. Conversely, change on a forest-wide basis is generally slow. It will be many decades before most of the existing old-growth stands naturally recycle to early successional stages Designated habitat areas will still be old growth well after this planning cycle has ended The Forest Service will evaluate the opportunities to substitute habitat areas in the next round of planning, and examine methods for providing future old-growth wildlife habitat (LRMP, Chapter IV, Designated Wildlife Habitat) Research in progress throughout the Pacific Northwest should help us make informed decisions when the Plan is next revised.

71 *COMMENT*. ELIMINATE USE OF CLEARCUTTING AS A REGENERATION SYSTEM

Response: The selection of a silvicultural system is guided by law and by selection criteria outlined in the Regional Guide for the Pacific Northwest Region (May, 1984). Clearcutting will be used only where determined to be the optimum method to meet the requirements and objectives of the Forest Plan (NFMA, P L. 94-588). The selection of a silvicultural system will evaluate site and stand conditions and management objectives on a site-specific basis; however there are combinations of conditions and objectives frequently encountered on the Siskiyou National Forest for which clearcutting is the optimum system These factors are discussed in detail in FEIS, Appendix G.

72. *COMMENT*: SHORTEN ROTATION OF EXISTING IMMATURE STANDS TO INCREASE SUSTAINED YIELD AND/OR FILL IN THE DEFICIT IN THE TIMBER INVENTORY.

Response: The Forest Service is directed by NFMA to schedule final harvest based on the culmination of net stand growth Policy interpretation of this law establishes the minimum rotation length for Forest Plan prescriptions at 95 percent of CMAI (FEIS, Appendix B, "Development of Management Requirements"). Alternatives with exceptions to this requirement, such as shorter rotations, may be developed to respond to particular issues or concerns (FEIS, Chapter II, "Alternatives Considered, but Eliminated from Detailed Study"). However, such an alternative must demonstrate clear multiple resource benefits (maximize net public benefits) in order to be selected and excepted from law and policy requirements.

Alternative D1 was developed with shorter rotations for all immature and managed stands. It provides another way to provide a higher level of timber outputs while projecting a nondeclining yield schedule; however, it may not meet the requirements of NFMA. Additional alternatives or variations of alternatives were considered, but eliminated from detailed study

73. *COMMENT*: DISCUSS THE COMPARATIVE EFFECTS ON ECOSYSTEMS OF THE VARIOUS REGENERATION SYSTEMS THAT WERE CONSIDERED.

Response: The effects on ecosystem components of the regeneration systems that were considered are compared in FEIS, Appendix G, "Comparison of Systems."

74. *COMMENT*: REFORESTATION SUCCESS NEEDS TO BE SUBSTANTIATED, IMPROVED, AND MONITORED.

Response: Many public comments and concerns about the success of the Siskiyou's reforestation program were received. In response, Forest personnel have reviewed and validated the reforestation records in the Total Resource Information (TRI) data base. These data have been summarized and discussed in FEIS, Chapter III, "Vegetation." They indicate a high rate of success for current reforestation practices on the Siskiyou National Forest. Additional support data for this analysis are available in the Planning Records ("Reforestation Status Report," 11/14/88)

Reforestation success will continue to be monitored in individual plantations according to prescribed exam schedules and procedures In addition, reforestation data will be summarized and monitored on a Forest-wide basis to measure attainment of Forest Plan objectives for prompt establishment and for stocking levels (LRMP, Chapter V, Table V-1, "Monitoring and Evaluation Program," and Appendix D, "Monitoring and Evaluation Program Background").

75. *COMMENT*: THE FOREST SERVICE SHOULD BE LOOKING AT OTHER HARVEST AND SILVICULTURE METHODS THAT DO NOT INVOLVE PRESCRIBED BURNING, OR SHOULD UTILIZE ALTERNATIVE SLASH TREATMENT METHODS, SUCH AS CHIPPING.

Response: The selection of a fuel treatment method is based on an interdisciplinary site-specific analysis which considers the site specific and adjacent resource needs as well as the cost of treatment (LRMP, Chapter IV, "Forest-wide Standards and Guidelines").

Chipping is a fuel treatment method that has been utilized to a limited degree on the Siskiyou National Forest Limited access, steep topography, heavy fuel loadings, and labor costs limit the effectiveness of this particular treatment.

76. *COMMENT*: THERE IS A HIGHLY SUCCESSFUL ALL-SPECIES FOREST ECOSYSTEM MANAGEMENT PROGRAM BEING PRACTICED BY SMALL WOODLAND OWNERS WHICH DOES ADDRESS ALL THE MAJOR ECONOMIC AND ENVIRONMENTAL ISSUES FROM A SUSTAINABLE POINT OF VIEW. IT IS KNOWN AS "NATURAL SELECTION FORESTRY" AND IS BASED ON THE BOOK, *THE FOREST FARMERS HANDBOOK* YOU SHOULD OPEN THE DOOR FOR AN ALL-SPECIES NATURAL SELECTION FOREST ECOSYSTEM MANAGEMENT CONCEPT.

Response: See the FEIS, Appendix G, "Selection of Silvicultural Systems," for an extensive discussion on silvicultural systems, Forest conditions, management goals and objectives, comparison of systems, and directions and guidelines for the choice of appropriate silvicultural systems.

Harvest Methods

77 *COMMENT*. ABSOLUTE RESTRICTIONS ON USE OF PARTICULAR LOGGING SYSTEMS (HORSE ONLY, OR NO HEAVY MACHINERY/CHAINSAWS) LOG FIRE SALVAGE WITH BALLOONS OR HELICOPTERS

Response: The selection of particular logging systems is not within the scope of the Forest Plan. It is a site-specific decision made in conjunction with area transportation planning and unit design needs at the project-level. No system is excluded from consideration on a Forest-wide basis. Rather, analysis of site and stand conditions and resource management objectives will guide the selection for each proposed harvest unit.

78. *COMMENT*: DEVELOP A COMPREHENSIVE LOGGING PLAN

Response: Logging systems planning will be accomplished at the project level. The selection of the most appropriate system is a site-specific decision within the context of the most cost-effective and environmentally sound area transportation plan. Logging systems planning does not affect the land allocation or resource output processes at the Forest planning level. Rather, the selection of a system will be guided by the Management Area prescriptions and Standards and Guidelines established in the Forest Plan

79. *COMMENT*· INDIVIDUALS WERE CONCERNED ABOUT THE EFFECT OF TIMBER HARVESTING ON LONG-TERM SOIL PRODUCTIVITY AND THE POTENTIAL FOR AN IRRETRIEVABLE LOSS OF SURFACE SOIL RESULTING FROM EROSION. SPECIFICALLY ONE WRITER COMMENTS THAT, "IF ONE GOES TO SHORTER ROTATIONS, WHAT WOULD BE THE EFFECT ON THE SOIL AND WATER RESOURCES?"

Response: The effect of 80- to 120-year rotations on long-term site productivity and water quality and quantity is somewhat uncertain at this time Research does not have definitive answers regarding long-term soil biology and nutrient levels There is, however, considerable research on long-term site productivity being initiated (LRMP, Chapter II, "Research and Information Needs") Basic mitigation measures such as streamside protection areas, retention of large woody material and wildlife reserve trees, site preparation and fuels treatments under high moisture conditions, and proper location of roads and harvest units will help to maintain site productivity and water quality and quantity (LRMP, Chapter IV, "Forest-wide Standards and Guidelines"). Under high soil and fuel moisture conditions of spring, a small percentage of the duff and litter is consumed in the burn.

Please note, though, that measurable changes in water quality and quantity are far more correlated with the degree of treatment, or "how much" and specifically "where" than with rotation length itself. If shortening rotation causes acres of harvest and associated roading within a basin or subwatershed to change by decade, then the effects are quantifiable (See Alternatives D1 and M in Chapter IV, FEIS, under Soil and Water, and Fish sections).

Soil (and site) productivity monitoring is currently evolving in the research community Monitoring of site productivity will focus on biochemical and physical values of large woody material as described in the "Monitoring and Evaluation Program," (LRMP, Chapter V). Monitoring and evaluation of soil conditions will take advantage of the close ties that have been developed with the research communities of Oregon State University and the Pacific Northwest Experiment Station Monitoring and updating of projects will be as specific and as current as the scientific community's research

80. *COMMENT* LIMIT THE SIZE AND/OR EXTENT OF CLEARCUTS

Response: The size of clearcuts is limited by management direction for opening size from the Regional Guide for the Pacific Northwest Region (1984) Sixty acres is the general maximum limit without public notice and Regional Forester review. Up to 90 acres may be permissible, but only in certain specified circumstances Natural catastrophic events are also excepted All other exceptions would require 60-day

public notice and Regional Forester review (LRMP, Chapter IV, "Forest-Wide Standards and Guidelines--Timber Management") While these are maximum sizes, the average clearcut size has been and is anticipated to continue to be much smaller Additional restrictions on clearcut size are imposed for Management Areas other than General Forest Specifics of harvest unit size and shape would be determined in project-level environmental analysis Regeneration potential, vegetation patterns, affected resource values, and logging systems are key considerations in unit design

The extent of clearcuts is limited by four Forest-wide Standards and Guidelines (LRMP, Chapter IV, "Forest-wide Standards and Guidelines--Timber Management"). The extent of clearcut harvest is also constrained on a watershed basis to avoid adverse cumulative watershed effects. If more than 20 percent of a Watershed Analysis Area is proposed for harvest in one decade, a cumulative effects analysis is required to demonstrate that watershed conditions will not be impaired.

81. *COMMENT*: IN OVERLY-STEEPENED TERRAIN, USE OF LOW INTENSIVE FOREST MANAGEMENT WHICH MAXIMIZES THE USE OF NATURAL REGENERATION, SHELTERWOODS OR SMALL PATCH CLEARCUTS, EXTENDED ROTATIONS AND AERIAL YARDING SYSTEMS OFFER OPPORTUNITIES FOR COMPROMISE.

Response· Alternative S, as developed in the FEIS, includes areas specifically identified for this type of management These are the Extensive Management overlay in the General Forest Management Area.

82. *COMMENT*. FURTHER FUNDING IS NEEDED TO RESEARCH MODERNIZATION OF LOGGING METHODS WHICH MINIMIZE ROADBUILDING.

Response: Current logging technology with large skyline yarders and helicopters provides yarding capabilities in excess of one mile Basic research into logging technology is beyond the scope of the FEIS Private industry and other government agencies have responsibilities in this area

On project-level analyses, which will be tiered to the FEIS (Chapter I, "Introduction to the Forest Plan"), the goal of site-specific logging and transportation planning is to minimize the road density and associated impacts while meeting the timber management objectives in a cost effective manner.

83. *COMMENT*· RECONSIDER THE MASSIVE CLEARCUTTING PROPOSED IN FAVOR OF SHELTERWOOD OR SELECTIVE CUTTING METHODS.

Response. The Forest Service will consider silvicultural methods on all harvest areas to include clearcut, shelterwood, and selective cutting on a site-specific basis (FEIS, Appendix G).

84. *COMMENT*· PRIORITIZE TIMBER STANDS FOR HARVEST ACCORDING TO NET GROWTH RATES (HARVEST STANDS WITH LOWEST NET GROWTH FIRST)

Response: This proposal is not within the scope of decisions made at the Forest Plan level. The prioritizing of stands for harvest will occur in the environmental analysis at the project level as specific proposals and alternatives for timber sales are developed Priorities will be based on site-specific information including the health, vigor, and growth rates of the stands, both timber production and resource objectives will be considered

85 *COMMENT*: CONSIDER/ANALYZE/ADOPT UNEVEN-AGED MANAGEMENT SYSTEM(S) (INCLUDES "NATURAL SELECTION FORESTRY," "RESPECTFUL FORESTRY").

Response: Uneven-aged silvicultural systems would be used on a site-specific basis in all alternatives analyzed in detail. Appendix G in the FEIS discusses the analysis process that was used for recommending appropriate silvicultural systems. The other systems proposed in these comments ("Natural Selection Forestry," "Respectful Forestry") appear to be single-tree selection system variants with specific criteria to identify trees for removal. The key elements of the analysis of single-tree selection systems are applicable.

The Regional Guide for the Pacific Northwest Region (1984) provides the basic criteria for selection of appropriate silvicultural systems, based on applicable laws and policy direction. The final selection of harvest method for any specific site will be part of the silvicultural prescription in concert with the project environmental analysis (FEIS, Appendix G, "Direction and Guidelines"). Appendix G provides suggested applications of the various silvicultural systems. These recommendations are based on comparison of the capability of various systems to meet the Regional Guide criteria, evaluating the interaction of management objectives, site conditions, and stand structure Single-tree selection was identified as an appropriate system for five of the 15 different combinations of Management Area, site, and stand conditions displayed in FEIS Appendix G, Figure G-1, "Silvicultural Systems Analysis."

86. *COMMENT*: DO NOT HARVEST AREAS THAT WOULD REQUIRE ECONOMICALLY INEFFICIENT REFORESTATION AND STAND MANAGEMENT PRACTICES.

Response. The economic efficiency of individual stand management practices is only one factor that is considered in optimizing net public benefits for the entire Siskiyou National Forest. Forest planning analyzes the overall costs and benefits of management activities, including harvest and reforestation, on a Forest-wide basis The FORPLAN model calculates the most cost-effective combination of prescriptions and schedules for the entire forest within the management objectives and land allocations of each alternative (FEIS, Chapter II, "Description of the Analysis Process"). These calculations consider not only the PNV of a timber management prescription for a particular analysis area, but also the scheduling and allocation interactions with all other analysis areas. Acres that do not contribute positively to PNV within an alternative are identified as economically unsuitable. Few acres on the Siskiyou fall in this category in any of the alternatives.

87. *COMMENT*: PROTECT/INCREASE USE OF BUFFER STRIPS TO PROTECT VARIOUS ENVIRONMENTAL/SCENIC VALUES.

Response· The Forest Plan land allocation process guides harvest practices through Management Area Goals, Standards and Guidelines "Buffer strips" where timber harvest is either restricted or prohibited to protect adjacent resource values are suggested or required in the following Management Areas:

Management Area 7 (Supplemental Resource)
Management Area 9 (Special Wildlife Site)
Management Area 10 (Scenic/Recreation River)
Management Area 11 (Riparian)
Management Area 12 (Retention Visual)
Management Area 13 (Partial Retention Visual)

Refer to LRMP, Chapter IV for explanation of each Management Area Alternatives consider a wide range of land allocations to these Management Areas (FEIS, Chapter II, Table II-2: "Acreage in Management Areas").

88. *COMMENT* SUBSTITUTE HELICOPTER (AND SKYLINE) SYSTEMS ON ENVIRONMENTALLY SENSITIVE OR ROADLESS AREAS, ALSO, DECREASE OR ELIMINATE CUTTING IN ENVIRONMENTALLY SENSITIVE AREAS.

Response: In general, the selection of particular logging systems is not determined by the Forest Plan level analysis. Logging system selection will be a site-specific decision made through project level environmental analysis No system is excluded from consideration on a forest-wide basis. The Forest Plan provides resource objectives and Standards and Guidelines which should be met on a site-specific basis by the selected logging system

Alternative S, which was developed between the Draft and Final EIS based on public comments, identifies some areas for "Extensive Management" where intensive forestry practices would not be applied. The areas identified tend to be more environmentally sensitive and development would require higher than average costs, both economically and environmentally. The assignment to Extensive Management is intended to allow these areas to be managed less intensively with less road construction and more helicopter or long-span skyline logging.

89. *COMMENT*· CLARIFY WHETHER 115-YEAR, LOW SITE MATURE TIMBER (NO TIMING CHOICE) IS ALLOWED FOR HARVEST.

Response: For analysis purposes, this model class was combined with the 190 year-old Low Site model class which has similar volume and growth It is allowed for harvest with timing choices beginning in the first decade.

90. *COMMENT*: ALLOW MORE THINNING CHOICES IN THE GENERAL FOREST COMPONENT.

Response: In developing the Managed Yield Tables for the Siskiyou National Forest (Craig, 1984), DP-DFSIM was used to search a multitude of possible thinning regimes for rotation ages ranging from 55 to 175 years. The overall objective was to find the combination(s) of thinning regimes and final harvest that would maximize forest-wide yield while complying with law and policy direction. Because the Siskiyou is a deficit inventory forest, a balance of relatively short rotation lengths and higher early commercial thinning volume would best fill future gaps in available inventory. Thinning and rotation regimes were studied and optimized through DFSIM projections; these regimes were used in Forest Plan analysis. Other thinning choices were studied, but did not meet the stated goal of maximizing overall forest timber yield. They were not included in further Forest Plan analyses. For more detailed discussion of this topic, reference *Managed Yield Tables for the Siskiyou National Forest*, "Analysis of Thinning Regimes" (Craig 1984).

91. *COMMENT*: HARVEST ONLY MANAGED STANDS; FOREGO HARVEST UNTIL MANAGED PLANTATIONS ARE COMMERCIAL SIZE.

Response: This proposal was not developed into an alternative to be considered in detail. The outputs and effects associated with this proposal would be intermediate between those of Alternative M and the Minimum Level Benchmark. The Minimum Level Benchmark does not satisfy many of the issues and concerns, particularly those related to developed recreation use, dispersed motorized recreation use, and timber supply. Alternative M proposes no new road development, and provides for the least harvest of unlogged stands in roaded areas. It does, however, satisfy several other Planning Problems to some extent. Accessible, unharvested stands would be managed for old-growth character on extended rotations, although they would eventually be harvested in the General Forest Management Area. This proposal would further restrict areas available for harvest to those with previous harvest activity; the use of optimum (shorter) rotations on those areas is implied A brief comparison indicates that the proposal

provides no better resolution of any Planning Problem than Alternative M. Moreover, it would provide substantially less resolution of the timber production Planning Problem in the short term than Alternative M.

92. *COMMENT*: CONCERN CENTERS ON HEAVY HARVESTING WITHIN A WATERSHED OVER A SHORT TIME PERIOD. "DISTRIBUTE HARVEST OVER SPACE AND TIME" WITHIN A WATERSHED OR RIVER BASIN.

Response: Distribution of harvest is modeled by applying harvest dispersion constraints in the FORPLAN model (See FEIS Appendix B). Harvest constraints vary by alternative and among the 18 Planning Basins according to risks from soil erosion, sensitivity of the watershed, past activities, past natural events, and projected activities on all ownerships.

Reforestation

93. *COMMENT*. BETTER REFORESTATION INFORMATION IS NEEDED TO CONFIRM ALLOWABLE SALE QUANTITY, INCLUDING: GROWTH AND YIELD, AND PROJECTIONS OF LOSS FROM WILDLIFE, STRESS, OR POOR NURSERY STOCK.

    SINCE THE REFORESTATION PROGRAM IS THE FOUNDATION OF THE PROPOSED ACTION AND CONTAINS MANY DATA GAPS, A WORST-CASE ANALYSIS SHOULD BE ACCOMPLISHED BEFORE PROCEEDING.

Response: Reforestation surveys and evaluation are an ongoing process on the Forest. The Reforestation Handbook (2409.26bR6) requires that all plantations receive surveys in the first, third and fifth year after reforestation. These surveys show that the Forest has a highly successful reforestation program and has achieved better than 98 percent satisfactorily stocked acres of all acres of regeneration harvest (FEIS, Chapter III, "Vegetation", and in "Reforestation Status Report," 11/14/88, Planning Records). In regard to future timber yields, monitoring reforestation success will continue (LRMP, Chapter V, and Appendix D) and a young stand inventory will be contracted in 1989.

Council on Environmental Quality (CEQ) regulations contained in Title 40 CFR, Section 1502 22(b), require a worst-case analysis to evaluate environmental risk. CEQ requires a worst-case analysis if information relevant to a reasoned choice among alternatives is not known and the cost of obtaining it is exorbitant. CEQ also requires a worst-case analysis if information relevant to adverse impacts is important to the decision and the means of obtaining it are unknown since reforestation information is both known and obtainable, as noted in the previous paragraph, a worst-case analysis is not required.

94. *COMMENT*. WILL IT MAKE SENSE TO INCUR A COST TO PLANT TREES ON THE SISKIYOU AS A FINANCIAL ENDEAVOR? WHERE IN THE FOREST DOES IT MAKE SENSE TO INVEST IN TREE GROWING? HOW INTENSIVE SHOULD INVESTMENTS IN TREE GROWING BE? ARE INTENSIVE MANAGEMENT PRACTICES ECONOMICALLY JUSTIFIABLE GIVEN THAT FAIRLY RAPID GROWTH IS ONE OF THE PRECONDITIONS? WHO WILL HAVE THE RESPONSIBILITY FOR FINANCING THE REFORESTATION? WILL MASSIVE SUBSIDIES BE REQUIRED FOR INTENSIVE MANAGEMENT PRACTICES ON SECOND GROWTH FORESTS? THESE QUESTIONS ON THE NEED FOR REFORESTATION ANALYSIS REQUIRE ANSWERS BEFORE THE SISKIYOU SELECTS ITS PROPOSED ACTION OR A SIMILAR ALTERNATIVE

Response: Reforestation costs are included in the calculation of present net value for the timber management levels associated with each alternative. Discounted benefits from timber management activities exceed discounted costs, and present net value is positive for all alternatives. See the FEIS, Chapter III, "Economic Efficiency Analysis of Alternatives," and appendix B, "Development of Timber Harvest Option Intensities" and "Determination of Economic Values" for a more detailed discussion.

A portion of the value received for timber harvested is collected to finance reforestation and brush disposal requirements. Other second-growth management activities are paid with appropriated funds.

95. *COMMENT*: THERE SEEMS TO BE GENERAL AGREEMENT THAT TREES GROW RATHER SLOWLY IN SOUTHERN OREGON WHILE OTHER REGIONS IN THE NORTHWEST, SOUTH AND OTHER COUNTRIES HAVE MORE FAVORABLE BIOLOGICAL GROWING CONDITIONS. WITH THESE FACTS IN MIND, THE QUESTION IS CAN THE SISKIYOU COMPETE ECONOMICALLY WITH THESE FASTER GROWING PLANTATIONS?

Response. See the LRMP, Chapter IV, "Management Area 14 - General Forest," for a discussion of rotation ages for different growing sites and management intensities. Since the Forest contains timber stands of various condition classes (FEIS, Table III-18), it is the demand/supply relationship that determines the economic viability of timber production and not necessarily growth rate. For a discussion of timber supply and demand, see the FEIS, Chapter III, "Economic and Social," "Current Demands, Wants, and Desires."

FOREST DIVERSITY

Biological Diversity

96. *COMMENT*. PUBLIC FOREST MANAGEMENT PRESCRIPTIONS FOR HARVEST ARE BEING WRITTEN FOR THE ELIMINATION OF OLD GROWTH IN FAVOR OF YOUNG TREE FARMS. PREFERRED ALTERNATIVE K WOULD, TO A LARGE EXTENT, CARRY OUT SUCH A PRESCRIPTION. THIS IS A VIOLATION OF THE NFMA, WHICH STATES. "MANAGEMENT PRESCRIPTIONS, WHERE APPROPRIATE AND TO THE EXTENT PRACTICABLE, SHALL PRESERVE AND ENHANCE THE DIVERSITY OF PLANT AND ANIMAL COMMUNITIES, INCLUDING ENDEMIC AND DESIRABLE NATURALIZED PLANT AND ANIMAL SPECIES SO THAT IT IS AT LEAST AS GREAT AS THAT WHICH WOULD BE EXPECTED IN A NATURAL FOREST IN THE DIVERSITY OF TREE SPECIES SIMILAR TO THAT EXISTING IN THE PLANNING AREA THE PREFERRED ALTERNATIVE CLEARLY WOULD RESULT IN A LOSS OF FOREST DIVERSITY.

Response: Although the Plan calls for a reduction of "old growth" in the general forest category, old growth is not being eliminated from the Forest landscape. Old-growth stands and extensive areas of old growth are being retained in a carefully planned distribution across the Forest, including land suitable for managing timber products.

Both NFMA and the implementing regulations call for maintaining diversity under a multiple-use Forest Plan. The area of consideration is on a Forest scale Diversity is being planned for by land allocations and active management, and is addressed in the Standards and Guidelines. All activities will be monitored and results of management evaluated for their effects on diversity.

97. *COMMENT*. CLAIMS IN THE DRAFT DOCUMENTS THAT BIOLOGICAL DIVERSITY ON THE FOREST WILL BE ENHANCED THROUGH THE PREFERRED ALTERNATIVE OR THROUGH VARIOUS DEVELOPMENT PRACTICES ARE MISLEADING AND NOT BASED ON A BIOLOGICALLY VALID OR REGIONALLY APPLICABLE DEFINITION OF DIVERSITY TO IMPLY THAT TIMBER

HARVEST AND OTHER HABITAT ALTERING MANAGEMENT ACTIVITIES INCREASE DIVERSITY FAILS TO TAKE INTO ACCOUNT THE SPECIES AND HABITAT THAT ARE RARE AND AT RISK.

Response· Species diversity is higher when there is a variety of seral stages across the landscape than it would be if all forest lands were either in pioneer or climax stage. The optimum mix depends on which type of species are valued. The public value all types of species for a variety of purposes and are keenly interested in maintaining viable populations of rare species. Some rare species require frequent disturbance while others depend on stability.

The strategy of the Forest Service is to provide a variety of habitat by both allocation of lands to categories where management is minimized (for species that require stability) and by Standards and Guidelines maintaining diversity on lands that are managed for timber. All lands will be monitored to determine the trends in diversity and the condition of rare species (see Chapter V and Appendix D of the LRMP).

98. *COMMENT*· COMPARE THE LARGE AREAS OF ORIGINAL FOREST ON THE SISKIYOU WITH SIMILAR AREA ON OTHER FORESTS IN OREGON AND WASHINGTON, IN ORDER TO ASSESS THEIR SIGNIFICANCE FOR REGION-WIDE DIVERSITY.

Response: It is beyond the scope of this document to compare large areas of original forest on the Siskiyou with similar areas elsewhere. However, on a more local level, the Siskiyou National Forest is linked to the Klamath, Six Rivers, and Rogue River National Forests, and two BLM Districts. Area-wide diversity is fostered by the spotted owl habitat areas on all National Forests and BLM lands which link or mesh together. This provides for species continuity between forests in southern Oregon and northern California. In addition, Wilderness, riparian areas, and other special Management Areas provide travel corridors for plant and animal species (FEIS, Chapter III, Affected Environment, "Wildlife").

More information and knowledge is needed for this area. This issue is more properly addressed on a region-wide basis and is identified as "Information Needed" in Chapter II of the LRMP.

99. *COMMENT*: THE FINAL PLAN SHOULD INCLUDE A MORE SPECIFIC AND ENFORCEABLE SET OF FOREST-WIDE STANDARDS AND GUIDELINES FOR PROTECTING AND PRESERVING THE DIVERSITY OF NATIVE PLANT COMMUNITIES EXISTING ON THE SISKIYOU.

Response: In response to public input, a number of changes were made to the Standards and Guidelines (LRMP, Chapter IV) to better protect and preserve diversity. For example, Standard and Guideline 13-1 deals with the general concept of biological diversity The Forest Plan (LRMP, Chapter V and Appendix D) deals with monitoring of biological diversity, the Biological Diversity monitoring element (ET121(g)) is described in detail in Appendix D.

Hardwoods

100 *COMMENT*· INTERSPERSED HARDWOOD STANDS AMONGST THE PINES ARE ALSO NECESSARY TO WILDLIFE AND DISEASE BREAKS WE CANNOT SACRIFICE HARDWOOD FOR A FOREST OF HARVESTABLE PINES FOR ECONOMIC REASONS

Response· Hardwoods are important wildlife habitat. About half of the identified hardwood stands on the Forest (47,000 acres) are within land allocations that preclude timber harvesting (FEIS, Chapter II). Under the Preferred Alternative, up to 7,500 acres of hardwoods (8 percent of the Forest total) may be converted to conifer production during the first decade (FEIS, Chapter II)

101. *COMMENT* COMMENTS WERE RECEIVED CONCERNING THE LEVEL OF HARDWOOD CONVERSION AND ITS EFFECTS ON FOREST DIVERSITY. SOME SUGGEST LESS HARDWOOD AREAS BE CONVERTED; SOME SUGGEST MORE.

Response: A range of allowable hardwood conversion acreage was incorporated in the alternatives considered in the FEIS A maximum allowable acreage of 14,000 per decade was evaluated in Alternatives B, C, D, and D1 Alternatives NC, E, and M were evaluated with no hardwood conversion planned The other alternatives had intermediate conversion acreages (FEIS, Chapter II, "Comparisons of Alternatives Considered in Detail--Vegetation"). For all alternatives, these acreages represent only maximum potential harvest; actual harvest may be less because of utilization requirements for harvested material (LRMP, Chapter IV, "Forest-wide Standards and Guidelines--Timber Management"). Actual utilization would be dependent on local market conditions for hardwood material, which may not be sufficiently high to make harvest economically viable.

A range of potential conversion per decade has been evaluated for its effects on all resources, including forest diversity. The potential harvest for each alternative is compared to the total hardwood acreage on land tentatively suitable for timber production, and the total suitable forest land area (FEIS, Chapter IV, "Vegetation"). Qualitative effects are also discussed; additional analysis and discussion of biological diversity has been incorporated into the FEIS Chapters III and IV based on public comment. Better understanding of the function of hardwoods in the ecosystem is needed as identified in the LRMP Chapter II, "Information Needs "

VEGETATION

Insect/Disease Control

102. *COMMENT*: FURTHER RESEARCH IS RECOMMENDED IN THE AREA OF PORT-ORFORD-CEDAR ROOT ROT. APPLY THE APPROPRIATE SILVICULTURAL PRESCRIPTIONS AND MONITOR EFFORTS TO CONTROL THIS DISEASE. THE PORT-ORFORD-CEDAR SHOULD BE GIVEN MORE PROTECTION. IT IS BASICALLY AN ENDANGERED SPECIES. CUT ONLY DISEASED OR DEAD CEDAR AND LEAVE THE HEALTHY ONES ALONE.

Response: The Forest Service has developed an Interregional Coordinating Group (Regions 5 and 6) to monitor the Port-Orford-Cedar (POC) Program management and make recommendations for change. This consensus group includes industry, agency, and university personnel as well as conservation-minded citizens. The Forest will continue working with the Pacific Northwest Experiment Station and concerned citizens to address the problem.

POC management is a special problem and special management strategies, research, and monitoring have been developed to assure POC viability in the ecosystem. In the FEIS, Chapter IV, and LRMP, Chapter IV, specific POC management direction is discussed. The suggested practices to be found in the *Port Orford Cedar Root Rot on the Siskiyou National Forest* (Harvey and others 1985) and *Ecology, Pathology and Management of Port Orford Cedar* (Zobel and others 1985) will be used.

103 *COMMENT*: THE POTENTIAL FOR SPREAD OF PHYTOPHTHORA LATERALIS IS GREATLY INCREASED BY THE ROAD ACROSS THE HEADWATERS OF THE NORTH FORK IT SHOULD BE GATED (CLOSED IN THE WET SEASON) AT POVERTY PASS AND AT THE SOUTH FORK

Response: The indicated road segment is part of a historical route which the public uses to travel between the Port Orford coastal area and the inland north-south arterial Agness Road. The spread of *Phytophthora lateralis* from roads presents a serious problem. Your suggestion that Collector Road 3353 be gated during the wet season to help slow the spread of the disease will be taken into consideration

104. *COMMENT*: PROHIBIT ENTRY INTO DRAINAGES WHERE PORT-ORFORD-CEDAR IS UNINFECTED UNLESS IT IS CONCLUSIVELY DETERMINED THERE WILL BE NO INCREASED RISK OF INFECTION.

Response: Port-Orford-cedar management will be integrated in environmental analysis and project planning for all areas containing the species. Management objectives are to reduce the spread or severity of Phytophthora root disease Control measures, including access management, will be prescribed on a site- or drainage-specific basis to meet these objectives (LRMP, Chapter IV, "Fire and Pest Management"). The analysis process for proposed projects with POC (Port-Orford-cedar) recognizes the importance of uninfected populations; the objective is to prevent the import of the disease into these populations in management activities.

105. *COMMENT*: IT SEEMS A LARGE NUMBER OF TREES ARE BEING LOST TO PINE BEETLES. ISN'T THERE A NEED TO FIGHT THIS VIGOROUSLY?

Response: Mountain Pine Beetles are endemic to the forest environment. The Pacific Northwest Regional Office and National Forests have ongoing pest monitoring programs. At this time, there are not significant Mountain Pine Beetle problems on the Siskiyou National Forest The LRMP, Chapter IV, provides direction for pest management practices

Herbicide/Pesticide Use

106. *COMMENT*: EVALUATE THE USE OF HERBICIDES.

Response: The issue of vegetation management practices is outside the scope of this Forest Planning analysis (see FEIS, Chapter II, "Alternatives Considered, but Eliminated from Detailed Study"). It is currently addressed in a Regional FEIS (1988) entitled "Managing Competing and Unwanted Vegetation." Environmental analysis and NEPA documentation for vegetation management proposals on the Siskiyou National Forest will be tiered to and in conformance with that document. All alternatives in this Forest Plan assume the availability of the full range of alternative treatment methods, including chemical. Stand condition and growth will be monitored during Forest Plan implementation, they could vary from plan projections because of changes from the assumptions used in Forest Plan analysis Adjustments to harvest levels would be based on monitoring results.

107. *COMMENT*· USE NO HERBICIDES OR PESTICIDES.

Response: Timber harvest outputs in the FEIS are based on the assumption that silvicultural techniques are available to be used. Chapter IV of the LRMP discusses the timber management practices that may apply on all lands selected for timber production However, before any cultural activities are undertaken, site-specific environmental analyses and silvicultural prescriptions will be prepared that will identify the most appropriate treatments The site-specific environmental analyses will be tiered to the Regional FEIS on vegetation management for silvicultural activities, such as release, that involve manipulation of

vegetation. Consideration of the use of herbicides will follow the requirements and guidance contained in the Regional FEIS.

Non-sensitive Plants

108. *COMMENT*: DO NOT INTRODUCE EXOTIC PLANTS.

Response: In regards to tree species, non-native species are not introduced and controls to prevent this from happening are provided in Standards and Guidelines (LRMP, Chapter IV). Recently there has been concern about the introduction of non-native species for erosion control and animal browse In response to this concern, a Standard and Guideline has been added to "plan for natural vegetation to stabilize cut and fill slopes" whenever possible (Standard and Guideline 7-5, Chapter IV, LRMP).

109. *COMMENT*. THE SISKIYOU NATIONAL FOREST SHOULD EMPLOY AT LEAST TWO FULL TIME BOTANISTS IF THE PUBLIC IS TO HAVE ANY FAITH IN THE RELIABILITY OF THE SENSITIVE PLANT PROGRAM, THE OVERALL CONSIDERATION TO BE AFFORDED TO THE PROPER MANAGEMENT OF NATIVE PLANTS, OR THE ADEQUACY OF YOUR PROPOSED GUIDELINES AND MONITORING PROGRAM

Response: The Siskiyou National Forest has had a Sensitive Plant Program since 1975. Volunteers, contractors, detailers, and various Forest personnel have worked to inventory and manage the Forest's botanical resources A shared botanical position (Rogue River and Siskiyou National Forests) was filled in September 1988.

110. *COMMENT*: SURVEY OF THE SILVER FIRE DAMAGE SHOULD INCLUDE A SURVEY OF WHAT SPRUCE TREES, IF ANY, WERE DAMAGED OR DESTROYED BY THE FIRE IN THE BIG CRAGGIES BOTANICAL AREA AND ALONG THE JOSEPHINE-CURRY COUNTY LINE BETWEEN TINCUP PASS AND DAILEY CREEK.

Response. Specific surveys in the burned areas to assess impacts of the Silver Fire on Brewer spruce have not been conducted at the time of this writing These areas will be added to our priority list of inventory sites for sensitive and rare plants

111. *COMMENT*. DEVELOP A SYSTEM TO IDENTIFY ALL PLANTS AND ANIMALS IN OUR NATIONAL FOREST AND PLACE A MORATORIUM ON CUTTING UNTIL THE FOREST SERVICE IS KNOWLEDGEABLE ABOUT THE IMPACTS THEY ARE HAVING IN THESE AREAS

Response: Knowledge is sufficient to harvest timber with minimum adverse impacts on native and desirable non-native plants and animals.

Concentration areas of rare plants will be inventoried as part of the Siskiyou's sensitive plant program Outside of RNA's and Botanical areas, sensitive plants would continue to be managed under Forest-wide Standards and Guidelines. As part of the Forest Plan, specific populations of sensitive plants would be monitored.

A bibliography of individual plants and propagational needs which is aimed at protection and enhancement of the ecosystem is being developed A product of the Pacific Northwest Regional Office Ecology Program is the publication, *Preliminary Plant Associations of the Siskiyou* (Atzet and Wheeler

1984), which addresses the ecology of most of the common plants found on the Siskiyou National Forest The RNA's and Botanical reserves (LRMP, Chapter IV) were designated to provide opportunities for research, observation and study of plant communities

OTHER FOREST PRODUCTS

112 *COMMENT*: INSTITUTE A PROTECTION POLICY FOR ALL PACIFIC YEW (TAXUS BREVIFOLIA) FOR ALL TREES FOUND ON THE NATIONAL FORESTS OF THE PACIFIC NORTHWEST. BARK FROM THE PACIFIC YEW HAS BEEN FOUND RECENTLY TO CONTAIN AN AGENT IN THE TREATMENT OF CANCER. RECOGNIZING THAT IT TAKES A SUBSTANTIAL AMOUNT OF TIME FOR A PACIFIC YEW TO GROW BARK OF ANY THICKNESS, THE FOREST SERVICE SHOULD MAKE IT A POLICY TO PROTECT AS MANY OF THE EXISTING YEW TREES AS POSSIBLE. THESE TREES MIGHT PROVE TO HAVE A VALUE THAT FAR EXCEEDS ANY OTHER RESOURCE FOUND IN THE SAME AREA.

Response: Although reports of the yew/cancer connection have appeared in various media in the last few years, there has not been any demand for harvesting of yew trees (or their bark) on this Forest. Yew is present in a variety of areas on the Forest, many of which are sites where timber harvest is prohibited or will not occur (FEIS, Chapter III, "Vegetation"). If the demand for harvest of yew becomes an issue on the Siskiyou, appropriate steps will be taken to protect and manage this valuable resource.

113. *COMMENT*: MUSHROOM PRODUCTION MAY EXCEED THAT OF TIMBER AND USES MAY CONFLICT. MANAGEMENT OBJECTIVES SHOULD BE TO PROVIDE FOR THE PRESERVATION OF PUBLIC ACCESS TO MUSHROOM PICKING AND PROVIDE FOR THE CONSERVATION OF THE RESOURCE.

Response: The Forest Plan will not prevent access to mushroom picking and is not expected to degrade the resource. One of the goals of the Forest Plan (LRMP, Chapter IV, "Forest Management Goals") is to maintain all seral stages of existing terrestrial, aquatic, and edaphic plant associations on the Forest. Site-specific conflicts could occur due to the harvest of timber and in some cases may cause local displacement of some mushroom species.

SOCIOECONOMICS

JOBS AND COMMUNITY STABILITY

114. *COMMENT*: SECOND-GROWTH CUTTING SHOULD LEAD TO THE MANUFACTURING OF FINISHED GOODS IN THE AREA INSTEAD OF SHIPPING THE RAW LOGS AND PULP ELSEWHERE TO BE CONVERTED TO FINISHED GOODS, HENCE DENYING THE AREA OF THE "VALUE ADDED" THAT MANUFACTURING JOBS BRING

Response: All logs from the Siskiyou National Forest except Port-Orford-cedar are required by Federal law to be processed within the United States The decision to allow log exports from federal, state, or private lands, and the decision to upgrade mills is not within the scope of this Forest Plan. Congress, the State Legislature, and individual mill owners make those decisions. The effects of these decisions on the local economy is reflected in the assessment of the local economies' reaction to changes in the quantity of products produced on the Forest (FEIS, Chapter IV, "Social and Economic Effects").

115. *COMMENT* PAYMENTS TO COUNTIES NEED TO BE MAINTAINED THROUGH O&C RECEIPTS EXPLORE ALTERNATIVE METHODS OF REVENUE.

Response: In addition to O&C monies, the Forest Service provides revenues for counties from the National Forest Fund consisting of 25 percent of timber sale receipts The Forest Service does not have the authority to change the distribution of timber receipts, raise property taxes, or initiate sales taxes. The U.S. Congress and local and state governments have that authority.

116. *COMMENT*: GOAL #2 (LRMP, CHAPTER IV) STATES THE FOREST WILL "PROVIDE A SUSTAINED YIELD OF RESOURCE OUTPUTS THAT WILL PROMOTE THE STABILITY OF LOCAL COMMUNITIES AND PROVIDE FOR REGIONAL AND NATIONAL NEEDS " YOU HAVE FALLEN SHORT OF THIS GOAL ALREADY WITH THE WITHDRAWALS MADE IN THE PAST FOR SUCH THINGS AS WILDERNESS, SUPPLEMENTAL RESOURCE, DESIGNATED WILDLIFE, AND RIPARIAN AREAS TO INCLUDE THE CUSTODIAL AREA (MANAGEMENT AREA 6) WOULD BE AN EVEN GREATER DEVIATION FROM THE GOALS.

Response· Promoting community stability entails consideration of economic factors, including income, employment, and payments to counties, as well as social structure and lifestyle. Local, regional, and National needs may be met in varying degrees by providing a mix of both quantitative and qualitative outputs from the Forest The alternatives described in the FEIS, Chapter II, were formulated to address local, regional, and National needs, concerns, and requirements

The total acreage allocated for each Management Area generally varies according to the resource objectives and emphasis of the alternatives. Consequently, each alternative would respond to each of the Forest Management Goals in varying degrees

117. *COMMENT*: THE ECONOMY OF THIS AREA IS MORE IMPORTANT THAN HABITAT CONSIDERATIONS. THE PREFERRED ALTERNATIVE IS IN CONFLICT WITH THE WISHES OF CONGRESS TO STABILIZE LOCAL COMMUNITIES

Response: The Forest's task is to balance the different uses (timber, wildlife and fisheries, recreation, range, and watershed) of the Forest. Congressional legislation states the National Forests will "ensure consideration of the economic and environmental aspects...to provide for outdoor recreation (including Wilderness), range, timber, watershed, wildlife, and fish" (NFMA, 1976) See LRMP, Chapter IV, "Forest Management Objectives."

118. *COMMENT*: HARVEST LEVELS SHOULD BE SET TO MAINTAIN COMMUNITY STABILITY TAKING INTO ACCOUNT THE VOLUMES AVAILABLE TO THE COMMUNITIES AFFECTED BY THE PLAN FROM ALL SOURCES: USFS, BLM, STATE, COUNTY, AND PRIVATE TIMBERLANDS.

Response: The economic and social section of Chapter III of the FEIS discusses the harvest levels which historically have occurred. Chapters II and IV of the FEIS display the relationship among alternatives and the historical and predicted harvest levels from different ownerships

119. *COMMENT*: WHEN DISCUSSING JOBS AND LOCAL ECONOMIES, THE PLAN SHOULD ADDRESS THE COMPARABLE WORTH OF LARGE NUMBERS OF RELATIVELY SHORT TERM JOBS TIED TO ONE HISTORICALLY DRAMATICALLY FLUCTUATING INDUSTRY VS. SMALLER NUMBERS OF PERMANENT JOBS IN A DIVERSIFIED ECONOMY.

Response· See the FEIS, Chapter II, "Economic Efficiency Analysis of Alternatives;" Chapter III, "Economic and Social;" and Appendix B, "Social and Economic Impact Analysis" for discussion of jobs and local economies and other socioeconomic considerations

120. *COMMENT*: THE LONG-RANGE GOAL OF ECONOMIC DIVERSITY NEEDS TO BE RECOGNIZED AS WELL AS THE SHORTSIGHTED GOAL OF TIMBER MANAGEMENT.

Response: See the LRMP, Chapter IV, for the long-range management direction and goals of the Forest. Timber management is one of several Forest activities contributing to both short- and long-range economic diversity.

121. *COMMENT*: STOP THIS DEPENDENCY ON FOREST TIMBER SALES FOR ECONOMIC STABILITY. EMPHASIZE INSTEAD TOURISM, FISHERIES, WILDLIFE, AND RECREATION.

Response Chapter IV of the LRMP contains "Forest Management Goals" addressing community stability and associated economic needs. Chapter III of the FEIS provides a discussion of the Forest's economic and social setting, while Chapter IV contains information on the social and economic interactions and effects of implementing the alternatives. Appendix B of the FEIS includes a social and economic impact analysis that examines the relationships among Forest activities and the communities and counties within the Forest's influence area.

The contribution of timber sales, recreation, tourism, fisheries, and wildlife to economic stability and the relative importance of each is a composite concern to which the Siskiyou National Forest strives to be responsive This responsiveness is reflected in the range of alternatives formulated and evaluated in the FEIS.

122 *COMMENT*: STOP THE PRACTICE OF GIVING TIMBER COMPANIES PURCHASER CREDITS FOR CONSTRUCTING LOGGING ROADS.

Response· Roads built with purchaser credits belong to the Federal government. This is but one tool established by Congress to accomplish needed road access. The use of Purchaser Credits allows the Forest Service to obtain the standard of road required for future management, and to control construction to minimize resource impacts

123 *COMMENT*: AFTER COMMERCIAL LOGGING IS DONE, LONG-TERM TOURIST APPEAL AND TOURIST MONEY IS LOST LOGGING THE SISKIYOU AREA SEEMS LIKE AN EXTREMELY SHORT-SIGHTED GOAL ECONOMICALLY

Response. Tourism and timber harvest can both be accommodated on the Forest. See the FEIS, Appendix B, "Social and Economic Impact Analysis" for discussions pertinent to tourism and timber and their respective socioeconomic roles and contributions to the Forest influence area

124. *COMMENT* YOU ARE TO BE COMMENDED FOR TAKING A STANCE TO FINALLY HALT THE RAPID DESTRUCTION OF THE FOREST TRAIL SYSTEM HOWEVER, MUCH MORE NEEDS TO BE DONE THE BUDGET IN THE PROPOSED PLAN FOR RECONSTRUCTION AND CONSTRUCTION IS INADEQUATE IN ALL ALTERNATIVES.

Response In response to public interest in trails, the LRMP, Appendix B, Table B-6 has been revised to increase capital investments in the Forest trail system.

125. *COMMENT*: THE DEIS COMPARES THE TIMBER HARVEST AND ECONOMIC EFFECTS OF THE ALTERNATIVES TO THE AVERAGE FOR 1975-84 AND TO ALTERNATIVE A (THE "CURRENT SITUATION"). IN ADDITION, THE HARVEST FOR THE LAST YEARS SHOULD SERVE AS A BENCHMARK. THE 1975-84 AVERAGES FOR TIMBER HARVEST, TIMBER SALES AND TIMBER-BASED EMPLOYMENT DO NOT REPRESENT WHAT THE SURROUNDING COUNTIES HAVE EXPERIENCED OVER THE LAST FEW YEARS THESE COUNTIES RECENTLY HAVE EXPERIENCED A MUCH HIGHER TIMBER-BASED EMPLOYMENT LEVEL THAN THE 10-YEAR AVERAGE AS COMPANIES CUT THEIR ACCUMULATED TIMBER-UNDER-CONTRACT WITH THE RETURN OF HIGH STUMPAGE PRICES.

Response: The 1975-84 average annual harvest was about 131 MMBF, while the 1978-87 average annual harvest was about 129 MMBF. Both ten-year periods reflect four phases of a business cycle. boom, peak, recession, and trough Using data for a shorter time period covering a selected phase of a business cycle as a benchmark would not provide as accurate an estimate of the timber-related employment in the local counties

126. *COMMENT*: THE ECONOMIC AND SOCIAL ANALYSIS DISPLAYED IN CHAPTER III AND ELSEWHERE IS INFORMATIVE BUT PERHAPS MISLEADING. THE BASE PERIOD SELECTED INCLUDES A HIGH PROPORTION OF TIME WHICH COULD HARDLY BE CONSIDERED TYPICAL IN RURAL, FOREST-BASED ECONOMIES. THE DEPRESSION IN THE TIMBER INDUSTRY IN THE EARLY 1980'S HAS SKEWED THE STATISTICS, INCLUDING CONSUMPTION PATTERNS AT A MINIMUM, CONSUMPTION EMPLOYMENT, STUMPAGE AND INCOME DATA SHOULD BE RECALCULATED FOR A TEN YEAR PERIOD FROM 1978 THROUGH 1987

Response: Employment by economic sector, including manufacturing of lumber and wood products, has been updated in Chapter III of the FEIS. Reported employment data in the four-county area is provided for in 1979, 1982, and 1986. The data are representative of business cycles encountered (over time) by the various economic sectors. See Table III-39 in the FEIS for reported employment data and its source

Personal income by major source and earnings by major industry for the four-county area have been updated in Chapter III of the FEIS. Reported income and earnings data is presented for 1980 and 1984 See Table III-40 in the FEIS for the data and its source.

Chapters II and IV, and Appendix B of the FEIS contain information pertinent to employment and income generated from timber harvest on the Forest The figures are presented for comparison purposes among the alternatives and should not be interpreted as absolute numbers of jobs and wages. See Appendix B, "Social and Economic Impact Analysis" for a more detailed discussion.

Stumpage values were developed from 1973-1982 data. The period contains years representing the four phases in a business cycle: boom, peak, recession, and trough. The suggested 1978-87 period includes five years of the selected period and also the four business cycle phases. Average annual volume harvested for 1973-82 was about 154 MMBF, while the 1978-87 period averaged about 129 MMBF per year.

127. *COMMENT*: THE BUDGET COSTS YOU USE FOR SILVICULTURAL PRACTICES SEEM TO BE ABOUT TWICE WHAT THE INDUSTRY CONTRACTS THIS WORK FOR THE BUDGET, FOR THE FINAL PLAN, NEEDS DIFFERENT TIMBER OUTPUT LEVELS GIVEN DIFFERENT BUDGET LEVELS. ALSO, THE FOREST SHOULD REQUEST THE BUDGET SHOWN IN THE FINAL PLAN. IT IS MOST

FRUSTRATING TO BUILD A MILL ANTICIPATING A TIMBER SUPPLY AND THEN FIND THE SUPPLY CONTINUALLY DECLINES BECAUSE THE FOREST DID NOT REQUEST THEIR BUDGET.

Response: The Siskiyou National Forest annually prepares an outyear budget request See the LRMP, Appendix B, Table B-1 for the requested budget for Fiscal Year 1991. It should be recognized that actual funding received in response to the submitted budget may not be the same as requested. Since Congress has the ultimate budget authority, the situation cannot be resolved through the Forest Planning process However, monitoring the level of timber outputs annually is provided for in the LRMP, Appendix D, to determine whether timber objectives are being met during Plan implementation

Silvicultural costs are discussed in the FEIS, Appendix B, "Benefits and Costs Used in the PNV Calculation," and have been extensively reviewed for accuracy.

128 *COMMENT*. REVISE YOUR ECONOMIC DATA TO UPDATE THE TIMBER JOBS MULTIPLIERS. THE CURRENT DATA USED IN THE PLAN IS BASED UPON 1977 INFORMATION AND OVERSTATES THE NUMBERS OF TIMBER-BASED JOBS THE FOREST PRODUCES BY 20-40%. USE CURRENT ECONOMIC DATA TO SHOW THE ACTUAL BALANCE OF ECONOMIC OUTPUTS TO LOCAL COMMUNITIES DON'T OVERSTATE THE TIMBER VALUES.

Response. The most current data available was used in the economic model (IMPLAN) Local economic indicators, including timber-related employment and income, were derived from generated changes in planned Forest outputs compared to the current direction Alternative A. The resulting figures are relative, not absolute, and are intended to provide a comparison among the alternatives and not absolute numbers for employment and income. See the FEIS, Appendix B, "Sources of Data" and "Information Generated From the Social and Economic Impact Analysis" for a more detailed discussion.

129. *COMMENT*: EMPLOYMENT AND INCOME INFORMATION NEEDS TO BE EXAMINED AT THE INDIVIDUAL COMMUNITY LEVEL IN ORDER TO ASCERTAIN THE TRUE IMPACTS ON THE PUBLIC THE LEVEL OF INFORMATION ON THIS TOPIC PROVIDED IN THE DEIS IS INADEQUATE.

Response: Employment and income information is presented at the county level See the Chapters III and IV, and Appendix B of the FEIS for discussions of social and economic considerations pertinent to communities, community types, and counties within the Forest influence area.

130. *COMMENT*: THE USE OF A HORIZONTAL DEMAND CURVE FOR TIMBER, WHILE MAKING COMPUTER MODELING EASIER, IS A SERIOUS MISREPRESENTATION OF OUR BUSINESS CLIMATE. IF YOU ULTIMATELY CHOOSE AN ALTERNATIVE THAT DROPS TIMBER SUPPLY, YOU WILL CAUSE STUMPAGE TO INCREASE AND WHILE MILL CAPACITY ADJUSTS TO AVAILABLE TIMBER SUPPLY, THE LOCAL OPERATING CONDITIONS FOR MILL OWNERS WILL BE MISERABLE.

Response. See Chapters III and IV, and Appendix B of the FEIS for detailed information regarding timber supply, demand, and other economic considerations. Appendix B also discusses timber demand curves.

131 *COMMENT*: IN ORDER TO COMPENSATE FOR SOME OF THE ECONOMIC DISLOCATION AND JOB LOSSES THAT WOULD OCCUR BY ADOPTING AN ALTERNATIVE THAT WOULD ALLOW LESS CUTTING THAN HAS OCCURRED DURING THE LAST TEN YEARS, THE SISKIYOU NATIONAL FOREST SHOULD SUBSTANTIALLY INCREASE THE RECREATION-ORIENTED RESOURCES.

Response In response to many people who want to see more recreation opportunities, the capital investment schedule for recreation has substantially increased the recreation-oriented investments (see LRMP, Appendix B). Also the Siskiyou National Forest will continue to seek partnership opportunities to enhance recreation and tourism (see LRMP, Chapter IV, "Forest Management Goals").

132. *COMMENT*: IS IT POSSIBLE FOR SOME OF THOSE MADE JOBLESS BY THE REDUCTION OF TIMBERING BY FIRE TO BE HIRED TO HELP IN REFORESTATION, MANUAL RELEASE, STREAM REHABILITATION, OR SLIDE STABILIZATION?

Response: All contracts for these types of projects on the Siskiyou National Forest are let by competitive bids Anyone can bid on these contracts, provided they meet bidder qualifications While the amount of work to be done will provide jobs, the Forest Service does not control to whom the jobs will go

133. *COMMENT*: THE FOREST SHOULD BE MANAGED PRIMARILY WITH THE GOAL OF MAXIMIZING ITS USEFULNESS TO THE PEOPLE THAT LIVE IN AND AROUND IT. IT IS IMPORTANT TO MAINTAIN A STABLE ECONOMIC ENVIRONMENT BY MAXIMIZING SUSTAINED YIELD FORESTRY, MAINTAINING AUM'S, AND PROMOTING MINERAL DEVELOPMENT.

Response: The Forest Service is required to be responsive to all people of the United States and the Nation's directives as provided by Congress. The Forest Service is required by Congress to "include coordination of outdoor recreation, range, timber, watershed, wildlife and fish, and wilderness" (NFMA, 1976). The various Management Areas are lands which provide for coordination of these different uses which include both commodity outputs and amenity values.

134. *COMMENT*: WHILE THE PROPOSED ALTERNATIVES INCLUDE NUMEROUS MEASURES TO MITIGATE THE EFFECTS OF THE ALTERNATIVES UPON FISH, WILDLIFE, AIR QUALITY, SEDIMENT, AND VISUAL RESOURCES, THERE ARE NO MEASURES DISCUSSED WHICH WOULD MITIGATE THE EFFECTS OF THE PROPOSED ALTERNATIVES UPON THE ECONOMIES OF THE FOUR-COUNTY AREA.

Response: Resource mitigation measures are part of the formulation of alternatives and are provided to lessen adverse environmental impacts which may result from certain management activities including road building and timber harvesting.

Local economic indicators, including jobs, income, and payments to counties, are primarily affected by changes in the allowable sale quantity (ASQ). Recreation, fisheries, and wildlife values are also significant to local economies. Appendix B of the FEIS contains a detailed social and economic impact analysis, while Chapter IV of the FEIS provides information on each alternative's social and economic effects.

Mitigation measures designed to provide the highest ASQ consistent with the resource objectives and emphasis of the alternatives include the following: use of the "maximize timber objective function" in the FORPLAN model; fertilization; hardwood conversions; commercial thinnings; and intensive management regimes including stocking control, planting and vegetative control, departures from nondeclining even flow, and short rotations.

The Siskiyou National Forest has no means available to directly compensate local economies for any reductions in jobs, income, or payments to counties that could occur as a result of implementing any of the alternatives

135. *COMMENT*. THE MAJOR REGIONAL PORT AT COOS BAY AND ITS ECONOMIC IMPACT ON THE REGION, AND THE STATE OF OREGON'S RECENT INVESTMENT IN THIS PORT, WAS NOT ADDRESSED IN THE PROPOSED SISKIYOU NATIONAL FOREST PLAN MORE FOREST PRODUCTS MOVE THROUGH THE PORT AT COOS BAY THAN THROUGH ANY OTHER PORT IN THE WORLD.

Response: The economic contributions of the Coos Bay port are reflected in the employment and income data presented for Coos County and are also factored into the economic model. See the FEIS, Appendix B, "Social and Economic Analysis "

136. *COMMENT*: LOCAL ECONOMIES SHOULD BE ACCOUNTED FOR ON A PERMANENT BASIS, AND NOT FOR JUST 10 OR 15 YEARS.

Response: Local indicators of economic and social stability, including employment, income, and payments to counties are provided as estimated effects resulting from implementing each of the alternatives described in the FEIS (Chapters II, IV, and Appendix B). These estimated effects are for the first decade of Plan implementation and should not be interpreted to mean local economies are not considered permanent Provisions of NFMA require Forest Plans to be revised every 10 to 15 years; Plans may be amended more often as conditions warrant.

137 *COMMENT*: ALTERNATIVE K BUDGETS $350,000 PER YEAR FOR FISH HABITAT ENHANCEMENT AND $230,000 PER YEAR FOR SOIL AND WATER RESOURCE IMPROVEMENTS. THESE AMOUNTS SHOULD BE THE ABSOLUTE MINIMUM AMOUNT BUDGETED. OUR CONCERNS ARE THAT IN PAST PRACTICES DURING BUDGET "CUT-BACKS" AND CONSTRAINTS, THESE ARE THE FIRST TO BE DROPPED AS THEY ARE USUALLY CONSIDERED A NON-PRODUCTIVE EXPENDITURE WHEN COMPARED TO FOREST HARVESTS.

Response· Should budget amounts received by the Forest be less than the amounts requested, certain reductions may be necessary in the various programs and activities. A portion of this budget is provided through timber sale returns, so these resource improvements are, in part, tied to a level of other resource activity.

Appendix D of the LRMP provides monitoring direction for all resource elements including fish habitat, soil and water. The purpose of monitoring is to determine whether or not the Management Direction in the Plan is being implemented and to what degree. If the fish habitat enhancements and watershed improvement objectives are not being attained as planned, then amendments may need to be made to the Forest Plan

138. *COMMENT:* CURRENT MANAGEMENT DIRECTION AND YOUR PREFERRED ALTERNATIVE ASSUME ECONOMIC PRODUCTION TO BE THE FOREST'S PRIMARY PURPOSE. ON WHAT IS THIS ASSUMPTION BASED AND WHERE IS IT LEADING US AND THE FOREST?

Response· The alternatives described in the FEIS, Chapter II, emphasize differing mixes of commodities and amenities in response to the public issues See the FEIS (Chapter II, "Alternative Development Process") and Tables II-5 and II-6 for both quantitative and qualitative comparisons among the alternatives.

139. *COMMENT*: IN LOOKING AT COMMUNITY STABILITY, THE DRAFT DID NOT INCLUDE THE EXPECTED REDUCTIONS IN LOCAL EMPLOYMENT IN THE WOOD PRODUCTS INDUSTRY DUE TO AUTOMATION. IN OTHER WORDS, THERE WAS NO COMPARATIVE OR SENSITIVITY ANALYSIS OF KEY FACTORS AFFECTING WOOD PRODUCTS EMPLOYMENT THAT WOULD

PROVIDE INFORMATION ON THE RELATIVE IMPORTANCE OF ALTERNATIVE FOREST MANAGEMENT PLANS ON THE SHORT-TERM ECONOMY. ABSENT SUCH ANALYSIS, THE DRAFT PLAN FIGURES ON POSSIBLE WOOD PRODUCTS EMPLOYMENT IMPACTS ARE MISLEADING BECAUSE THEY ARE INCOMPLETE AND TOO ABSTRACTED FROM REALITY. OF EVEN GREATER SIGNIFICANCE, HOWEVER, IS THE AVOIDANCE OF ANY TRULY LONG-TERM LOOK AT THE AREA'S ECONOMY. NOTABLY ABSENT, AGAIN, IS ANY EVALUATION OF A NATIONAL PARK ALTERNATIVE IN TERMS OF ITS LONG-TERM IMPACT.

Response: Changes in technology within the wood products industry that may result in few related jobs, such as increasing automation in wood processing facilities, are not within the scope of the Forest Plan These decisions are made within the industry.

The local economic indicators, including jobs and income related to timber harvest levels, are presented as estimates based upon the best available data. The figures are intended for comparisons among the alternatives and should not be interpreted as absolute numbers of jobs and income. Reduced employment due to increased automation would not affect the relative difference among the alternatives with respect to jobs and income related to timber harvest levels. Further discussions of the economic aspects are provided in the FEIS, Chapter II, "Economic Efficiency Analysis of Alternatives;" Chapter IV, "Economic and Social," and Appendix B, "Social and Economic Impact Analysis "

Alternatives proposing National Park designation were considered but eliminated from further study See the FEIS, Chapter II, "Alternatives Considered But Eliminated From Detailed Study," for additional information.

TOURISM AND RECREATION

Economic Values

140 *COMMENT*: THE OPTIMISM ABOUT IMPROVING TOURISM THROUGH WILDERNESS OR OTHER SINGLE USE DESIGNATION IS A FALLACY. WILDERNESS USE IS INSIGNIFICANT, WHEREAS OTHER RECREATION USER NUMBERS GROW CONSISTENT WITH ROAD ACCESS TO FISHING, CAMPING, HIKING, ETC. IN THAT VEIN, VISUAL MANAGEMENT PLANS ARE OVERDONE, TOO DETAILED, AND INAPPROPRIATE FOR THIS PLAN.

Response. Wilderness use is described throughout the FEIS as being very low relative to other areas in the Wilderness System. The level of actual and projected use does not project large or "inflated" figures or increases when viewed against existing recreation use data or local and regional trends.

The Forest Plan, however, does place increased emphasis on recreation and supports local governments in their goal of developing the recreation tourism industry. Toward this end, the capital investment program has been increased in the areas of developed site construction and trail construction (both Wilderness and in other areas of the Forest). Capital investments over the next five years are detailed in the Forest Plan (Appendix B, "Recreation Capital Investments" and "Trail Capital Investments"). Potential development projects are listed for each Ranger District at the end of each schedule.

The FEIS displays a range of alternatives, from Alternatives S, G, E, and M, that manage a high number of acres in Preservation, Retention, and Partial Retention, to Alternatives C, B, D, and D-1 which allow for most Modification (See FEIS, Chapter IV, "Visual Resources"). Management Area prescriptions (LRMP, Chapter IV) for Partial Retention Visuals and Retention Visuals are not intended to be detailed Visual Management Plans, but provide general guidelines for the area. More detailed Visual Management Plans

can be developed for site-specific areas through project development for specific areas like a certain road or river corridors (e g Rogue National Wild and Scenic River Management Plan)

141. *COMMENT*: YOUR PLANNING FOR RECREATIONAL USE OF THE FOREST IS BASED ON A GROWTH IN DEMAND OF ONLY 1/2 PERCENT PER YEAR. THIS ASSUMPTION IS INADEQUATE GIVEN NATIONWIDE TRENDS IDENTIFIED IN THE RECENT REPORT FROM THE PRESIDENT'S COMMISSION ON AMERICANS OUTDOORS, AND THE EMERGING LOCAL EMPHASIS ON DEVELOPING AND PROMOTING TOURISM TO STIMULATE THE ECONOMY. IN ADDITION YOU HAVE NOT ALLOWED FOR ANY INCREASE IN REAL PRICES DURING THE LIFE OF THE PLAN, NOR HAVE YOU MADE ANY ESTIMATE OF USAGE OF THE FOREST BY NON-LOCAL PERSONS. THIS, COUPLED WITH YOUR REDUCTION OF 37 PERCENT FROM THE 1985 RPA FIGURES, HAS GROSSLY UNDERVALUED RECREATION'S CONTRIBUTION TO THE NET PRESENT WORTH CALCULATIONS IN YOUR ECONOMIC ANALYSIS

Response: The projected growth rate of recreation demand is an estimate based upon the best available information and recreation use data for Forest visitors regardless of where visitors live. These recreation use figures are specific to the Siskiyou National Forest and provide a more accurate basis for projecting demand than broader National reports.

The dollar values displayed for recreation visitor days by recreation setting are slightly higher than the 1985 RPA Program figures for Region 6 See the FEIS, Appendix B, for additional discussions pertinent to recreation and economics.

Growing emphasis on recreation and related tourism and the importance to local economies is a major consideration reflected in managing the Forest. For example, the Siskiyou National Forest is involved in cooperative recreation projects and activities with four local counties, the State of Oregon, three neighboring National Forests, two Bureau of Land Management Districts, and private groups

Recreation Opportunities

142. *COMMENT*: ALL WILDERNESS WITHIN THE SISKIYOU NATIONAL FOREST SHOULD BE CLOSED TO HORSEBACK TRAVEL AND HUNTING AT ALL TIMES. HORSE TRAVEL IS HIGHLY DESTRUCTIVE TO TRAILS AND PLANT COMMUNITIES, AND HUNTING UPSETS THE NATURAL BALANCE OF PREDATOR/PREY WHICH MUST EXIST IN A STABLE ECOSYSTEM.

Response: Wilderness management is based on the direction contained in the Wilderness Act. The Act specifically excludes only motorized or mechanized equipment from use in the Wildernesses. Horse travel is considered an acceptable use within Wilderness However, horse usage in the Forest's five Wildernesses is very light at present, impacts of past usage have been negligible, at most. Changes in this type of use are not expected to be significant during this planning period

Current management provides that all trails be inspected annually to identify trail maintenance needs (LRMP, Chapter IV, Forest-wide Standards and Guidelines) and the management prescription for Wilderness (LRMP, Chapter IV, MA-1) includes Standards and Guidelines for corrective actions when monitoring indicates Wilderness use exceeds the degree of impact established through the Limits of Acceptable Change system. Corrective actions could include closing a zone to all recreation use until the area is restored to wilderness conditions, if necessary.

The Forest Service is responsible for the management of wildlife habitat (including Wilderness), and the State is responsible for the management of wildlife. The State is responsible for the administration and

development of hunting regulations on National Forest lands. Although the Forest Service may recommend changes in the hunting regulations to Oregon Department of Fish and Wildlife, hunting is considered an acceptable Wilderness activity.

143 *COMMENT*: THE LIMITATION ON GROUP SIZE GOING INTO THE WILDERNESS TOGETHER IS TOO RESTRICTIVE.

Response. Regional direction for management of groups within Wilderness is found in Forest Service Manual 2322.03 (R-6 Supplement 81). Under these Standards and Guidelines, group size limits range from 6 to 12, and could go to 18 including livestock depending on the number of encounters expected. Larger groups, particularly those using horses, must obtain a special use permit in order to avoid unnecessary impacts to Wilderness resources. The size of groups recreating within Wilderness is not further limited in the Forest's Standards and Guidelines (LRMP, Chapter IV) or in the Wilderness Management Plans (LRMP, Appendix A).

144. *COMMENT*· PRESERVE VARIED HABITAT FOR HUNTING, FISHING, AND MORE DEVELOPED RECREATIONAL OPPORTUNITIES.

Response: All alternatives provide habitat for hunting and fishing, and developed recreation opportunities. They vary in the amount of habitat in a "preserved state" (see FEIS, Chapter II, Table II-5). Developed recreation opportunities are similar for each alternative in the first several decades All alternatives can meet the demand for developed recreation until approximately the seventh decade of the planning horizon (see FEIS, Chapter II, "Recreation Settings").

145. *COMMENT*. THE SISKIYOU NATIONAL FOREST NEEDS TO TAKE A MORE ACTIVE ROLE IN INCREASING RECREATION OPPORTUNITIES AND TOURISM NEEDS INCLUDE: MORE DESIGNATED SITES, PARKING LOTS, AND TRAILS; AND DISPLAYS, MAPS, AND BROCHURES IN THE LOCAL RANGER HEADQUARTERS.

Response: In response to increased public interest in recreation, the Forest has implemented a strategy that includes partnerships with County, State, and other Federal agencies for the purpose of developing the recreation and tourism industry. The strategy includes the development of computer video displays illustrating the recreation sites in the area, the development of a Southern Oregon recreation map, computer-assisted trail information, and a variety of brochures, pamphlets, and other information which will be made available at District offices, information centers, and other locations throughout southern Oregon and the Pacific Northwest In addition, construction and rehabilitation of 17 developed recreation sites and construction or reconstruction of approximately 114 miles of trails, trailheads, and bridges are planned for the first half of the decade. These projects are part of the "Recreation Capital Investment Schedule" (LRMP, Appendix B).

Supporting recreation and tourism is, and will continue to be, an important part of implementing the National Recreation Strategy. The program involves aggressive marketing strategies which are designed to "advertise" the availability and the abundance of recreational opportunities available on National Forest lands. The concept of Backcountry Recreation was developed in the FEIS, and acres allocated to these areas were increased in the Preferred Alternative S to provide recreation opportunities in areas which will have no programmed timber harvest (LRMP, Chapter IV, "Management Prescriptions"). The objectives of the National Recreation Strategy have been incorporated into the Forest Plan and will continue to be an important part of the Recreation Program (LRMP, Chapter IV, "Forest Management")

146 *COMMENT*: WINTER SPORTS IN THE SISKIYOU NATIONAL FOREST ARE BECOMING INCREASINGLY MORE POPULAR. THERE WAS NO MENTION OF CROSS-COUNTRY SKIING, SLEDDING, ETC. IN THE DRAFT.

Response: In the past, there has been little interest in the development of facilities that would support these types of activities There are few areas on the Forest that would provide the quality experience that winter recreationists prefer Since the publication of the Draft, there has been active interest in the development of a winter sports facility in the vicinity of Page Mountain on the Illinois Valley Ranger District. In response to interest in this project, the Page Mountain Snopark is identified in the Recreation Capital Investment Schedule (LRMP, Appendix B). The facility is planned for segregated use by cross-country skiers and snowmobilers Plans are currently being developed and construction is anticipated in the near future due to the involvement of interested volunteer groups. Development of additional facilities would be encouraged in areas of the Forest with sufficient snow and public interest, however both have been rather limited to present

147. *COMMENT*: ALTERNATIVE K IN THE DRAFT STATED THAT IT INCREASES AVAILABLE PRIMITIVE AND SEMI-PRIMITIVE RECREATION OPPORTUNITIES. THIS IS NOT SO, BECAUSE THE GREATEST OPPORTUNITY FOR PRIMITIVE AND SEMI-PRIMITIVE RECREATION IS THE PRESENT MANAGEMENT SITUATION INCREASE THE AREA AVAILABLE FOR UNROADED PRIMITIVE AND SEMI-PRIMITIVE RECREATION.

Response Table II-5 (Monster Matrix) and Table II-57 (FEIS, Chapter II) show approximately 261,000 acres currently available (Alternative A) for Pristine, Primitive, and Semi-primitive Non-motorized recreation. Alternative K projected about 269,000 acres available for these recreation opportunities, a slight increase over current management. In response to public comments on the DEIS, development of the Preferred Alternative S in the FEIS included an increase in the area available for unroaded Primitive and Semi-primitive recreation opportunities to approximately 293,500 acres.

148. *COMMENT*: SPECIFIC SITES FOR CAMPGROUND OR PICNIC AREA DEVELOPMENT WERE SUGGESTED. NO NEW FACILITIES SHOULD BE CONSTRUCTED UNTIL ALL EXISTING CAMPGROUNDS ARE RESTORED TO FULL USE, AND BETTER MAINTENANCE OF CAMPGROUNDS IS NEEDED.

Response: Specific areas mentioned are already developed or have been scheduled for development (LRMP, Appendix B). The Forest Plan includes a programmed recreation budget that would allow a full level of maintenance for facilities (LRMP, Appendix B, "Projected Budget"). As new sites are constructed, the maintenance budget would be increased In addition, the Forest Plan includes a program of new construction which would emphasize facilities closer to local communities, as well as rehabilitation or reconstruction of existing facilities to modern standards (LRMP, Appendix B, "Recreation Capital Investments"). In the past, developed sites that received minimal use were closed or dropped from the maintenance schedule and operated for dispersed use. If monitoring determines that existing developed sites receive minimal use, the Forest would continue to close them or operate them for dispersed use

149. *COMMENT*· REDUCE THE NUMBER OF COMMERCIAL FLOATERS AND INCREASE THE NUMBER OF PRIVATE FLOATERS ON THE ROGUE RIVER

Response· Changes in river management for both the Rogue and Illinois wild and Scenic Rivers was not included in the scope of this Forest Planning effort The Forest Plan incorporates, unchanged, the Rogue National Wild and Scenic River Management Plan (LRMP, Chapter I, "Special Area Plans") However, the Forest does intend, in cooperation with the Bureau of Land Management, to re-evaluate the River

Management Plan over the next five years This evaluation will include capacity levels and permit allocation for guided and non-guided river users.

150 *COMMENT*: USE TRAILHEAD BOXES FOR MONITORING NUMBERS OF HIKERS IT COULD NOT BE DETERMINED FROM THE DEIS WHETHER FIELD MONITORING FOR EACH ACTIVITY WOULD BE AT LEAST PART OF THE BASIS FOR EVALUATION. IF NOT, IT SHOULD BE.

Response: Hiker registration boxes at all formal trailheads are being, and will continue to be, used The information provided is used as a reference for monitoring numbers of hikers. Information collected from trail registration boxes is normally compiled within the Recreation Information Management (RIM) inventory on a yearly basis. This information is basic to tracking the level and type of uses that are occurring on the various trail systems (LRMP, Chapter V, "Monitoring").

151. *COMMENT*. A VISITOR CENTER AT AGNESS IS NOT REALLY A SOUND INVESTMENT AS THIS IS SO FAR FROM POPULATION CENTERS ABOUT THE ONLY PEOPLE USING THIS WOULD BE PEOPLE AT THE END OF THEIR RIVER TRIPS, AND THIS WOULD BE SORT OF ONE WAY.

Response: There has been an increasing demand for visitor information services from people driving into the Rogue and Illinois Wild and Scenic River corridors via Gold Beach and the Coast. In many instances, visitors come to see the river and are unaware of the many recreation opportunities available. The Agness facility (located near the Illinois River Bridge) would provide valuable information as to the availability of camping facilities, trailheads, motels, private campgrounds, closures, fire restrictions, and more The development of this facility remains on the schedule in order to meet the increasing demand for this type of service (LRMP, Appendix B, "Future Recreation Capital Investments").

However, before this facility is approved for construction, the project will be subject to a project-level environmental analysis. At this point, both Forest Service personnel and the public will be given the opportunity to participate in identifying issues, proposing alternatives, and reviewing the documented analysis. Whether it is a sound investment or not would be a most appropriate concern to raise at that time.

152. *COMMENT*: THE SENIOR CITIZEN GROUP NEEDS TO BE CONSIDERED FOR RECREATION FACILITIES IN THE SISKIYOU NATIONAL FOREST. CAMPGROUNDS AND PICNIC AREAS ARE NEEDED FOR VIEWING.

Response· The FEIS (Chapter II, Table II-4) lists all of the developed recreation sites and potential developed sites that are currently available for use on the Forest. The Forest has proposed a "modest program" of recreation construction for the future, which appears to be in line with projected levels of use. The program can be expanded if warranted by unexpected levels of demand. Most of these sites would be compatible for use by Senior Citizens (either individuals or groups).

153. *COMMENT*: THE FOREST SERVICE SHOULD NOT BE IN THE RECREATION BUSINESS (THROUGH DEVELOPED SITES, CONCESSIONS, MUSEUMS, ETC.).

Response: Congress has directed that the National Forests "be administered for outdoor recreation" in addition to other resources (Multiple-Use, Sustained-Yield Act of 1960). An objective of the Forest Service is to provide recreation opportunities for the public The policy in the past has been, and will continue to be, not to develop recreation sites close to private campgrounds that would create a competitive situation. Fees are collected at some developed recreation sites on the Forest, however, these are collected in order to provide funds for the maintenance and repair of the sites.

The philosophy behind the concessionaire program is to provide a business opportunity and to reduce the cost to the government for the maintenance and repair of these sites The concessionaire concept has been explored on the Siskiyou National Forest and is not considered feasible at this time, though there may be concessions in the future

The Forest maintains displays of artifacts that have local historic significance. These are open to the public at the Supervisor's Office and Ranger District Offices during business hours free of charge.

154. *COMMENT*. SPECIFIC SUGGESTIONS WERE MADE ABOUT THE FOREST PROVIDING "WILDLIFE VIEWING CORRIDORS" ALONG THE ROGUE RIVER (IN WHICH NO HUNTING WOULD BE ALLOWED) AND OTHER MAJOR TRAVEL CORRIDORS.

Response: The Rogue River is valuable for recreation and wildlife resources, as well as fisheries and other resources. Wildlife viewing along the length of the River is encouraged, though no "official" designations for that activity exist

The Oregon Department of Fish and Wildlife regulates hunting along the River. Establishment of a no-hunting corridor would best be pursued through that agency. At present, all land within one mile of the Rogue River between Grave Creek and Lobster Creek is closed to bear hunting In addition, the discharge of firearms is prohibited on all land within 1/4 mile of the Rogue River in the "Wild" River section from Grave Creek downstream to Watson Creek, except during authorized hunting seasons. Beaver and otter trapping is prohibited along the entire length of the Rogue River from Grave Creek to the mouth at Gold Beach.

Nonconsumptive use of wildlife is believed to be as high or higher than consumptive use (USFWS 1976). The Siskiyou National Forest has begun doing these types of projects, but many more opportunities are available. The Galice Ranger District recently closed the road through Horse Creek to vehicle travel. This special wildlife site is open to foot traffic; a bird and butterfly list is available. Other sites lend themselves to wildlife viewing and education, and the Forest will develop their ideas and those of the public as time and funds permit. A number of projects are scheduled as capital investments during the first decade after plan implementation. Examples of the types of possible projects are· educational signs in osprey and bald eagle habitat areas; Foster Bar elk viewing area; Adams Prairie overlook and educational signs; Bearcamp overlook kiosk, Happy Camp Road old-growth site information display; Lobster Creek old-growth trail; Illinois River Falls interpretive signs for salmon runs; interpretive trails through Habitat Areas allocated to spotted owls, pileated woodpeckers, and pine marten (the Waters Creek SOHA is particularly appropriate); wildlife interpretive signs along the Coquille River; brochures featuring viewing areas such as Horse Creek; development of species lists and other educational brochures; bluebird trails, highlighting of special wildlife areas through interpretive signs and brochures; development of wildlife viewing trails (such as in the Burned Timber meadow area).

155. *COMMENT*· BABYFOOT LAKE APPEARS TO GET ALOT OF USE. THE FOREST SERVICE NEEDS TO DEVELOP A PLAN TO PROTECT IT FROM BEING OVERUSED AND TO PREVENT THE SENSITIVE VEGETATION SURROUNDING IT FROM BEING DAMAGED.

Response: Babyfoot Lake is a very popular recreation site and is moderately to heavily used. At present, camping is not permitted within 200 feet of the lake in order to allow some vegetation recovery and protect existing vegetative cover Babyfoot Lake is just within the boundary of the Kalmiopsis Wilderness. As such, it is managed under the concept of "Limits of Acceptable Change " As recreation use causes unacceptable impacts to the Wilderness, resource users would be channeled to other areas or prohibited altogether. Management prescriptions for Wilderness are described in the Forest-wide Standards and Guidelines (LRMP, Chapter IV).

Trails

156. *COMMENT*: THE TRAIL SYSTEM SHOULD BE A PRIORITY NO MORE TRAILS SHOULD BE LOST TO ROADS AND LOGGING. ABANDONED SEGMENTS SHOULD BE REOPENED. TRAIL SEGMENTS WHICH IN THE PAST HAVE BEEN SUPERSEDED BY ROADS AND CLEARCUTS SHOULD BE RELOCATED TO ALLOW NON-MOTORIZED TRAVEL THROUGHOUT THE FOREST.

Response: The Forest Trail System is a priority The Forest received substantial comment concerning the protection and expansion of the trail system after the publication of the DEIS. In response, the Forest has placed more emphasis on the protection and maintenance of the entire Forest trail system Forest-wide Standards and Guidelines (LRMP, Chapter IV, "Dispersed Recreation") have been strengthened so that trail systems are thoroughly analyzed before roads can be built over them. If displaced, new sections of trail will be constructed that would be designed to maintain the integrity of the system. Trail maintenance funding has been increased (LRMP, Appendix B) so that one half of the entire trail system would be maintained annually.

Additional funds have been programmed that would expand the trail system through a modest program of construction and reconstruction. Approximately 114 miles of trail, trailheads, and bridges are identified in the capital investment schedule (LRMP, Appendix B) to be built in the first five years New trail construction emphasizes the development of loop opportunities within or between existing trails. Some abandoned segments of trail (such as the South Bank of the Illinois River) will be reopened for public use. Interagency trail development is anticipated as the result of the recently formed partnership between three National Forests, the Bureau of Land Management, the State of Oregon, and Josephine, Douglas, Jackson, and Curry Counties. Backcountry Recreation allocations will provide additional trail systems for both motorized and non-motorized recreation opportunities. Day use systems are planned in several areas of the Forest that provide interpretive opportunities and access for specific user groups such as equestrian groups or mountain bike enthusiasts.

157. *COMMENT*. MORE PROTECTION OF THE TRAIL SYSTEMS IS NEEDED, SUCH AS THOSE ON THE ROGUE AND ILLINOIS RIVERS.

Response· The Upper Rogue River Trail (#1160) is 42 miles in length and all but 16 miles are administered by the Bureau of Land Management. The majority of the section administered by the Forest Service is located within the Wild Rogue Wilderness (15 miles) where timber harvest is precluded by law (Wilderness Act 1978) The remaining one mile is located in an area of the Forest that is considered "visually sensitive" due to the large amount of recreation use that occurs The area within view of this portion of the trail would be managed at a constrained level to achieve the Retention and Partial Retention visual objectives under all alternatives in order to retain the character of the forest landscape. In the Preferred Alternative S, the foreground area (roughly within 1/4 mile of the rivers edge) is managed under a Supplemental Resource allocation which provides for no programmed harvest.

The Illinois River Trail (#1161) is located in a "visually sensitive" area of the Forest as well. The first six miles of the trail (between the trailhead at Oak Flat and Silver Creek) is a designated National Recreation trail and is located either within or immediately adjacent to the Illinois Wild and Scenic River. The remainder of the trail is located within the Kalmiopsis Wilderness where timber harvest is precluded by law. The area within view of the trail (outside of the Wilderness) would be managed at minimum levels to achieve Partial Retention under several alternatives (B, C, D, and D1; reference Chapter IV, FEIS). The remaining alternatives would manage the same area as a Backcountry Recreation area of varying size. Viewshed protection is provided under all alternatives

158 *COMMENT*: A MAJOR TRAIL SYSTEM SHOULD BE ESTABLISHED THAT CONNECTS THE GRANTS PASS AREA TO THE OCEAN.

Response: There are several cross-Forest trail systems that very nearly accomplish the link to the ocean (#1160, #1166, #1162, #1102, and #1210) It is possible that these trail systems could be expanded and linked with State or County trail systems, however none of these trails are scheduled for expansion at this time. In addition, there is an All Oregon Trail proposal (also unscheduled) that would provide access to the ocean. If built, this trail would begin in the vicinity of Cape Blanco, pass through the Grassy Knob and Kalmiopsis Wildernesses, and eventually terminate in the Hells Canyon National Recreation Area in the northeastern corner of the State.

159 *COMMENT*: SO MANY ROADS RUIN OPPORTUNITIES FOR OFF-ROAD HUNTING AND HIKING.

Response: Off road or cross country travel on the Forest is limited by terrain and vegetation, and is considered by most to be difficult at best. In that sense, roads provide access to unroaded areas that would otherwise be inaccessible to all but the most rugged backcountry traveler. The Forest has recognized the importance of the trail system and the related recreation opportunities that these facilities provide. The Forest Plan (LRMP) places more emphasis on the protection and maintenance of the entire trail system in the Forest-wide Standards and Guidelines. Several alternatives were considered in the FEIS that provided Backcountry Recreation allocations where access is limited to trails or off-road vehicle "ways " Off-road recreation opportunities including hunting would remain available in these areas (LRMP, Chapter IV, Management Area 6, and Appendix E)

160. *COMMENT*: IMPROVE THE CONDITION OF MANY OF THE HIKING TRAILS AND THE INFORMATIVE SIGNS ALONG THEM

Response: The Forest Plan has programmed full maintenance through projected budgets (LRMP, Appendix B) for the entire trail system every other year (one-half the system fully maintained each year) and anticipates visible improvement to the entire system in the near future Signing varies over the Forest. In areas outside the Wildernesses, the objective is to provide an adequate level of signing that will provide clear guidance through the trail system being used. Informative signs in appropriate locations will receive greater emphasis in the future. A number of trail projects are being developed that feature interpretive signs for historical values, fire behavior, and salvage efforts (LRMP, Appendix B). Inside the Wildernesses, the objective is to provide only enough signing to ensure the safety of recreationists. Self reliance is a part of the Wilderness experience and users are expected to research their route prior to departure

161. *COMMENT*: INSTEAD OF SINGLE DESTINATION "IN AND OUT" TRAILS, ADOPT THE GOAL OF LINKING AREAS LIKE THE RED BUTTES WILDERNESS AND SISKIYOU WILDERNESS VIA THE BOUNDARY TRAIL EXTENSION. DEVELOP TRUNK TRAILS THAT HAVE FEEDER TRAILS OFF THEM TO HIKE LOOP SYSTEM TRAILS. DEVELOP MORE LINK TRAILS

Response: A primary objective in the development of additional trails is to provide links between, or loops within, existing systems. The trail capital investments include development of trails that create these opportunities both in the Wildernesses and in other areas of the Forest. For example, the Forest has added trail development projects such as the Eagle Gap Trail (#1221A) to the investment schedule that would provide a valuable link between the Kalmiopsis Wilderness and the Scenic section of the Illinois Wild and Scenic River corridor. The trail #1144 from Florence Saddle to Flattop Mountain is listed as a potential trail and will be developed as the need arises.

Other loop opportunities are anticipated in the vicinity of Briggs Valley on the Galice Ranger District, Game Lake on the Gold Beach District, and in the Silver Creek drainage. Interpretive trails such as the Osgood Ditch project on the Illinois Valley Ranger District will provide a link between existing trail systems Tentative trail locations have been identified in the Grassy Knob Wilderness and, based on the public response to the DEIS, have been added to the list of potential trail projects. The connection to the Rogue River Trail is being considered as well The Grassy Knob Trail and Rogue River tie have been proposed as part of an All Oregon Trail The tie to the Rogue River trail is being considered in several alternative locations. These trail developments are displayed in the Capital Investment Schedule (LRMP, Appendix B)

162. COMMENT: THE GRASSY KNOB RIDGETOP TRAIL SHOULD BE USEABLE FOR HORSE TRAVEL AS WELL AS FOOT TRAFFIC.

Response· The management objectives for the proposed trail have not been developed at this time. Prior to construction, objectives will be identified (including the feasibility of horse use) and, if considered appropriate, the trail would be constructed to accommodate travel by horse

163. *COMMENT*: TRAILHEADS TO SERVE THE KALMIOPSIS WILDERNESS WILL MAKE THAT AREA ACCESSIBLE TO MORE PEOPLE.

Response: Recreation is an activity that can occur in Wilderness, but is secondary to the primary goal of the maintenance of the natural condition for which the area was designated (LRMP, Chapter IV, "Management Prescriptions, Management Area 1-Wilderness"). At present there are 13 trailheads that provide access to the Kalmiopsis Wilderness. There are no plans for the development of additional trailheads at present, although potential trailheads have been identified (LRMP, Appendix B) which can be developed as the need arises.

Visual Resources

164. *COMMENT*. THE FOREST SERVICE NEEDS TO INCREASE ITS PROTECTION OF SCENIC VALUES ESPECIALLY ALONG ROAD AND RIVER CORRIDORS, AS WELL AS AREAS SEEN FROM COMMUNITIES AND FROM TRAILS.

Response· Visual management allocations were re-evaluated based on the public response. Lands allocated to Management Areas 12 and 13 (Retention and Partial Retention) reflect the most sensitive travel routes and recreation use areas (LRMP, Chapter IV, "Management Prescriptions"). While some management may be evident in some of these areas, they are managed under constrained levels of harvest so that views to a natural or near natural Forest setting are expected to prevail.

Visual allocations have been made in areas of the Forest visible from the communities of Grants Pass, Takilma, Cave Junction, Brookings, Agness, and Powers. Other areas allocated include the Rogue and Illinois River corridors, major travel routes including Highway 199, the Bear Camp Road, the Coquille River Road, and other areas of the Forest identified in this Plan (LRMP, Chapter IV, "Management Prescriptions, Retention Visual and Partial Retention Visual").

Major rivers are protected by one of two allocations unless specifically stated otherwise in this Forest Plan (LRMP, Chapter IV, "Management Prescriptions") The Supplemental Resource allocation restricts harvest within 1/8 mile of the bank on either side of the river. Designation as a Wild and Scenic River restricts or precludes timber harvest within 1/4 mile from the bank on either side of the river. Wild and Scenic designation is often accompanied by allocations to visual resource management which place varying levels of constraints on timber harvest and other activities from ridge to ridge in the river corridor

In the development of Alternative S, preservation of visual quality was increased by approximately 131,000 acres primarily through the Backcountry Recreation allocation (Management Area 6) Allocations to Retention (Management Area 13) and Partial Retention (Management Area 12) were increased in areas of the Forest such as the Chetco, Elk, and Winchuck River corridors, the Wilderness access route in the vicinity of Game Lake, and in areas of the Forest that are visible from the city of Grants Pass (reference Table II-3, Chapter II, FEIS) However, overall there is a reduction in the inventory of Retention and Partial Retention carried in current management direction (Alternative A). This reduction is accounted for in two ways. (1) There were, of necessity, trade-offs made in favor of other resource values Areas currently managed for Partial Retention such as Copper Mountain and Frog Lake would be managed for Modification These reductions occurred primarily in areas of the Forest receiving very low recreation use, or in areas that are not visible from the primary travel routes. (2) Management Areas with restrictions that limit or preclude timber harvest were made that override the inventoried visual objective. For instance, the allocation to Backcountry Recreation restricts timber harvest (allowing salvage only under catastrophic circumstances) and would be managed under the Preservation visual objective This allocation would constitute an upgrade of the existing inventory and account for a significant portion of the apparent reduction in area allocated to Retention or Partial Retention.

Some specific suggestions regarding viewsheds and rivers were considered in developing Alternative S. A variety of options were used to protect the viewsheds specified In some cases, land allocations were already considered to be enough protection, such as those views overlapped by the Supplemental Resource allocation where the only harvest allowed would be a result of catastrophes. Other viewsheds were protected with a Retention Visual or a Partial Retention Visual allocation. Harvest could occur in these areas, providing visual objectives are met In general, activities must be designed to blend with the surrounding landscape so that they are not readily apparent to "casual Forest visitors".

165. *COMMENT* VISUAL MANAGEMENT CLASSIFICATIONS SHOULD BE ELIMINATED FROM THE PLAN. INSTEAD, EDUCATE PEOPLE ABOUT ACTIVITIES, THE REASONS FOR PERFORMING THEM, AND THE SHORT-TERM NATURE OF THE "NEGATIVE" VISUAL IMPACT. VISUAL MANAGEMENT IS APPROPRIATE TO WILDERNESS AND NATIONAL PARKS, NOT MULTIPLE-USE FORESTS WHERE VISUAL MOSAICS EXIST FOREST-WIDE.

Response: The elimination of visual quality objectives would not meet the requirements of NFMA implementing regulations. The visual resource shall be inventoried and evaluated as an integrated part of evaluating alternatives in the Forest Plan Visual objectives are assigned based on the Agency's perception of viewer sensitivity. Visual Quality Objectives (VQO's) are assigned to every acre of National Forest land (FEIS, Chapter III, "Visual Resource"), including those managed as General Forest. Harvest coefficients have been developed for each objective The Retention and Partial Retention objectives constrain harvest and require longer harvest rotations in order to maintain the natural or near natural character of the landscapes (LRMP, Chapter IV, "Management Prescriptions"). These objectives require smaller harvest units, and greater spatial dispersion These harvest constraints have been utilized in sale planning and implementation over the course of the last six years and have resulted in the successful achievement of visual objectives.

Last, it is agreed that the public perception varies widely. Public education as to the reasons for a given activity and the short-term nature of the impact (in many cases) definately needs increased emphasis. It is with this intent that visitor centers, public contacts by Forest officers, ties with the news media, and other forms of information and involvement are built into the management operations.

166. *COMMENT*: CREATE A FEW VIEWSHEDS THROUGH THE HARVEST OF TIMBER FOR TOURISTS AND FOR SPORTSMEN.

Response. The visual resource system is an inventory of Visual Quality Objectives that are based on the Forest Service perception of viewer sensitivity. Visual Management is based on the positive manipulation of vegetation toward specific objectives Included in those objectives is the strategic location of harvest units that are correctly sized and shaped to open views on various travel routes throughout the Forest.

167. *COMMENT*: TREES SHOULD BE HARVESTED TO THE ROAD WITH NO BUFFER ZONES, SO IN THE NEXT 15 YEARS THE DEER AND ELK ARE VISIBLE GRAZING IN THE CUT OFF AREAS AND THE VIEW IS MUCH IMPROVED, LEAVING TREES AT ROADWAYS ONLY BLOCKS THE VIEW OF THE SCENERY AND THE WILDLIFE.

Response: The Forest has established visual management objectives along most of the main traveled roads. In some cases these visual management objectives call for the maintenance of natural or near natural conditions within the viewing area from the road In those cases, management would try to screen activities, in other areas timber harvest may occur next to the road. In addition, one of the management tools used is to cut viewing windows along roads where it is desirable to open vistas or wildlife viewing areas that offer good viewing opportunities.

168. *COMMENT*: STREAM STRUCTURES OFTEN LOOK ARTIFICIAL AND MAR THE SCENIC ASPECT OF STREAMS

Response: In the past, stream structures were constructed that only considered the functional aspects of the facility. As the Forest Plan is implemented, new structures provided for improvement of fish habitat are planned (LRMP, Appendix C, "Fish Capital Investments") and will be installed within the constraints of visual objectives considered appropriate for the area. Forest-wide Standards and Guidelines and Management Area prescriptions for Retention Visual, Partial Retention Visual, and General Forest (LRMP, Chapter IV) speak to this requirement. Structures will be designed and constructed utilizing materials that blend with the surrounding environment.

169. *COMMENT*: WHAT ABOUT VISUAL OBJECTIVES THAT CANNOT BE MET DUE TO PAST LOGGING? WILL THESE AREAS BE MITIGATED? MITIGATION CAN NEVER BE SUBSTITUTED FOR LOST VISUAL QUALITY. THE AGENCY SHOULD ERR ON THE SIDE OF THE VISUAL RESOURCE AND MITIGATE THE IMPACT ON HARVEST LEVELS.

Response: Rehabilitation is a recognized Visual Quality Objective that is used in situations where past management has exceeded inventoried or allocated visual objectives. In all alternatives, rehabilitation would be used to mitigate past harvest effects in areas allocated to visual resource management (USDA Handbook #462)

Off-Road Vehicle Use

170 *COMMENT*: MAKE MORE TRAILS OPEN TO THE PUBLIC FOR MOTORIZED USE. LOCAL GROUPS WANT RECREATIONAL OPPORTUNITIES FOR USING MOTORCYCLES AND ALL-TERRAIN VEHICLES.

Response: In response to public interest in motorized recreation, several changes were made since the DEIS. The Backcountry Recreation Management Area was expanded in the Preferred Alternative to include motorized use for the major acreage in this allocation (LRMP, Chapter IV, "Management Prescriptions"). Standards and Guidelines were changed to accommodate both motorized and non-motorized uses,

depending on location and Management Area goals (LRMP, Chapter IV) All trails have been re-assessed for use by off-road vehicles. Of approximately 233 miles of non-Wilderness trail on the Siskiyou, about 171 miles (73 percent) are unrestricted use. The updated list of trails and those closed to motorized uses are listed in the LRMP, Appendix E. Opportunities for trail system development in the motorized areas are identified for off-road vehicles, including jeep-type vehicles, also in Appendix E (LRMP).

171. *COMMENT*: THE FOREST PLAN SHOULD CONTAIN PROVISIONS TO ELIMINATE OFF-ROAD VEHICLE RECREATION ORV USERS SHOULD BE RESTRICTED TO PRIVATE LANDS OR, AT LEAST, TO SPECIFIC AREAS, TO LIMIT ENVIRONMENTAL DAMAGE AND TO SEPARATE THEM FROM OTHER FOREST USES THEY SHOULD NOT BE ALLOWED ON TRAILS BUILT ON SOFT GROUND OR ON STEEP GRADES.

Response: The National Forest System is managed under the concept of multiple uses, including providing an array of recreation opportunities that range from heavily developed sites to very primitive opportunities One of the uses that is acceptable is off-road vehicular use, although it is prohibited in areas where resources may be adversely affected (LRMP, Appendix E). The Forest recognizes the sensitivity of some areas and regulates their use. At present, the Forest has approximately 450 miles of trail Of these, approximately 217 miles of trail are located within the Wildernesses, and another 62 miles are closed to vehicular access for various reasons (LRMP, Appendix E). The remainder of the trails, about 171 miles, or 38 percent of the total trail system, are open to vehicular use.

All trail systems should be inspected annually to identify trail maintenance needs. Sufficient maintenance shall be provided to protect soil and water resources (LRMP, Chapter IV, "Forest-wide Standards and Guidelines"). If unacceptable resource damage is occurring and maintenance does not solve the problem, then the Forest could close that system until the damage is repaired, or close the trail to motorized uses permanently.

172. *COMMENT*: ORV USAGE AREAS SHOULD BE DESIGNATED SO THAT RESULTING NOISE WILL NOT CARRY INTO WILDERNESS OR OTHER RECREATIONAL AND WILDLIFE AREAS

Response: The Backcountry Recreation allocations (Management Area 6) made in several of the alternatives are designed to accomodate both non-motorized (includes mechanized but not motorized vehicles) and motorized (generally limited to ORV's) uses. In general, those areas located immediately adjacent to Wildernesses would be managed for non-motorized uses and the remainder for motorized uses This is expected to provide a range of opportunities at the same time maintaining the feeling of solitude in the Wildernesses In wildlife areas (Management Area 9), motorized activities "should be prohibited" except where such use is not detrimental to wildlife (LRMP, Chapter IV, "Management Prescriptions").

173. *COMMENT*. ALL TRAILS THAT LEAD TO WILDERNESS AREAS SHOULD BE CLOSED AT THE TRAILHEAD TO ORV'S AND ALL-TERRAIN BICYCLES TRAILS AUTHORIZED FOR MOTORCYCLE AND ALL-TERRAIN BICYCLE (ATB) USE SHOULD BE OF SUCH A STANDARD THAT A GROOVE WILL NOT RESULT IN THE TRAIL FROM THEIR USE.

Response: At present, trails located outside of Wilderness but accessing Wilderness trail systems are not closed to motorcycles and all-terrain bicycles. Trailheads are posted, notifying users that the Wilderness is closed to vehicular use (LRMP, Appendix E). In addition, the Forest is making the effort to educate the public prior to use, rather than allowing the issue to become an administrative problem Trails that are open to motorized use are maintained to a standard that is higher than that used for pedestrian trails to avoid such problems as grooves from vehicle use The Trail Management Objectives will identify the maintenance

level required for each of the Forest system trails (LRMP, Chapter IV, Forest-wide Standards and Guidelines).

174. *COMMENT*. ALLOW NO OFF ROAD VEHICLES IN ROADLESS AREAS.

Response: Areas inventoried as roadless were released to multiple-resource management as a result of the 1984 Wilderness Acts. An array of management prescriptions was considered for these areas in the different alternatives considered in the FEIS. Some of these roadless areas would be managed as Backcountry Recreation Management Areas that would not allow off-road vehicle use. Other alternatives allowed motorized use in some of the Backcountry areas (See FEIS, Chapter II, "Wilderness and Roadless Areas").

Historic use and public input were used in developing the Preferred Alternative S, including the Backcountry Recreation Management Area. In Alternative S, some roadless areas would be in a non-motorized Backcountry Recreation area Others, with historic four-wheel drive use and mining roads, such as the South Kalmiopsis, would be in a motorized Backcountry Recreation area (LRMP, Chapter IV, "Management Prescriptions").

175. *COMMENT*: YOU SHOULD ADD A STRATEGY TO CONSIDER THE SUCCESSES OF USER-COOPERATIVE PROGRAMS, SUCH AS ADOPT-A-TRAIL/ROAD, WHICH HAVE BEEN A HIGHLY SUCCESSFUL MANAGEMENT TOOL IN MANY FORESTS. WE REQUEST THAT YOU REVERSE THE INCREASING CLOSURE TO 4WD VEHICULAR USE THROUGH SHARING MANAGEMENT RESPONSIBILITIES WITH INVOLVED USER GROUPS.

Response: Motorized recreation opportunities are provided on the Forest, including use by ORV's and four-wheel drive vehicles (LRMP, Chapter IV, "Management Prescriptions"). While this program exists, should additional user groups desire cooperative involvement in an adopt-a-trail/road project, the Forest would welcome that participation.

EDUCATIONAL VALUES

176 *COMMENT*: MORE INTENSIVE FOREST SERVICE OUTREACH EDUCATIONAL PROGRAMS ARE NEEDED TO PROVIDE AN UNDERSTANDING OF FOREST MANAGEMENT AND GOALS. PERHAPS TOURS OF LOGGING OPERATIONS COULD BE ARRANGED, OR COURSES PRESENTED WHICH DISCUSS THE ECOSYSTEM AND FOREST RELATIONSHIPS.

Response: The Siskiyou National Forest does, and will continue to, provide educational material and presentations to any group that requests such information. This is generally accomplished on an individual request basis by Ranger District or Forest Supervisor's office personnel. Interpretation programs can be initiated by the Forest, for example, for cultural resource sites (LRMP, Chapter IV, "Standards and Guidelines") As the demand for more educational programs increases, there are opportunities to increase the interpretation program. It would certainly be one method to support recreation and tourism in the area (LRMP, Chapter IV, "Forest Management Goals").

177. *COMMENT*: THE SISKIYOU NATIONAL FOREST SHOULD DEVELOP SEVERAL INTERPRETIVE AREAS FOR EXAMPLE, A DARLINGTONIA BOG, A KALMIOPSIS PATCH, THE AREA CONTAINING THE BIGGEST OLD-GROWTH TREES ON THE FOREST, AND GEOLOGICAL ATTRACTIONS - TOURIST TYPE THINGS WITH EASY ACCESS

Response: The Forest has long recognized the uniqueness of the biological, historical, and geological diversity of the Siskiyou Recreation use is encouraged in areas offering high educational value, though development and access may be limited to trails due to the sensitivity of the areas These suggestions for interpretive areas are excellent, and the Forest will try to incorporate these in site-specific proposals, as well as enlist the support of the local community through partnership and cooperative efforts to accomplish the projects.

178 *COMMENT*: MORE INTERPRETIVE SIGNS ARE NEEDED AT RESOURCE SITES SO THE PUBLIC KNOWS WHAT SPECIFIC SITES ARE BEING MANAGED FOR.

Response: Interpretive signing will receive greater emphasis in all resource areas in the future. Capital investment projects are scheduled that incorporate interpretive signing such as at the Bear Camp and Shasta Costa Overlooks (LRMP, Appendix B) Signing at these locations will address historical values and a variety of other resources, including visual resource management, vegetative diversity, and geological interests A number of trail projects are being developed that feature interpretive signing for historical values, and for fire behavior and salvage efforts

INVESTMENTS AND TIMBER VALUES

179. *COMMENT*: NATIONAL SUPPLY AND DEMAND PROJECTIONS ARE FACTORS WHICH NEED TO BE CONSIDERED WHEN EVALUATING THE AMOUNT OF TIMBER OFFERED FROM NATIONAL FOREST LAND

Response: The effect of the National consumption of softwood forest products, the future economic markets, and the cumulative effects of different ownerships for timber production are discussed in the FEIS, Chapters II, III, and IV, "Timber "

180. *COMMENT*: INDIVIDUAL TIMBER SALES HAVE BEEN SOLD AT AN ECONOMIC LOSS AND THESE LOSSES SHOULD BE AVOIDED, EITHER BY SETTING MINIMUM BID PRICES FOR TIMBER TO ASSURE COSTS WILL BE COVERED, OR BY REMOVING ECONOMICALLY UNSUITABLE LAND FROM THE TIMBER BASE. THE ILLINOIS VALLEY RANGER DISTRICT HAS BEEN IDENTIFIED BY THE COMMENTS AS HAVING DIFFERENT CONDITIONS WHICH CAUSE IT TO HAVE MANY "BELOW COST" SALES. IT WAS SUGGESTED THAT THESE DIFFERENCES SHOULD BE MODELED BY HAVING DIFFERENT STAND DENSITY INDEXES FOR EACH DISTRICT.

Response: The Forest Service does not consider the cash flow from an individual sale as the indicator of the economic suitability of the land base. Such cash flow includes the costs of capital investments such as road construction and tree improvement, and maintenance of investments such as road reconstruction. These investments have a longer life span than the timber sale and need to be amortized over the life span of the road. The cash flow from an individual sale does not account for the Forest-wide effects over time in the timber program Such effects have been taken into account by the FORPLAN model. It is a tool designed to screen lands in the General Forest, Partial Retention Visual, Retention Visual, and Riparian Management Areas for timber management if (1) that selection of land groupings is economically efficient, and (2) it accounts for the Forest-wide effects on allowable sale quantity for a period of 150 years.

The Forest Service also compares costs which occur in different time frames by discounting the costs and values to the present. To simply add costs and values from different years does not account for the value or cost of money over time.

In 1988, the Timber Sale Program Information Reporting System (TSPIRS) analysis for the annual timber program on the Siskiyou National Forest indicates a large positive value for the timber sale program.

The Forest Service does not include payments to counties as a cost when making a Forest Planning decision. The transfer of funds from the Federal government to the local government, whether it is for welfare payments, revenue sharing, or payments to counties from timber revenue, is subject to Congressional legislation and is not within the scope of the Forest Service planning decisions or analysis If the Forest Service chose to include a macro-economic analysis, which includes the Federal payments to local governments, then such analysis would also include Federal and state income tax generated from Forest Service activities, social security payments, and welfare transfer payments such as food stamps. However, all of those items are not decision variables for the Siskiyou National Forest and, consequently, are not included in the Forest analysis.

The timber inventory, as documented in the FEIS, Appendix B, is divided into high, moderate, and low site classes. Each Ranger District has differing percentages of high, moderate, and low site classes depending on the local growing conditions. Consequently, the analysis has resolution reflected to site classes which represent productivity for each District. Forest-wide average costs, which include such items as precommercial thinning (which may not occur on low site lands), are appropriate for use when examining one District's timber program.

181. *COMMENT*: TIMBER PRICES USED IN THE FORPLAN MODEL ARE TOO HIGH AND THE TIMBER PRICE TREND IS UNREALISTIC, RESULTING IN UNREALISTIC TIMBER REVENUES

Response. The timber market has been a cyclic market with periodic robust times and hard times. Timber prices in the FORPLAN model reflect cut values for timber sales sold between 1973 and 1982. This period includes both the high and low markets for timber More recently, in 1988 several sales have sold at rates over $500/MBF (which is higher than the rate used in FORPLAN). Even the salvage sales with the fire-killed timber from the 1987 fire seasons have had substantial overbids. Conversely, during the depressed market of the early 1980's, bids were low with very little overbid The figures used in FORPLAN represent an average over a decade for stumpage harvested from the Siskiyou.

The Forest Service tested the sensitivity of the Siskiyou FORPLAN model to lower stumpage prices (an average of $167/MBF as suggested by Randall O'Toole). The results did not reflect any change in allowable sale quantities for Alternative K from the higher stumpage rates used in the DEIS. Consequently, no change in outputs would be predicted for Alternative K even if lower stumpage values were used. However, the PNV of the alternative changes substantially with the lower stumpage rates. Alternative K uses the maximum timber objective function which masks the effect of the lower stumpage rate

When a lower stumpage rate is used for the max-PNV Benchmark ($167/MBF), a seven percent reduction occurs in the first decade allowable sell quantity. However, the amount of suitable lands managed for timber only decreases by 8,000 acres (one percent decrease). The lower stumpage rates change the management intensity regimes and options which are economically efficient. It does not drop many acres of suitable land due to economics. With lower stumpage rates, extensive regimes are more economically efficient for timber management.

Using the results from the PNV Benchmark run and discounting the effects of the timber price trend, the first 10 decades of timber management would have total timber revenues exceeding total timber costs. However, the next five decades would have a negative cash flow. The effects of the price trend with the stumpage rates used in the FEIS are documented in Appendix B.

182. *COMMENT*: THE PROPOSED PLAN MAY CAUSE RISING STUMPAGE PRICES THROUGH SPECULATIVE BIDDING BY MILLS PRESSED TO MEET DEMAND.

Response: Speculative bidding is not controlled by the Forest Planning process, and is outside the scope of the Forest Plan. Available timber supplies from all ownerships interact with the aggregate demand for wood products to determine bid prices (FEIS, Chapter III, "Economic and Social").

183. *COMMENT*: CROSS SUBSIDY OF LOW VALUED STANDS WITH HIGH VALUED STANDS VIOLATES THE FOREST SERVICE TRACT VALUE POLICY.

Response: The Forest Service Manual, Section 2403.25--1 reads, "Offerings of timber will not be made under conditions which permit leaving usable portions of trees Offerings will not ordinarily be made which provide for removing only certain more valuable species from mixed stands . As a general rule, the *total* appraised value of a tract of timber will not be reduced to obtain utilization of a species, size, or class material. Average appraised stumpage prices may, however, be reduced in order to obtain more complete utilization, provided that the additional volume included as a result of the reduction is sufficient to obtain a return of at least the same total appraised value."

184. *COMMENT*: INVESTMENTS FOR SECOND-GROWTH MANAGEMENT ARE UNECONOMICAL.

Response The Forest Service is required by law to reforest harvested lands. Consequently, if a stand is harvested, then second-growth management will occur. The question to be answered, then, is, "Should the lands be harvested?" Such an economic question will compare the costs and benefits of harvest activity, reforestation costs, and timber stand improvements. To exclude the stumpage values and harvest costs of existing stands when analyzing second growth management would only be meaningful if the Forest Service could consider harvest without management of second growth.

The analysis for second growth management should also include the Forest-wide effects of different silvicultural practices. A silvicultural practice may not pay for itself on a per acre basis, but may allow the harvest of more acres due to faster tree growth This allowable cut effect is appropriate to consider when evaluating second growth management

The FORPLAN model for the Siskiyou National Forest has been used to consider the harvest questions and allowable cut effect for different management intensities of second growth It incorporates the harvest values and costs of existing stands, the allowable cut effects, and the costs and benefits of second growth management (FEIS, Appendix B)

185. *COMMENT*: FUTURE TIMBER VALUES SHOULD BE LOWER THAN PRESENT BECAUSE MORE LOWER GRADE WOOD WILL BE REMOVED VIA LOGGING EFFICIENCY.

Response· Future timber values are modeled as a function of the average diameter of the harvested material. The function accounts for the differences in grade between old-growth and second-growth timber (FEIS, Appendix B).

186. *COMMENT*: $40 MILLION IS PLANNED FOR ROAD CONSTRUCTION IN THE FIRST DECADE THE NEED FOR THIS AMOUNT OF MONEY TO BE SPENT ON ROADS, WHICH ARE FOR THE VAST MAJORITY ALREADY BUILT (DEIS, III-2), IS NOT JUSTIFIED IN THE PLAN OR DEIS

Response: Alternatives vary from low roading projections (and costs) in Alternatives M, G, and E, to higher amounts of road (and associated costs) to be built in Alternatives B, C, D, and D-1. The other alternatives (NC, K, and S) are in between (FEIS, Chapter IV, "Improvements"). Projected roads are ones that have not yet been built. The Siskiyou National Forest has many areas which are yet unroaded. Much of the terrain requires expensive road construction to avoid adverse environmental impact. The expensive roads are offset by the relatively high stumpage values of the timber located on the Forest

PLANNING

ADEQUACY OF THE DOCUMENT

Adequacy/Accuracy of Data

187. *COMMENT*: THE DRAFT ENVIRONMENTAL IMPACT STATEMENT IS NOT WRITTEN IN LANGUAGE WHICH MAKES THE PLANNING PROCESS UNDERSTANDABLE BY THE GENERAL PUBLIC. UNLESS A REVIEWER HAS A SUBSTANTIAL PRIOR UNDERSTANDING OF THE PLANNING PROCESS, ORGANIZATION, MODELS, ANALYTICAL TOOLS, AND IMPLICATIONS OF THE ALTERNATIVES, IT IS IMPOSSIBLE TO GLEAN THE NECESSARY INFORMATION FROM THE DEIS TO COMMENT MEANINGFULLY

Response. Part of the analysis, by its requirements and inherent nature, is difficult for ease in understanding. In the Final Environmental Impact Statement, we have attempted to explain the analytical details in a simplified, comprehensible fashion. However, some technical concepts simply do not translate to clean and simple language For that reason, much of the discussion regarding analytical processes (i e , "models and tools") is found in an appendix (B) to the FEIS rather than in the main body.

Members of the Interdisciplinary Team have given considerable time explaining and interpreting the technical aspects and resource interrelationships to any and all people who have requested assistance. This assistance and continuing dialogue has persisted since issuance of the Draft Environmental Impact Statement. Many "white papers" were prepared and distributed in response to requests for additional discussion and clarification. Only a limited few have delved into the documents in great detail, these analysts have been provided the time and explanation necessary to comment meaningfully

Last, by the very nature and complexity of Forest Planning and accompanying environmental documents, light reading and simplicity are not their virtue. The Interdisciplinary Team and writer-editors have attempted to reduce technical jargon and the extemely interwoven issues to an understandable level This effort has occasionally backfired in cases where the more technically-minded reviewer sharply critiqued the discussions as being too basic or incomplete. For most, the table of contents, detailed index, and tracking of issues by Planning Problems helps immensely. And, as noted, members of the Interdisciplinary Team and Forest staff are always willing lend assistance where clarity is not apparent

188. *COMMENT*: INVENTORY NUMBERS AND ASSOCIATED STATISTICS ARE INADEQUATE (DUE TO INADEQUATE SAMPLE OR FIRE EFFECTS)

Response: The Siskiyou National Forest was mapped and inventoried in 1978-79 The statistical accuracy has been validated for the degree of precision and reliability needed at the Forest Plan level of resolution. The Forest-wide volume estimates are within 10 percent at the 67 percent confidence interval.

The effects of the 1987 fires have been evaluated and are described in FEIS Chapter III, "1987 Fires." This relationship with the alternatives is described in the FEIS Chapter II, "Implications of the 1987 Fires."

The Siskiyou National Forest is scheduled to be reinventoried in the next two to three years FORPLAN outputs for the Forest Plan will be reanalyzed with these new data as part of the Monitoring Plan The need for adjustments to ASQ and other projections will be studied in light of this analysis (LRMP, Chapter V, "Table V-1: Monitoring and Evaluation Program").

189. *COMMENT*: THE INVENTORY FOR, OR DEFINITION OF, LAND SUITABLE FOR TIMBER PRODUCTION IS INACCURATE OR TOO BROAD A LARGE PROPORTION OF ROADLESS AREAS WOULD BE ELIMINATED FROM SUITABLE LANDS, AND ASQ REDUCED, IF MORE ACCURATE INFORMATION WAS USED

Response: Land suitability is defined by the physical capability of the lands to comply with legal requirements if managed for timber production. These requirements are described in FEIS, Appendix B, "Suitability Analysis." All available data sources were compiled and evaluated by knowledgeable, qualified Ranger District personnel (silviculturists, soil scientists, and geologists) to determine and map suitable lands on a site-by-site basis The latest reforestation technology, including applicable results from Forest Intensive Research (FIR), was considered when determining the potential of various sites for prompt reforestation without irreversible resource damage.

Two potential circumstances could modify the suitable land base in the future. Further field examination of sites may refine the existing information base and indicate that changes in suitability classification are necessary on a site-specific basis Changes in reforestation, soil erosion control technology, or special harvest systems and site prescriptions may permit some additional lands to be promptly reforested without irreversible resource damage These changes will be monitored for significance of their aggregate effect on Forest Plan projections as described in LRMP, Appendix D, "Monitoring and Evaluation Program Background."

190. *COMMENT*: IT IS NOT CLEAR WHY BASIN HARVEST CONSTRAINTS ARE SET AT THE SPECIFIC PERCENTAGES OF THE GENERAL FOREST AND ALSO THE BENEFITS AND COSTS OF LEVELS DIFFERING FROM THE ONES CHOSEN.

Appendix B of the FEIS describes how the Planning Basin harvest dispersion constraints were developed for the alternatives. In response to public input, the timber harvest dispersion constraints were re-evaluated as used in the original model, FORPLAN Version I, compared with Version II. Changes were made as described in Appendix B and Chapter II of the FEIS. The benefits and costs of levels are also briefly described in Appendix B.

191. *COMMENT*: WHY WAS THE 150-YEAR HARVEST SCHEDULE USED INSTEAD OF THE RPA 50-YEAR PLANNING HORIZON? OR 200 YEARS?

Response: The alternatives presented in the FEIS contain management direction for the Plan period The Plan period covers the next 10 to 15 years. The NFMA regulations define the Plan period as one decade (36 CFR 219.3 (1982)), while the law permits a 15-year maximum (16 USC 1604 (f)(5)). the Forest Plan analysis considers a 150-year planning horizon to ensure that management plans can be implemented over the long term, and to disclose and evaluate long-term environmental consequences (FEIS, Chapter I, "National, Regional, and Forest Planning")

192 *COMMENT*: BOARD FOOT/CUBIC FOOT RATIOS ARE INACCURATE (OR NOT DISPLAYED) AND SHOULD VARY ACCORDING TO THE MATERIALS BEING PRODUCED IN THE FIRST DECADE

Response: The BF/CF ratio used for display of the board foot volume ASQ for the first decade has been revised to more closely reflect the actual volume expected to be harvested. This revision better reflects the conversion ratio for the average product size that will be produced in the first decade. This change is mentioned in several places in the FEIS and discussed in Appendix B, "Forest Planning Model Development of Yield Coefficients."

193. *COMMENT*: A TIMBER PRODUCT DEMAND FORECAST COULD NOT BE FOUND IN THE DOCUMENT.

Response. The timber product demand forecast can be found in the following tables: "Projected Consumption of National Forest Timber-Coos and Curry Counties," and "Projected Consumption of National Forest Timber-Jackson and Josephine Counties" (FEIS, Chapter III, "Economic and Social").

194. *COMMENT*. THE ANALYSIS UNDERESTIMATES TRUE DEMAND FOR WOOD PRODUCTS, CURRENT AND PROJECTED.

Response: Demand has been re-analyzed in the FEIS (Chapter III, "Economic and Social") Region Six/Pacific Northwest Experiment Station projections were used and greater demand was projected than in the DEIS

195. *COMMENT*: INCLUDE THE PROJECTED INVENTORY OF WOOD VOLUME IN THE CHART OF PROJECTED SUPPLY AND DEMAND.

Response: Projected wood volume inventories have been modeled in the references cited in the FEIS, Chapter III, "Economic and Social." These inventories were used to project future harvests from different ownerships that are displayed in tables in that section

196. *COMMENT*: JUSTIFY THE USE OF SELL RATHER THAN CUT DATA FOR HISTORIC HARVEST LEVELS.

Response: Both the Forest Plan comparison of projected outputs by alternative (FEIS, Chapter II) and estimates of economic effects (FEIS, Chapter IV) assume that all National Forest timber offered for sale in the future will be sold and harvested This assumption is necessary to provide a common point for comparison of alternatives and analysis of effects. If all timber offered is not sold and harvested, then effects and comparisons may be different than estimated. Also displayed in Chapter II for comparison purposes is the historic cut data from 1963 through 1987.

197. *COMMENT*: PROJECTIONS OF FUTURE TIMBER SUPPLY FROM OTHER PUBLIC AND/OR PRIVATE LANDS ARE WRONG (TOO LOW); REFER TO PNW PAPER.

Response: Timber supply projections have been revised in the FEIS based on Region Six/Pacific Northwest Experiment Station projections (FEIS, Chapter III, "Economic and Social").

198 *COMMENT*. THERE ARE NO PROVISIONS FOR POPULATION GROWTHS AT VARIOUS LEVELS. THERE COULD BE MORE PRESSURE FOR. TIMBER CUTTING, PERMITS ON THE ROGUE RIVER, LOCATIONS FOR HOMES, HUNTING, FISHING, AND RECREATION.

Response. Projected demand for hunting, fishing, and recreation are based on the projected population growth over the next 50 years. Timber demand is influenced by markets over wider areas (National and international); studies of timber demand include projections of needs for housing and other factors The Forest monitoring program has demand and consumption trends as a monitoring item for tracking increased pressure on the Forest resources (LRMP, Chapter V) Changes will be made in the future as trends become more evident. Sensitivity analysis has been done for timber prices and recreation trade-offs (FEIS, Appendix B)

199. *COMMENT* CONCERN WAS EXPRESSED THAT THERE ARE MORE LANDS UNSUITABLE FOR TIMBER HARVESTING THAN HAS BEEN ESTIMATED IN THE CURRENT INVENTORY

Response: An inventory of lands suitable for timber production was made by use of aerial photos and field verification. Whereas this provides a good approximation, this process was not designed to identify all unsuitable areas (FEIS, Appendix B). Following the initial inventory, data is collected annually through project-level field analysis and inventory, with an update of the suitability lands map made each decade That ten-year update would include changes of unsuitable and suitable lands identified during the course of the decade, as well as a review of current suitability maps. Suitability maps are located at Forest Supervisor and Ranger District offices. The monitoring plan provides for re-evaluation if the acreage adjustments indicated during the Planning period reaches a significant level (LRMP, Chapter V, Appendix D).

200. *COMMENT*: AS STATED BY THE FOREST SERVICE ITSELF IN ITS SOIL INVENTORY, 1/3 OF THE 624,240 ACRES TENTATIVELY SUITABLE FOR LOGGING AND ROAD BUILDING IS RATED AS "HIGH EROSION HAZARD" (DEIS III-65). THE PREFERRED ALTERNATIVE DESIGNATES ONLY 22,206 ACRES AS UNSUITABLE DUE TO IRREVERSIBLE SOIL DAMAGE, WHERE, ACTUALLY, GREATER THAN 200,000 ACRES SHOULD BE DESIGNATED AS UNSUITABLE. THIS IS ONE INSTANCE OF MISREPRESENTING THE FACTS, OR, MORE ACCURATELY, IGNORING THE AGENCY'S OWN RESEARCH.

Response: Soils rated as high erosion hazard are not equivalent to lands classified as unsuitable for timber production (FEIS, Appendix B). Many highly productive and reforestable soils have a high potential for erosion, but would incur little soil loss with a minimum of ground disturbance "High erosion hazard" as discussed in the Soil Resource Inventory represents the potential, and is not evaluated in light of applying mitigation measures provided in the Standards and Guidelines and associated Best Management Practices (LRMP, Chapter IV and Appendix F). Classification of lands unsuitable for timber harvest, on the other hand, is based on several criteria, including potential mass wasting and potential surface erosion. As a result, there is much less unsuitable land than high erosion hazard land.

201. *COMMENT*· A SHORT, CONCISE PLAN SHOULD HAVE BEEN PREPARED WHICH WOULD PROVIDE CONGRESS AND "WE THE PEOPLE" YOUR BEST ESTIMATE OF PRESENT VALUE OF THE OLD-GROWTH TIMBER ON YOUR ENTIRE FOREST, THE POSSIBLE ANNUAL INCOME THAT THE FEDERAL AND OTHER GOVERNMENT BODIES COULD EXPECT BY UTILIZING ALL TIMBER RESOURCES (EXCEPT FOR A FEW SMALL AREAS RESERVED FOR PUBLIC ACTIVITIES), AND THE PRESENT INCOME AND EXPENDITURES FOR YOUR ENTIRE FOREST.

Response· The present value of the timber program on the Forest is presented in Chapter II of the FEIS The average net receipts to the Federal Government are displayed in Table II-62, "Indicators of

Responsiveness to Planning Problems". The present income and expenditures for the Forest are estimated for the No Change Alternative in Chapter II Tables.

202. *COMMENT*: DEVELOP A LARGE-SCALE MAP SHOWING DETAILS OF THE EXISTING STATE OF THE FOREST AND PROPOSED HARVESTS.

Response. Because of limited demand and high cost, large-scale maps have not been produced for distribution on a regular basis. Maps of the many of the individual layers used in the Forest Plan analysis have been produced at a 3/8-inch to one-mile scale. These have been made available for inspection by various people wishing to see them, and at numerous public meetings. They are in the Process File in the Forest Supervisor's Office Others could be produced if needed. These maps provide the same resolution and detail used in Forest planning at the programmatic level Large scale maps of proposed timber sale analysis areas for the first decade of the Forest Plan are available for inspection at the Ranger District offices. However, individual harvest units will be identified in the project environmental analysis and are outside the scope of the Forest Plan programmatic analysis.

203. *COMMENT*: PROJECTIONS OF RECREATION USE SHOULD BE BASED ON HISTORICAL USE TRENDS ON THE FOREST AND DEMOGRAPHIC TRENDS FROM LOCATIONS THAT PROVIDE A MAJORITY OF THE USE.

Response: The Siskiyou National Forest is not considered a heavily used recreation Forest when compared with other Forests in California or the Pacific Northwest. Rates of increase based on demographic trends from surrounding communities were considered, but the results did not seem consistent when compared to historic rates of growth. A growth rate of one-half percent per year over the life of the Plan was taken from research sources (Oregon State University Research Bulletin #28, 1979) and used in making projections (FEIS, Appendix B, "Development of Yield Coefficients"). When projected over time, this rate of increased use was found to be consistent with historic trends. Since initiating the Forest Planning process, annual recreation use figures do not indicate a major shift from this projection. For more information on this analysis, see the Planning Records at the Siskiyou National Forest Supervisor's Office

204. *COMMENT*: A SERIOUS DEFICIENCY OF BACKGROUND RESEARCH AND INFORMATION, ESPECIALLY ON WILDLIFE, DISQUALIFIES THE FOREST PLAN AS LEGALLY VALID OR COMPLETE UNDER THE PROVISIONS OF NFMA. ADDITIONALLY, THIS INADEQUATE INVENTORY AND RESEARCH BASE RENDERS THE MONITORING PROGRAM ILLEGAL AND INEFFECTIVE UNDER THE TERMS OF THE ACT.

Response: It was necessary to proceed with the Forest Plan with the best information currently available. We agree that there are deficiencies in available information in many areas, including on many species of wildlife. Incomplete or unavailable information needed for better Forest planning and management are identified in the Forest Plan (LRMP, Chapter II, "Information Needs"). Research is ongoing, and the Plan can be modified if new research findings indicate the need. The Plan could also be modified if monitoring indicates problems with implementation (LRMP, Chapter V, "Monitoring and Evaluation" and "Amendment and Revision").

205. *COMMENT*. A MODIFICATION OF TABLE IV-5 IN THE DEIS USING PERCENTAGES RATHER THAN ACREAGES IS NEEDED. IT MAY BE EASIER TO ENVISION THE COMPARISON AND COMPREHEND THE EFFECTS EACH ALTERNATIVE MAY HAVE ON MINERAL RESOURCES.

Response: Figure II-19 in the FEIS is a bar graph designed to illustrate the differences among the alternatives with respect to access restrictions. The figure is intended to complement Table IV-5 and the accompanying text addressing effects of alternatives related to minerals development.

206. *COMMENT*: THE DRAFT DOCUMENTS FAIL TO MEET THE BEDROCK STANDARDS OF THE NEPA AND NFMA. WHERE IS THE DATA TO SHOW WHICH AREAS ARE UNSUITABLE FOR LOGGING BECAUSE FINANCIAL COSTS WOULD BE LARGER THAN THE VALUE OF THE WOOD? HOW MANY BELOW-COST OR CROSS-SUBSIDIZED TIMBER SALES CAN WE EXPECT?

Response: Discussions regarding the suitability of forest lands for timber production are found in the FEIS, Chapter III, "Suitability," and Appendix B, "Suitability Analysis." Additionally, see the LRMP, Chapter II, "Resource Supply Conditions," and Chapter III, "Response to Planning Problems."

Essentially none of the lands that were determined to be tentatively suitable for timber production were subsequently determined to be inappropriate for timber production solely on the basis of cost efficiency.

See the FEIS, Chapter IV, Tables IV-16 through IV-27 for the relative difference among alternatives pertinent to their respective potential for below-cost sales. Alternatives B, C, D, and D1 are projected to have the largest number of sales where the immediate cash flow could be negative These alternatives would harvest large amounts of hardwood stands which have low product values and consequently a high potential for some individual timber sales to have costs exceeding revenues However, timber program benefits exceed timber program costs in all alternatives.

207. *COMMENT*: THE CHANGES IN TIMBER SUPPLY FROM THE NATIONAL FOREST WHICH RESULTED FROM THE MAJOR FOREST FIRES BEGINNING ON AUGUST 30, 1987 (AFTER THE PLAN WAS PUBLISHED), ARE NOT ADDRESSED IN THE PLAN

Response: The FEIS for the Silver Fire Recovery Project has been incorporated by reference in the FEIS for the Forest Plan A discussion regarding changes in timber supply and the 1987 fires has now been included (FEIS, Chapters II, III, and IV, "1987 Fires").

208. *COMMENT*: FUNDAMENTAL TO YOUR ANALYSIS IS THE DIVISION OF THE FOREST INTO 19 PLANNING UNITS WHICH ROUGHLY FOLLOW WATERSHED BOUNDARIES. YOU SHOULD INDICATE THE LOCATION OF THESE PLANNING UNITS ON YOUR ALTERNATIVE MAPS, THUS MAKING THEM EVEN MORE VISIBLE.

Response: A comparison of the Planning Basin Map (FEIS, Chapter III) to the alternative maps will provide a general idea of activities by Planning Basin For more detail, planning records are available for public review at the Forest Supervisor's Office.

Individual projects implemented under the Forest Plan will provide site-specific information with respect to the individual Planning Basins A detailed discussion of watershed and fishery effects is provided in the FEIS, Chapter IV, "Environmental Consequences by Planning Basin."

209 210 *COMMENT*: BENCHMARK OUTPUTS (TABLE II-2, LRMP) INDICATE THAT NONWILDERNESS AND WILDERNESS RECREATION AND RANGE VALUES DO NOT VARY. WHY, IF VARIATIONS IN SUPPLY ARE AVAILABLE?

Response· The outputs for recreation and range are dependent on the demand for these resources. The Forest has excess capacity in both of these areas None of the benchmarks would reduce capacities below the projected demand in these areas, so the use does not vary

Modeling (e.g. FORPLAN)

211. *COMMENT*· WHAT MODEL WAS USED FOR TIMBER INVENTORY AND ASQ PROJECTIONS?

Response: ASQ calculations were based on yield tables developed by one of two different methods, depending on whether the stand is unmanaged or is a plantation resulting from timber harvest Then the FORPLAN linear programming model was used to determine optimal prescriptions and scheduling to produce the highest Present Net Worth (PNV) for each land allocation alternative (FEIS, Appendix B, "Lost Efficiency and Net Public Benefit").

Yield tables for unmanaged immature stands of natural origin were developed through statistical analysis of Forest inventory data. Stand volume and growth were projected for each combination of Productivity Class and Condition Class Empirical yield tables were developed using a statistical regression analysis correlating stand volume with age for each model class. These projections, and supporting data and development processes, are part of the Plan process records (FEIS, Appendix B, "Development of Yield Coefficients")

Yield tables for existing plantations and future managed stands were developed using the stand simulation model for Douglas-fir, DFSIM Yield projections were made for the various combinations of Productivity Class, Prescription Emphasis, and Management Intensity. An adjunct dynamic programming model (DP-DFSIM) identified optimum variations of rotation and thinning regimes to maximize timber yield on a Forest-wide basis. Local tree height/age relationships were used in growth functions and output was modified for stockability limitations of low productivity sites. The yield tables and supporting information are found in *Managed Yield Tables for the Siskiyou National Forest* (Craig, 1984).

These yield tables, current Forest inventory data, and predictions for the production of other Forest resources were combined, and economic values were developed for selected resource outputs. These data and projections were used by the FORPLAN linear programming model to determine the optimal combination of management prescriptions for maximum PNV for each alternative. The ASQ is calculated by FORPLAN and presented for each of the alternatives considered in detail This process is described in detail in FEIS, Appendix B, "Forest Planning Model."

212. *COMMENT*: PROJECTIONS OF NET GROWTH OF IMMATURE TIMBER ARE NEEDED IN THE DOCUMENTS.

Response: Growth for existing immature stands was estimated by one of two different methods, depending on whether the stand is unmanaged or a plantation resulting from timber harvest. Yield tables for unmanaged immature stands of natural origin were developed through statistical analysis of Forest inventory data Stand volume and growth were projected for each combination of Productivity Class and Condition Class. These projections, and supporting data and development processes, are part of the Plan process records (FEIS, Appendix B, "Development of Yield Coefficients") Yield tables for existing plantations (stands resulting from regeneration harvest) were developed using the stand simulation model for Douglas-fir, DFSIM Yield projections were made for the various combinations of Productivity Class, Prescription Emphasis, and Management Intensity These tables and supporting information are found in the Process File in a separate document prepared for the planning record, *Managed Yield Tables for the Siskiyou National Forest* (Craig, 1984), available in the Siskiyou National Forest Supervisor's Office.

213 *COMMENT.* FORPLAN IS INCAPABLE OF MODELING SPATIAL PATTERNS, ECOLOGICAL DIVERSITY, AND NON-MARKET VALUES. BECAUSE OF THESE DEFICIENCIES, ITS USE CONFUSES AND OBSCURES REAL ISSUES AND TRADEOFFS.

Response: The capability of the model is relative to the degree of resolution needed to address the planning question The FORPLAN model does represent spatial patterns at the Forest level The Identifiers in the model include. Planning Basin, Roaded versus Unroaded, Vegetation Condition, and Productivity Class (FEIS, Appendix B, Forest Planning Model). This provides the resolution needed for the Interdisciplinary Team to assess the implications of program level decisions on spatial patterns and ecological diversity. The model does not have the resolution to identify individual stands or units that could be treated; however, this level of specific detail is more appropriate at the project planning level where site-specific analysis is conducted

Many non-market values, such as recreation visitor days or wildlife viewing, are represented economically in the model (FEIS, Appendix B, Determination of Economic Values) The Forest Service recognizes that many values are not "priced" and do not have economic representations in the model. The definition of Net Public Benefit includes consideration of nonpriced values or outputs (FEIS, Appendix B, Cost Efficiency and Net Public Benefit). In view of the limitations of the model to represent the total picture of Net Public Benefits, the Forest Service has developed a wide range of alternatives and described the costs and benefits, both economic and environmental, in Chapter IV of the FEIS and compared the alternatives in Chapter II. These descriptions of effects and comparisons include discussions of many nonpriced elements such as visual quality and old-growth habitat and effectively analyze tradeoffs.

214 *COMMENT* FORPLAN MODEL MAY NOT BE CAPABLE OF MODELING THE STANDARDS AND GUIDELINES OF THE LRMP. THESE GUIDELINES APPEAR TO BE CONSTRAINTS THAT MAY BE VULNERABLE TO LEGAL APPEAL.

Response: The Standards and Guidelines are part of each alternative (FEIS, Appendix D, and LRMP, Chapter IV, "Forest-wide Standards and Guidelines"). The FORPLAN model is designed to represent those having a measurable effect on Forest-wide activities and outputs or environmental conditions. It is not intended that the model would be a perfect representation of the total Forest and all the actions that could take place. Restrictions imposed by Standards and Guidelines are represented in several ways. In some cases, the resource yields or economic values are adjusted to allow for specific actions that may be required on each acre. The model may be constrained to assure that a particular condition will be achieved, or that a condition can be avoided. In other cases, acres may be constrained to a specific prescription designed to accomplish the desired effect. The representations in FORPLAN are adequate to project the outputs and environmental conditions that may be expected under each alternative with its complement of Standards and Guidelines.

215. *COMMENT.* DO NOT "HARDWIRE" PRESCRIPTION CONTROLS IN FORPLAN; ALLOW MORE MANEUVERING ROOM TO OPTIMIZE A SOLUTION

Response· Sensitivity testing with the FORPLAN model indicated that when given a choice, the model tends to opt for the prescription with the highest timber output in all cases. To develop a range of alternatives and represent allocations of some specific land areas to groups of prescriptions designed to *emphasize other resource values (many of which are nonpriced), it is necessary* to "force" FORPLAN through prescription controls or coordinated allocation choices. The Siskiyou elected to use controls on prescriptions to simulate the land allocations for alternatives designed by the Interdisciplinary Team rather than trying to build the linkages in the model to get logical allocations of contiguous acres to Management Areas that would provide the desired benefits Given the land allocation and the prescription intensities and timing choices, the FORPLAN model solves for the most efficient (optimum) set of prescriptions and

schedule of activities for each alternative. The analysis process is described in Appendix B (FEIS), and summarized in the FEIS, Chapter II "Description of the Analysis Process "

216. *COMMENT*: USE THE ORGANON MODEL FOR FEIS TIMBER PROJECTIONS BECAUSE IT USES LOCAL GROWTH DATA IN ITS PROJECTIONS.

Response. While the ORGANON model was developed in southwest Oregon, the data used in its development does not cover the geographic area of the Siskiyou National Forest. This model was not available when the yield projections were made for the Forest Planning analysis. The Forest Service considered use of ORGANON to examine the yield projections between the Draft and Final EIS, but rejected this idea for the several reasons The ORGANON model begins simulation at age 20; some method of estimating stand conditions at age 20 for each combination of productivity class and management intensity would need to be developed. Data would also have to be developed to calibrate the model to represent stand development under Siskiyou National Forest growing conditions The work needed for ORGANON to be operational for the Siskiyou will be on-going and much of the data needed will be collected in the upcoming inventory for young stands. In addition to these considerations for the orderly progression of implementation of this new model, no evidence has been offered that the DFSIM model used for this analysis is less than adequate.

217. *COMMENT*: TIMBER MANAGEMENT AFFECTS WILDLIFE POPULATIONS BUT THE MODEL IS RELATIVELY INSENSITIVE TO CHANGES IN WILDLIFE POPULATION LEVELS WITH CHANGES IN HARVEST LEVEL. DURING THE NEXT DECADE, THE WILDLIFE POPULATION PORTION OF THE MODEL NEEDS A THOROUGH REVIEW, OR THE FOREST NEEDS TO QUIT RESERVING TIMBER TO PROTECT WILDLIFE POPULATIONS.

Response: The Forest Plan represents the best possible effort to manage all the Forest's resources, including wildlife The Forest Plan attempts to balance the needs of all wildlife species. For example, to accommodate species which use mature and old-growth forest, Management Area # 8 (Designated Habitat) was created (LRMP, Chapter IV, "Management Prescriptions")

The Forest is continually gathering more information. At the next revision of the Forest Plan in ten to fifteen years, wildlife data will be considerably improved and refined. (One would not expect timber management to cause wildlife populations to fluctuate drastically over the short term.) The Forest normally harvests 5,000 acres per year (50,000 per decade) out of a total land base of 1.1 million. This is less than one-half of one percent (0.5) of the Forest land base per year, and less than five percent per decade. In addition, in the various FEIS alternatives, timber harvest levels fluctuate only 54 percent below or 18 percent above the current level (Alternative M not included). Given those bounds, wildlife population figures are not going to fluctuate wildly over the short term. Over the long term (an entire rotation), some wildlife populations, such as those dependent on mature or old-growth forest, could drop to less than viable levels if measures (such as creation of Management Area 8) are not taken now to provide adequate quality habitat.

218. *COMMENT*: USE ALL ALLOCATIONS AND MANAGEMENT ASSUMPTIONS FROM THE CURRENT PLAN TO PRODUCE THE BENCHMARK FORPLAN OUTPUTS.

Response. The Current Direction Benchmark is based on the land allocations and management direction established prior to the Forest Plan, however, it does use state-of-the-art techniques for modeling and for projecting yields. It also includes the requirements of law and regulation that are not a part of "current plans" (meaning those plans approved prior to this Forest Plan). The No Change Alternative in the FEIS represents carrying forward the current plans with the allocations and assumptions of those plans Since the purpose of the benchmark analysis is to define the decision space and provide a framework for the

development of alternatives, state-of-the-art modeling techniques and requirements of law and regulation are incorporated in all benchmarks (FEIS, Appendix B, "Benchmark and Constraint Analysis")

219. *COMMENT*. YOUR TABLES OF ROAD CONSTRUCTION SHOULD HAVE INCLUDED ALL POTENTIAL ROADS PERMANENT OR TEMPORARY. TEMPORARY ROADS LEAVE SCARS PLUS DISTURB DRAINAGE PATTERNS. THROUGH THIS DATA ONLY CAN WE JUDGE THE IMPACT OF ROAD BUILDING FORPLAN SHOULD BE ON THE HIGH SIDE OF ROAD BUILDING AND NOT ON THE LOW SIDE

Response· Estimates of potential temporary road construction, and any associated environmental effects, were not included in the FORPLAN model calculations. The estimates of costs and effects would be relatively insignificant when compared to those of Forest Development Roads as they are limited in number, extent of construction, and life. These temporary roads are generally closed (i.e., "put to bed") upon termination of the project and post-treatment activities; drainage is reinstalled to original contour and revegetation is attained by either mitigative treatments and/or natural means.

Methods used, timing, and site-specific mitigation for temporary roads will be made in accordance with site-specific project planning (LRMP, Chapter IV, "Forest-wide Standards and Guidelines")

220. *COMMENT* BECAUSE FORPLAN WAS DEVELOPED AS A TIMBER MANAGEMENT MODEL, MOST OTHER RESOURCES ARE DEALT WITH MERELY AS "CONSTRAINTS" LIMITING THE PRINCIPAL MANAGEMENT OBJECTIVE OF MAXIMIZING PRICED OUTPUTS. RATHER THAN *ACCORDING EQUAL TO EACH OF THE FOREST PLANNING CONSIDERATIONS SPECIFIED IN* NFMA REGULATIONS (SEE 36 CFR 219), THE PLAN TREATS THE MAXIMIZATIONS OF PNV AS THE BASE LINE TO WHICH OTHER POSSIBILITIES AND TRADEOFFS MUST BE COMPARED. THIS APPROACH INEVITABLY FAVORS FOREST USES THAT PRODUCE EASILY QUANTIFIABLE ECONOMIC BENEFITS OVER USES FOR WHICH ECONOMIC BENEFITS HAVE NOT YET BEEN DETERMINED

Response: FORPLAN Version 2 provides both an analysis and accounting system for long-range National Forest planning. The model's primary analysis function is to assist in: (1) analysis of the management situation; (2) formulation of alternatives; (3) estimation of effects of alternatives; and (4) evaluation of alternatives. These four steps are integral in development of the Forest Plan and are described in the NFMA regulations, Title 36 CFR, Section 219.12 e-h.

While many Forest values do not have a price, many of these nonmarket values such as recreation visitor days, sport fishing, and wildlife viewing are represented economically in FORPLAN (FEIS, Appendix B, "Determination of Economic Values").

Alternatives

221. *COMMENT* THE DEIS FAILS TO EXPLAIN WHY THE PREFERRED ALTERNATIVE WAS SELECTED THERE IS NO EVIDENCE THROUGHOUT THE DEIS THAT THE SISKIYOU CONSIDERED THE STATUTORY DIRECTIVES (ORGANIC ACT AND OTHERS) IN ITS SELECTION OF THE PREFERRED THE SISKIYOU MUST SPECIFICALLY ADDRESS THESE DIRECTIVES AND EXPLAIN HOW THE PREFERRED ALTERNATIVE SATISFIES SPECIFIC CRITERIA BETTER THAN OTHER ALTERNATIVES. THE FOREST SERVICE NEVER PROVIDES ANY INDICATION OF THE WEIGHT IT GIVES ANY OF THE FACTORS CONSIDERED.

Response The purpose of the FEIS is environmental disclosure, the purpose of the Record of Decision (ROD) is to provide the rationale for selection The Agency decisionmaking procedures and disclosure of the decision are directed by CEQ Regulations (40 CFR 1505) and subsequent Forest Service policies and procedures.

The Draft Environmental Impact Statement (DEIS) is designed to inform the public of the Agency's intent to plan actions and make decisions The DEIS provides disclosure and discussion of the major environmental impacts associated with the alternatives. It is prepared in accordance with the range of actions, alternatives, and impacts decided upon in the scoping process Issuance of the DEIS insures that the public and other agencies are made aware of the proposed action and information as to its potential environmental effects. Public scrutiny of the issues that are truly significant to the action is essential to implementing NEPA.

The "Preferred Alternative" in the DEIS is a NEPA requirement, the purpose is simply to identify the Agency's preference or proposed action in seeking more focused public and other agency comments.

222. *COMMENT* THE RANGE OF ALTERNATIVES CONSIDERED FOR TIMBER PRODUCTION IS INADEQUATE. THE ALTERNATIVES IN THE DEIS HARDLY DISTRIBUTE TIMBER PRODUCTION BETWEEN THE "MINIMUM" AND "MAXIMUM" RESOURCE POTENTIAL AS REQUIRED BY 36 CRF 219 12 (f)(1). THE FOREST PLAN, THEREBY, FAILS TO REFLECT THE FULL RANGE OF MAJOR COMMODITY USES AND VALUES THAT CAN BE PRODUCED ON THE FOREST IN THE MAXIMUM TIMBER ALTERNATIVES.

Response: The cited NFMA regulations also state that alternatives shall be distributed *between* the minimum and maximum resource potential to *reflect, to the extent practical*, the full range of major commodity and environmental resource uses and values that could be produced. The alternatives in the FEIS provide, in comparative form, a strong range of options. These allow the issues to be sharply defined and provide the Regional Forester and public a clear basis for choice among them

The possible number of reasonable alternatives suggested by numerous individuals and organizations was very large. The possible permutations of alternatives was infinite. For each major issue identified, an attempt was made provide either the maximum range or some reasonable facsimile thereof Many of the alternatives included in this analysis were developed directly from public input during the scoping process. Those alternatives developed in detail and analyzed in the FEIS, the Preferred Alternative in the FEIS, the Benchmarks, and other alternatives considered but not studied in detail, all contribute to a wealth of variations in theme and range within and among the major issues addressed (FEIS, Chapter II).

223. *COMMENT*: THERE SHOULD BE A CHOICE OF ALTERNATIVES DESIGNED AROUND SPECIFIC LAND ALLOCATIONS WITHIN AN "ACCEPTABLE" RANGE OF ASQ (140-160 MMBF), PARTICULARLY REFLECTING VARIATION IN MANAGEMENT AREAS AFFECTING THE RECREATION, EDUCATION, AND BIOLOGIC NEEDS OF THE FOREST.

Response: Because there could be a infinite number of possible alternatives, the Forest attempted to develop an array that reflects most concerns expressed by the general public. The Forest Plan and Environmental Statement accomplishes this objective. Alternatives K and S are within the range suggested for Allowable Sale Quantity (FEIS, Chapter II, "Alternative Descriptions".

224. *COMMENT*· A RANGE OF PARTIAL-WILDERNESS ALTERNATIVES SHOULD HAVE BEEN DISCUSSED, AT LEAST IN APPENDIX C. THE ALL-OR-NOTHING TREATMENT ALLOWS THE

WRITERS TO DISMISS WHOLE AREAS AS UNMANAGEABLE WHEN A LITTLE TRIMMING WOULD PRODUCE OBVIOUSLY LOGICAL UNITS.

Response. The FEIS Appendix C provides a site-specific analysis of each unroaded area to evaluate its allocation to either continued unroaded status, development, or an intermediate level of development. Each unroaded area was evaluated for its Wilderness potential. How all or portions of each unroaded area have been allocated varies among the alternatives Chapter III and IV of the FEIS offers additional discussion and analysis of the specific roadless areas, or portions thereof, that currently retain substantive characteristics and potential for Wilderness.

225 *COMMENT*: USE OF THE EXISTING PLAN (NO CHANGE ALTERNATIVE) IN MEASURING IMPACTS OF THE PREFERRED ALTERNATIVE IS INADEQUATE.

Response. The Current Direction Alternative (Alternative A) is the No Action Alternative for comparison purposes among the alternatives, including the Preferred Alternative. See the FEIS, Chapter II, "Background on the No Change and No Action Alternatives," for a more detailed discussion.

Standards and Guidelines

226. *COMMENT*: THE FOREST HAS NOT DISPLAYED STANDARDS OR METHODS FOR PROTECTING DEAD AND DOWN WOODY HABITATS FROM SUCH ACTIVITIES AS FIREWOOD CUTTING AND PRESCRIBED BURNING DURING SITE PREPARATION.

Response: The Standards and Guidelines in the LRMP call for the retention of dead and down coarse woody material The Standards and Guidelines for dead and down woody material apply to all activities including fuel treatment and firewood cutting (LRMP, Chapter IV). Detailed plans for the protection of this material would be developed as part of the site-specific fuels treatment plan and prescribed fire plan for each activity site.

227. *COMMENT*. IN THE STANDARDS AND GUIDELINES, THE FOREST HAS DEFINED "LARGE WOODY DEBRIS" AS MATERIAL OVER 12 INCHES IN DIAMETER AND 15 FEET LONG. BROWN (1985) STATES THAT LARGE WOODY DEBRIS SHOULD BE OVER 18 INCHES IN DIAMETER. WE RECOMMEND THAT THE MINIMUM STANDARD FOR LARGE WOODY DEBRIS BE 18 INCHES IN DIAMETER WITH AN AVERAGE DIAMETER OF 22 INCHES

Response. Large woody material for site productivity is defined in the Standards and Guidelines as log pieces, "at least 20 inches in diameter at the large end, and at least 40 cubic feet volume in a range of decomposition classes " For wildlife use, "the logs should be at least 12 to 17 inches in diameter at the large end, and 20 or more feet in length." Most logs reserved as large woody material are cull, and in decomposition classes 1 and 2. All decomposition class 3, 4, and 5 logs are reserved (LRMP, Chapter IV, "Forest-wide Standards and Guidelines")

228. *COMMENT*· THE STANDARDS AND GUIDELINES FOR WATER NEED TO BE MORE FULLY DEVELOPED IN THE FINAL EIS/PLAN.

Response· The Standards and Guidelines for soil and water have been revised based on public comments on the Forest Plan DEIS In particular, the Standard and Guideline for Best Management

Practices (BMP's) was more fully developed, and Appendix F of the Forest Plan added to describe the process for implementing BMP's

229. *COMMENT*: THE LANGUAGE IN STANDARDS AND GUIDELINES NEED TO BE STRENGTHENED. USE THE MANDATORY WORD, "SHALL;" WORDS LIKE "SHOULD," "WHERE PRACTICAL" AND "MAY" DO NOT PROVIDE ADEQUATE PROTECTION FOR RESOURCES THEY ALLOW THE DECISIONMAKER TO IGNORE THE STANDARDS AND GUIDELINES WHILE ALLOWING TIMBER ACTIVITIES.

Response: No timber management activity occurs on much of the total Forest acreage in all alternatives. Forest-wide Standards and Guidelines govern activities on Management Areas which have a programmed harvest (LRMP, Chapter IV) The Standards and Guidelines have been revised, based on comments received from the public and government agencies (LRMP, Chapter IV). Direction statements have been changed to "shall" where appropriate. The direction terms are defined in the introduction to the Standards and Guidelines; they each have very specific uses. The use of the word "should" will not allow the decisionmakers to "ignore" specific direction. Also, a monitoring element is specifically designed to evaluate Standards and Guidelines related to all resource elements (LRMP, Chapter V and Appendix D).

230 *COMMENT*: THE PLAN'S MANAGEMENT STANDARDS AND GUIDELINES ARE INADEQUATE IN PREVENTING LANDSLIDES AND EROSION ON THE FRAGILE LANDS THAT REMAIN IN THE SUITABLE TIMBER BASE

Response The Standards and Guidelines addressing "mass-movement" require qualitative landslide hazard maps and risk assessment for timber harvest activities, including road construction (LRMP, Chapter IV). These, and many other mitigation measures associated with the Best Management Practices (LRMP, Appendix F), are designed to prevent and/or minimize landslides and erosion on lands determined to be suitable for timber production. This suitability determination, in itself, is an initial step in separating the low to higher risk areas from those where management practices would be unacceptable. Landslide monitoring will also provide inventory information about landslide frequency under natural, roaded, and harvested conditions (LRMP, Chapter V and Appendix D) in order to better differentiate risks and track practices which were designed to avoid or reduce soil and water impacts.

231. *COMMENT*: REGARDING SOIL AND WATER STANDARDS AND GUIDELINES: THE STANDARD THAT 85 PERCENT OF AFFECTED (TIMBER HARVEST) AREAS SHOULD BE IN A NON-COMPACTED AND NON-PUDDLED CONDITION IS SOMEWHAT CONFUSING. THE 85 PERCENT STANDARD NEEDS MORE EXPLANATION. IT IS UNCLEAR WHY OR FOR WHAT PURPOSE ONE WOULD USE THE 85 PERCENT WITHOUT USING THE PERCENTAGE COMPACTED IN ROADS
