1995

INTERIOR COLUMBIA BASIN
ECOSYSTEM MANAGEMENT PROJECT

Preface

The following report was prepared by University scientists through cooperative agreement, project science staff, or contractors as part of the ongoing efforts of the Interior Columbia Basin Ecosystem Management Project, co-managed by the U.S. Forest Service and the Bureau of Land Management. It was prepared for the express purpose of compiling information, reviewing available literature, researching topics related to ecosystems within the Interior Columbia Basin, or exploring relationships among biophysical and economic/social resources.

This report has been reviewed by agency scientists as part of the ongoing ecosystem project. The report may be cited within the primary products produced by the project or it may have served its purposes by furthering our understanding of complex resource issues within the Basin. This report may become the basis for scientific journal articles or technical reports by the USDA Forest Service or USDI Bureau of Land Management. The attached report has not been through all the steps appropriate to final publishing as either a scientific journal article or a technical report.

BRYOPHYTES OF THE COLUMBIA RIVER BASIN, SOUTH OF THE CANADIAN BORDER

Purpose and scope of project

As part of the vegetation analysis of the Interior Columbia River Basin Ecosystem Management Project, the bryophyte (liverwort, hornwort and moss) flora was investigated. The study area included the Columbia River Basin south of the Canadian border, part of the northern Great Basin, and part of the upper Klamath River watershed (Fig. 1). The Cascade Range and northern Rocky Mountains are relatively well known bryologically, but the intermountain region is poorly known. Traditionally, these components of the basin have been treated separately south of the Canadian border, and usually separately by state. This project presented an excellent opportunity to collate information and treat the bryoflora of the Columbia basin as a cohesive floristic unit. The objectives of this project were to identify (1) what species are known to occur in the study area, (2) where they occur, (3) their role in the ecosystem, (4) rare species or habitats in need of special management, and (5) aspects of the regional bryoflora needing further investigation.

Previous work

Reference to bryophytes occurring in the Columbia River basin were found in papers on bryophyte taxonomy and floristics, as well as general plant ecology. Publications that we used to obtain distributional data for the Columbia basin are listed in Appendix A, but time did not permit a complete search for each state. There are virtually no publications that treat the bryophytes of the Columbia basin as a cohesive phytogeographic unit. Jones (1929) described the moss flora of portions of the Palouse, Columbia Basin, Okanogan Highland and Bitterroot Mountains sections. Flowers (1973) treated Utah, but his book is useful throughout the arid intermountain area. Spence (1988) compiled a checklist for the Great Basin that includes the southern portion of our study area.

Lawton (1971) treated the moss flora of the entire Pacific Northwest, but provided no distributional data within each state. All states but Washington and Wyoming have relatively recent checklists or floras of their bryophytes, but not all contain distributional data.

Idaho: Hong (1976), McCleary and Green (1971), Christy and Johnson (1988).

Montana: Hong (1975, 1977a), Eversman and Sharp (1980), Elliott and Moore (1989), Elliott (1993).

Nevada: Clark (1957), Lawton (1958), Lavin (1981).

Oregon: Hong (1978a), Christy et al. (1982).

Utah: Flowers (1961, 1973).

Washington: Hong (1978b), Lawton (1971).

Wyoming: Porter (1933, 1935), Hong (1977b), Spence (1985).

The earliest documented collections of bryophytes in the study area were made along the

Columbia River by David Douglas in 1826-1827. Although mosses had been collected by the Lewis and Clark expedition of 1804-1806, none are known to have been gathered within the Columbia basin. John Newberry collected bryophytes in 1855 along the east slope of the Oregon Cascades during the California-Oregon railroad survey. David Lyall collected bryophytes along the U.S.-Canadian border during the international boundary survey of 1858-1861. Sereno Watson made collections in Nevada and Utah in 1869 during the government survey of the 40th parallel. Julius Roell collected on Mt. Hood, Yellowstone National Park and in the Ellensburg area of Washington in 1888, and John Leiberg collected in the Rockies between 1884-1905.

Widespread, general collecting by an increasing number of individuals began after 1900, and accounts for the majority of extant records from the Columbia basin. T.C. Frye, Lois Clark, George Neville Jones and their students became active in the 1920's and 1930's. Seville Flowers began collecting in Utah and elsewhere in the 1920's, and made excellent ecological observations. Fay MacFadden, William Weber and Betty and Noe Higinbotham began collecting in the region in the 1940's, Elva Lawton, Kathleen Young and Rexford Daubenmire in the 1950's, and Fred Hermann and Wilfred Schofield in the 1960's. Doyle Anderegg and Alma Steele collected widely in Idaho in the 1970's. Many of these specimens were distributed widely to herbaria throughout North America.

Griffiths (1902) is probably the first ecological work to refer to bryophytes in the study region, where he observed *Tortula ruralis* to be a significant soil binder in the northern Great Basin. Other ecological works, or floristic works that include ecology, are Flowers (1933), Cooke (1955), Hoffman (1966), Daubenmire (1970), McCune (1977, 1979), Steele (1978), Maurer (1980), Spence (1981), Rosentreter (1984, 1986), Eversman et al. (1987), McIntosh (1987), Eversman (1990), Lesica et al. (1990) and McCune and Lesica (1992). Distribution maps for many species in or adjacent to the Columbia River Basin were provided by Vitt et al. (1988) and Schofield (1992b).

METHODS

Before we could identify issues affecting diversity and distribution of bryophytes in the Columbia River basin, we had to construct a basic database of occurrences in the study area, to delimit the flora. The primary effort of the project was to obtain locality data from (1) herbarium collections and (2) the bryological literature.

Subdivision of study area. The study area (Fig. 1; Table 1) and data collection was divided among John Christy (Oregon, Utah, Nevada), Patricia Eckel (Wyoming), Joe Elliott (Montana), Alma Hanson (Idaho) and Judy Harpel (Washington). Rene Belland provided the database from the University of British Columbia, and John Davis provided collection data from the eastern Columbia River Gorge.

Database and herbaria. Collection data were stored in a Paradox database designed to

capture all label data. Table 2 identifies the 25 fields used in the database. Acronyms for herbarium collections cited as sources in the database are listed in Table 3, and literature cited as sources in the database were listed in Appendix A.

Ecological provinces. Specimens were assigned to 21 sections within 7 ecological provinces (Table 4), delineated by Bailey et al. (1994) and described by McNab and Avers (1994). Better resolution was obtained using a map prepared by Andy Wilson of the Region 6 GIS facility, combining a layer showing county boundaries with the Bailey section boundaries. Although most specimens could be assigned to a given section, inadequate locality data precluded placement of a number of specimens.

Substrate codes. To identify ecological groups, two-letter substrate codes (Table 5) were assigned to specimens whenever possible, based on information provided on labels, to sort them into habitat categories. Substrate categories were chosen from available data. We kept the categories conservative to simplify the sorting process. While many labels provided detailed substrate data, many others were inadequate, and in such cases substrate was assigned based on general knowledge of the species. Very few labels or references contained enough information to assign specimens to vascular plant communities or associations. Finally, many species occur within several substrate categories, depending on location or habitat.

Aquatic, submerged (AQ). This group includes both moving and ponded waters, regardless of pH. References to rocks or wet limestone were placed in wet rock category. References to rich fens were placed in the peatland category, unless specimens specifically were cited as being submerged.

Decaying wood, wet or dry (DW). Substrates were restricted to stumps and logs, wet or dry. Some humus and duff species also occur here.

Epiphytic (EP). This group includes species occurring at the base or higher on living trees and understory shrubs. Ground-dwelling species at the base of trees were sometimes placed in humus and duff category.

Humus and duff (HD). Species here were restricted to humus, duff, and litter on forest floor. Some species from the dry soil and decaying wood categories also occur here.

Peatlands, including fens and bogs (PE). This group included all species on peat or in wet areas referred to as bogs or fens, regardless of pH. Relatively few collectors distinguished between acid or calcareous conditions, or between bogs and fens.

Rock, calcareous (RC). These species were mentioned specifically as occurring on limestone, sandstone or conglomerate. Wet calcareous rocks were placed in the wet rock category.

Rock, other (RO). Species on all other non-calcareous rock types were lumped here. Most rocks mentioned were basalt and granite. Wet rocks were placed in the wet rock category.

Rock, wet (RW). All references to wet rocks in streams or ponded areas, regardless of pH, were lumped here. Many rocks described as "wet" or "moist" are probably seasonally dry, depending on exposure. Wet calcareous and other wet rock types were included here.

Soil, alkali (SA). All references to alkaline soil, wet or dry, were grouped here. There were relatively few references or specimens in this category, as few have collected in this habitat, and some collectors may not have realized they were in alkaline soils.

Soil, dry (SD). This group included all soil categories not mentioning moisture, including sand. Some duff or humus types probably occur here. Many of these soils were probably seasonally wet, but dry at the time of collection.

Soil, wet (SW). All species on damp soil or mud were placed here. Perennial moisture is inferred in this category, but seasonal moisture may be present in some cases. References to peat were placed in the peatland category.

Identity of specimens. Time did not permit verification of the identity of specimens. In general, specimens cited in recent monographic works should be correctly identified and annotated. The remaining specimens in regional herbaria vary widely on the reliability of identification, depending on the genus or group involved. In our experience, the more common or distinct mosses are misidentified only about 5% of the time, but 20-30% of specimens in difficult genera such as *Brachythecium* or *Grimmia* can be misnamed. Most *Sphagnum* collections in larger herbaria were revised by Richard Andrus in the last ten years. Up to 50% of the liverworts in regional herbaria may be misidentified, a legacy of errors made by Lois Clark and T.C. Frye earlier in the century (David H. Wagner, pers. comm. 1995).

Species nomenclature. Nomenclature from all sources was revised, and follows Anderson (1990) and Anderson et al. (1990) for mosses, and Stotler and Crandall-Stotler (1977) for liverworts. Old names as given on specimens or in citations were listed in the "miscellaneous" field in the database.

RESULTS

We compiled 12,671 records from 53 herbaria and 127 published and unpublished sources. Eleven institutional herbaria and seven personal collections were searched. A total of 808 species, subspecies and varieties were recorded from the study area (Appendix B), of which

3 were hornworts (0.4%), 200 were liverworts (25%), and 606 were mosses (75%) (Table 6).

The quality of the data on herbarium labels varied widely. Most did not have legal descriptions or latitude and longitude, and many lacked useful habitat or ecological information. Old collections, while being the most interesting from a historical perspective, have the least precise locality information, which can frustrate attempts to draw comparisons between the past and present bryoflora of an area.

Typographical errors and duplicate records in the database were corrected whenever possible, but many no doubt remain. We did not have time to do an exhaustive search of literature reports, published and unpublished. Although most species no doubt were captured, there are probably many more additional occurrence records that could be added to round out distribution patterns within the study area. We also did not have time to examine the collections of Seville Flowers and William Weber, housed at COLO. We recorded taxa reported by Elliott (1993) to be housed at COLO and MONTU, but did not obtain label data for Montana specimens from those herbaria. Elliott's research was based on examination of material from both COLO and MONTU, and on Seville Flowers' field notes housed at COLO.

In general, mosses are better represented in collections and in both floristic and phytogeographical literature than are liverworts. This difficulty is compounded by the suspect identification of many liverwort specimens. When assessing the relative rarity of liverworts poorly represented in the Columbia River Basin, authoritative works by Hong and Schuster often are contradictory in their interpretation of distribution patterns and relative abundance.

Biogeography

Appendix C lists bryophyte taxa in the Columbia River Basin by ecological section ("physiographic province"). Although Bailey et al. (1994) divided the Columbia basin into 7 ecological provinces and 21 sections (Table 4), the bryoflora has not been treated previously at such a fine level of resolution. Numerous papers specifically describe global distribution patterns of bryophytes (e.g., Schuster 1983, Schofield 1992a), but few of these are at a scale useful for the Columbia basin assessment. Schofield (1969) provided the most comprehensive distributional information suitable for the study area, treating endemic species and those with broader global distributional patterns by geographic areas within the Pacific Northwest. Schofield (1980) and Hong (1987) treated the region in a somewhat broader continental context. Detailed studies of neighboring regions that are useful for the Columbia basin include Schofield (1976, 1988), Tan (1980), McIntosh (1986, 1989) and Spence (1987). Vitt et al. (1988) provided distribution maps for some species within the study area. In addition to papers specifically focused on phytogeography, floristic and ecological papers listed in Appendix A often provided additional information. As done in Appendix E, the bryoflora of the Columbia River Basin can be divided into the following phytogeographical groupings:

Circumpolar. The majority of bryophyte species in the Columbia basin have a circumpolar distribution, a broad category that includes taxa occurring in arctic, boreal and north temperate regions. Many so-called alpine taxa may occur in the mountains well below timberline, in suitable microhabitats. Mountainous areas within the study area include the Cascade Range, northern and central Rocky Mountains, the Blue Mountains, and the fault-block ranges within the northern Great Basin. Circumpolar species may be found throughout the study area, from coniferous forests to shrub-steppe. Many of the species more typical of eastern North America, occurring along the eastern edge of the Columbia River Basin, are circumpolar in distribution. They are absent from the Pacific Northwest, and are rare in the study area.

Disjunct taxa. The bryoflora of the Columbia River Basin includes a variety of taxa with discontinuous distributions, forming disjunct populations within the study area. These distributions include (1) bipolar, (2) North Pacific Ocean, (3) humid interior ("maritime extension"), (4) western North America-western Europe, (5) western North America-eastern North America, (5) circumalpine and (6) broken circumpolar. The most significant group of disjunct taxa is that exhibiting the humid interior or "maritime extension" pattern. It is an inland extension of coastal and Cascadian species that follow a lobe of moderated climate inland along the U.S.- Canadian border. This phenomenon extends as far east as the west slope of the Rocky Mountains in Glacier National Park, and as far south as the Bitterroot Range. It has been known since at least the 1920's to have influenced the distribution of many species of flowering plants, and it is also reflected in the distribution of non-vascular plants (Hong 1975; Schofield 1976; McCune 1984; Schofield 1988; Elliott and Moore 1989; DeBolt and McCune 1993; Elliott 1993). A few of the species exhibiting this distributional pattern also extend along the northern Pacific coast to Alaska, Russia and Japan.

Mediterranean and arid austral climates. Other disjunctive distributional pattern is that of taxa restricted to (1) arid winter wet-summer dry "Mediterranean" climates in the world (Schofield 1980, 1994), and (2) arid, low-elevation sites western North America and Eurasia (McIntosh 1986, 1989). Although the bryophyte flora of the arid lands is not rich, it contains species found nowhere else in the study area. It has been poorly collected because of the misconception that arid lands contain no bryophytes. Many of these species are important components of cryptogamic (also called "cryptobiotic" or "microphytic") soil crusts. Although such crusts are widespread throughout the Columbia River Basin, most have been degraded or destroyed by agriculture and grazing.

Endemism. About 50 taxa occurring in the Columbia River Basin are endemic to western North America (Appendix E, in part). Several of these have narrower ranges and can be categorized as being endemic to the (1) dry intermountain region (*Orthotrichum hallii*, *Orthotrichum holzingeri*, *Pseudocrossidium obtusulum*, *Pottia nevadensis*), (2) Columbia River Basin proper (*Bryoerythrophyllum columbianum*, *Grimmia brittoniae*), or (3) the central or northern Rocky Mountains (*Pseudoleskea incurvata* var. *tenuiretis*, *Pseudoleskea radicata* var. *pallida*).

Ecological groups

Appendix D lists species by substrate code for each of the 21 sections of the ecological provinces. The taxa listed for each substrate were used as "ecological groups" to broadly define some function in the ecosystem. There are few specific references to ecological groups within the study area. Taxa did not always sort clearly by substrate group, because there were inconsistencies in the way substrate data were recorded on labels. For example, the calciphile *Fissidens grandifrons* may have been reported as occurring on wet rocks, or just "rocks", without reference to calcareous rocks. In such cases, the taxa for such habitats as calcareous rocks may be somewhat inaccurate in the summary statistics. Also, "wet soil" may have been reported by collectors as "dry soil" if they had visited the same site later in the season, hence skewing the figures for taxa restricted to wet soils versus dry soils.

Aquatic, submerged. This group occurs mostly in montane areas where water is abundant, although specimens have been collected in arid areas from irrigation ditches, vernal pools and water troughs. Habitats range from perennially cold, clear water to organic ooze in water with low or no flows. Many of these habitats may dry up seasonally, but it is usually impossible to tell from label data if this is the case. Most species involved, except some aquatic liverworts such as *Chiloscyphus polyanthos*, can tolerate seasonal drying. Plants may be abraded by waves, ice and other debris, and are habitat for a wide array of invertebrates, amphibians and fish. They also are efficient sediment trappers, removing suspended particles, but cannot tolerate prolonged periods of turbidity. Upstream land use patterns that affect water clarity can cause declines in these species.

Decaying wood, wet or dry. These species occur consistently as a group throughout the region, exclusively on decorticated to well-rotted logs and stumps. Cool to moist forest stands in deep shade are the most typical habitat, and most occur in riparian areas and stream terraces. The group contains the highest proportion of liverworts in the study area, and is composed of relatively common species that are widespread in forested habitats throughout the region. Species diversity is richest in old-growth stands that provide cool, moist conditions and much decayed wood. The group is very sensitive to changes in light level and moisture. Removal or thinning of the canopy results in elevated temperatures, desiccation and increased light levels, all of which will diminish viability. Their existence also depends on continued inputs of rotten wood in various decay classes and diameters for their required substrate. These logs are extremely important sites for vertebrate and invertebrate habitat, nitrogen fixation, mycorrhizal activity, seedbeds and retention of water. The liverworts have their own mycorrhizal fungi whose functions are poorly understood. They may be associated with decomposer fungi or mycorrhizae of vascular plants (During and van Tooren 1990).

Epiphytic. This group has not been well studied in the Columbia River Basin except in

Montana (Lesica et al. 1991; McCune and Lesica 1992), and has generally been underreported. One hundred taxa were listed as epiphytic, the majority occurring on the east slope of the Cascades (47 taxa), with a significant showing from the "maritime extension" zone, including the Palouse Prairie (26 taxa), Idaho Batholith and Bitterroot Valley (27 taxa each) and Okanogan Highlands (21 taxa). The remaining sections had fewer than 15 taxa reported from each. Epiphytic bryophytes are best developed in shaded, cool and humid forest conditions, especially in riparian areas and on stream terraces. Western red cedar, western hemlock, grand fir, subalpine fir and Engelmann spruce are the major tree species with good epiphyte cover. Douglas fir in drier sites contains a sparse epiphyte flora that is relatively drought-tolerant and produces little bryophyte biomass. Steele (1978) found *Dicranum tauricum* to be the only true epiphyte in her study plots. Ponderosa pine, lodgepole pine, pinyon pine and juniper have a poor bryophyte flora because of drier habitat and flaking bark (Hong 1975; Eversman 1982; Eversman et al. 1987; Eversman 1990).

Humus and duff. These species occur on shaded duff and humic soil in relatively dry forests at middle to upper elevations. They typically occur at midslope, on benches or in concave microtopography subject to snow accumulation. All but *Brachythecium hylotapetum* are common and widespread. *Rhytidiopsis robusta* is collected commercially for the floral trade and may be depleted locally. Canopy removal increases light levels and temperature, and ensuing desiccation leads to replacement of these species by a suite of other more drought-tolerant bryophytes. Steele (1978) found that species of moss occurring in mesic forest associations were limited to those associations, but those of drier forest associations spanned several different associations.

Peatlands, including fens and bogs. Although a number of palynological studies were done in peatlands (e.g., Hansen 1939a, 1939b, 1939c, 1942, 1947a, 1947b), the bryoflora has been neglected until recent work by Andrus and Layser (1976), Bursik and Moseley (1992a, 1992b), Bursik (1993), and Chadde and Shelly (1994). Bogs form when peat builds up high enough to inhibit upward capillary movement of groundwater that has been in contact with mineral soil. In these cases, precipitation becomes the only source of scarce nutrients available to plants growing on the peat. Fens, in contrast, are rich in nutrients because of calcareous soils or bedrock, and because peat does not build up high enough to inhibit the effects of enriched groundwater. A distinctive group of bryophyte species occurs in each wetland type, all of which are circumboreal in distribution. The peatland flora encountered in the study area is more similar to that in the northern Rocky Mountains of Alberta and British Columbia than it is to peatlands in the Cascade Range, reflecting the floristic differences of contrasting maritime and continental climates. These habits have not been explored adequately.

Rock, calcareous. As in fens, calcareous rocks have a characteristic bryophyte flora, although many common rock-inhabiting taxa also occur on calcareous rocks. Calcareous outcrops are uncommon in the Columbia basin, and few bryophytes have been collected

from them. Sixty-one taxa were recorded from calcareous substrates, including well-known calciphiles such as *Eucladium verticillatum*, *Fissidens grandifrons*, *Gymnostomum aeruginosum* and two species of *Seligeria*.

Rock, other. Rocks and rock outcrops are ubiquitous in the study area. They range from arid lands at low elevation to forested outcrops and talus slopes at middle to upper slopes and along ridgetops, as well as rocks at or above timberline. A distinctive array of bryophyte species occurs on rocks, tolerant of extremes in heat, cold and drought. Most are widespread throughout the region, and in many arid areas the bryophyte flora is composed exclusively of rock-dwelling species. Species diversity is much greater on undisturbed rocks and outcrops than in road cuts and clearcuts. In exposed areas at all elevations, most bryophyte cover occurs on shaded or otherwise protected rock faces where moisture persists longer (McCune 1977; Nash et al. 1977; Spence 1981; Lavin 1982). They may also be subject to nitrogen enrichment at bird roosts and packrat latrines, which can limit bryophyte growth on rock faces. Rock-dwelling species adapted to shade in forest stands, such as at the base of undisturbed outcrops, are replaced by xerophytic species when the forest canopy is removed. Because of their position on slopes and ridges, stands at the base of outcrops are subject to catastrophic fire, and the bryophytes in this species group probably develop only after long periods of canopy stability.

Rock, wet. This group occurs wherever there is perennial to seasonal water, both along streams and rivers, and on seasonally wet rock outcrops where seepage occurs. Rosentreter (1984) found species to occur in distinct zones, depending on substrate stability, current and hydroperiod. He found that the zone of normal seasonal high water was dominated by *Scouleria aquatica* and the lichen *Dermatocarpon reticulatum*, while the extreme high flood zone was dominated by *Didymodon vinealis* var. *rubiginosus* and *Grimmia montana*. Like aquatic bryophytes, these species are abraded by waves, ice and other debris, and perform many of the same functions for invertebrate, amphibian and fish habitat, and sediment trapping. Although they are efficient sediment trappers, these species cannot tolerate excessive turbidity or siltation. As with the aquatic group, species on wet rocks could be adversely affected by land use patterns upstream.

Soil, alkali. We found so few collections (4 records, 2 taxa) consistently labeled as coming from alkaline habitats that, for purposes of data analysis, we lumped them in the dry soil category. Few collectors have worked in these areas, but given the widespread occurrence of alkali, there is probably a richer flora than that reported here. Some collectors probably did not note that they were collecting in alkaline areas because they didn't realize it. The bryophyte flora of alkaline areas is poor, and is mostly restricted to where vascular plants such as *Sarcobatus*, *Atriplex*, *Kochia* and *Distichlis* can grow. Sites typically have some seasonal flooding that concentrates salts upon evaporation. Flowers (1933) noted that mosses can tolerate up to an average of about 0.8% alkali. He found no mosses on sodium carbonate, tolerance up to 0.5% of sodium chloride, but a

relative abundance of mosses on calcium phosphate. Flowers (1933, 1973) and McIntosh (1986) found some species characteristic of, or restricted to, alkaline sites (e.g., *Desmatodon heimii*, *Pottia nevadensis*), while other species could tolerate alkali but also grew in non-alkaline habitats (e.g., *Bryum caespitium*, *Ceratodon purpureus*, *Conardia compacta*, *Funaria hygrometrica*, *Leptobryum pyriforme*, *Pterygoneurum subsessile*, *Tortula brevipes*, *Tortula ruralis*). The latter species may occur on alkali because of the seasonal availability of water. The bryoflora of this habitat needs further investigation in the Columbia basin.

Soil, dry. These species occur on exposed or shaded mineral soil at all elevations. Primary succession on recently-disturbed soil includes many common, opportunistic species that rapidly colonize sites, stabilize soil and enhance invasion by other cryptogams or vascular plants. These are often drought-tolerant, short-lived assemblages that are replaced by others within a year or two. At low elevation in arid areas, bryophytes are a significant component of soil crusts, where they harbor nitrogen-fixing bacteria, stabilize soil by trapping particles, reduce wind erosion, help maintain soil moisture, and enhance seed germination (Anderson and Rushforth 1976, Harper and Marble 1988). In contrast to pioneer associations on disturbed soil, these crusts take many years to form, are long-lived, and suffer long-term damage from fire and overgrazing (Johansen et al. 1984; Rosentreter 1986; Beymer and Klopatek 1992). At middle to higher elevations, soil-dwelling bryophytes occur in shaded forests, on root balls of windthrown trees, and exposed soil of trails, roads and earth slumps. Near timberline they occur on glacial moraines and outwash, especially where protected by rocks in areas where snow may accumulate (Spence 1981). Some of these associations may also be long-lived, rather than recent immigrants. The distribution of some soil-dwelling species is irregular and unpredictable.

Soil, wet. This group occurs on moist to wet soils, with or without organic content. Most species are widespread and occur wherever water is available. Habitats include edges of lakes and streams, moist organic soil over rocks in shrub thickets, margins of avalanche tracks, seepage areas and the bases of talus slopes. Sites often have late-lying snow beds. In spite of the widespread occurrence of this habitat, distribution of species may be sporadic and unpredictable. Some species need the shaded, moist microclimate provided by a forest canopy, and are very sensitive to desiccation. They are readily replaced by other species in more exposed situations. Common wet soil bryophytes in riparian areas, such as *Marchantia polymorpha* and *Philonotis fontana*, are readily extirpated by livestock trampling.

Rare or sensitive species

Schofield (1984) defined a rare bryophyte as "one that shows a restricted geographic range, usually of less than five square kilometers, or one that is known from fewer than five

localities, even when these localities are widely distant from each other." This definition of rarity is essentially the same as that developed by The Nature Conservancy, used by Natural Heritage Programs and Conservation Data Centers to rank global and state/provincial rarity of organisms or plant communities (Master 1991, Andrus et al. 1992). Using Paradox, we tallied the total number of occurrences of each taxon in the study area, and selected as potentially rare all taxa with five or fewer occurrences in the study area. Inherent in the interpretation of rarity in bryophytes is the problem of poorly collected areas. What looks rare on paper may actually be abundant in the field, and its apparent rarity is only an artifact of undercollecting.

A count of all taxa with five or fewer records in the Columbia River Basin yielded 411 taxa (Appendix E), of which 2 were hornworts (0.2%), 106 were liverworts (26%), and 303 were mosses (74%). Such an unacceptably large number, approximately half the total bryoflora of the study area, is congruent with attempts to rank bryophytes and lichens in Oregon, and reflects not the actual rarity of species, but only our ignorance about their distribution patterns (Christy 1991). It is important to recognize that this list is subject to change as few of these specimens have been verified.

To simplify interpretation of the results, the 411 taxa in Appendix E were assigned to 12 categories, some of which overlap, depending on type of category.

- (1) endemic
 - (a) western North American
 - (b) dry interior
 - (c) Columbia River Basin
 - (d) central and northern Rocky Mountains
- (2) Mediterranean climate in western North America
- (3) eastern North America
- (4) arid southern climate
- (5) circumpolar
- (6) discontinuous distribution, including:
 - (a) bipolar disjuncts
 - (b) North Pacific Ocean
 - (c) humid interior "maritime extension"
 - (d) western North America and western Europe
 - (e) western North America and eastern North America
 - (c) broken circumpolar
 - (d) circumalpine
- (7) cited in literature as rare
- (8) problem taxa:, including:
 - (a) species concepts poorly known
 - (b) needing verification, possibly representing range extensions
 - (c) invalid names or probable misidentifications

Tables 6a and 6b list 378 bryophyte taxa that appear to be rare in the Columbia River Basin. These include the 411 taxa listed in Appendix E, less the 52 "problem taxa" listed in Appendix E, section 12. Table 6 also includes several other taxa that are well documented as being rare, even though they may have more than five records from the study area. Table 6a is a simple list of taxa, while Table 6b lists taxa by state, physiographic province, and substrate.

Because these are the most poorly known of all the taxa in the region, some are lacking even the most basic information. We compiled this list within the context of the entire Columbia River basin, not individual states. Taxa considered rare in one state may be more common elsewhere in the study area, so our list will differ from those of individual states. State Heritage Programs in Idaho, Montana and Oregon are tracking occurrences of rare or sensitive bryophytes. A list for Washington is being compiled. The Bureau of Land Management, the Forest Service and the Oregon Department of Agriculture have included some or all of these species on their lists of sensitive plants. Undoubtedly, many of the taxa listed in Table 6 will be found to be more abundant than is presently known, but for the present we must list them as rare, until further collecting shows otherwise.

Research and management needs

Appendix F lists specific localities, habitats and research needs for areas of the seven states within the study area. The data for Nevada and Utah are scanty. Despite the fact that thousands of collections of bryophytes have been made in the Columbia River Basin over the last 150 years, vast areas have not been collected systematically or at all. In particular, liverworts have been undercollected and chronically misidentified, and need careful attention in future work.

Surveys for rare species. Obviously, the rare taxa listed in Table 6 need to be sought throughout the study area, to better determine distributions and abundance. The localities of the taxa listed in Appendix E as occurring at the edge of their range (e.g., species primarily of eastern North America) are important for study for their role in migration or as relictual areas. Habitat needs for specific species are beyond the scope of this report.

Arid habitats and soil crusts. Arid habitats of all types are undercollected and need further attention throughout the region. These include desert, shrub-steppe, pinyon-juniper woodland, oak woodland, and ponderosa pine forest. The composition and function of soil crusts, while relatively well studied in the Great Basin, particularly in Utah, is virtually unknown in the Columbia River basin. Some general collecting has been done in a few areas, but the problem needs to be approached on a regional basis, studying crusts in different plant associations and on different soil types. The effects of livestock trampling should be included in any such studies.

Old-growth and late-successional forests. Most of the issues identified in Thomas and

Raphael (1993) also apply to forested areas of the Columbia River Basin and need not be repeated here. The greatest similarities in the bryophytes flora and relative biomass in these forests occur in the mesic forests of the so-called "maritime extension" area in Idaho and Montana. Commercial harvest of moss in these forests is a growing concern, and needs regulation and monitoring to ensure that rare or disjunct species are not being depleted, and that recruitment is adequate to sustain harvest levels. Ponderosa pine forests have few bryophytes as epiphytes or in the understory, but representative stands need to be protected and managed correctly to maintain floristic composition.

Calcareous rocks. Calcareous substrates provide habitat for a distinctive group of bryophyte species. A few calcium-rich areas have been collected, particularly in the northern Rocky Mountains and elsewhere in Idaho, but those of Oregon and Washington are poorly known and need further work

Mineralized areas. Mineral deposits, usually occurring in areas previously mined for gold, silver, copper, mercury and other materials, often provide substrate for a distinctive group of bryophytes. While these areas have received some attention in the Rocky Mountains, other sites within the study area have not been surveyed adequately for these species. It is the same sulfides, especially in mine runoff, that pollute streams and groundwater. Mine tailings and debris undoubtedly have increased suitable habitat for some of these species, which often favor disturbed or barren soils.

Peatlands. Until recently, wetlands were much ignored by land managers, and there is not a good history of collecting in these sites except by a few individuals. With the advent of wetland fill regulations and community classifications, they are receiving more attention and some records now thought rare should become more common. Included in this category are bogs and fens, the latter occurring on calcium-rich sites, which have been poorly-collected outside of the Rocky Mountain region. Impacts from grazing in peatlands have received little attention in the Pacific Northwest, but observations suggest that bryophytes are severely impacted by trampling, as noted in the wet soil group.

Floodplains. These habitats have received recent attention because of wetland and riparian protection. Thomas and Raphael (1993) identified how important floodplains were for bryophyte species diversity, and how many species, particularly liverworts, were concentrated in old-growth forests occurring there. A similar situation exists in the Columbia River basin, especially in the "maritime extension" areas of Idaho and Montana, where species depend on shade, wet soils, logs and other organic debris, and humid microclimate. As with the aquatic and splash zone species in streams, this group of species can be affected to some degree by land ownership patterns and adverse conditions originating upstream on non-federal lands, although impacts would be less pernicious because few of these species are in the stream channel. The effects of livestock trampling should be included in any such studies.

Geothermal areas. Geothermal areas are sometimes known for unusual assemblages of

plants that survive outside of their normal distributional limits, because heated ground provides snow-free conditions and a longer growing season (Lange 1973, Given 1980). Although many bryophyte specimens were collected from hot springs in Idaho and Montana, none appear to be restricted to this habitat on a regional basis, or to exhibit an unusual distributional pattern. Eversman (1990) found lichens to be absent from geyser areas, presumably because of particulate matter and sulfurous fumes from geysers, but the flora was more normal near thermal springs. More work needs to be done in these areas to better describe their effects on bryophytes.

Isolated gorges and narrow canyons. Steep, narrow canyons provide ideal conditions for bryophytes to persist in areas outside their normal distributional limits. Shade, moisture and cold air drainage all contribute to unusual species being found in these areas, sometimes as relics from cooler periglacial climates. Impacts from livestock and humans are often limited here because of restricted access. More work needs to be done to inventory such sites, particularly those with historical bryological collecting that can be used for comparative purposes to monitor changes in the flora.

Rivers and streams. Aquatic and splash zone bryophytes are subject to the same impacts described in Thomas and Raphael (1993), and need not be repeated here. Galvanized culverts, like roof flashing, may be toxic to aquatic bryophytes and may diminish species diversity on some streams (David H. Wagner, pers. comm.).

Program needs

Training for identification and management. Agencies need to implement programs for training of field personnel to survey and manage for bryophyte species. The limitations are essentially the same as those identified in Thomas and Raphael (1993). There are few bryophyte taxonomists in the region and very few individuals are now being trained in universities.

Typification of flora by plant association. Despite the great strides taken by regional ecology programs over the last twenty years to classify vegetation by plant association, no effort has been made to include bryophytes in plot data. A vast amount of habitat-specific information, with implications for management and distributional studies, could be obtained by including these plants in the classification scheme. Again, a lack of bryological training for ecologists is the principal reason for this shortcoming.

Inventory of protected areas. Research Natural Areas, ACEC's, wilderness areas, riparian zones and other administratively protected areas should be inventoried for bryophytes. Crater Lake National Park has been poorly collected, in contrast to Glacier, Yellowstone and Grand Teton National Parks, which have been collected heavily since the 1870's. Baseline data should include bryophytes to identify distributional and management issues, and to provide a historical basis to monitor future trends of the bryoflora.

Acknowledgements

This study could not have been completed without the assistance of many individuals. Rene Belland provided the extensive database from UBC. John Davis, Patricia Eckel, Joe Elliott and Alma Hansen provided critical data and many long hours in herbaria. Peter Neitlich provided additional records from a previous herbarium search. Joe Elliott and Alma Hanson also provided accounts for Montana and Idaho in Appendix F. Andy Wilson prepared much-needed maps that vastly simplified our work. The draft was much improved by valuable criticism from Patricia Eckel, Joe Elliott, Alma Hanson, Won Shic Hong, Daniel Norris, Roger Rosentreter, Wilfred Schofield and David Wagner. We are grateful to Lisa Croft for her support of the study, and her infinite patience with our many delays.

Table 1. Counties within Columbia River basin for which bryophyte occurrences were recorded.

IDAHO: all counties.

MONTANA: Deer Lodge, Flathead, Granite, Lewis and Clark, Lake, Lincoln, Mineral, Missoula, Powell, Ravalli, Sanders, Silver Bow.

NEVADA: Elko, Humboldt

OREGON: Baker, Crater Lake National Park, Crook, Deschutes, Gilliam, Grant, Harney, Hood River, Jefferson, Klamath, Lake, Malheur, Morrow, Sherman, Umatilla, Union, Wallowa, Wasco, Wheeler.

UTAH: Box Elder.

WASHINGTON: Adams, Asotin, Benton, Chelan, Columbia, Douglas, Ferry, Franklin, Garfield, Grant, Kittitas, Klickitat, Lincoln, Okanogan, Pend Oreille, Spokane, Stevens, Walla Walla, Whitman, Yakima.

WYOMING: Fremont, Lincoln, Sublette, Teton.

Table 2. Explication of field names used in database of bryophytes in Columbia River basin.

GENUS

SPECIES

EXT -- variety (V) or subspecies (S)

EXT NAME -- varietal or subspecific name

M/H -- moss (M) or liverwort (H)

STATE -- two-letter acronym

COUNTY -- first four letters

AGENCY -- land ownership by federal or state agency

LOCALITY -- place of collection

TWP, RNG, SEC -- location by township, range, section

LAT, LONG -- location by latitude and longitude

PHYS PROV -- ecological section, after Bailey et al. (1994)

SUBSTRATE -- two-letter substrate code (Table 4)

HABITAT

MISC -- synonymy, exsiccati, other miscellaneous

DET BY -- individual who identified specimen, if other than collector

ELEV -- elevation in feet(F) or meters (M)

COLL -- collector

OTHER COLL -- secondary collector

COLL NO -- collector's collection number

COLL DATA -- date of collection

SOURCE -- location of specimen, by herbarium acronym (Table 3), or source of literature
citation (Appendix A)

PLAGIOMNIUM	MEDIUM			M	342I	SW

Southern Rocky Mountain Steppe:
open woodlands, coniferous forest, alpine meadow

M331A Yellowstone Highlands (ID, WY)

M331D Overthrust Mountains (ID, WY)

Appendix E. Taxa with five or fewer occurrences in the study area, categorized by endemic status, phytogeographical affinities, documented rarity or problem status. Several taxa with more than 5 occurrences were included if they were well documented as rare. There is overlap in some categories depending on the taxon.

1. ENDEMIC TAXA

A. Western North America

These taxa are confined to the area in or west of the Rocky Mountains. (Schofield 1984)
Taxa with narrower endemism within the study area listed separately in Sections B, C, and D.

Liverworts:

Frullania franciscana
Porella bolanderi
Riccia trichocarpa
Sphaerocarpos hians

Hornworts:

Phaeoceros hallii

Mosses:

Amphidium californicum
Anacolia menziesii var. *baueri*
Brachythecium bolanderi
Brachythecium holzingeri
Bryum calobryoides
Bryum gemmascens
Bryum meesioides
Dendroalsia abietina
Dichodontium olympicum
Dicranum rhabdocarpum
Encalypta intermedia
Fissidens ventricosus
Homalothecium arenarium
Isothecium cristatum
Orthotrichum bolanderi
Orthotrichum praemorsum
Pohlia bolanderi
Pohlia bolanderi var. *seriata*
Pohlia tundrae
Porotrichum vancouveriense

Pseudoleskea atricha
Pseudoleskea incurvata var. *gigantea*
Pseudoleskea radicata var. *denudata*
Racomitrium brevipes
Racomitrium depressum
Racomitrium obesum
Racomitrium varium
Schistidium cinclidodonteum
Tripterocladium leucocladulum

B. Endemic to Northern or Central Rocky Mountains

Mosses:

Pseudoleskea incurvata var. *temuiretis*
Pseudoleskea radicata var. *pallida*

C. Endemic to Dry Intermountain Region ("Dry Interior")

Mosses:

Orthotrichum hallii
Orthotrichum holzingeri
Pseudocrossidium obtusulum
Pottia nevadensis

D. Endemic to Columbia River Basin

Mosses:

Bryoerythrophyllum columbianum
Grimmia brittoniae

2. MEDITERRANEAN CLIMATE IN WESTERN NORTH AMERICA

These taxa are confined to winter wet- summer dry climatic areas of the world. (Schofield 1980, 1994) Those marked with an asterisk (*) are endemic to Western North America as listed in Section 1.

Hornworts:

Phaeoceros hallii *

Liverworts:

Douinia ovata

Frullania franciscana *

Lumularia cruciata (a greenhouse weed in the Columbia Basin)

Mosses:

Amphidium californicum *

Porotrichum vancouveriense

Claopodium whippleanum

Crumia latifolia

Dendroalsia abietina *

Desmatodon obtusifolius

Ditrichum ambiguum

Entosthodon fascicularis

Fissidens ventricosus *

Homalothecium arenarium *

Isothecium cristatum *

Racomitrium varium *

Timmiella crassinervis

Tortula laevipila

Tortula subulata

3. EASTERN NORTH AMERICA

These taxa are widespread east of the Rocky Mountains, and many have a circumpolar distribution. They occur mostly along the eastern edge of the Columbia Basin, at the western edge of their range. (Schofield 1980)

Liverworts:

Blepharostoma trichophyllum ssp. *brevirete*
Calypogeia fissa ssp. *neogaea*
Calypogeia integristipula
Lophocolea bidentata
Pedinophyllum interruptum
Porella platyphylloidea

Mosses:

Amblystegium varium
Atrichum angustatum
Atrichum crispum
Barbula unguiculata
Brachythecium campestre
Brachythecium digastrum
Brachythecium oxycladon
Brachythecium populeum
Callicladium haldanianum
Campylium hispidulum
Climacium americanum
Cyrto-hypnum minutulum
Dicranella schreberiana var. *robusta*
Dicranum montanum
Dicranum viride
Herzogiella turfacea
Hygroamblystegium noterophilum
Hygroamblystegium tenax
Hypnum imponens
Macrocoma sullivantii
Orthotrichum pumilum
Paraleucobryum longifolium
Philonotis fontana var. *caespitosa*
Philonotis muehlenbergii
Physcomitrium hookeri
Plagiomnium ciliare
Plagiomnium cuspidatum
Platygyrium repens
Pohlia elongata

Pohlia longicolla
Thuidium delicatulum
Tortella humilis
Tortula papillosa

4. SOUTHERN ARID AFFINITIES

Taxa of more arid austral climates. (Schofield 1980)

Liverworts:

Fossombronia longiseta
Mannia fragrans
Sphaerocarpos texanus

Mosses:

Brachythecium fendleri
Desmatodon plinthobius
Grimmia plagiopodia
Grimmia poecilostoma
Jaffueliobryum raui
Mnium arizonicum
Orthotrichum flowersii
Physcomitrium pygmaeum
Tortula bartramii

5. CIRCUMPOLAR

Taxa with continuous arctic, boreal or north temperate distributions, excluding those cited for Eastern North America in Section 3. This list also excludes taxa with discontinuous distributions, which are cited in Section 6.

Liverworts:

Anthelia juratzkana
Apometzgeria pubescens
Asterella gracilis
Asterella lindenbergiana
Asterella saccata
Barbilophozia attenuata
Barbilophozia floerkei
Barbilophozia kunzeana
Barbilophozia quadriloba var. *quadriloba*
Bazzania tricenata
Calypogeia neesiana
Calypogeia sphagnicola
Cephalozia catemulata
Cephalozia connivens
Cephaloziella elachista
Fossombronia foveolata
Gymnocolea inflata
Harpanthus flotovianus
Hygrobrella laxifolia
Jungermannia evansii
Jungermannia hyalina
Jungermannia obovata
Lophozia badensis
Lophozia latifolia
Lophozia opacifolia
Marsupella sphacelata
Marsupella ustulata
Metzgeria conjugata
Moerckia blytii
Nardia breidlerii
Nardia compressa
Nardia geoscyphus
Nardia scalaris
Pleuroclada albescens
Ptilidium ciliare
Riccardia chamedryfolia
Riccia cavernosa

Riccia fluitans
Riccia frostii
Riccia glauca
Scapania cuspiduligera var. *cuspiduligera*
Scapania paludicola
Tritomaria polita
Tritomaria quinquedentata var. *quinquedentata*

Mosses:

Aloina brevirostris
Amblyodon dealbatus
Arctoa fulvella
Brachythecium reflexum
Brachythecium turgidum
Bryum arcticum
Bryum calophyllum
Bryum cyclophyllum
Bryum pallens
Bryum schleicheri
Calliergon richardsonii
Calliergon trifarium
Campylium halleri
Campylium hispidulum
Campylium stellatum var. *protensum*
Catoscopium nigratum
Cirriphyllum cirrosum
Conostomum tetragonum
Desmatodon cernuus
Desmatodon leucostoma
Desmatodon systylium
Dicranella heteromalla
Dicranella palustris
Dicranella rufescens
Dicranella schreberiana
Dicranum acutifolium
Dicranum elongatum
Dicranum fragilifolium
Dicranum majus
Dicranum spadiceum
Didymodon asperifolius
Didymodon rigidulus var. *icmadophilus*
Didymodon tophaceus
Drepanocladus aduncus var. *polycarpus*
Drepanocladus fluitans

Eucladium verticillatum
Fissidens fontanus
Fissidens grandifrons
Fontinalis antipyretica var. *gigantea*
Grimmia trichophylla
Hypnum bambergeri
Hypnum pallescens
Hypnum pratense
Hypnum recurvatum
Hypnum vaucheri
Limprichtia revolvens
Meesia longiseta
Meesia triquetra
Meesia uliginosa
Myurella julacea
Myurella tenerrima
Orthothecium chryseum
Orthotrichum pylaisii
Orthotrichum speciosum
Oxystegus tenuirostris
Paludella squarrosa
Palustriella decipiens
Philonotis marchica
Plagiobryum demissum
Plagiobryum zieri
Plagiomnium drummondii
Plagiopus oederiana
Plagiothecium cavifolium
Platyhypnidium riparioides
Pogonatum dentatum
Pohlia atropurpurea
Pohlia bolanderi var. *seriata*
Pohlia filum
Pohlia ludwigii
Polytrichum commune var. *jensenii*
Polytrichum commune var. *perigoniale*
Polytrichum norvegicum
Pylaisiella polyantha
Racomitrium affine
Racomitrium fasciculare
Racomitrium lanuginosum
Rhytidium rugosum
Seligeria domniana
Scorpidium scorpioides
Sphagnum compactum

Sphagnum contortum
Sphagnum jensenii
Sphagnum platyphyllum
Sphagnum riparium
Sphagnum rubellum
Splachnum ampullaceum
Stegonia latifolia
Tayloria ligulata
Tayloria serrata
Tayloria splachnoides
Thuidium recognitum
Tortella arctica
Tortella tortelloides
Tortula muralis

6. DISJUNCT DISTRIBUTIONS

These taxa represent disjunct elements found in Western North America, artifacts of discontinuous distribution patterns. (Schofield 1969)

A. Bipolar

These taxa occur disjunctively at middle to high latitudes in both hemispheres and are absent in between.

Mosses:

Polytrichum formosum

Sphagnum palustre

Sphagnum subnitens

B. North Pacific

These taxa are distributed around the rim of the North Pacific Ocean, between North-western North America and Japan. Some of the taxa extend inland to the Rocky Mountains. (Schofield 1980)

Liverworts:

Blepharostoma arachnoideum

Frullania tamarisci ssp. *nisquallensis*

Radula bolanderi

Scapania bolanderi

Mosses:

Hypnum dieckii

Oligotrichum aligerum

Oligotrichum parallelum

Pogonatum contortum

Polytrichum sphaerothecium

Racomitrium muticum

Rhizomnium nudum

C. Humid Interior ("Maritime Extension", "Coastal Disjuncts")

These taxa are widely distributed west of the Cascade Mountains, and reappear in the Rocky Mountains. (Schofield 1976) Taxa with an asterisk (*) are endemic to Western North America, as listed in Section 1.

Mosses:

Dichodontium olympicum *

Ditrichum heteromallum

Hookeria lucens
Pseudotaxiphyllum elegans
Racomitrium brevipes *
Schistostega pennata
Tetraphis geniculata

D. Western North America and Western Europe

These taxa are mostly oceanic in distribution, with some occurring in alpine areas (Schofield 1969)

Mosses:

Bryum canariense
Bryum violaceum
Encalypta spathulata
Fabronia pusilla
Funaria muhlenbergii
Hygrohypnum alpinum
Hygrohypnum styriacum
Orthotrichum pulchellum
Orthotrichum striatum
Paraleucobryum enerve
Philonotis yezoana
Plagiothecium undulatum
Pottia lanceolata
Scleropodium cespitans
Tortula latifolia

E. Western North America and Eastern North America

Liverworts:

Diplophyllum obtusifolium

Mosses:

Buxbaumia aphylla
Heterocladium macounii
Neckera pennata
Pleuridium subulatum
Pohlia andalusica
Pohlia erecta
Tortella inclinata

F. Broken Circumpolar

These taxa occur in alpine areas within the Northern Hemisphere, but are absent from the arctic regions.

Liverworts:

Diplophylum albicans (suboceanic)

Mosses:

Andreaea nivalis
Buxbaumia aphylla
Campylopus fragilis
Crumia latifolia
Ditrichum ambiguum
Ditrichum pusillum
Encalypta affinis var. *macounii*
Hygrohypnum duriusculum
Hygrohypnum cochlearifolium
Hypnum procerrimum
Leskea polycarpa
Leskella nervosa
Pterogonium gracile
Schistidium pulvinatum
Schistidium tenerum

G. Circumalpine

Liverworts:

Anthelia julacea
Cephalozia leucantha
Gymnomitrium concinnatum
Gymnomitrium obtusum
Marsupella brevissima

Mosses:

Grimmia mollis
Oligotrichum hercynicum

7. TAXA CITED IN THE LITERATURE AS RARE IN NORTH AMERICA

Hepaticae:

- Blepharostoma arachnoideum* (Schofield 1969)
- Cephalozia lacimulata* (Schuster 1974)
- Pedinophyllum interruptum* (Schuster 1980)
- Scapania apiculata* (Schuster 1974)
- Scapania gymnostomophila* (Godfrey 1977)

Mosses:

- Brachythecium bolanderi* (Lawton 1965)
- Bruchia bolanderi* (Rushing 1986)
- Bryum gemmilucens* (Spence 1988)
- Calliargon trifarium* (Crum & Anderson 1981)
- Didymodon vinealis* var. *nicholsonii* (McIntosh 1986)
- Encalypta spathulata* (Horton 1983)
- Entosthodon fascicularis* (Lawton 1971)
- Grimmia brittoniae* (Herman 1969)
- Grimmia incurva* (Crum & Anderson 1981)
- Grimmia plagiopodia* (Crum & Anderson 1981)
- Hamatocaulis vernicosus* (Lawton 1971)
- Hygrohypnum cochlearifolium* (Grout 1931)
- Macrocoma sullivantii* (Crum & Anderson 1981)
- Orthotrichum flowersii* (Vitt 1973)
- Orthotrichum holzingeri* (Vitt 1991)
- Pohlia andalusica* (Shaw 1982)
- Pohlia ludwigii* (Shaw 1982)
- Polytrichum sphaerothecium* (Christy 1980)
- Pottia lanceolata* (Lawton 1971)
- Pottia nevadensis* (Lawton 1971)
- Pseudocalliargon turgescens* (Crum & Anderson 1981)
- Pseudoleskea saviana* (Lawton 1971)
- Racomitrium aquaticum* (Schofield 1976)
- Splachnum sphaericum* (Crum & Anderson 1981)
- Tayloria acuminata* (Crum & Anderson 1981)
- Timmia norvegica* (Crum & Anderson 1981)

8. PROBLEM TAXA

A. Species Concept Poorly Known

Liverworts and Hornworts:

Anthoceros fusiformis

Poorly segregated from *A. punctatus*. (Frye & Clark 1947) Widespread and common in western Oregon. (Sanborn 1929) *Aspiromitus* (syn. *Anthoceros*) is a good species but Schuster (1992) does not give range information.

Lophozia wenzelii

"Much confused with other species thus the range is poorly". In western North America reported from Alaska and the Yukon. (Schuster 1969)

Mosses:

Atrichum hausknechtii

"Paroicous specimens of western North America, Japan and Europe can be put into *Atrichum undulatum* var. *gracilisetum*". (Crum & Anderson 1981) May be rare in North America, need to determine the chromosome number for this species. (Noguchi & Osada 1960)

Brachythecium reflexum var. *pacificum*

Lawton (1971) states that *B. reflexum* is rare in the western US, and calls this species *B. reflexum* var. *pacificum*. According to Crum & Anderson (1981), this variety probably belongs to *B. reflexum*.

Bryum uliginosum

"A poorly known species". (Spence 1988)

Fissidens hallianus

Crum & Anderson (1981) does not feel that this taxon is genetically distinct from *Fissidens fontanus*.

Fissidens taxifolius

This is an eastern species, and most western material was referred by Pursell (1976) to *Fissidens aphelotaxifolius*.

Funaria americana

"Of scattered occurrence in the continental interior, especially in the prairie states". Lawton's wider range may be attributed to nomenclature confusion with *F. muhlenbergii*. (Crum & Anderson 1981)

Gymnostomum calcareum

Zander (1977) combined this taxon with *G. aeruginosum*, but it is still recognized by Anderson et al. (1990).

Orthotrichum palousense

There is no record of this species in Vitt (1973). It is probably an unpublished herbarium name.

Sphagnum recurvum

"The complete range is somewhat uncertain owing to a confusion of taxonomic concepts". (Crum 1984)

Rhytidadelphus subpinnatus

This taxon was placed in *R. squarrosus* by Anderson et al. (1990). Yet some feel that it is a valid species. (Koponen 1971, 1975) (Schofield 1991)

B. Taxa Needing Verification, And If Correct Would Represent A Significant Range Extension:

Liverworts:

Barbilophozia atlantica

A high elevation taxon in New England, Great Lakes and in the Hudson Bay area. (Schuster 1969) Unlikely in the Columbia River Basin. (Schofield pers. comm. 1995)

Cephalozia bicuspidata var. *ambigua*

An arctic-alpine species, the American distributions are poorly known, in Alaska and in a few high latitudes eastern locations. (Schuster 1974)

Cephalozia bicuspidata var. *lammersiana*

Poorly known in North America, Schuster (1974) is skeptical of the reports from western North America.

Cephalozia loitlesbergeri

Found in southern and middle California, disjunct in Texas, Oklahoma, Kansas, Arkansas, and Louisiana. (Schuster 1992)

Jungermannia gracillima

A holarctic taxon restricted to the eastern half of the North American continent. (Schuster 1974)

Jungermannia polaris

Generally a rather rare and sporadic taxon with an arctic-alpine distribution, known from alpine British Columbia sites and doubtful from Alberta. (Schuster 1969)
Doubtful in the Columbia River Basin. (Schofield pers. comm. 1995)

Odontoschisma sphagni

Rare and very localized in eastern North America with prior taxonomic problems. (Schuster 1974) Poorly documented in Western North America. (Schofield pers. comm. 1995)

Riccia campbelliana

A northern taxon restricted in range in eastern North America, so unknown from the west. (Schuster 1974)

Mosses:

Anomodon viticulosus

An eastern species. (Crum & Anderson 1981)

Bartramia stricta

Probably based on an unusual morph. of *B. ithyphylla*. (Schofield pers. comm. 1995)

Brachythecium calcareum

An endemic eastern North American taxon with disjuncts in Alaska, British Columbia and the Yukon Territory. (Ireland 1982)

Campylopus schimperi

Mostly in northern sections of eastern North America, the only western records are from Alaska, the Yukon, and the Queen Charlotte Islands. (Crum & Anderson 1981)

Cynodontium polycarpon

"May not even occur on this continent. We have seen only one North American collection correctly named ... from the Lake Superior region. (Crum & Anderson 1981)

Dicranum angustum

A circumpolar, subalpine-alpine taxon from Alaska and northern North America only. (Persson and Holmen 1961) (Persson 1952)

Didymodon fallax var. *reflexus*

A circumtemperate taxon, rare in British Columbia. (McIntosh 1986)

Drepanocladus brevifolius

An arctic-alpine taxon from the Rocky Mts. of Alberta, Alaska and Greenland.
(Lawton 1971)

Grimmia pulvinata var. *africana*

This species "is extracted from *Grimmia orbicularis*, *Grimmia decipiens*, includes *Grimmia leibergii*". (Sayre 1952)

Grimmia unicolor

An eastern taxon, "records from British Columbia and Washington are presumed to be incorrect". (Crum & Anderson 1981)

Orthotrichum sordidum

Very common in the east and disjunct in Alaska. (Vitt 1973)

Pottia crinita

A maritime European taxon found on moist banks. (Smith 1978) On sea coasts, on rocks and banks in England. (Dixon 1954)

Pottia intermedia

William's (1966) reports the first North American location as Ontario, Canada. Zander (1993) combined this into *Tortula intermedia*. It is often confused with other *Pottias*.

Ptychomitrium polyphyllum

Rare, more common in western most Norway and eastern Europe and Macaronesia, no North American sites listed. (Nyholm 1960) Not listed by Anderson et al. (1990)

Rhodobryum ontariense

Sporadic from New Finland to Alberta, south to North Carolina. (Ireland 1982). This is the eastern species of *Rhodobryum*, while the *R. roseum* is found in the west. (Schofield pers. comm. 1995)

Rhodobryum roseum

Crum & Anderson (1981) considered the differences between *R. ontariense* and *R. roseum* "trivial and troublesome" and because the ranges overlap they use *R. roseum* for their plants. It is found in Alberta, Alaska and British Columbia. Schofield (pers. comm. 1995) feels that this is the western taxon.

Schistidium maritimum

A maritime taxon found along both coastal eastern and western North America. (Crum & Anderson 1981)

Sphagnum fallax

Is apparently completely absent from the northern Rocky Mountains. (Andrus & Layser 1976)

Sphagnum lescurii

An Amphiatlantic, eastern North American taxon with unclear distribution details due to the similarity between this and other related species. (Andrus 1980) Crum (1984) puts this species into *Sphagnum subsecundum* var. *rufescens*.

Sphagnum tenellum

An eastern taxon that also occurs in southeast Alaska and British Columbia. (Crum 1984). Andrus (1980) gives the western distribution as along the Pacific Coast from Alaska to Vancouver Island, British Columbia.

Thamnobryum alleghaniense

An eastern taxon. (Crum & Anderson 1981)

Timmiella anomala

A southwestern US taxon, records "from Washington and British Columbia so named appear to be *Timmiella crassinervis*. (Crum & Anderson 1981)

Tortula laevipila

A epiphytic taxon, Foster's Wallula collection is not very likely. The locations within the Columbia River Gorge region are probably correctly identified.

Ulota phyllantha

A maritime taxon found along both coastal eastern and western North America. (Crum & Anderson 1981)

C. Taxa That Are No Longer Valid, Or Are Probably Misidentified:

Mosses:

Brachythecium acutum

Excluded from North America. (Crum & Anderson 1981)

Brachythecium erythrorrhizon var. *thedenii*

Excluded from North America. (Crum & Anderson 1981)

Brachythecium glareosum (This is not considered a rare taxon because there are 12 records) Excluded from North America. (Anderson et al. 1990)

Cynodontium gracilescens

Excluded from North America. (Crum & Anderson 1981)

Distichium capillaceum var. *compactum*

Excluded from North America. (Anderson et al. 1990)

Hygrohypnum obtusifolium

This is probably a typographical error and the name does not exist in the literature.
It is probably *Scleropodium obtusifolium*.

Plagiomnium affine

Excluded from North America (Anderson et al. 1990)

Pohlia rothii var. *compacta*

Placed into *Pohlia andalusica* (Shaw 1981)

Appendix F. Special habitat and research needs for states in Columbia River Basin

Contents

A. Nevada	1
B. Oregon.	4
C. Utah	9
D. Wyoming	12
E. Montana	15
F. Idaho	23
G. Washington	30

A. Nevada.

Concerns about the bryoflora of the study area in northern Nevada can be divided roughly into lowland and montane categories. Habitats and specific management and program issues span the boundaries of the two sections, and can be treated as a broad group.

General research needs

1. High peaks within the lowland provinces, particularly to the east, need be searched to detect the presence of Rocky Mountain species and habitats that may have served as refugia or aided in migration between the Rockies and the Cascade-Sierra axis. Wetland habitats in these areas need the most attention, as these are the modal sites for bryophytes in the arid Great Basin.
2. Soil crusts throughout the region need thorough analysis, to identify regional differences due to climate or soils. They appear to differ from those of the southern Great Basin, where they have been studied extensively. Few good remnant stands have been found to date. Remnants should be sought wherever topography has precluded entry by livestock, such as in rimrock areas.
3. Species of cold springs and riparian areas need to be characterized, to determine what role they play as refugia and in dispersal across an arid landscape. Most riparian areas in the region have been severely degraded by livestock and beaver trapping, and loss of woody species indicates that bryophytes have long since been extirpated. Many springs have been developed for livestock or residential purposes, further degrading habitat for aquatic and wetland bryophytes.

4. Hot springs need to be inventoried, as they have received virtually no collecting.
5. All protected areas such as Research Natural Areas and Areas of Critical Environmental Concern need to be inventoried and their bryofloras identified. There are virtually no collections from any of these places.
6. Few alkaline areas have been collected in any detail.
7. Exposures of calcareous rock, if present, have not been collected.
8. Peatlands: Peatlands contain a large group of boreal taxa that reach their southern limits only in these habitats. Some may be relicts of earlier postglacial floras that have disappeared from elsewhere in the landscape.

LOWLANDS

The lowland areas as discussed here include the northern Great Basin (Northwestern Basin and Range), and the Owyhee Uplands sections. A significant portion of the Jarbridge Mountains are included in the Northwestern Basin and Range section, with peaks to 10,000 feet (the Matterhorn) occurring within these predominantly lowland provinces.

The most widespread vegetation in the lowlands is sagebrush and bunchgrass shrub-steppe, with inclusions of alkali soils and both juniper and ponderosa pine in areas transitioning to montane elevations. The Northwestern Basin and Range and the Owyhee Uplands encompass some of the driest portions of the state, and include alkaline areas that support a vascular vegetation of greasewood, saltbush and saltgrass. Soil crusts are present in a few areas not heavily grazed. Riparian zones support the most luxuriant vegetation, and include several species of willow, creek dogwood, wild rose, aspen and cottonwood.

Most of the Basin and Range and the Owyhee sections are managed by BLM and the Humboldt National Forest. Livestock grazing is the principal use of most of the country, and much of the rangeland has been degraded by 130 years of overuse.

Bryophytes have been very poorly collected in this part of Nevada. Lawton collected mostly in the Santa Rosa Range and the Ruby Mountains, both outside of the study area (Clark 1957, Lawton 1958). The only reports of lowland mosses are those of Lavin (1981, 1982). There are no historical accounts for bryophytes in the area.

Lowland sections

Northwestern Basin and Range -- 342B

1. Peaks: Matterhorn, White Peaks.
2. Soil crusts: mostly in lowlands.
3. Cold springs and riparian: Salmon Creek, Cedar Creek.
4. Hot springs: None known.
5. Protected areas: all RNAs, ACECs, state natural areas.
6. Alkali: Throughout lowlands.
7. Calcareous: None known.
8. Peatlands: None known.

Owyhee Uplands -- 342C

1. Peaks: Trout Creek Mountains, Calico Mt.
2. Soil Crusts: None known.
3. Cold springs and riparian: Owyhee River and tributaries.
4. Hot springs: None known.
5. Protected areas: All RNAs, ACECs.
6. Alkali: Throughout lowlands.
7. Calcareous: None known.
8. Peatlands: None known.

MONTANE

The Jarbridge Mountains occur in the Northwestern Basin and Range section, which is otherwise mostly lowland. The montane areas are forested by aspen, ponderosa pine and Douglas-fir forests at the lower elevations, and lodgepole pine, fir and Engelmann spruce at upper elevations. There are also extensive grasslands such as Idaho and green fescue, alpine meadows and rockfields at timberline. Peatlands are rare and have not been explored. Lawton collected mostly in the Santa Rosa Range and the Ruby Mountains, both outside of the study area (Clark 1957, Lawton 1958).

Northwestern Basin and Range -- 342B

1. Peaks: The Jarbridge Mountains may contain Rocky Mountain species, and may have served as refugia or routes of migration in the past. The high peaks, especially the Matterhorn, need to be collected systematically to characterize their flora.
2. Soil crusts: Soil crusts are no doubt present in some areas of the Jarbridge Mountains. They have received virtually no attention.

3. Cold springs and riparian: No specific sites known, but all are worthy of attention for unusual species.
4. Hot springs: None known.
5. Protected areas: Virtually no collections are known from any of these areas.
6. Alkali: None known.
7. Calcareous: None known.
8. Peatlands: None known.

B. Oregon

Concerns about the bryoflora of the study area east of the Cascade Range can be divided roughly into lowland and montane categories. Habitats and specific management and program issues span the boundaries of the provinces and sections, and can be treated as a broad group.

General research needs

1. High peaks within the lowland provinces, particularly to the east, need be searched to detect the presence of Rocky Mountain species and habitats that may have served as refugia or aided in migration between the Rockies and the Cascade-Sierra axis. Wetland habitats in these areas need the most attention, as these are the modal sites for bryophytes in the arid Great Basin.
2. Soil crusts throughout the region need thorough analysis, to identify regional differences due to climate or soils. They appear to differ from those of the southern Great Basin, where they have been studied extensively. Few good remnant stands have been found to date. Remnants should be sought wherever topography has precluded entry by livestock, such as in rimrock areas.

3. Species of cold springs and riparian areas need to be characterized, to determine what role they play as refugia and in dispersal across an arid landscape. Most riparian areas in the region have been severely degraded by livestock and beaver trapping, and loss of woody species indicates that bryophytes have long since been extirpated. Many springs have been developed for livestock or residential purposes, further degrading habitat for aquatic and wetland bryophytes.
4. Hot springs need to be inventoried, as they have received virtually no collecting.
5. All protected areas such as Research Natural Areas and Areas of Critical Environmental Concern need to be inventoried and their bryofloras identified. With the exception of the Boardman RNA and Lindsay Grassland Preserve, there are virtually no collections from any of these places.
6. Few alkaline areas have been collected in any detail.
7. Exposures of calcareous rock have been collected in Malheur County, but these are the only ones known from lowlands in the region.
8. Peatlands: Peatlands contain a large group of boreal taxa that reach their southern limits only in these habitats. Some may be relicts of earlier postglacial floras that have disappeared from elsewhere in the landscape. Calcareous fens are particularly rare in the region, known from only a few places in the Wallowa Mountains and on the east slope of the Cascade Range.

LOWLANDS

The lowland areas as discussed here include the northern Great Basin (Northwestern Basin and Range), the Owyhee Uplands, the High Lava Plains, and the Columbia Basin. However, significant montane areas, such as Steens Mountain and Hart Mountain (9,000 and 7,000 feet elevation, respectively) exist within some of these predominantly lowland provinces.

The most widespread vegetation in the lowlands is sagebrush and bunchgrass shrub-steppe, with inclusions of alkali soils and both juniper and ponderosa pine in areas transitioning to montane elevations. The Northwestern Basin and Range and the Owyhee Uplands encompass some of the driest portions of the state, and include alkaline areas that support a vascular vegetation of greasewood, saltbush and saltgrass. Soil crusts are present in a few areas not heavily grazed. Riparian zones support the most luxuriant vegetation, and include several species of willow, creek dogwood, wild rose, aspen and cottonwood.

Most of the Basin and Range and the Owyhee sections are managed by the Lakeview, Burns and Vale BLM districts. Livestock grazing is the principal use of most of the country, and much of the rangeland has been degraded by 130 years of overuse. Large areas have been converted to crested wheatgrass, while agriculture is restricted to bottomlands where irrigation is possible. The Columbia Basin and High Lava Plains are mostly privately owned. The Columbia Basin was formerly dominated by bluebunch wheatgrass with scattered sagebrush, occurring on deep loess soils. Most of this area has been converted to wheat farms. Near the Columbia River, shallow-soiled scabland stripped by the Missoula floods contains much exposure of rock. The area is crossed by Interstate 84 and contains many accessible areas. The region around Bend is experiencing enormous residential sprawl and associated recreational pressures on the surrounding countryside.

Foster (1907) and Jones (1936) are the only historical records for bryophytes in the region. Jones did not cite a specific locality for his work, and virtually all of the original riparian zone described by Foster has been flooded by dams on the Columbia River.

Lowland provinces

Northwestern Basin and Range -- 342B (61 records, 40 species: 2 liverworts, 38 mosses)

1. Peaks: Steens Mountain, Hart Mountain, Pueblo Mountains, Hat Butte, Wagontire Mountain, Squaw Butte, Trout Creek Mountains.
2. Soil crusts: Malheur National Wildlife Refuge, Squaw Butte Experiment Station, Hart Mountain and lower Steens Mountain.
3. Cold springs and riparian: Roaring Springs, Malheur Refuge, Donner und Blitzen River and tributaries.
4. Hot springs: Borax Lake, Mickey Hot Springs and others in the Alvord region.
5. Protected areas: all RNAs, ACECs, state natural areas, Nature Conservancy preserves.
6. Alkali: Alvord Desert, Warner Valley, Lake Abert, Catlow Valley.
7. Calcareous: None known.
8. Peatlands: None known.

Owyhee Uplands -- 342C (10 records, 10 species: 0 liverworts, 10 mosses)

1. Peaks: Mahogany Mountain, Saddle Mountain, Grassy Butte, Black Butte.
2. Soil Crusts: Jordan Craters Kipukas.
3. Cold springs and riparian: Owyhee River, Honeycombs area, Three Forks.
4. Hot springs: Three Forks
5. Protected areas: Honeycombs, Leslie Gulch, Jordan Craters, Stockade Mountain.
6. Alkali: Dry Creek Butte.

7. Calcareous: Burnt River Canyon
8. Peatlands: None known.

High Lava Plains -- 342H (37 records, 21 species: 3 liverworts, 18 mosses)

1. Peaks: None significant as refugia.
2. Soil crusts: The Island RNA, Crooked River National Grasslands
3. Cold springs and riparian: Crooked River, Oak Springs, Deschutes River and tributaries, John Day River, Lower White River.
4. Hot springs: None known.
5. Protected areas: The Island RNA, Horse Ridge RNA, John Day Fossil Beds National Monument
6. Alkali: None known.
7. Calcareous: None known.

Columbia Basin -- 342I (207 records, 86 species: 8 liverworts, 78 mosses)

1. Peaks: None significant as refugia.
2. Soil crusts: Boardman RNA, Lindsay Grassland Preserve
3. Cold springs and riparian: None known.
4. Hot springs: None known.
5. Protected areas: Boardman RNA, Lindsay Grassland Preserve
6. Alkali: None known.
7. Calcareous: None known.
8. Peatlands: None known.

MONTANE

Blue Mountains -- M332G (630 records, 230 species: 57 liverworts, 173 mosses)

This section is part of the Middle Rocky Mountain Steppe province, and includes the Wallowa, Strawberry, Ochoco and Elkhorn Mountains. The montane areas are forested by ponderosa pine and Douglas-fir forests at the lower elevations, and forests of lodgepole pine, fir and mountain hemlock at upper elevations. There are also extensive grasslands such as Idaho and green fescue, alpine meadows and rockfields at timberline. Peatlands and other wetlands are also best represented in these sections.

1. Peaks: All the major ranges in the Blue Mountains may contain Rocky Mountain species, and may have served as refugia or routes of migration in the past. The high peaks, especially the Wallawas, contain the greatest habitat diversity of the

region. The Wallows have received the most attention from collectors, with the earliest report being that of Duvall (1938) and Clark and Rakestraw (1938). The Elkhorn, Strawberry and Ochoco Mountains all need to be collected systematically to characterize their flora.

2. Soil crusts: Soil crusts are present in some areas of the Blue Mountains, particularly in grasslands on tabular basalts. They have received virtually no attention.
3. Cold springs and riparian: No specific sites known, but all are worthy of attention for unusual species.
4. Hot springs: Blue Mountain Hot Springs, Ritter Hot Springs.
5. Protected areas: Virtually no collections are known from any of these areas.
6. Alkali: None known.
7. Calcareous: The only known sites are in the Wallowa Mountains, where a few collections have been made.
8. Peatlands: A few collections have been made in peatlands in the Wallowa Mountains. A calcareous fen has been discovered there recently (Peter F. Zika, pers. comm.), with interesting vascular plants, but the bryoflora has never been examined.

East slope Cascade Range, Southern Cascades and Modoc Plateau

The vascular vegetation of these sections is predominantly forest of fir, lodgepole and ponderosa pine and Douglas-fir at lower elevations, grading into fir, Engelmann spruce, mountain hemlock and whitebark pine at higher elevations. Peatlands are common in glaciated basins at upper elevations, and there are extensive exposures of rock. The bryoflora of the east slope of the Cascade Range (Cascade Mixed Forest province) **does not** differ appreciably from that of the Sierran Steppe, which in Oregon includes part of the Southern Cascades and Modoc Plateau sections. Species diversity is greatest on the east slope of the Cascades, and is about as rich as the Blue Mountain section, but decreases from north to south because of increasing aridity. The low numbers of collections from the Southern Cascades and Modoc Plateau indicate that these two sections are, like the Owyhee Uplands, the most poorly known in eastern Oregon. The greatest numbers of liverworts recorded were from the east slope of the Cascades, reflecting the moister climate than in the Blue Mountains. Because of its accessibility from Portland and Hood River, Mount Hood has been the best collected peak in the Oregon Cascades, the first reports dating from Röhl (1890, 1893). We found no records from peaks south of the South Sister. Crater Lake National Park has received sporadic collecting, but nothing when compared to Glacier, Yellowstone and Grand Teton National Parks.

1. Peaks: Three Sisters Wilderness, Diamond Peak Wilderness, Mountain Lakes Wilderness. All high peaks south of the South Sister should be examined for boreal and arctic-alpine elements. No doubt some northern species reach their southernmost limits in this area.

2. Soil crusts: Some rudimentary crusts were seen near Lake of the Woods. They become more common southward with increasing aridity. These should be examined to determine composition and differences from crusts at lower elevation.
3. Cold springs and riparian: Such habitats exist in abundance in this region, and may yield interesting records such as *Tritomaria quinquedentata*.
4. Hot springs: None known.
5. Protected areas: Sporadic collections from the Three Sisters Wilderness, Gearhart Mountain Wilderness, and Crater Lake National Park have yielded some interesting records. The peatland flora in Many Lakes RNA has been collected in detail, but no other collections are known from the region. All other protected areas should be examined.
6. Alkali: None known.
7. Calcareous: Many Lakes RNA is and Benchmark Fen are the only known sites for calciphile vegetation, although not underlain by calcareous bedrock.
8. Peatlands: Peatlands are frequent on the east slope of the Cascade Range, decreasing further south because of increasing aridity.

C. Utah

Concerns about the bryoflora of the study area in northwestern Utah can be divided roughly into lowland and montane categories. Habitats and specific management and program issues span the boundaries of the two sections, and can be treated as a broad group.

General research needs

1. High peaks within the lowland provinces, particularly to the east, need be searched to detect the presence of Rocky Mountain species and habitats that may have served as refugia or aided in migration between the Rockies and the Cascade-Sierra axis. Wetland habitats in these areas need the most attention, as these are the modal sites for bryophytes in the arid Great Basin.
2. Soil crusts throughout the region need thorough analysis, to identify regional differences due to climate or soils. They appear to differ from those of the southern Great Basin, where they have been studied extensively. Few good remnant stands have been found to date. Remnants should be sought wherever topography has precluded entry by livestock, such as in rimrock areas.
3. Species of cold springs and riparian areas need to be characterized, to determine what role they play as refugia and in dispersal across an arid landscape. Most riparian areas in the region have been severely degraded by livestock and beaver trapping, and loss of woody species indicates that bryophytes have long since been extirpated. Many springs have been developed for livestock or residential purposes, further degrading habitat for aquatic and wetland bryophytes.
4. Hot springs need to be inventoried, as they have received virtually no collecting.
5. All protected areas such as Research Natural Areas and Areas of Critical Environmental Concern need to be inventoried and their bryofloras identified. There are virtually no collections from any of these places.
6. Few alkaline areas have been collected in any detail.
7. Exposures of calcareous rock, if present, have not been collected.
8. Peatlands: Peatlands contain a large group of boreal taxa that reach their southern limits only in these habitats. Some may be relicts of earlier postglacial floras that have disappeared from elsewhere in the landscape.

LOWLANDS

The lowland areas as discussed here include the northern Great Basin (Northwestern Basin and Range) section. Parts of the Grouse Creek Mountains, Middle Mountain and the Raft River Mountains are included in the Northwestern Basin and Range section, occurring within a predominantly lowland province.

The most widespread vegetation in the lowlands is sagebrush and bunchgrass shrub-steppe, with inclusions of alkali soils. Both pinyon-juniper woodland and ponderosa pine mark transitions to montane elevations. The section includes alkaline areas that support a vascular vegetation of greasewood, saltbush and saltgrass. Soil crusts are present in a few areas not heavily grazed. Riparian zones support the most luxuriant vegetation, and include several species of willow, creek dogwood, wild rose, aspen and cottonwood.

Most of the section is managed by BLM and the Sawtooth National Forest. Livestock grazing is the principal use of most of the country, and much of the rangeland has been degraded by 130 years of overuse.

Bryophytes have been very poorly collected in this part of Utah. We located only 8 references or specimens from Box Elder County, from the Raft River Mountains (George Creek) and Pilot Butte. The rest of the section appears to be completely uncollected. There are no historical accounts for bryophytes in the area.

Northwestern Basin and Range -- 342B

1. Peaks: None known in lowlands.
2. Soil crusts: Mostly in lowlands.
3. Cold springs and riparian: Raft River.
4. Hot springs: None known.
5. Protected areas: All RNAs, ACECs, state natural areas.
6. Alkali: Throughout lowlands.
7. Calcareous: None known.
8. Peatlands: None known.

MONTANE

The Grouse Creek, and Raft River Mountains, and Middle Mountain occur in the Northwestern Basin and Range section, which is otherwise mostly lowland. The montane areas are forested by pinyon-juniper, aspen, ponderosa pine and Douglas-fir forests. There are also extensive grasslands such as Idaho and green fescue.

Northwestern Basin and Range -- 342B

1. Peaks: Grouse Creek and Raft River Mountains, Middle Mountain, Pilot Butte. The high peaks need to be collected systematically to characterize their flora.
2. Soil crusts: Soil crusts are no doubt present in some areas at lower elevations. They have received virtually no attention.
3. Cold springs and riparian: George Creek only site known, but all are worthy of attention for unusual species.
4. Hot springs: None known.
5. Protected areas: Virtually no collections are known from any of these areas.
6. Alkali: None known.
7. Calcareous: None known.
8. Peatlands: None known.

D. Wyoming

Concerns about the bryoflora of the study area in Wyoming can be divided roughly into lowland and montane categories. Habitats and specific management and program issues span the boundaries of the provinces and sections, and can be treated as a broad group.

General research needs

1. High peaks outside of Yellowstone and Grand Teton National Parks need be searched to detect the presence of arctic and boreal species that may not have been detected by collectors. Habitats may have served as refugia or aided in migration between the Rockies and the Cascade-Sierra axis.
2. Soil crusts throughout the region need thorough analysis, to identify regional differences due to climate or soils. They appear to differ from those of the southern Great Basin, where they have been studied extensively. Few good remnant stands have been found to date. Remnants should be sought wherever topography has precluded entry by livestock, such as in rimrock areas.
3. Species of cold springs and riparian areas need to be characterized, as aquatic species are frequently overlooked. Most riparian areas in the lowlands have been severely degraded by livestock and beaver trapping, and loss of woody species indicates that bryophytes have long since been extirpated. Many springs have been developed for livestock or residential purposes, further degrading habitat for aquatic and wetland bryophytes.

4. Hot springs outside Yellowstone National Park need to be inventoried, as they have received no collecting.
5. All protected areas such as Research Natural Areas and Areas of Critical Environmental Concern need to be inventoried and their bryofloras identified. Outside of Yellowstone and Grand Teton National Parks, virtually no collections have been made from any of these places.
6. Few alkaline areas have been collected in any detail.
7. Exposures of calcareous rock should be sought and collected.
8. Peatlands: Peatlands contain a large group of boreal taxa that reach their southern limits only in these habitats. Some may be relicts of earlier postglacial floras that have disappeared from elsewhere in the landscape.

LOWLANDS

The lowland areas as discussed here include a very small portion of the Snake River Basalts section, on the west slope of the Teton Range, and Jackson Hole and lowland areas of Grand Teton National Park in the Overthrust Mountains section. The remainder of the sections are mountainous.

The most widespread vegetation in the lowlands is sagebrush and bunchgrass shrub-steppe, with inclusions of ponderosa pine in areas transitioning to montane elevations. The lowland portions of the Snake River Basalts and the Overthrust Mountains sections encompass the driest portions of the state within the study area. Soil crusts are present in a few areas not heavily grazed. Riparian zones support the most luxuriant vegetation, and include several species of willow, creek dogwood, wild rose, aspen and cottonwood.

The small portion of the Snake River Basalts section and Jackson Hole is privately owned, except for the National Elk Refuge. The lowland areas within Grand Teton National Park have not been grazed since the 1940's. Outside of the park, livestock grazing is the principal use of most of the country, and much of the rangeland has been degraded by 130 years of overuse. Jackson Hole is experiencing enormous residential sprawl and associated recreational pressures on the surrounding countryside.

There are virtually no collections from lowland areas in the region, and no historic record.

Lowland provinces

Snake River Basalts -- 342D

1. Peaks: None significant.
2. Soil crusts: None known.
3. Cold springs and riparian: Throughout west slope of Teton Range.
4. Hot springs: None known.
5. Protected areas: None known.
6. Alkali: None known.
7. Calcareous: None known.
8. Peatlands: None known.

Overthrust Mountains -- M331D

1. Peaks: None significant.
2. Soil Crusts: Best remnants will be on terraces of Snake River within Grand Teton National Park.
3. Cold springs and riparian: Snake River, within Grand Teton National Park.
4. Hot springs: None known.
5. Protected areas: Grand Teton National Park, National Elk Refuge.
6. Alkali: None known.
7. Calcareous: None known.
8. Peatlands: None known.

MONTANE

Montane areas within the study area include the Overthrust Mountains section and a small portion of the Yellowstone Highlands section, south of the Continental Divide. The Yellowstone Plateau and the Teton, Gros Ventre, Wyoming and Salt River Ranges contain most high elevation habitat. The montane areas are forested by lodgepole pine, ponderosa pine, Douglas-fir, fir and spruce. There are also extensive grasslands, alpine meadows and rockfields at timberline. Peatlands and other wetlands are also best represented in these sections. Collecting in the national parks (539 records from Yellowstone and 190 from Grand Teton) has occurred since the 1870's, with scattered collections occurring in the Gros Ventre and Salt River Range. Ownership is divided between Yellowstone National Park, Grand Teton National Park, and the Bridger-Teton National Forest. Much of the National Forest has been intensively managed for timber production, and grazing leases occur throughout the area.

Montane sections

Yellowstone Highlands -- M331A

1. Peaks: The Red Mountains, with Mt. Hancock and Mt. Sheridan, both over 10,000 feet, are the tallest peaks. They should be collected systematically to characterize their flora.
2. Soil crusts: None known. They have received virtually no attention.
3. Cold springs and riparian: No specific sites known, but all are worthy of attention to document flora.
4. Hot springs: Despite the abundance of thermal features in the park, there were few records from hot springs proper.
5. Protected areas: The flora of the park is well known in more accessible areas, but not in the backcountry.
6. Alkali: None known.
7. Calcareous: None known.
8. Peatlands: None known.

Overthrust Mountains -- M331D

1. Peaks: Peaks outside Grand Teton National Park should be examined to characterize the flora and search for boreal or arctic-alpine species.
2. Soil crusts: None known at elevation.
3. Cold springs and riparian: springs, creeks and rivers outside Grand Teton National Park should be examined to characterize the flora.
4. Hot springs: None known.
5. Protected areas: RNAs outside Grand Teton National Park should be inventoried.
6. Alkali: None known.
7. Calcareous: None known.

E. Montana

Joe C. Elliott
Conservation Biology Research
Helena, Montana

Distributions of mosses and other plants are influenced by the moist, cool Pacific maritime climate, particularly in extreme northwestern Montana in the Yaak and Kootenai River drainages, and in the northern Bitterroot, Purcell and Whitefish Mountain ranges extending eastward to Glacier National Park. Some mosses with floristic affinities in the Pacific coastal region reach their eastern-most distribution within this area of Montana. Vitt et al (1988) show

numerous bryophytes and lichens with Pacific coastal centers of distribution, extending inland to northwestern Montana.

Intermontane valleys, in rain shadows of western Montana mountain ranges, were dominated by Palouse Prairie grasslands (Semiarid Steppe) but much of the area has been converted to cropland or greatly altered by invasion of noxious weeds (e.g., spotted knapweed and leafy spurge). Although these dry habitats do not have a rich bryophyte flora, they provide habitat for widely distributed mosses. These native grasslands have been poorly investigated bryologically but, studies in British Columbia (McIntosh 1989) indicate that rare mosses may be present in these habitats. McIntosh (1989) found several mosses with disjunctions between western North America and arid regions of Eurasia in Semiarid Steppe habitats of British Columbia.

The north-south trending mountain ranges in western Montana are contiguous with the Rocky Mountain chain extending into Canada and south to Mexico. High peaks and alpine areas of these mountains provide habitat for arctic and boreal species which may have been more widespread during cooler, wetter climatic periods. Some mountain peaks and alpine areas provide refugia for northern mosses which were more common during the last glaciations (Schofield 1980). Vitt et al (1988) show distribution patterns of mosses common in montane and boreal habitats of Canada extending southward into the United States along western Montana mountain ranges.

Some uncommon and rare mosses in Montana appear to be closely associated with specific habitats, usually restricted to small areas greatly different from surrounding areas. Such habitats include calcareous fens, fens low in nutrients, warm springs, and limestone outcrops. These isolated habitats are widely distributed throughout western Montana. Cool fens, like alpine areas, often provide cool, moist environments for species more widely distributed at higher latitudes.

Areas Needing Research

Ecological provinces of Montana, within the Columbia River drainage, are Bitterroot/Clark Fork River Valley, Flathead Valley, Northern Rockies, and Bitterroot Mountains.

Bitterroot/Clark Fork Valley (M332B) and Bitterroot Mountains (M333D)

Warm Springs

The Bitterroot/Clark Fork Valley has several warm springs needing additional studies including:

Bearmouth Warm Springs and Nimrod Warm Springs, Granite County, west of Missoula, along the Clark Fork River; Phosphate Warm Springs, Powell County, near Garrison. The occurrence in Montana of *Drepanocladus sendtneri*, *Eucladium verticillatum*, *Fissidens fontanus*, *Hygroamblystegium tenax* appears to be limited to warm springs and associated mineral deposits.

Sleeping Child Hotsprings, Ravalli County, east of Darby; Lolo Hotsprings, Missoula County; and Lost Trail Hotsprings, Ravalli County. These hotsprings have been developed but some remaining habitat may exist.

Semiarid Steppe

I can find no indication that mosses have been collected from any Palouse Prairie habitats in Montana. Remnants of native Semiarid Steppe grassland/shrubland exist in the following areas.

Mount Sentinel and Mount Jumbo in the Missoula Valley.

The east side of the Bitterroot Valley from Lolo south to Darby.

The Clark Fork Valley from Beavertail Hill east to the Continental Divide along the Little Blackfoot River and south to Butte along the Clark Fork River and Silver Bow Creek.

The Blackfoot River Valley near Clearwater Junction, Monture Game Range, and Ovando. Relatively intact remnants of rough fescue prairie remain in the Clearwater - Monture area. Unique kettle-kame topography exist in the Ovando area with a high diversity of interspersed wetland, native grassland, and dry forest habitats.

The Nevada Creek Valley from Helmville to Avon.

The upper Flint Creek Valley near Phillipsburg.

Mountain Peaks and Alpine areas

The Bitterroot and Sapphire mountains have received some attention by bryologists but, like nearly all of Montana, they remain under-collected. Several interesting arctic-alpine collections from Saint Mary's Peak in the Bitterroot Mountains (*Dicranum acutifolium* and *Grimmia incurva*) and Skalkaho Pass in the Sapphire Mountains (*Sphagnum compactum* and *Andreaea rupestris*) indicate that the potential for additional discoveries is high in these habitats.

Some lower elevation canyons in the Bitterroot Mountains support disjunct populations of Pacific Coast maritime plants (McCune 1984). These canyons serve as cold air drainages in which high mountain plants extend to unusually low elevations (Lackschewitz 1991). The only known occurrence in Montana of the Pacific maritime moss, *Porotrichum bigelovii*, is in Big Creek Canyon. McCune (1984) also found lichens with Pacific maritime affinities in eastern canyons of the Bitterroot range.

Areas needing additional study include:

High mountain peaks and alpine areas of the Bitterroot Mountains (e.g., Lolo, Mormon, Saint Mary's, and Trapper peaks).

Canyons on the east slopes of the Bitterroot Mountains (e.g., Tin Cup, Kootenai, Bass, Bear, Big, and Mill creeks).

Rattlesnake Mountains, north of Missoula.

Fens and other Wetlands

Chadde and Shelly (1994) describe both vascular plants and bryophytes growing in significant peatlands of western Montana. Fens in the Bitterroot/Clark Fork River Valley Ecological Province support several boreal species with centers of distribution substantially farther north or Pacific coastal (*Meesia triquetra*, *Sphagnum magellanicum*, *Sphagnum mendocinum*, and *Sphagnum riparium*).

Areas needing additional study include:

Mary's Frog Pond and Shoofly Meadow, Missoula County.

Lost Trail Pass fen near Sula, Ravalli County.

Rock Creek fen near Como Lake, northwest of Darby.

Fens and other wetlands in the Bitterroot and Rattlesnake Mountains.

Flathead Valley and Associated Mountains (M333B)

Warm Springs

Camas Hotsprings, Little Bitterroot Valley, Sanders County.

Semiarid Steppe

Intermontane grasslands west of Flathead Lake, along the Flathead River, south of Flathead Lake, and the Little Bitterroot Valley (mostly Flathead Indian Reservation).

Remnants of rough fescue grassland on the National Bison Range near Moiese.

Fescue grassland in the Jocko Valley between Arlee and Ravalli.

Mountain Peaks and Alpine areas

The only montane area within the Flathead Valley Ecological Province that has been researched with a modicum of intensity is Glacier National Park. Hermann (1969) and various other bryologists have reported the following species, only known from this location in Montana: *Bartramia stricta*, *Bryum calobryoides*, *Bryum schleicheri*, *Drepanocladus brevifolius*, *Hypnum bambergii*, *Plagiobryum demissum*, and *Racomitrium aquaticum*. These species or other rare arctic-alpine mosses would also be expected to occur in the Mission, Swan, and Whitefish mountains. These mountain ranges, especially at high elevations are essentially uncollected. Areas with a high potential for harboring uncommon or disjunct species include:

Mission Mountains from Gray Wolf to McDonald peaks.

Bob Marshall, Great Bear, and Bob Marshall wilderness areas.

Ten Lakes Scenic Area in the Whitefish Mountains

Fens and other Wetlands

Chadde and Shelly (1994) identified significant peatlands within this province and included

mosses in lists of flora. Many fen species with limited occurrence in Montana are present in these fens. More extensive investigation of these fens would probably expand species lists and ecological relationships. Fens and other wetlands needing additional study include:

Swan River, Porcupine, Point Pleasant, Plum Creek, Lost Creek, and Napa Creek fens in the Swan Valley, south of Swan Lake.

Bowen Creek, Gregg Creek, North Sanko Creek, South Sanko Creek, and Sheppard Creek fens in the Tally Lake Ranger district of the Flathead National Forest.

Ambrose fen on private land south of Creston, Montana.

Bent Flat, Trail Creek, Mud Lake, Butcher Mountain and Trout Lake fens in the Spotted Bear Ranger District of the Flathead National Forest.

Crystal and Windfall Creek fens, Swan Lake Ranger District, Flathead National Forest.

Other

The moss, *Grimmia brittoniae*, was collected in 1896 by Williams (1902). This species is endemic to Badrock Canyon, near Columbia Falls in northwestern Montana. Over the past several decades, smelter emissions have subjected portions of Bad Rock Canyon to chronic air pollution which may have affected this rare species. This species should be sought to determine if it remains extant.

Northern Rockies Ecological Province (M333C)

The Northern Rockies Ecological Province is defined in this report as being comprised of lands within the drainage of the Kootenai River. This province includes the Cabinet, Salish and Purcell Mountains, and northern periphery of the Bitterroot Mountains. Areas needing additional study include:

Warm Springs

There appear to be no warm springs within this province.

Semiarid Steppe

The Tobacco Plains near Eureka has remnants of Palouse prairie grassland.

Mountain Peaks and Alpine Areas

Northwest Peak Scenic Area of the Purcell Mountains.

Cabinet Mountains Wilderness.

Fens and Wetlands

Dudley Slough, a calcareous fen near Trego. *Scorpidium scorpioides*, a rich fen species has been collected from this site and other rich fen species also may be present.

Wetlands in the Pinkham Creek drainage. Calcareous seeps and fens are present in this area.

Lower Cody Lake fen. Fisher River Ranger District. Kootenai National Forest.

Hawkins Pond fen, Northwest Peaks Scenic Area, Kootenai National Forest.

Teepee Lake fen, Libby Ranger District, Kootenai National Forest.

Overview of Ecological Regions

Distribution of the moss flora of Idaho is highly influenced by climatic patterns. In Northern Idaho, the Okanogan Highlands, Flathead Valley, Bitterroot Mountains, and parts of the Idaho Batholith have a moist, cool maritime climate. These areas, especially in the canyons and lake regions of the Priest, Kootenai, Pend Oreille, Clearwater, Lochsa, and Selway drainages support a variety of humid, coniferous, forest, bryophytes separated from the main coastal populations.

Palouse Prairie grasslands of Idaho lie on the western edge of the Northern Rocky Mountains. Most of the grasslands have been converted to agriculture lands and little bryological research on the few surviving remnants has been done. Herbarium searches show that Daubenmire collected some mosses from the grasslands in the 1940's.

The climate of the Owyhee Uplands, Snake River Plains, and Basin and Range sections of southern Idaho is semi-arid and supports a variety of grass/shrub communities. Like the Palouse Prairie, large areas of the Snake River Plains have been converted to agricultural and industrial uses. The area has been poorly investigated bryologically, but some mosses with affinities to the southern and dry interior regions have been found.

The Middle Rocky Mountain ranges of the Sawtooth and Salmon, in central Idaho, lack the maritime influence of northern Idaho and have a dry, cool, climate. The high peaks and mountain meadows along with the dry, coniferous, forests provide habitat for a variety of northern boreal and alpine bryophytes.

Throughout Idaho, microhabitats support rare mosses, and add to the diversity of the ecological regions. Limestone outcrops, warm springs, bogs, fens, and old growth forests provide some of these unique habitat.

All of the ecological provinces of Idaho lie within the Columbia River Drainage. The ecological provinces within the state include the Palouse Prairie, Bitterroot Mountains, Flathead Valley, Okanogan Highlands, Idaho Batholith, Beaverhead Mountains, Challis Volcanics, Overthrust Mountains, Northwest Basin and Range, Owyhee Uplands, Snake River Basalts, and

small sections of the Blue Mountains, Yellowstone Highlands, and Bear Lake.

Three mosses are endemic to the Columbia River Basin, *Bryoerythrophyllum columbianum*, *Grimmia brittoniae*, and *Orthotrichum holzingeri*. Only one, *Orthotrichum holzingeri*, was found in Idaho.

Herbarium searches throughout the northwest were used to determine the extent and occurrences of endemic, disjunct, and rare moss in the Columbia River Basin. Table 1. shows the moss species, endemic to western North American, that occur in Idaho. Table 2 shows the disjunct mosses found in the Idaho. Table 3 shows the rare taxa occurring in Idaho.

Table 1. Endemic Western North American Taxa found in Idaho.

Research Needs

1. Okanogan Highlands/Bitterroot Mountains Wet Coniferous Forests

A number of historical collections in Laird Park, Moscow Mountain, Priest Lake, Pend Orielle Lake, and the Clearwater and Selway drainages where done in the 1940 and 50's. Some of the historic collecting areas done in climax *Thuja-Tsuga* communities, has since been altered by logging, and development. These areas should be revisited to investigate the effects on the bryological flora and habitat.

A number of species endemic to North America occur in this region. They include: *Aloina brevirostris*, *Anacolia menziesii*, *Dichodonium olympicum*, *Fissidens ventricosus*,

Grimmia trichophylla, *Orthotrichum striatum*, *Pseudoleskea radicata* v. *denudata*, *Racomitrium varium*, *Schistidium concludodonteum*, and *Tripterocladium leucocladulum*.

Disjunct species in this area not only reflect the maritime climate but also the extension of the Northern and Bipolar mosses into the fens and the mountainous regions of northern Idaho. Coastal disjuncts include: *Anacolia menziesii* v. *baueri*, *Dichodontium olypticum*, and *Hookeria lucens*. Western Europe, Northern Pacific and Bipolar disjuncts include: *Hygrophyllum alpinum*, *Oligotrichum aligerum*, *Plagiothecium undulatum*, *Pogonatum contortum*, and *Polytrichum formosum*. Research on the fens of northern Idaho should be continued for they provide a unique habitat for moss flora found nowhere else in the state.

2. Palouse Grasslands

While remnants of the Palouse grasslands occur around Garfield and along the uplands of the Snake River, little collecting has occurred in this ecological region. Some of Daubenmire's moss collections were from grasslands but no extensive collections or research on the bryological components of the grasslands was found.

Grimmia trichophylla, and *Orthotrichum holzingeri*, both endemic species to Western North America were reported from the grasslands. Both species typically grow on rock and may not represent typical grassland species.

Orthotrichum holzingeri, the only endemic Columbia River Basin reported from Idaho, was first reported from Nez Perce county in 1892 by Sandberg. No other collections of this species from Idaho were found in the herbarium search. Since the original collection, air pollution from local wood pulp-mills could have effected the habitat. Relocation of the population and surveys of the surrounding Snake and Clearwater Canyons should be conducted.

3. Idaho Batholith/ Challis Volcanics/Beaverhead Mountains

The maritime climatic influence of northern Idaho extends into the northern part of the Idaho Batholith. In the Selway, Lochsa, and Clearwater drainages, endemic and disjunct bryological species are similar to those in the Okanogan and Beaverhead wet coniferous forests.

In the central part of the Idaho Batholith, Challis Volcanics, and Beaverhead mountains, historic collections by Lieberg, Frye, and MacFadden still are the main records for endemic, disjunct, and rare mosses.

Endemic species found in this region include: *Bryum pallens*, *Encalypta intermedia*, *Grimmia*

trichophylla, *Homalothecium arenarium*, *Orthotrichum hallii*, and *Orthotrichum striatum*.

Disjunct mosses include *Pottia lanceolata*.

Throughout this region, the microhabitats produced by warm springs, fens, calcareous outcrops, and canyonlands have been under-collected. *Bryum calobryoides* has been reported in Idaho only from a spring near Atlanta. This site should be revisited to determine the status of the species. Other numerous hot springs in the Snake, and Salmon River drainages should be investigated. Recreational use of these areas have the potential to alter hydrological flows and change the habitat.

A number of endemics, disjunct, rare mosses are known to occur on rocky outcrops and calcareous substrate. Neither the rocky canyonlands of the Snake and Salmon River drainages nor the limestone areas of the Lost and Lemhi mountains and valleys have not been extensively collected.

True arctic-alpine areas in Idaho cover a small area and like much of Idaho, they remain uncollected or under-collected. Alpine areas in the White Clouds, Big Horn Crags, Pioneer, and Boulder mountains need additional studies.

4. Owyhee Uplands/Snake River Basalts/Bear Lake/Basin & Range

While the Snake River Basalts, are one of the most developed areas in Idaho, it is also one of the most under-collected areas for bryophytes. Both commercial and agricultural development of the Snake River Basalt area has the potential to effect the bryological flora. Current investigations of the cryptogamic crust should be continue to help determine the ecological role of bryophytes in soil development and stabilization.

Pottia nevadensis, a dry interior endemic and rare species, was found in the Box Canyon area. Box Canyon is known for its large underground springs. Commercial and/or agriculture development of the area could effect the habitat of this species. Collecting in similar sites and a revisit to the original site should be done.

Orthotrichum flowersii, another rare species, has been found in the Owyhee Uplands. This species is possibly a northern extension of the southern population. Investigation of Owyhee Uplands should be done to determine the extent of southern species into Idaho.

Summary

Even though the number of the endemic, disjunct, and rare species of mosses currently known from Idaho is low, these species greatly increase the bryological diversity of the state. A review of the collection dates of these species show that most were collected before the 1970's. No evidence of monitoring or relocation of the earlier sites was found in the literature or herbarium collections.

Relocation of original sites and surveys for endemic, disjunct, and rare species should be conducted throughout the state to ensure that bryological diversity is maintained. Because rich bryological flora is often correlated with wetlands and humid microsites with woody debris, changes in canopy covers and hydrological functions could modify the habitat needed to maintain a diverse bryological flora.

Qualified taxonomists should verify the endemic, disjunct, and rare collections reported in Idaho. These verifications would ensure that incorrect identification of species do not lead to invalid range and distribution extensions.

Knowledge about the distribution, ecological role, and indicator value of bryophytes in the ecosystem are severely limited by the lack of research. While finances to conduct bryological research is difficult to obtain, training governmental agency botanists in bryophyte identification could rapidly increase local knowledge of bryological flora.

G. Washington

Washington Palouse Prairie Section

331A

Issues For Analysis:

There are a total of 112 species for this section. Since the boundaries of the Palouse Prairie Section were not clearly defined with regard to the county boundaries it is difficult to determine if some of these species belong to this section to the Blue Mountain Section. Therefore there may be some overlap with regards to the drier areas next to the Blue Mountains. There are several sites within this region that have a large number of disjunctions of humid interior species, while the remainder of the region has mostly dry interior species. *Fabronia pusilla*, an uncommon moss in Washington, has been reported from near Wawawai. It would be important to confirm this species and look for additional populations.

Areas For Research Needs:

1. Kamiak Butte, Whitman Co.

This area has a high number of Humid Interior species, and there is a fair amount of historical information available, thus it would be interesting to see if these species are still there.

2. Steptoe Canyon and Steptoe Butte, Whitman Co.

Many of the Dry Interior Cordillera Species occur here and again there is some historical information available.

3. Almota, Whitman Co.

This is the only location for *Funaria americana* within Washington.

4. Anatone and 2 miles west of Anatone

Both *Buxbaumia piperi* and *Roellia roellii* have been found here. This is one of the areas that may be within the Blue Mountains Section but it is difficult to tell. This area should be look at as these two species represent disjunct Humid Interior species and there may be more interesting disjuncts present.

5. Asotin Creek, Whitman Co.

Fissidens grandifrons has been found here. The exact location is not clearly defined but since this species is restricted to calcareous sites it should not be too hard to locate it again. According to Schofield (1980) *Fissidens grandifrons* is a persistent remnant of the milder climates that occurred before the Pleistocene glaciations. Today the populations of *Fissidens grandifrons* in Washington are restricted to only a few sites. Also there are other interesting calcicole bryophytes that could be located within the same area, and these would be worth looking for.

6. Lime Hill, Asotin Co., T7N, R47E, Sec's. 19, 20, 29, 30

There is some historical collection information for this area, and it is also a known limestone site Mills (1962). Thus it would be possible for some of the calcicole bryophytes to be in the area. If these species are there they could represent range extensions from other calcareous sites in the Great Basin Area.

Disjunctions:

Anacolia menziesii
Atrichum setwynii

Buxbaumia piperi
Didymodon vinealis v. *brachyphyllus*
Didymodon vinealis v. *rubiginosus*
Eurhynchium oreganum
Plagiomnium insigne
Roellia roellii
Trachybryum megaptilum

Interior Cordillera Endemic Species: (Schofield, 1980)

Coscinodon calyptraeus
Homalothecium nevadensis

Washington Columbia Basin Section
342I

Issues For Analysis:

This section has a total of 156 species and several of these represent the only sites known for Washington. There are also several type locations which would merit protection if they are not already protected. Additional research should be done especially on the U.S. Fish & Wildlife lands as they contain some of the best wetland habitat within this dry region. Also several Record of Decision C3 species occur scattered through out the region.

Areas For Research Needs:

1. Arid Lands Ecological Reserve

This area has been closed to the public and should have some of the best undisturbed crusts in the region. Also brief collections made by McIntosh indicate that there are several unusual dry site species in this area., ie *Trichostomopsis australasiae*.

2. Wallula, Horse Heaven Country, and Wallula Gorge, Bluffs of the Columbia River, Walla Walla Co.

This area is the Type location of *Bryoerythrophyllum columbianum*, a Columbia River Gorge endemic species (Schofield 1969).

3. Robinson Canyon west of Thorp, Kittitas Co.

This is the only location for *Orthotrichum praemossum* in Washington and represents only the third location in North America. This canyon is located in the DNR Lt. Murray Wildlife Recreation Area, abt. 47°N, 120°45'W.

4. Yakima River area near Thorp, Yakima Co.

This is the Type location for *Schistidium cinclidodonteum* while the location is somewhat vague the general area should be checked to confirm the population and locate additional sites. The Yakima River is also given as the location of *Scouleria marginata* but the exact location is not known.

5. Skamania Co.

According to Hong (1994) *Tritomaria quinquedentata* v. *quinquedentata* occurs in the "Chiquash Mountains", or SW of Mt. Adams and E. of Wind River. This is a Suksdorf collection that according to Hong is located at WS. As this is a Record of Decision C3 species it would be important to confirm the location of this population.

Disjunctions:

Orthotrichum bolanderi, collected by Leiberg in Spokane, Vitt (1973) considers this species to be rare and endemic to the dry mountains of western and central California, thus the population represents the only disjunct location for the species.

Orthotrichum sordidum found in Ellensberg would represent a range extension from Eastern North America. Vitt (1973) does not show this population on his distribution map nor does he mention it in the text. Thus it is doubtful that this is a good determination.

Western North American Endemic Species: (Schofield 1980)

Amphidium californicum

Brachythecium hylotapetum

Didymodon vinealis v. *brachyphyllus*

Didymodon vinealis v. *rubiginosus*

Homalothecium aeneum

Homalothecium fulgescens

Homalothecium pinnatifidum

Plagiomnium venustum

Scleropodium obtusifolium

Scouleria aquatica

Scouleria marginata

Trachybryum megaptilum

Interior Cordillera Endemic Species: (Schofield 1980)

Coscinodon calyptratus

Homalothecium nevadense

Record of Decision C3 Species

Antitrichia curtispindula

Ptilidium californicum

Scouleria marginata

Tritomaria quinquedentata

Washington Eastern Cascades Section
M242C

Issues For Analysis:

This is an extremely large section with a diverse number of habitats that range from alpine to dry oak woodland. Therefore a total of 408 species can be found within this section. Near the Columbia River area it was difficult to determine the exact cut off for the Columbia Basin Section, so for the purpose of this report all collections west of the Klickitat River were considered to be in the Columbia Basin Section. Thus all collections from the White Salmon, Bingen and including the Klickitat River are placed within the Eastern Cascades Section. In the future this may be an area that would need further study as the Columbia River Gorge area is rather unique and may represent its own section.

Areas For Research Needs:

1. Mt. Adams Area, Yakima Co.

a. Bird Creek Meadows Area, This area has several interesting bog sites as well as cliff areas, thus providing a wide variety of unique high elevation sites. While there is also good historical data from the area it would still be important to do a through study of the Mt. Adams area. *Targionia hypophylla* is a disjunct liverwort (Schofield 1984) is also reported from the Mt. Adams area.

2. Klickitat River, Klickitat Co.

This is a location for *Scouleria marginata* a Record of Decision C3 species. This river should be rechecked as all of the records for this are 30 or more years old. Also the surrounding drainage's may also have this species so it would be important to look at them as well.

3. Catherine Creek Area, T3N R12E Sec. 30, Klickitat Co.

This area has several "Mediterranean Climate" species of moss, including: *Orthotrichum lyellii*, *Grimmia pulvinata*, *Ptychomitrium gardneri*, and *Pseudohraunia californica*. It also has a large number of Western North American endemic species. Therefore this location needs to be further study in order to obtain a complete list of the species. It would also be possible for *Scouleria marginata* to be in this drainage.

4. 4mi. W. of Stehekin near Rainbow Falls, Wenatchee Nat. Forest, Chelan Co.

This is a site for *Buxbaumia viridis*.

5. Bingen, Klickitat Co.

There are two historical collections, one each of *Buxbaumia aphylla* and *Buxbaumia piperi*.

6. Lake Kachess, Kittitas Co.

This is the location for historical collections of *Buxbaumia piperi*. These are old collections and probably were done before the dam was put into place. Historical

collections also indicate that this is a very rich bryological area and the area probably should be rechecked to see what is still there.

7. Tiffany Mtn. E. North Cascades, ca. 20mi. NE of Winthrop, Okanogan Co.

This is a location for the Record of Decision C3 species *Tritomaria exsectiformis*. Other locations within Okanogan Co. include:

- a. Beaver Lake
- b. Buster Mt.
- c. Lost Lake
- d. Sweat Creek

Radulla bolanderi
Phaeoceros hallii

Record of Decision C3 Species:

Antitrichia curtipendula
Ptilidium californicum
Scouleria marginata
Tritomaria exsectiformis

Washington Blue Mountains Section
M332G

Issues For Analysis:

There has been very little historical bryophyte research done within this area, thus a small database of only 25 species exists for a very interesting region. One historical collection, *Anomodon viticulosus*, represents one of only two collections in Western North America. This species is widespread in Europe, Southern Siberia, Japan, Canary Island, North Africa, The Caucasus, the Himalayas and several parts of Eastern Asia. The North American distribution is: Nova Scotia to Ontario and Michigan, south to Virginia, Tennessee and Arkansas. The normal habitat for this species is on shaded calcareous cliffs and boulders, and rare at or near tree bases. (Crum & Anderson, 1981, Ireland 1982).

Research Needs:

The location and historical collection of *Anomodon viticulosus* should be rechecked and verified. Checking the historical collection will be difficult as the collector and location of the collection is unknown. Field checking should be easier as the location is given as Seven Sisters Springs, Blue Mts., Asotin Co., Washington, habitat is on bases of trees (Jones, 1929).

Disjunctions:

Anomodon viticulosus
Dicranum howellii
Dicranum tauricum
Roellia roellii

Humid Interior Speceis (Schofield 1976)

Western North American Endemic Species:

Homalothecium pinnatifidum
Brachythecium hylotapetum
Roellia roellii

Doubtful Species:

Homalothecium nuttallii

Washington Okanogan Highlands Section
M333A

Issues For Analysis:

This bryophyte flora is composed of 217 species, of which several represent new records for Western North America. According to Andrus and Layser (1971) there is a strong boreal influence in the northeastern portions of the section. When this is combined with the coastal influence of increased precipitation and the bog communities found within the lake remnants and cirque basins many refugia sites are available for boreal species. They further state that this area has been very under botanized. Thus the bryophyte flora of this region really should be looked at very carefully as it could provide some other significant range extensions.

Areas For Research Needs:

1. Pend Oreille River Gorge, Pend Oreille Co., BLM & USFS land, T39N R43E Sec's. 2 & 10

This area is very rich in limestone deposits that are combined with an aquatic environment, thus providing an excellent site for calcicole mosses. Several of the calcicole mosses found here include: *Fissidens grandifrons*, *Hymenostylium recurvirostre*, and *Cratoneuron commutatum* v. *falcatum*. Since limestone deposits are not very abundant within the state these rich calcareous areas should be protected.

2. Lake Remnants And Cirque Basins With Bog Communities (Andrus & Layser 1971, 1976)

- a. Bunchgrass Meadows, T37N R44E Sec. 24
- b. Diamond Lake, T30N R44E Sec. 2
- c. Deerhorn Meadows, T36N R45E Sec. 22
- d. Granite Creek, T37N R44E Sec. 1
- e. Gypsy Lake, T40N R45E Sec. 19
- f. Huff Lake, T37N R45E Sec. 2
- g. Onata Creek, T37N R44E Sec. 16
- h. Sema Meadows, T37N R45E Sec. 26
- i. Watch Lake, T40N R45E Sec. 30
- j. Lake Thomas, T36N R42E Sec. 17

Pend Oreille Co.

Stevens Co.

The following species of *Sphagnum* have been reported from some of the areas listed above: *Sphagnum centrale*, and *Sphagnum contortum* are new records for the western United States. *Sphagnum jensenii* is a range extension from the only other known site in Wyoming. *Sphagnum riparium* according to Crum (1984) is rare and scattered in the United States, this record is new for the contiguous western US as well as the only record for the State.

3. Republic, in Grosche's Canyon

The historical collections of *Ptilium crista-castrensis*, *Mnium spinulosum*, *Metaneckera menziesii*, and *Hedwigia ciliata* indicate that this could be a very

interesting area to explore. The distribution of the *Ptilium* is not well known for eastern Washington and at the present time this is the only location known.

4. Harvey Creek, Pend Oreille Co.

This is the site for the Record of Decision C3 species *Tritomaria exsectiformis*

5. West Deer Creek, Stevens Co.

This is the site for Record of Decision C3 species *Tritomaria exsectiformis*

6. Calispell Peak, abt. 20mi. SE of Colville, Stevens Co.

This is the site of *Buxbaumia aphylla*. Schofield, (1976) states that this species is rare in southern British Columbia thus it probably should be considered as rare in eastern Washington.

7. Fort Colville, Stevens Co.

Plagiothecium undulatum was collected from this site. Schofield (1976) states that this species is restricted to west of the Cascades, thus if this is verified as a valid species then it would be a range extension for the region.

Disjunctions:

Anacolia menziesii

Atrichum setwynii

Dicranum tauricum

Heterocladium macounii

Heterocladium procurrens

Hypnum circinale

Pseudotaxiphyllum elegans

Leucolepis acanthoneuron

Metaneckera menziesii

Plagiomnium insigne

Plagiothecium laetum

Porotrichum bigelovii

Rhytidiopsis robusta

Rhytidiadelphus squarrosus

Roellia roellii

Scouleria aquatica

} Humid Interior Species (Schofield 1976)

Western North American Endemic Species: (Schofield 1980)

Amphidium lapponicum

Brachythecium hylotapetum

Brachythecium leibergii

Heterocladium procurrens

Hypnum circinale

Leucolepis acanthoneuron

17
Plagiomnium insigne
Porotrichum bigelovii
Rhytidiopsis robusta
Roellia roellii
Scouleria aquatica
Thamnobryum neckeroides
Trachybryum megaptilum

Interior Cordillera Endemic Species: (Schofield 1980)
Homalothecium nevadense

Record of Decision C3 Species:
Ptilidium californicum
Tritomaria exsectiformis
